According to Gibson and Birkinshaw (2004) and Gupta et al. (2006), the dependent variable ambidexterity is calculated as the multiplicative score between explorative and exploitative innovations. Explorative innovation (EXP) and exploitative innovation (EXPL) are measured using 3 items each, adapted from Jansen et al (2006). The respondents indicate the extent to which they agree or disagree with six statements about the extent to which collaborations have performed, over the last three years, against the objective of generating respectively new or improved innovations.

3.3 Statistical procedure

This study used the two-stage structural equation modeling (SEM) approach suggested by Anderson and Gerbing (1988), using AMOS 21 with maximum likelihood (ML) estimation. In the first stage, the validity and reliability of the measurement model were assessed and in the second stage the structural model was analyzed.

4.1 Measurement model: validity and reliability

To improve content validity we employed previously validated scales and pre-tested the questionnaire following recommendations by Forza (2002). More specifically the instrument was pre-tested using a panel of firms, selected in order to represent the investigated subsectors. Minor changes were made to the questionnaire, thanks to the suggestions emerged during the pre-test phase.

Confirmatory factor analysis was performed to examine if all measures were psychometrically sound. In all cases, the items load well on the constructs they were intended to measure with little evidence of cross loadings. Convergent validity was assessed using standardized parameter loadings of the measurement items on their respective constructs. All standardized parameter loadings were significant (p-value <

0.01) and ranged from 0.45 to 0.8, with most of the items greater than 0.6 (see appendix 1).

Construct reliability was assessed via Cronbach's alpha and composite reliability (Shah and Goldstein, 2006). Typically, values of 0.6 or higher for Cronbach's alpha (Nunnally, 1978) are considered to be adequate. In addition, composite reliability (Bagozzi and Yi, 1988) values for all constructs meet the threshold value of 0.6. As reported in Table 1, all constructs exceed this value. Overall, these results show that the theoretical constructs exhibit good psychometric properties.

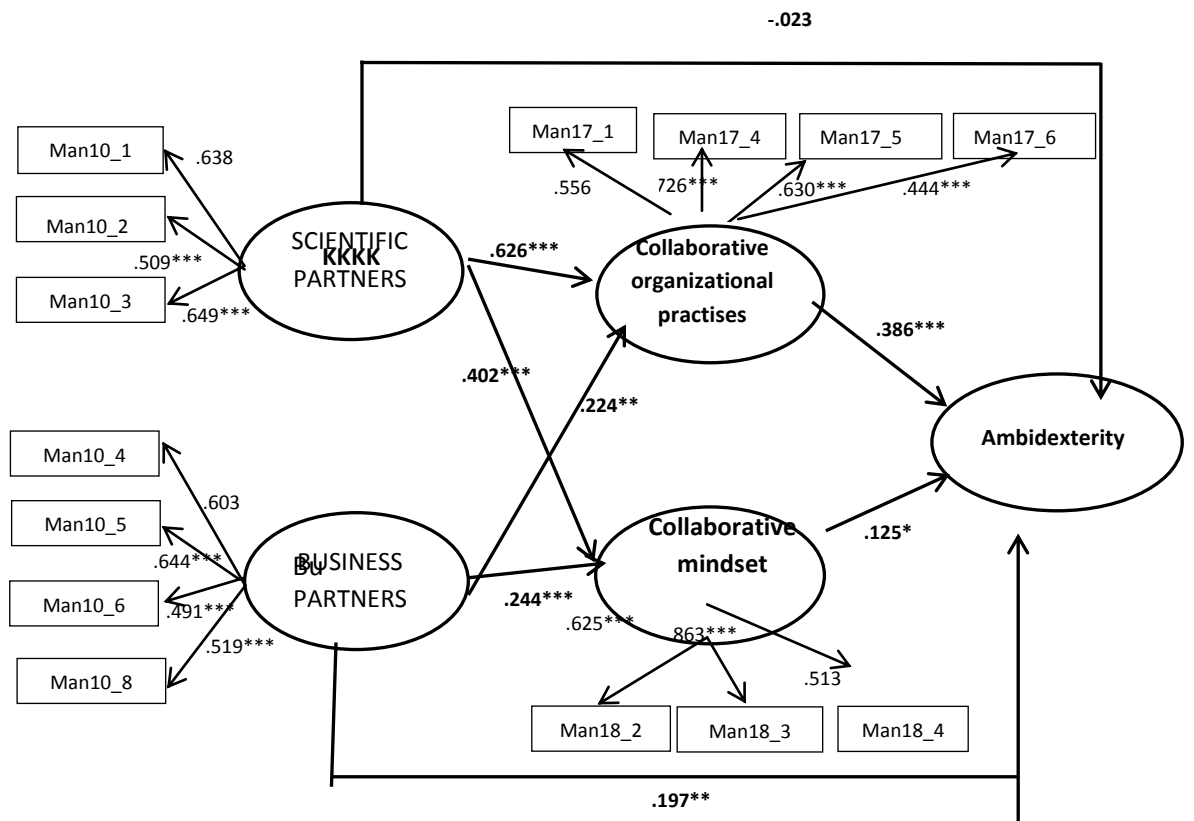

Discriminant validity was assessed checking whether, as shown in Table 1, all pairs of constructs have construct intercorrelations that are less than 0.7 (MacKenzie et al., 2005). Finally, unidimensionality was evaluated by the overall model fit that can be tested using the comparative fit index (CFI), incremental fit index (IFI), Tucker-Lewis index (TLI), root mean square error of approximation (RMSEA), and normed chi square (i.e. χ^2 per degree of freedom) (Bryne, 1989; Hair et al., 2006). Indices (CMIN=376.115;DF=155;CMIN/DF=2.427;CFI=0.904;IFI=0.905;TLI=0.882;RMSEA=0.059) show that the models fit the data well and, hence, establish unidimensionality.

Table 1: descriptive statistics, validity and reliability measures

	BN	SN	CM	CO P	EX T	EX P
Business partners (BP)	-					
Scientific partners (SP)	.677	-				
Collaborative mindset (CM)	.481	.643	-			
Collaborative org. practices (COP)	.352	.460	.594	-		
Innovative exploration (EXT)	.407	.375	.333	.382	-	
Innovative exploration (EXP)	.417	.378	.419	.612	.682	-
Mean	3.294	2.856	4.038	3.206	3.884	4.129
Standard deviation	1.192	1.381	1.123	1.195	1.331	1.269
Cronbach alpha	.654	.628	.712	.688	.809	.719
Composite reliability	.741	.742	.697	.719	.812	.730

5. Results

The final structural equation model with standardized regression weights and standardized error, depicted in Figure 2, has the following fit values: CMIN = 293.55, CMIN/DF = 3.537, NFI = 0.799, IFI = 0.847, TLI = 0.804, CFI = 0.845, and RMSEA = 0.078. All hypotheses were supported. The overall fit statistics of the structural model are on the commonly accepted thresholds and, therefore, demonstrate acceptable fit.

Notes: Numbers in bold are related to the structural model
 *Significant at 5%, **significant at 1%, ***significant at 0.1%
 No p-value means that the parameter has been fixed at 1

Figure 2: Standardized Estimated path model

The hypothesis 1-2-3-4 predict that both business and scientific partners positively impact on collaborative organizational practices and collaborative mindset. As shown on figure 2 and table 2, all the coefficients are positive and significant, thus supporting the

hypothesis. Moreover, we find evidence supporting both hypothesis 5 (the use of collaborative organizational practices/mechanisms will lead to higher levels of ambidexterity) and hypothesis 6 (the use of collaborative mindset will lead to higher levels of ambidexterity). The last four hypothesis predict that the internal context (collaborative mindset and collaborative organizational practices) mediate the relationship between business and scientific partners and ambidexterity. We used the decomposition of effects results, in which the total effect of an independent variable on a dependent variable is disaggregated into its indirect and direct effects (Tabachnick and Fidell 1996). Table 2 reports the direct and indirect effects for all paths.

Table 2: Standardized structural estimates of the structural model.

<i>PATH</i>	<i>Model</i>
Direct Path	
<i>BP → CM</i>	.244***
<i>BP → COP</i>	.224**
<i>SP → CM</i>	.402***
<i>SP → COP</i>	.626***
<i>CM → AMB</i>	.125*
<i>COP → AMB</i>	.386***
<i>BP → AMB</i>	.197**
<i>SP → AMB</i>	-.023
Indirect Path	
<i>SP → AMB</i>	.292**
<i>BP → AMB</i>	.117*

When taking into consideration the indirect effects, a significant indirect effect indicates that a relevant quantity of the independent variable's total effect on the dependent variable happens via the hypothesized mediators. Particularly, collaborative mindset and collaborative organizational practices fully mediate the relationship between scientific partners and ambidexterity while they partially mediate the relationship between business partners and ambidexterity. In sum, the overall model supports the idea that the effect of establishing business and scientific networks on ambidexterity is mediated by the right internal context; in other words, having employees with a collaborative mindset and putting in place collaborative organizational practices make it possible to fully exploit the potential of the external partnerships.

5.1 Robustness check

In order to conduct robustness check, we compared the hypothesized model to other models to determine which model fits the data best (Paulraj et al., 2008). Thus, our proposed model was compared to rival models to assess whether it provides the best fit. In our proposed model (Model 1), CM and COP partially mediate the relationship between our independent variables and ambidexterity. A second full mediation model was tested in which we cut the direct paths from BP and SP to ambidexterity (model 2). A third direct model was assessed in which we considered the direct paths from BP, SP, COP, CM to ambidexterity. The following table 3 shows the results of the three models:

Table 3: robustness check

	Partial mediation (Model 1)	Full mediation (Model 2)	Direct model (Model 3)
SP to AMB	-.023		.053
SP to CM	.402	.394***	
SP to COP	.626	.613***	
BP to AMB	.197		.235***
BP to CM	.244	.260***	
BP to COP	.224	.271***	
CM to AMB	.125	.163**	.160**
COP to AMB	.386	.431***	.378***
CMIN/DF	3.537	3.561	5.269
CFI	.845	.840	.727
TLI	.804	.802	.670
IFI	.847	.842	.730
NFI	.799	.793	.687
RMSEA	.078	.079	.102

As shown in Table 2, the proposed model (Model 1) fits the data well considering the model fit indices (CFI TLI, IFI, RMSEA) of the other two models. Particularly, the more restricted full mediation model fits the data in a worse way than the partial mediation model, as indicated also by the RMSEA. Additionally, all the indexes for the direct effects model are worse than those for the partial mediation model. Taken together, information provided by the comparison of the direct effects and partial mediation models shows that the former do not fit the data as well as the latter. So we can assert that data support the partial mediation hypothesis. Additionally, we used the bootstrap method to test for the significance of indirect effects.

6 Discussion and conclusions

Overall, the results show that our hypotheses are supported. First, we find further evidence in line with literature suggestions on a positive relationship between the context (managerial and social) and the degree of openness. Collaboration with different types of partners requires people able to exchange information and thus characterized by appropriate socio-psychological features or mindset (Hillebrand and Biemans, 2004; Cabrera and Cabrera, 2005; Jolink and Dankbaar, 2010). Moreover, managing different sources (actors) of knowledge requires high levels of coordination and thus more sophisticated (and more intensively applied) project management systems (Foss et al., 2011).

Second, the social and managerial context factors are able to improve innovative performance from collaborations. As concerns the former, our results confirm that people who are already used to communicate and internally cooperate are likely to be more receptive and able to foster different types of learning (i.e. explorative and exploitative), creating the premises for all the facets of innovative performance (Hillebrand and Biemans, 2004). A complementary role is exerted by the managerial factors, creating a conducive context which enables firms to share, exchange and transform knowledge and thus fostering innovative performance.

Third, and particularly significant, is our finding showing that the use of collaborative organizational practices and the creation of a collaborative mindset mediate the relationship between both collaboration with business and scientific partners and ambidexterity. When taking into consideration the indirect effects, a significant indirect effect indicates that a relevant quantity of the independent variables' total effect on the dependent variable happens via the hypothesized mediators. Thus, our findings extend Foss et al., (2011) evidence ("that customer interaction enhance innovative performance only through the operating of some organizational practices") to a situation in which innovation is carried out with different types of partners (i.e. open innovation). In addition, our evidence extends that of Hillebrand and Biemans (2004), specifically focus only on suppliers and customers: high levels of internal collaborative mindset are crucial also when companies are engaged in collaborations with several partners. Thus it seems to be confirmed that what happens within the company (i.e. firms' internal organization and social context) is crucial to explain the success or failure of open innovation

(Dahlander and Gann, 2010). Particularly, data support full mediation for scientific network and partial mediation for business network.

This study contributes on the debate on both open innovation and ambidexterity literature in at least two important ways. First, it sheds light on how firms reap the benefits of their partnership, showing that firms can leverage partners' knowledge and foster innovation performance by designing an appropriate internal context.

Second, it shows that ambidexterity can be achieved through the combination of external and internal factors: establishing scientific and business partnerships requires the creation of both a collaborative mindset and collaborative organizational practices which in turn lead to the generation of ambidextrous innovative performance. Consequently, this paper answers to the recent literature's call for more empirical research that links a "firm's exploitative and exploratory strategies with its collaboration behavior" (Schamberger et al, 2013), thus showing that ambidexterity can be achieved not only by intra organizational settings, but also through the establishment of a portfolio of alliances.

As practical implications, the study suggests that collaborations with different typologies of partners should be carefully managed, through the development and implementation of organizational and HR practices, in order to foster ambidexterity. In this way both scientific and business networks lead to the development of exploitative and explorative innovations: in the former case, only the use of an appropriate and formal set of collaborative practices and an employee's attitude towards openness leads to the development of ambidexterity.

Structured Abstract

Purpose – In the current context of economic crisis, there is an increasing need for new approaches for solving social problems without relying upon public resources. With this regard, social entrepreneurship has been arising as an important solution to develop social innovations and address social needs. Social entrepreneurs found new ventures that aim at solving social problems.

The main purpose of this research is to identify the general profile of the social entrepreneurs and the main features of social companies, such as geographic scope, profit or non-profit approach, collaborative networks, decision making structure, and typologies of customers that benefit from their social actions.

Design/methodology/approach– The present research is based on both primary and secondary sources of data, that were used to perform both qualitative and quantitative analyses. Specifically, we selected two Spanish social entrepreneurs networks, as “Ashoka Spain” and “HUB Madrid”, on the basis of their representativeness of Spanish

social entrepreneurs. A survey was developed and distributed among the entrepreneurs members of the mentioned networks. This survey covers several aspects, such as the socio-demographic profiles of social entrepreneurs and the main features of their companies. Finally, the results from the statistical analyses were discussed with a panel of experts through personal semi-structured interviews.

Originality/value –The conducted research shows general features of social entrepreneurship in Spain. Among the obtained results, it is worth noting the orientation of the companies towards a self-sustaining model without donations and public transfers, the prevalence of women in human resources within companies, the trend towards the creation of global and not local businesses, the prevalence of profit approach over non-profit approach, the adoption of participatory decision making structure, the tendency to establish collaboration with private sector over public sector, and the strong social vocation of entrepreneurs over the perception of business opportunity as motivation inspiring social entrepreneurship initiatives.

Practical implications– Results point out that social companies in Spain tend to focus their activities on customers who have their access to basic services and products covered. On the contrary, people belonging to the lower Bottom of Pyramid (BOP) are mainly left unattended by social companies, receiving only the help of the public authorities. Future studies could extend the research through a cross-cultural validation in different countries.

Keywords –Social Entrepreneurship, Social Entrepreneur, Social Innovation, Bottom Of Pyramid, Case Study.

Paper type – Academic Research Paper

1 Introduction

The field of social entrepreneurship is growing rapidly and it is attracting attention from many sectors. The term itself shows up frequently in the media, it is referenced by public officials, it has become common on university campuses, and it refers to use of entrepreneurial principles and behaviour in order to create social value and generate positive social change by providing economic return (Martin et al., 2007).

The phenomenon of globalization produced an exponential increase of capital, ideas, and products flow, contributing to an unparalleled expansion in products and services consumption. In turn, globalization caused also deep-seated environmental and social problems (Fisac et al., 2011).

Often, public intervention is inefficient in dealing with this kind of problems, due to the heavy bureaucracy and the instability of governments that make difficult the continuity of actions that aim at generating a positive social impact.

It is precisely this type of context that encouraged the development of entrepreneurial initiatives aiming at providing an effective solution to social and environmental problems.

Social entrepreneurs and social companies are the main actors of this kind of initiatives and of social innovation within the current globalization context.

There are many currents of thought and theories focusing on how social companies and social entrepreneurs should behave to create a positive social impact, on what should be their organizational structure, on how they should support their social mission, and on how they may procure resources and assets.

Accordingly, this research aims at understanding the way of behaving of social companies and social entrepreneurs, and particularly the main features of social companies, such as their geographic scope, their profit or non-profit approach, their use of collaborative networks, and their decision making structure. Additionally, attention is also paid to the motivations and general profile of social entrepreneurs, as well as to the typologies of customers that benefit the most from these social actions.

In this research, data were collected from two Spanish social entrepreneurs networks, namely “Ashoka Spain” and “Hub Madrid”, being representative of Spanish social entrepreneurs networks. A survey was developed and distributed among the members of the mentioned networks, and they were used to perform a statistical analysis. Moreover, semi-structured interviews with a panel of experts, were used to support the analysis of the results.

The reminder of the paper is organized as follow. In Section 2 we discuss the theoretical background. In Section 3 we portray social innovation as result of network and collaborative systems. In Section 4 we offer a description of the two social entrepreneurs networks from that data for the research were collected (“Ashoka Spain” and “Hub Madrid”). In Section 5 we present the research methodology. In Section 6 we discuss the findings of the research. Finally, in Section 7, conclusions and directions for further researches are provided.

2 Theoretical background

2.1 Social Economy

Organizations and various actors acting in social entrepreneurship context tend to be considered as active parts of an economic sector called social economy. In particular, the majority of social companies belongs to this sector or had their origin inside it (Defourny et al., 2012). The behavior of individuals belonging to this sector do not obey only to market rules, but it is influenced by purely social factors and logics.

Social economy is commonly considered as the third sector of the economy (Monzon et al., 2008; Social Economy Lisburn, 2013) since the two other economic sectors are generally considered the private business sector, which is motivated by profit, and the public sector, which is managed by governments (Monzon et al., 2008).

Moreover, social economy can be defined as that part of the economy that is composed by established organisations with volunteer members, board of directors and management committees whose activities are oriented to generate local benefits; it is composed by communities' organizations and businesses, managed by local people, that work for the welfare of the communities and marginalized groups (Social Economy Lisburn, 2013). Social economy includes those organizations that are driven by the principle of reciprocity in pursuing both economic and social objectives, often through social control of capital (BALTA, 2013). Therefore, social economy is promoted by private and formally organized companies, having autonomy of decision and freedom of membership, created to match the needs of their members by producing goods and providing services, as insurance and financial services. Moreover, within these companies, decision making and any distribution of profit and surplus among the members are not related to the stakes owned by each member, each of which has one vote (Monzon et al., 2008). Thus, we identify two social economy sectors: (i) the market or business sector; and (ii) the non-market sector (Monzon et al., 2008). The market sector is populated by cooperatives and mutual societies, business groups controlled by cooperatives, and some non-profit institutions that provide services to other companies that are part of the social economy. In turn, the non-market sector includes associations and foundations, although may also be found organisations with other legal forms according to the typologies considered non-market producers by national accounting policies (Monzon et al., 2008).

According to a report presented by the Social Economy Lisburn (2013), social economy sectors may be classified in: (i) the community sector, which includes organizations working at local or community level, usually small, modestly funded and largely dependent on voluntary rather than paid work, as vigilance services, small associations of communities, small support groups; (ii) the voluntary subsector, which includes non-profit organizations having a formal constitution, independent from governments and autonomous, and operating with a significant degree of voluntary involvement, ashousing cooperatives, large charity organizations, large community associations, national organizations of the countryside; (iii) the social companies sector, which includes companies having primarily social objectives whose surpluses are reinvested for the social aim within the enterprise or within the community, rather than being used to maximize profit for shareholders and owners, as cooperatives, building societies, credit unions (Social Economy Lisburn, 2013).

2.2 Social Company

Social companies are private organizations dedicated to solving social problems, serving the disadvantaged, and providing socially important goods and services that were not adequately provided by public agencies or private markets (Dees, 1994).

These organizations combine innovation, entrepreneurship and social purpose and seek to be financially sustainable (Haugh et al., 2004).

The main feature of social companies is that social mission prioritises social benefit above financial profit (Haugh et al., 2004; Mair et al., 2005).

Social companies may be profit or non-profit organisations (Hayden, 2010; Mataix, 2013; Schwab 2013). However, there are currents of thought that consider as social companies only for-profit entities, excluding foundations and non-profit associations (Andreu, 2013; Parra, 2013); other considering as social companies only non-profit entities, adopting, hence, a non-profit business approach (Defourny et al., 2012).

A typical feature of social companies is their propensity to reinvest all the surplus, if any, in favour of their social actions (Haugh et al., 2012; SEUK, 2013) or to adopt a policy of restriction in dividends distribution (Defourny et al., 2012). However, according to some currents of thoughts social companies could also seek the return of invested capital in favour of shareholders (Andreu, 2013).

Concerning the issue of the economic sustainability, there are significant differences between two existing traditions of social company: (i) the Anglo-Saxon tradition, according to which social companies should achieve their economic sustainability by adopting a strategy of own incomes generation; (ii) the continental European tradition, according to which social companies can sustain their business by using also hybrid resources provided from public and civil sector, such as private donations, public donations, public subsidies and volunteer human resources (Fisac et al., 2011).

These traditions differ also in the importance and emphasis given to the role of the entrepreneur in the dynamics of the social companies. Anglo-Saxon tradition emphasizes the central role of the entrepreneur and the importance of his leadership. Instead, the European tradition emphasizes the collective and participatory dynamics that should characterize the nature of the social companies, especially in the decision-making processes (Defourny et al., 2012).

2.3 Social Entrepreneur

The social entrepreneur differs in several features from the traditional entrepreneur who fits perfectly within the market dynamics and whose main purpose is the profit generation (Dees, 2001).

Bill Drayton, founder of the largest network of social entrepreneurs in the world, Ashoka, defines the social entrepreneurs as individuals offering innovative solutions to the most pressing social problems, people who pursue a social objective, and that, to achieve it, use methods traditionally associated with the business world (Sanchez, 2011).

The main feature that distinguishes the social entrepreneur from the traditional business-oriented entrepreneur is the priority he attributes to the social purpose and to the creation and sustenance of social value (Dees, 2001). Therefore, the social purpose must be the single objective pursued by social entrepreneur, he should not seek any form of return on invested capital (Leadbetter, 1997; Peredo et al., 2005) . However, according to other currents of thoughts, the social entrepreneur may balance social purposes with profit purposes (Boschee, 1998), also combining them (Shwab, 2013). Accordingly, the generation of profit and wealth may be part of the model that the social entrepreneur embrace, but they must be the means to achieve the social goal, not the objectives (Dees, 2001).

The social entrepreneurs perceive the opportunities to cover unsatisfied social needs and they are able to bring together the necessary resources, such as people, capital, and facilities (Dees, 2001; Mair et al., 2005), and use them to solve social problems and to drive social innovation and change in various fields (Shwab, 2013).

3 Social innovation as result of network and collaborative systems

The result of the activities of social entrepreneurs and social companies is often referred to as social innovation (Phills, 2009).

Social innovation is defined as any new and useful solution to a need or a social problem, which is better than existing approaches (e.g., more effective, efficient, or sustainable) and for which the created value brings benefits to the society as a whole, rather than to private individuals (Phills, 2009), or its generated social utility is at least as important as the return on investment (Lorca, 2013). The new solutions can be a product, a production method, a process, a technology, a service, a market, a model, but also a pragmatic approach, a principle, an idea, a rule, a social movement, an intervention, or a combination of them (BEPA, 2010; Murray et al., 2010) that meet social needs, improve acting abilities of society, and create new social relations and collaborations.

The supply of products and services that meet those needs are often not guaranteed by the market or by the government, and that is why there is space for the actions of private social sector forces, such as social companies and social entrepreneurs, to create social improvements.

Usually the social entrepreneurs and social companies, in order to give positive outcomes to their ambitions of social innovation, shall interact with a very complex system that includes different actors, such as public institutions, traditional businesses, and civil society and its organizations (Davies et al., 2012). In fact, collaborations between entities belonging to different sectors have the purpose to obtain and share resources from multiple agents (Montgomery et al., 2012). These resources may be material and non-material resources, as financial, cognitive, cultural, and institutional (Montgomery et al., 2012). Moreover, social companies may also use collaboration in order to share ideas and create support networks to achieve the social change goal (Montgomery et al., 2012). A collaborative system composed by local government authorities, non-governmental organizations, local communities, financial institutions, infrastructure manufacturers and other types of traditional businesses is necessary for the

“Strategies for the Bottom of Pyramid”. These are social entrepreneurship models adopting the purpose of offering products and services to the Bottom of Pyramid (BOP), which is composed by the 4 billion people of the world population (about half of the total world population) whose purchasing power is less than 1,500 \$ per year (Prahalad et al., 1999).

In recent times, the perception of the need for a strong collaborative network in order to give positive result to social change ambitions led to formation of entrepreneurs networks, such as Ashoka and Hub Madrid networks.

4 Ashoka and Hub Madrid

4.1 Ashoka

Ashoka is the largest social entrepreneurs network in the world, with about 3,000 members in 70 countries (2013, 07 10), who put into practice in global scale their ideas of worldwide systemic change (Ashoka, 2013c). It was founded in 1980 by Bill Drayton and provides financing services to start-ups, professional support services and connections to a global network that extends around the business and social sectors (Ashoka, 2013c). Moreover, Ashoka offers a platform for people devoted to social change. Ashoka's purpose is the creation of “changemakers” by providing people all over the world the skills and connections that they need to achieve their intentions for social change. The operational approach of the Ashoka network is based on three points. First, Ashoka offers support to social entrepreneurs, by identifying main social entrepreneurs and invests on them and helps them to achieve the highest possible social impact. Second, Ashoka promotes the collaboration between social entrepreneurs groups and networks to make social impact faster and more widespread, by engaging entrepreneurs communities and developing effective collaboration models that could create social changes in many areas. Third, the network cares about the infrastructures construction for the citizen sector, because a global network of "changemakers" requires means and support systems to generate sustainable social solutions. Accordingly, Ashoka creates the necessary infrastructures, such as access to social financing, connections with the academic and business sectors, and structures for collaborations that allow to create social and financial value (Ashoka, 2013a).

Ashoka defines its business model as an hybrid value chain (Ashoka, 2010). This is a business model based on a commercial partnership between firms and civil sector organizations (such as neighbourhood associations, foundations and cooperatives), that leverages the capabilities of each actor to enable the provision of needed goods and services to low-income populations in a more cost-effective way. In this model, the businesses' benefits are the access to new markets and the customers base expansion. Additionally, civil sector organisations take advantage from the partnership because they increase their social impact through generation of new income sources for their programs and expand their range of offered services. Conversely, low income populations improve their living conditions because they can satisfy their basic needs and see the emergence of new economic opportunities. Through the hybrid vale chain the limitations that constrain the potential social impact of civil sector organizations (constrained by their dependence on donations and their limited ability to operate) and businesses (constrained by their limited knowledge of local consumers and local resources, and by their lack of confidence all inside of the local context) may be overcome by combining and sharing their complementary strengths. In particular, the strengths of civil society organizations are: the ability to understand the needs of low-income consumers, the confidence of the local population towards them, the ownership of consolidated infrastructure and networks within these territories, the ability to define feasible solutions based on the context, and the ability to mobilize communities and other stakeholders such as local governments and financial institutions. Instead, the strengths provided by the firms are the ability to operate on a large scale, the ability to develop processes efficiently, the possession of a good reputation and the strength of a recognized brand, the capacity for investment, the capacity to find new investors, and the ability to strategically plan and manage monetary flows (Ashoka, 2010).

4.2 Hub Madrid

Hub Madrid is part of an international community of entrepreneurs and social innovators called Hub, with 31 co-working spaces around the world and a professional network composed of more than 5,000 members (2013, 7 10). Thus, Hub Madrid is a co-working space, a meeting place for social entrepreneurs and social innovators, located in Madrid city centre and created in 2009 (Hub Madrid, 2013a). It was conceived with the purpose to facilitate collaboration and cooperation between social entrepreneurs by

making available a physical, and not just virtual, space within which they exchange ideas, inspire each other, share knowledge, resources and dreams, develop new ideas and new projects having the ambition to promote positive social change (Hub Madrid, 2013b). Even in Hub Madrid, as for Ashoka, collaboration among people who want to spur social change is considered essential in order to realize projects, meet goals and support social innovation. In Hub Madrid network there are about 230 entrepreneurs and professionals acting in different projects related to various areas, from social change and sustainability, to technology, culture and education (2013, 7 10). The work in Hub Madrid is oriented towards the creation of an entrepreneurial ecosystem that is strengthened through the creation of networks and through the collaboration with non-profit organizations, businesses, educational institutions, NGOs, and public institutions. Among the events organized in Hub Madrid there are trainings, meetings, dinners and many events that stimulate creativity and collaboration (Hub Madrid, 2013a).

Hub Madrid is the one headquarter of Hub community in Spain, and its members operate in many areas of Spain, not only in Madrid area.

5 Methodology

5.1 Survey

In order to collect the data needed for the study, we developed a survey which was distributed among the social entrepreneurs members of “Ashoka Spain” and “Hub Madrid”, as representative of Spanish social entrepreneurs. The survey was developed with the purpose to identify the main features and characteristics of individuals and companies involved in social business, especially with regard to the contrasting issues, previously discussed, about existing conceptions and theories concerning social companies. Thus, the survey aims at highlighting the social business models that are actually put in practice by social entrepreneurs.

A first group of questions in the survey covered general aspects, such as entrepreneur age, foundation year, headquarter location, employees number, and percentages of volunteer and female employees in the social company. A second group of closed questions covered other aspects, such as profit or non-profit approach of the company, dividends sharing policy, geographic scope, collaborative networks, and typologies of customers that benefit from these social actions in regard to their location with respect to

the BOP. Finally, the last group of questions was based on a Likert scale ranging from 1 to 5, through which the entrepreneur was called to carry out an assessment about other aspects, such as motivations of his commitment in entrepreneurial social actions, financing sources used by his company, and decision-making system adopted.

5.2 Statistical analysis methodology

The data collected have been used to obtain data about trends within the studied sample and to subsequently perform a statistical analysis. In particular, Pearson chi-square (χ^2) test and Mann-Whitney U test were applied to verify the existence of significant trends differences within the sample with respect to the examined aspects. The results of the statistical analysis were tested with 95% level of significance (Johnson et al., 1998).

Pearson χ^2 test was used for the analysis of qualitative data, collected by questions that did not require a quantitative assessment, such as the questions of the first group requiring a non-numerical response, and the second group of questions of the survey .

Mann-Whitney U test was used to analyse quantitative data, such as the numerical data of the first group of questions and the data collected in the third group of questions of the survey, because they corresponded to quantitative variables that could assume a value ranging from 1 to 5, in accordance with the adopted Likert assessment scale.

5.3 Experts interviews

The results of the statistical analysis were discussed with a panel of experts through personal semi-structured interviews. The interviews were used to support the interpretation of survey's results.

In particular, we interviewed Catalina Parra who developed broad knowledge of the dynamics of social entrepreneurship, on the basis of her wide direct field experience. Especially, she is president and founder of "Fundación Hazlo posible", a foundation having the purpose to innovatively promote interaction and social participation in charitable initiatives using new technologies; she is president and founder of "Asociación UEIA", a non-profit association having the main purpose to promote entrepreneurship, social action and technology as a platform for new projects related to the social context in order to make them viable and sustainable entrepreneurial initiatives over time; she is also co-president and co-founder of "Philanthropic Intelligence", a consultancy organization

that promotes and facilitates better philanthropy among Spanish families and individuals, with the purpose of enabling people having significant assets to realise their philanthropic projects.

We also interviewed Jaime Moreno, due to his global experience and knowledge in the field of social companies. Especially, he was a visiting scholar in Grameen Danone in Bangladesh, that is one of the most popular and successful model of social company in the world, and he is social entrepreneur and co-founder of "Integra-e, inclusión social a través de la tecnología", that is an organization operating in Spain, that trains young people who have left school and are in social exclusion risk in leading web development technologies and in fostering neighbourhood micro-entrepreneurship.

We also interviewed Carlos Mataix, due to his specific knowledge as expert in social innovation and social entrepreneurship, being these among his main specific working areas; he is professor at "Universidad Politecnica de Madrid" and director of "Innovation and Technology for Development Centre", that is a space and a collaborative network that combines scientific, critical and reflective thinking, with practical knowledge to find solutions to the challenges of the lack of sustainability and equity in the current global context.

6 Findings

6.1 General findings

In the sample, the average age of the social entrepreneur resulted 38 years old, that is consistent with the overall average age of the Spanish entrepreneurs, which is a little over 38 years (GEM, 2012). 58% of Spanish social entrepreneurs operates through for-profit companies and the remaining 42% operates through non-profit companies (Figure 1).

Figure 1: *Percentage proportion of profit and non-profit social companies.*

Within the for profit companies, the 40% of them distributes dividends among its members, and the remaining 60% does not distribute dividends.

Results concerning the composition of human resources employed showed that the 58% of social companies employees are women (Figure 2), that is a higher percentage with respect to the overall business sector in Spain where women are the 48% of employees, according with the “Informe sobre la Brecha de género en la empresa” (Report on gap gender in Companies, conducted in 2010) (El Pais, 2013).

Figure 2: *Average percentage of women and men employed in social companies.*

According to Mataix, the prevalence of women over men among social companies employees, common to non-profit sector trend, is due to the traditional family structure in Spain, which drives women to prefer part-time jobs without gaining more money than men. According to Moreno, this trend occurs because women have an empathy and altruism sense different than men, and they get involved in social initiatives because they are supportive, instead men are motivated by their own innovating spirit and by the

emotions that social actions can generate in them, because social activities excite them and make them feel good.

Moreover, it was found that the 59% of social companies employs volunteers, the remaining 41% does not use volunteer employees (Figure 3).

Figure 3: Proportion of companies using and not using volunteer employees.

Among companies employing volunteers, the average portion of volunteer over total employees was 51%. By applying the χ^2 test, we found a statistically significant difference between profit and non-profit companies in using volunteer employees, in particular non-profit companies have a larger propensity to use volunteer employees than profit companies (Table 1).

Table 1: χ^2 test: independent variable: profit/non-profit company; dependent variable: collaborations and volunteer employees use (* $p < 0.05$).

		Volunteer employees	
		No	Yes
Non-profit	Observed	3	11
	Expected	5.8	8.2
Profit	Observed	11	9
	Expected	8.2	11.8
df		1	
χ^2		3.832*	

The data regarding the typology of customers showed that the proportion of social companies serving customers that do not have access to basic goods and services is 25%. According to Moreno, this is due to the fact that in Spain basic needs, such as health and education, are covered enough. On the same line of thought is Parra, that associates this outcome to the specific social situation in Spain, in comparison with country having different social conditions, that does not stimulate the launch of social entrepreneurship initiatives oriented to the BOP.

Analysing the data regarding the geographic scope of social companies, we noticed that 54% of companies has global scope of operations, 16% operates at continental level, 16% operates in a single country, and the remaining 14% limits their activity to a local context (Figure 4).

Figure 4: *Percentage of companies operating in local, national, continental and global scope.*

The χ^2 test highlighted a statistically significant difference in the geographic scope of less recently incorporated and more recently incorporated companies; in particular, more recent companies have larger scope, with a major propensity to act in continental and global contexts (Table 2).

Table 2: χ^2 test: independent variable: company foundation year; dependent variable: operative scope (* $p < 0.05$).

		Foundation year	
		≤ 2010	> 2010
More Countries	Observed	20	5
	Expected	16.7	8.3
One Country	Observed	4	7
	Expected	7.3	3.7
df		1	
χ^2		6.545*	

6.2 Social entrepreneur motivations

We spotted that social entrepreneurs establish their initiatives due to social vocation. The survey also showed that pure business opportunity and the need to find employment are less prominent motivations in inspiring social entrepreneurship initiatives (Figure 5).

Figure 5: Average rating (1-5) of the importance of the different motivational factors in order to launch initiatives of social entrepreneurship.

This result is in contrast with the overall trend of Spanish entrepreneurship; in fact, according to the report of Global Entrepreneurship Monitor (2012), a large part of entrepreneurial activities in Spain was motivated by unemployment and by the need to create a job for the entrepreneur, that is the so-called phenomenon of “self-employment” (GEM, 2012). According to Mataix, the entrepreneur who seeks to employ himself does it in more accessible and faster return areas rather than in social entrepreneurship.

6.3 Financing system

Survey’s answers indicate that the most spread funding source among social companies is the income generation through their operating activity. The use of other financing sources, such as public donations and subsidies, and private donations is less spread (Figure 6).

Figure 6: Average rating (1-5) of the use of the different financing sources.

By applying the Mann-Whitney U test (Table 3), we found significant deviations from this general self-sustaining model with regard to social companies that serve BOP people. Their main financing source is not the income generation through the operative activity, instead they rely more on public donations and on subsidies and private donations (Table 3).

Table 3: Mann-Whitney U test. Independent variable: served people; dependent variable: financing sources (1-5). Results having p value <0.05 were considered statistically significant.

Financing	Mean		U	p
	Served people			
	Covered basic needs	Uncovered basic needs		
Own incomes	4.65	3	16	0.018
Private donations	1.6	3.5	16.5	0.023
Public donations or public subsidies	1.45	3.75	14	0.012
Collaboration with companies	1.75	3.25	21.5	0.12
Public patronage	1.3	1.5	34.5	0.458
Private patronage	1.7	2.75	28.5	0.267
Investors capital contribution	2.35	2.33	27.5	0.8
Crédit	2.21	2.41	16.5	0.207

According to Mataix, there are social companies that act with extremely vulnerable groups and they can operate only if they are sustained by subsidies. Basically, this is what happens with social companies serving a weak segment such as the BOP.

6.4 Collaborative system

We found that 74% of social companies has collaborative relationship with NGOs, 56% with public institutions, 38% with public companies, 74% with private companies, 59% with civil society organizations, and 24% has generated a joint venture (Figure 7).

Figure 7: Percentage of social companies that collaborate with each one of the indicated entities.

By applying the χ^2 test, we noticed significant difference between profit and non-profit companies collaborative systems. In fact, non-profit companies have larger propensity to collaborate with public sector (public institutions and public companies) than profit companies (Table 4).

Table 4: χ^2 test: independent variable: profit/non-profit company; dependent variable: collaborations (* $p < 0.05$).

		Collaborations											
		NGOs		Public Institutions		Public Companies		Private Companies		Joint Venture		Civil Society	
		No	Yes	No	Yes	No	Yes	No	Yes	No	Yes	No	Yes
Non-profit	Observed	4	11	3	12	6	9	3	12	3	5	7	13
	Expected	4	11	6.6	8.4	9.3	5.7	4	11	4.5	3.5	11.2	8.8
Profit	Observed	5	14	12	7	15	4	6	13	16	10	12	2
	Expected	5	14	8.4	10.6	11.7	7.3	5	14	14.5	11.5	7.8	6.2
df		1		1		1		1		1		1	
χ^2		0.001		6.333*		5.384*		0.577		1.434		8.591*	

We also found a significant larger propensity to collaborate with public institutions among social companies serving BOP people (Table 5).

Table 5: χ^2 test: independent variable: served categories; dependent variable: collaborations (* $p < 0.05$).

		Collaborations											
		NGOs		Public institutions		Public companies		Private companies		Joint venture		Civil society	
		No	Yes	No	Yes	No	Yes	No	Yes	No	Yes	No	Yes
Covered basic needs	Observed	6	13	11	8	12	7	8	11	17	2	8	11
	Expected	5.8	13.2	9.1	9.9	12.4	6.6	7.4	11.6	15.7	3.3	7.4	11.6
Uncovered basic needs	Observed	1	3	0	4	3	1	1	3	2	2	1	3
	Expected	1.2	2.8	1.9	2.1	2.6	1.4	1.6	2.4	3.3	0.7	1.6	2.4
df		1		1		1		1		1		1	
χ^2		0.068		4.439*		0.204		0.406		0.584		0.406	

The rationale of this is that this kind of companies, in order to sustain their social actions, generally, need not only financial resources from public institutions, but also other resources such as facilities that can be provided by public administrations (Mataix, 2013).

6.5 Decision making structure

The data analysis revealed that social companies tend to use a democratic decision making system. Their decision-making processes are primarily managed through a totally participatory system, in which all the members of the company actively participate, and, secondly, by a collective governing organ. From the analysis, we do not spot emerging tendencies regarding the centralization of the decisions in the person of the entrepreneur

or a single manager, or adopting a decision making structure depending on the capital contributions of each member of the organization (Figure 9).

Figure 9: Average rating of the importance of different factors in decision-making system.

7 Conclusions

The available scientific literature deals with the conceptual definition of social entrepreneurship, i.e. types of activities and business susceptible of being termed social, or focuses on particular case studies of individual social company. Contrarily, in this research insights about the general characteristics of subjects and companies involved in social business in Spain are given. In this research, by taking data from a sample of social entrepreneurs, we do not restrict the sample to define the way of acting of a specific company, but we obtain general guidelines that are common to social companies and social entrepreneurs, independently from the specific social field in which they operate.

The purpose of this research is to identify the main features of social companies, such as profit or non-profit approach, geographic scope, financial sources, collaborative networks and decision making structure. To complement the study, attention is also paid to the motivations and general profile of social entrepreneurs, as well as to the type of customer that benefit from these social actions, with respect to the BOP.

The research methodology is based on the data collected from the members of two Spanish social entrepreneurs network, namely “Ashoka Spain” and “Hub Madrid”. A survey was developed and distributed among the entrepreneurs members of the mentioned networks. Finally the results from the statistical analyses have been discussed with a panel of experts through semi-structured interviews. Several interesting results emerged.

First, the results of the research reveal that the generation of social entrepreneurship activities is generally motivated by the entrepreneurs’ social vocation and not by the perception of a business opportunity in this field or the self-employment need.

Second, the majority of social companies are for profit companies and have a low tendency to distribute dividends among their members. Concerning the financing system adopted, it is worth noting the orientation towards a self-sustaining model, without donations and public transfers. This result may be due to the current crisis that reduced the availability of subsidies and donations. Moreover, from our results, the preference to adopt collaboration with private sector over public sector emerges as a significant trend.

Regarding the composition of employed human resources, the results show that social companies make a wide use of volunteer employees. A peculiar feature of social companies is also the prevalence of women over men among employees.

Concerning the scope of the social companies, the creation of global and not local businesses is spotted as a favored trend.

Results regarding the decision-making system reveal that in social companies a democratic and participatory decision-making system is adopted.

Finally, results point out that social companies in Spain tend to focus their activities on customers who have their access to basic services and products covered. On the contrary, people belonging to the lower BOP are mainly left unattended by social companies, receiving only the help of the public authorities.

Of course, our study features some limitation that necessitate further research. Especially the study was limited to the analysis of those data collected from social entrepreneurs members of Hub Madrid and Ashoka Spain, therefore future research could extend the research through a cross-cultural validation in different countries. In particular, the developed survey could be distributed among members of Hub community and Ashoka network external to the Spanish context in order to conduct a more global analysis.

Acknowledgements

The authors are very grateful to the social entrepreneurs of Hub Madrid and Ashoka Spain that have provide needed information for the research by responding the survey. We are also particularly indebted to Carlos Mataix, Jaime Moreno and Catalina Parra for the contribution provided through the interviews.

Structured Abstract

Purpose – The purpose of this paper is to provide a conceptual financial analysis process model that depicts intangible assets for researchers and practitioners that can assist them to enhance their understanding of valuation issues.

Design/methodology/approach – We propose an approach a theoretical/conceptual framework described as “The Throughput Model”

Originality/value –This methodology puts in evidence the processes that decision-makers use to select different types of information, which supports their position, and have ignored other information, which does not support their position. Also, the model is useful in depicting latter stages of investment bankers and financial analysts’ processes, such as judgment, that are implemented in supporting individuals’ positions.

Practical implications – The outcomes of the application of the Throughput Model helps uncover the observations and values that investment bankers and financial analysts rely upon when taking positions on issues.

Keywords – Intangible Assets, Valuation, Throughput Modelling.

Paper type – Academic Research Paper

1. Introduction

The typical financial analysis model has changed primarily due to the shift from industrial age method of valuing assets to the knowledge age method. As such, valuation has become more volatile as a result of organizational assets becoming more “intangible.” Due to this “intangible nature” of assets, ethical complexities and issues have arisen since unseen assets (e.g., copyrights, patents, knowledge products, etc.) are easier to confiscate than tangible assets (e.g., equipment, machines, tools etc.). Hence, this paper focuses on a *Throughput Model* that serves to improve the investment bankers or financial analysts’ propensities in dealing with sustainability issues in Finance (Foss and Rodgers, 2011). Moreover, the Throughput Model implements the value of knowledge and how it can be modelled to address the following financial concerns that may impede sustainability:

- a. Extraordinary leverage and increasing returns;
- b. Fragmentation, leakage, and the need for refreshment;
- c. Uncertain value; and,
- d. Uncertain value sharing.

2. Throughput Modelling Paradigm

The central insight of the *Throughput Model* approach is that perceptual inputs can be influenced by ethical considerations. This ethical insight is depicted as part of “perception” in Figure 1. *Perception* involves the process of individuals framing their problem solving set or philosophical view of the world (Rodgers, 1997). Further, Rodgers (2009) argued that perception represents a person’s expertise, classifying and categorization of information. For example, an investment banker may effectively implement cognitive heuristics by discussing about and delivering financial products to customers when other potential customers are in the same vicinity thereby influencing investment deals.

Ethics can be considered as a set of moral principles or values with the express intend to reduce harm (Rodgers, 2006). We each have such a set of values, although we may or may not have considered them explicitly. Philosophers, moral leaders, religious institutions, and others have defined in many instances ideal sets of moral principles or values. Examples of pre-set moral principles or values at the implementation level contain laws and regulations, church doctrine, codes of business ethics for professional groups

such as notary publics, and a code of conduct within distinct organizations. Quite a few individuals bifurcate or separate ethics and morality. Nonetheless, in this paper, we adopt what other philosophers tend to use that is ethics as a general term referring to both moral beliefs and ethical theories (Rodgers and Gago, 2001).

Information stage (Figure 1) includes the set of financial and non-financial information available to a decision-maker for problem solving purposes. The financial information includes liquidity (e.g., current assets/current liabilities), profitability (e.g., net income/sales), leverage (e.g., debt/equity), as well as market performance (e.g., price-earnings ratio). Whereas, non-financial information can be divided into three sub-groups of intangibles assets, namely, includes human, organizational, and relational assets (Rodgers, 2003).

Human assets include abilities, attitudes, perceptions of employees; as well as their motivation commitment and adaptability to the organization. These assets also captures individuals' knowledge has and can generate to help an organization. Human capital is critical since it is the source of innovation and renewal, whether from creative activities or a list of quality suppliers. Areas that at the cornerstone to manage human capital are:

- a. capturing a database of employee competencies;
- b. capable knowledge transfer systems enabling the needed knowledge or skill when required.
- c. implementing an evaluation and incentive system tied to the acquisition and application of competency that supports the organization's strategic objectives.

Organizational assets include intangible assets such as brands, copyrights, patents, trademarks, culture, and process capability. In addition, organizational capital contains knowledge that has been retained in knowledge repositories including the structure, processes, and culture of an organization. Moreover, knowledge sharing and knowledge transfer requires structural intangible assets such as distribution channels, communication systems, laboratories, competitive and market channels, which converts employee's knowhow into the property of an organization.

Finally, relational assets include but are not limited to knowledge of and acquaintance with communities, competitors, customers, governments, and suppliers in which the organization performs. Further, relational assets promote the brand value obtained by a

customer from conducting business with a supplier of goods and/or services. Brand value, which is part of relational assets rely upon the following components:

- a. the sustainability feature that an organization puts back into the economy;
- b. partnering and joint venturing;
- c. the license to operate in society;
- d. reputation among customers and suppliers; and,
- e. stakeholder value as influenced by an organization's ethics.

The *judgment* stage (Figure 1) contains the process individuals' implement to analyze incoming information (financial and non-financial), as well as the influences from the perception stage. From these sources, rules are implemented to weigh, sort, and classify knowledge and information for problem solving or decision-making purposes. Finally, in the *decision choice* stage (Figure 1) an action is taken or not taken. The next subsections discuss the major concepts of perception, information, judgment and choice in much more detail.

Figure 1 - Throughput Modeling Diagram
Where P= perception, I= information, J= judgment, and D= decision choice.

In relationship to $I \rightarrow P$, information influences and can reshape a person's ethical perspective as part of perception. This reshaped perceptual frame may provide a person with a modified or new ethical perspective in problem solving or decision making. $I \rightarrow J$ infers no inference from an individual's perception. That is, in a problem solving task, the information is processed or retrieved from memory and acted upon by decision rules as practiced or implemented in one's profession (such as an investment banker or financial analyst). These decision rules are encoded in the judgment stage in the model. These rules provide guidance in sorting, arranging, ranking and rating of financial and non-financial information before a decision choice or action is taken. Finally, the relationship $I \rightarrow J$

does not imply an incorrect learning or memorization of the person regarding financial and non-financial information. But, $P \rightarrow I \rightarrow J$ or $I \rightarrow P \rightarrow J$ could lead to a bias judgment. Of course time pressures, uncertain information, unstable environment and the expertise of the decision-maker contribute to whether or how many biases can distort the judgment stage.

The diagram can of course be easily further enhanced by the inclusion of the idea of auditing the financial statements which are being used. The auditor is working to ensure that the accounts show a ‘true and fair view’ and they also comply with the appropriate legal requirements. The ‘auditor’ would be set between the Perception / Information link and the Judgement as shown in Figure 2. The model then becomes more innovative in that it has the capability of ensuring that the information being used by an individual to make decisions is presented in an appropriate manner. The presence of the auditing link also removes the time pressures, uncertain information and unstable environment mentioned above since by definition the audit uses time and enables reflection by the auditor. The auditor themselves has other issues. The valuation of intangibles is a complex area and the carrying value of the asset can have a significant effect on the presentation of financial statements. Consideration must be made of the audit work undertaken.

Figure 2 - Audit Modifier in Throughput Modeling
A = Audit

3. Conclusions

In summary, the *Throughput Modeling* begins with individuals stating their views of what should be done. The advantage of this approach is that it helps decision-makers understand why individuals have selected some information, which supports their position, and have ignored other information, which does not support their position. This

approach helps uncover the observations and values that investment bankers and financial analysts rely upon when taking positions on issues. Also, the model is useful in depicting latter stages of investment bankers and financial analysts' processes, such as judgment, that are implemented in supporting individuals' positions. In sum, the model should help to better understand financial risk while addressing the following:

1. Insiders trading risk,
2. Higher costs of capital,
3. Misallocation of capital due to intangibles over or under evaluation,
4. Decreased incentives for entrepreneurs and knowledge workers, and
5. Increased volatility.

Changing the Change: E.M.E.M. A Dynamic Model for Sustainable Change

Lynes Patrick Ph.D.

Department of FEP
University of Montréal
3744 Jean Brillant, Montréal, Canada H3C 3J7

Structured Abstract

Purpose – This article proposes a global model for change that takes into account the organic reality and diversity of operating methods of individuals in order to favour the flexibility and adaptability necessary to establish a regenerative work climate and build a sustainable development strategy within enterprises.

Design/methodology/approach – We propose an empirical and phenomenological approach

Originality/value –This methodology puts in evidence the limits of pursuit of short-term profitability and the doing *more with less* mindset that produces an excessive demands on worker's capacity for change. In the current context of economic crisis, we observe flagging momentum for these specialized operating methods which imperil employees' health and the medium-term profitability of businesses.

Practical implications – The outcomes of the application of the E.M.E.M. Model offer a global guideline for individuals and human resources management to evaluate the risks with results from asking always more efforts and performance from the employees.

Keywords – E.M.E.M., organizational change, managerial change, over-adaptation of employees, sustainable development.

1 Introduction

The challenges posed by ideological, economic, technological and ecological changes are complex (Thureau-Dangin, 2012) to the point of calling into question our concept of humanity (Guillebaud, 2001). Individuals and organizations alike seek both to adapt to new paradigms and to maintain their cohesion while undergoing this dynamic of change. To do so, they rely on information or experiences that have previously proven useful and seek ways to adapt them to the new strategic challenges they face. This generates new operational models that should offer solutions to overcome our personal or organizational obstacles.

Unfortunately, these models often exhibit major shortcomings. Namely, they are based on premises that no longer hold true (ex: the availability and abundance of primary resources, overestimation of the principle of doing more with less). Or, they develop idealistic operational models which seem logical and efficient at first glance but fail to fully consider the human realities they should serve and thus meet with strong resistance when they are applied on the ground (Frietag, 1995, Lynes, 2007). Finally, the operationalizing of these idealistic models is more suited to generalized applications that deny the imperfect realities they seek to improve, deprived as they are of the flexibility and adaptability required to pursue the process of change (de Gaulejac, 2005; Lynes, 2007; Taylor, 1992).

Our continually changing world forces us not only to find new solutions but also new ways to apply them (Bouchard, Bos, 2006). In the context of this paper, I propose to present a global model for change that takes into account both the diversity of individual needs and the flexibility and dynamism we need to adapt to new contemporary realities.

2 The ultimatum of short-term profitability

The economic crisis provoked among others by the market meltdown appears to be tough to shake off. The recovery is proving stubbornly slow, exerting considerable pressure and instilling a sense of urgency within enterprises. Embroiled in a context of economic uncertainty, enterprises are terrified at the prospect of posting a poor quarterly earnings report which could unnerve investors and threaten a severe devaluation of their stock price. Moreover, with an aim to remaining profitable and competitive or simply surviving the crisis, companies engage in an intense pursuit of new short-term strategies. Occasionally, to dress up their balance sheet, they must hastily sever positions, increase reliance on sub-contractors and intensify employee workloads.

This short-term profit optimization approach has indeed led to the identification and correction of certain lapses, helped improve employee performance and maximized the gains offered through the implementation of new technologies. These operating methods, which have now been in use for several years, are however starting to show signs of flagging momentum. A ceiling can be reached in the pursuit for new ways to always do more with less. This approach calls for reliance on traditional top-down management methods which impose directives without consultation or preparation, reducing the autonomy, freedom to take action and possibilities for acceptance of change by those who

must submit to it. Consequently, this constant focus on short-term returns exposes employees to a climate of unrelenting urgency and permanent stress that overtaxes their capacities to adapt. To use an analogy, just as the acceleration of natural resource exploitation increases the ecological footprint; growing demand for the short-term profitability of enterprises menaces their medium-term survival and mortgages their workers' health.

In fact, over the past several years, worker absenteeism due to mental health and adaptability issues has been escalating. Within enterprises and organizations, insurers observe that they have become the primary reasons for sick leave and that they generally require more time for rehabilitation. Professional fatigue is a progressive syndrome brought about by prolonged exposure to work-related stress. This stress can result from external objective factors (the enormity of the task, unrealistic goals, lack of available resources, etc.) or internal factors (feeling unappreciated, excessive expectations, role conflicts, undermining of one's professional reputation, a feeling of inadequacy, etc.). Contrary to the common perception held two decades ago, we observe that this syndrome particularly affects the best employees; namely those who apply themselves the most, who aspire to meet their employer's expectations and achieve professional success. Aubert and Gaulejac contend that in their quest for excellence, these employees ascribe to the enterprise's ideals to the point of disregarding their needs and limitations and end up becoming estranged to themselves.

To motivate employees, enterprises suggest that they seek inspiration in the paths to success followed by exceptional role models such as Olympic champions. However, the general depiction of these prime models of excellence is flawed in several respects; to attain such heights these individuals must set aside entire aspects of their personal life, only a small minority ever reaches the podium, their career is short-lived, and reintegration into normal life is exceptionally challenging for quite a few of these elite athletes. In short, this model only considers the competitive aspect of work: rivalry, short-term success, neglect of anything that might impede optimal performance, and the merciless disqualification of anyone who fails to attain excellence. It implicitly discredits cooperation, time investment for the long haul, impediments to sustaining a high level of performance and any possible margin for error. Not only does this view disregard quality of life at work, it can even prove counterproductive in relatively short order. The current economic context puts competition first even as new issues that must be addressed arise:

retention of top employees, innovation, the need to stimulate synergy between various departments and hierarchical structures within enterprises, and setting parameters for sustainable development. All become preoccupations that cannot be addressed by the prevalent narrow approach of competitive performance for short-term gain.

In this context, to managers of enterprises and organizations I will propose a model for change that can promote adaptability, sustainable development, employee engagement and quality of life. This is the transposition of a dynamic experiential model for individual change I devised several years ago – the E.M.E.M. (Evolutionary Model of Experiential Movement) (Lynes, 1987-2014).

3 E.M.E.M.: a model for sustainable change

The E.M.E.M. is a model for change based on a dynamic and experiential approach. Relying on concepts developed in mind-body therapy and dance therapy, this model relates physical body movements and life attitudes. It is thus inspired by the physiology and diversity of human expressiveness. It strives to empower individuals to see how they fit into a predetermined, specialized operating method without being overwhelmed by it.

The model features two axes. The first horizontal axis represents tonus. This is a state that can clearly be felt within and can be measured by the psychogalvanic response or by blood pressure but is not easily observable from the outside. It extends from the release pole to that representing tension, passing through all the degrees of expression between these two extremes. In its positive form and dependent upon circumstances, release corresponds to the capacity to let go, to recharge one's batteries and wipe the slate clean. At other times and for certain individuals, the release state can also correspond to a lack of tonus, laxness and negligence. At the opposite end, in its positive form the tension pole corresponds to the capacity to make an effort, summon endurance and show determination. For certain individuals or in other circumstances, it can also adopt an adverse aspect which corresponds to an overestimate of one's strengths or an underestimate of needs.

RELEASE

TENSION

o-----T-----O-----N-----U-----S-----o

The second axis intersects the first vertically at the centre. This is amplitude. Much easier for an observer to perceive, this axis goes from contraction to extension while passing through all the degrees of expression between these two extremes. Physically, we can easily identify a contracted or restrained posture by the slumped shoulders, discrete body language, reserved expressivity, bowed back, bent legs, and eyes focused on the floor. In its positive manifestation it can correspond to the ability to bend to meet demands, to revitalize and to constructively recognize one's limitations. But in other circumstances or for certain individuals, it can express being weighed down, servility, lack of initiative, and trouble with recognizing one's self worth or taking one's rightful place.

At the opposite end of the amplitude axis is the extension pole. The individual found to varying degrees within this pole will have expressive body language, a bulging chest; with eyes fixed on the horizon and a forceful vocal tone, he or she will exude an impression of confidence. In its positive form, an individual characterized by this pole will be affirmative, seek to overcome obstacles, have confidence in his abilities and may even be an inspiring leader. But yet again, for certain individuals or in other circumstances, this posture may express an inflated view of one's importance, a preoccupation with always appearing to be in control even when the person feels or knows he is out of his depth, and a quest for the spectacular in defiance of reality's limitations.

CONTRACTION

EXTENSION

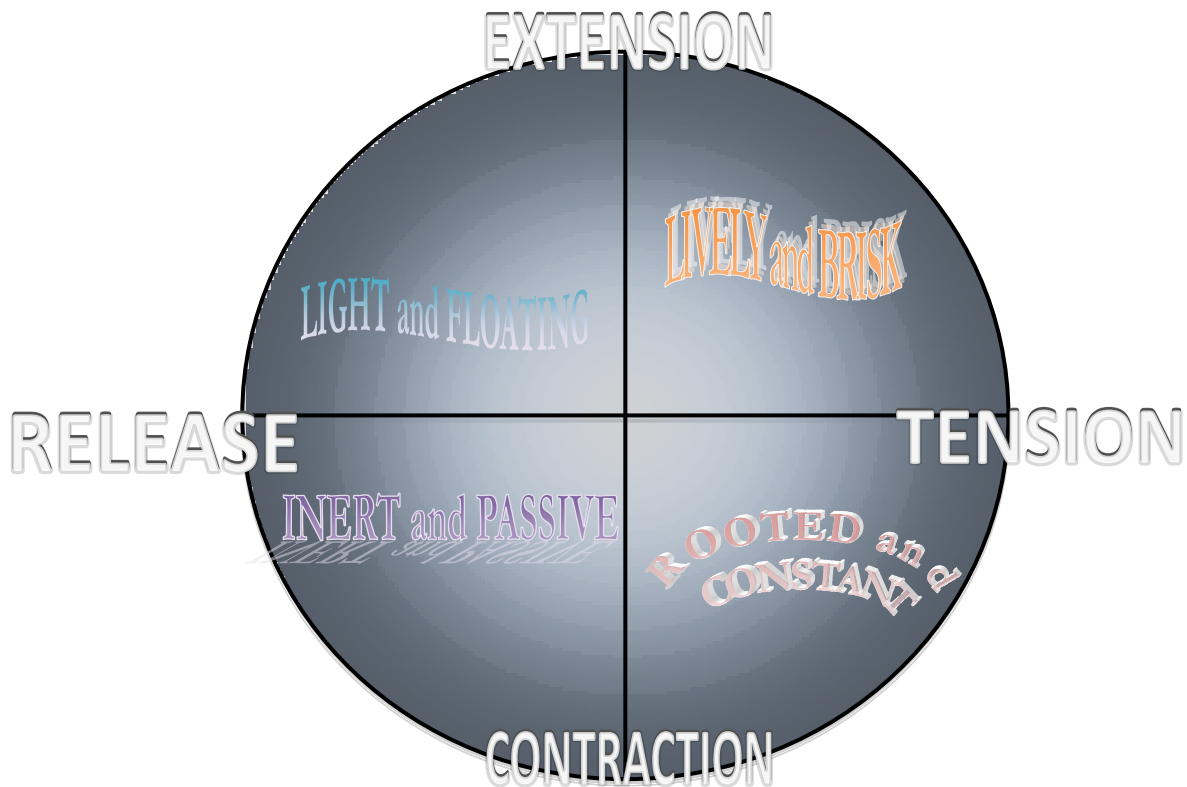

o-----A-----M-----P-----L-----I-----T-----U-----D-----E-----o

3.1 The four rhythms

In crossing, these two axes delineate four quarters which correspond to rhythmic expressions. Each of these is as important as any of the others. Some persons, due to their personality, education and experience, tend to recognize themselves more easily in one of these and less so in others.

E.M.E.M.: Evolutionary Model of Experiential Movement

Patrick Lynes 2014

To present them, we will proceed clockwise with the hands of the clock. Therefore, the rhythmic section that falls between noon and three, namely that falling between extension and contraction, will correspond to the lively and brisk rhythm.

Lively and brisk

Here gestural expression is quick, expansive, efficient and irregular. This is the rhythm assumed by someone running an obstacle course. It allows one to remain alert, ready to switch directions at any moment if the situation calls for it, and to exert the necessary energy to achieve goals. This rhythm stimulates the secretion of adrenaline which spurs action, as well as that of cortisone to alleviate pain. In its extreme expression, this electrifying rhythm mobilizes survival mechanisms; the individual will not retreat

from any effort, determined to dominate the situation and see things through to the end. This is the rhythm that allows for surpassing of limitations, achievement of exploits, and victory over one's adversary. Associated with conquest and efficiency, this is the rhythm most prized by enterprises presently. However, maintaining this rhythm systematically at a high intensity for prolonged stretches proves unsustainable. Subjected to permanent stress, the individual tends to disperse their energy, running on empty, and must summon even greater exertion to obtain the same results, while never appreciating successes which always seem to him to be insufficient, leaving him feeling overwhelmed and irritable. If the person is not sufficiently attentive to these symptoms and insists on continuing at this pace, he can even break down.

Rooted and constant

The next rhythmic quarter, located between three and six on the clock face between the poles tension and release, is that of rooted and constant. This is the rhythm of continuity, conducive to the execution of certain repetitive but necessary tasks. This is also the rhythm at which we can be present and aware of our actions. This rhythm is helpful for the fisherman untangling his nets, the massage therapist who unknots a muscular tension, or a person who must conduct a meticulous inspection. In enterprises there are persons who adopt this rhythm either as a natural tendency or as a function of the work to be done. Even if they are efficient, some of them object to looking bad and seeming to be dragging their feet in the eyes of those who prefer a more flamboyant rhythm. However, the concentration and precision required by certain tasks is ill suited to the adoption of a more expansive rhythm. It is essential to recognize the quality of work performed and the contribution of these employees, who although more discreet accomplish unavoidable tasks, if an enterprise wants to continue to rely upon their professional commitment. Being systematically constrained in an intense manner to such a rhythm also has its limits of effectiveness. The individual can become isolated in a monotonous routine, withdraw into the comfort zone of absolute control over too small a space, feel out of touch or a hostage to workplace objectives, suffer from a lack of recognition for efforts made and the enormity of the task accomplished, extending to an unwillingness to risk communicating to others the challenges faced and demands involved in the work he performs.

Inert and passive

The next quarter, between six and nine on the clock face, is that of inert and passive. At the opposite end of the spectrum from lively and brisk, and associated with doing nothing, this is the rhythm held in the most contempt. At given times, certain persons don't want to do anything whatsoever, but out of guilt still force themselves to take action. It must be noted that there is an implicit social imperative inciting us to always do more, resulting in a constant sense of withdrawal if we try to satisfy this need through recourse to external means. However, it is essential to catch one's breath to resume our path more effectively. This rhythm is that of internalization and reflection. It favors intimacy and depth. Some find themselves plunged into this rhythm during a depressive period. At such times, they would be best served to take stock, re-evaluate their situation and make better life choices that take their needs into account more suitably. These moments of inaction can thus help us avoid forging on in a way that no longer agrees with us. Some professionals who practice yoga and meditation affirm that these techniques help them strike a compensatory balance to the intensity of their professional lives. In the creative process, this rhythm corresponds to the fecund incubation period which fosters the hatching of new ideas and ways to bring them to fruition. Hours spent passively gazing at screens filled with images to which we pay scant attention are one way to satisfy this need to do nothing while having the opposite impression of being active. But then again, remaining systematically at this rhythm can prevent us from realizing our potential. Avoidance, seeking out protective isolation, and escaping into a dream world can become paralyzing. It is by engaging with the outside world, confronting adversity and prevailing over challenges that we learn to know ourselves and progress. If out of complacency or withdrawal we systematically seek refuge in passivity and avoidance of effort, the potential benefits of recourse to this rhythm fade and condemn the person who indulges in this state to a quagmire of powerlessness and incapacity.

Light and floating

Lastly, the rhythm found between nine and noon, between the poles release and tension, is that of light and floating. This is the rhythm felt by those swept up in a love affair, those celebrating a momentous occasion or even dancers who let themselves get spirited along to the tune of a waltz's melody. Sometimes simply hearing from a friend, receiving a compliment from a boss or a sign of affection from a loved one or feeling

useful to someone can stir this feeling of lightness in us, lifting the weight of the demands and responsibilities we usually bear. Tapping into this rhythm requires a capacity to let go and be receptive. We can neither decide when to experience such moments of joy or monopolize them. We can only lay the groundwork so conditions are fertile for their emergence. In poetic terms, we could say that taking a plunge into this rhythm is to experience life's generosity.

In its warrior mentality, the enterprise is wary of letting go. We are entitled to rejoice only when we have succeeded. In the economically challenging times we currently face, it could be useful to appreciate others for what they are as well in all their uniqueness and diversity and not just to underscore the achievement of a performance that current economic conditions often renders unattainable. Such generosity of spirit could help alleviate the morose atmosphere that permeates many workplaces and promote a spirit of cooperation and solidarity in these trying times.

Trying to sustain this heightened rhythm on a nonstop basis is as intolerable for oneself as it is for others. We know the sad stories of stars adored by the public and enjoying unbridled wealth who spiral to vertiginous depths of distress and despondency. The accessibility of distractions and facile access to drugs can give the impression of remaining in control for a while, but disenchantment rapidly weighs in. The dark side of existence or ideologies cannot be avoided, either for individuals or organizations. Accordingly, to take flight one must first start on solid footing. We cannot arrive at such moments of lightness of being without awareness of our imperfect reality. Trying to deny or avoid it only results in an even harder fall back to earth.

4 Conclusion; Favoring adaptability and sustainable change

This dynamic model for change has proven useful in practice to illustrate the limitations of resorting to a single operational mode. Just as a healthy diet needs access to various food sources, to arrive at a sustainable lifestyle the individual must not rely solely on a single rhythmic expression or systematically rely upon a single specialized operational mode.

Empirically, what emerges is the complementary aspect of rhythmic expressions. In fact, the more a person aspires to systematically and intensely prevail in a certain state, the more he risks being plunged as deeply into the opposite state. Thus, the person who always wants to be the best (the extreme of the extension pole) and dedicates every effort

to achieve this (the extreme of the tension pole), in denial of any impediments he encounters, can end up at the opposite extreme from his aspirations, crushed by the weight of his demands (the extreme of the contraction mode) and unable to act due to lack of energy (the extreme of release). Thus winded, he will have to gradually learn to recognize his needs and limits, so as to avoid falling yet again into a hyper-specialized lifestyle to the exclusion of all the other aspects of his humanity that allow him to pursue his life's path.

In my opinion, the former individual example can be transposed to enterprises which, out of exclusive concern for short-term gain aspire idealistically for all stakeholders within their organization to pursue the exemplary path of elite athletes. However, this unrealistic expectation exhausts employees, poisons workplace atmosphere, sets targeted objectives at unattainable levels, and incites some persons to sacrifice work quality in order to attain quantitative fixed standards or demoralizes those who, unable to conform to such laxness, are chastised for their "poor performance".

Such stress solely on quantifiable returns and the search for ways to always do more with less is unsustainable; it threatens individuals' health and commitment and impacts the operations and profitability of enterprises. I believe that we must urgently re-evaluate our operating methods and install the conditions most apt to ensure quality of life at work. We may also collectively call into question the tyrannical imperative of the constant pursuit of profit that shareholders impose on enterprises, compelling them to adopt measures that deplete and endanger their employees.

Sustainable development models are economy-centric, ecology-centric, or socio-centric (Thureau-Dangin, 2012). These perspectives are however closely linked and we are unable to intervene on one aspect to the detriment of the others without creating an imbalance and invalidating the proposed solution. Concurrently, since we must find solutions that adequately address all three components, we must recognize that this equilibrium is not static and is in constant flux as events influence us. The dynamic model for change proposed urges us to constantly readjust to accommodate these realities. Rather than seeking means to do more of what we are already doing too much of, we must learn to progress while taking into account the real time needed to assimilate the transformations that emerge and the priorities they impose along with the strengths and limitations to our capacities for change. Our world is threatened by a sclerotic or engrained subjugation to established models which deepen inequalities and accelerate the

predation of resources. But it is also possible for us, as ever, to cooperate to create a perfectible world in which our common humanity will reclaim its rightful place.

Urban Communities and meta-communities

Structured Abstract

Purpose Urban communities and meta-communities

The scientific debate has recognized that the sustainability cannot exist without a radical change of behaviours, and the community is the most suited place for this course. On this basis, a model of city as a cluster of villages (this definition has been recently formulated by Vandana Shiva) has been proposed, but it pays no attention to the recent innovations, most of all the ICT, which can give a deeper sense to the the concepts of network, cooperation and community. The focus is not the invention of urban communities, but returning a communitary dimension to the cities, to which it has been detracted by the modernity: the local structures have always played a central role, offering complex services, hosting relationships networks, economic activities, voluntary mutual aid societies and assuming so strong features to define the identity of their inhabitants. The crux is in lending new contents to this traditional heritage, connecting the communities and generating a virtuous circle of people, products, exchanges, relationships, aid and resources, starting with the energy ones: according to Rifkin, the energy production from renovable sources has left the "petroleum logic" of the great plants, migrating to a self-sufficiency and community logic. The proposed model regards the city as a strong network of communities, in which economic, human, cultural and energetic assets are produced and shared, with a new concept of self-sufficiency, an interconnected self-sufficiency. The virtual projection of assets, people and informations which constitutes the network is, de facto, a meta-community, a place and its projection at the same time. In brief, the features and the benefits of the urban communities can be so epitomized:

- More rational organisation: the technologies, mixed with a smaller scale, allow an optimal management.
- Targeted investments: the community manages the funding resources according to the needs, it has more assets than the individual and can benefit from more advanced technologies.
- Networked energy production: the community can choose the best solution to produce energy, common plants or individual networked plants, and it can use the network as accumulator.
- Exchanges, mutual aid, more relationships: the city is the network among the citizens and the places, paraphrasing Weber and Geertz, it secretes the relationships and it's secreted by the relationships. One of the main functions of the community is the importance acquired by the mutual exchange and aid and by the cooperation.
- Social control: in the huge and undefined metropolitan context, the good and bad actions are dissolved in a mare magnum; in a community, on the contrary,

everyone can check the outcomes of his own and other people's practices. The neighborhood watch, modern version of the multiparental control, falls under the same category.

Design/methodology/approach The proposed approach matches the instruments of several disciplines, a peculiar tract of the ecology as science. In particular, anthropology, history and the latest acquisitions of the sustainable city planning build a combination of traditional thoughts and new solutions, as well as of quantitative and qualitative evaluations. The methodology is prompted by the thick description approach, proposed by Clifford Geertz, which is composed not only of facts but also of commentary, interpretation and interpretations of those comments and interpretations. The thick description leads to a re-definition of sub-urban identities, the substratum on which we can rebuild sub-urban communities, filling them up with cultural meanings, economic contents, praxis and relationships. The combination of the communities and the potentialities of the network generates that implemented projection of community which we call meta-community.

Originality/value – This methodology puts in evidence the complexity of the problem, using more disciplines to approach it, and the importance of the social and anthropological aspects of the sustainability; it also underlines how a part of solution be already located in the cities and in their past, constituting a fundamental long term asset.

Practical implications – This survey aims to indicate a model of urban organisation which could be easily realised in european cities; it will be the object of a european JPI Urban programme in the next year.

1 Urban Communities and meta-communities

Interpretative anthropology, especially as explained by Clifford Geertz, taught us that a cultural phenomenon may be and should be interpreted as a text, whose relevant features are not only the forms in which it has revealed itself and the categories through which it has been perceived and interpreted, but also the description of the cultural issue made by internal and external observers and, of course, the vertical and horizontal relationships between these elements¹. Therefore, the analysis becomes a narrative operation which is in a dialectic relationship with the great meta-narrative systems - or even in opposition to them - that marked the period identified as modernism by some disciplines, often in a mutual morphogenetic connection with that phase called post modernism: according to Lyotard, the fading of significance of meta-narrations constitutes the distinctive element of post-modern. The ambiguity of this category discourages its use, yet it is a fact that the recent years – studded by powerful social,

1 CLIFFORD GEERTZ, *The Interpretation of cultures*, Basic Books, New York, 1973.

cultural, technologic and environmental phenomena – have experienced a linguistic explosion and a semantic wear and tear so powerful that they could not help leaving a trace on settlements, beginning with the cities. In 1979 Lyotard also recognized an atomization of language and its dispersion in “clouds of narrative elements” which, actually, produced a corresponding spatial atomization, the coming apart in the relationship between place and signification, in which the place was made up of the city category: Lyotard, Foucault, Fish and other scholars interpreted this phenomenon as a fragmentation which generated “interpretive communities” as defined by Fish, or a “platelet reticular network” as defined by Lyotard². Therefore, they claimed a process which would replace the modernist concept of a rational city based on large scale urban plans with a type of city seen as a composition of nuclei and, moreover, as a palimpsest, since the diachronic element concerning “space which encloses and contains time” had entered the debate over urban planning and the nature of cities. It can be noticed that this image of reticular communities – or community networks – which are mutually and perpetually changing - closely reminds us of the “liquid” category proposed by Bauman as a hermeneutical key to modernity which loses most of its innovative allure in the contest: not liquid but “soft” was London – as an ideal type of city – as described by Raban in the early Seventies: a set of stages on which the individual showed himself in a series of interpretations, whose lifeblood was made up of “signs, styles and quick, highly functional communication systems”. “The city” – Raban summarized – “our great modern form, is malleable and referable to an amazing sensual variety of lives, dreams and interpretations”³.

The weakening of “tough rhetoric” which had covered the form of the city with an improbable neo-enlightenment simplification, revealed the complexity of an organism subject to modifications induced by tensions – from an etymologic point of view – among a number of cultural production centres which are organised, according to Cosgrove, into dominant, residual, emergent and excluded cultures⁴: the great geographer underlines that even residual cultures play an active part in the morphogenesis of a city. On the basis of these results, in the late Eighties Leon Krier proposed a development model for England, in which a great urban expansion was to come, with cities made up of complete finished

urban communities: this would have been, according to Krier, the only remedy for widespread symbolic poverty caused by functional zoning⁵. More than a proposal, Krier makes an analysis which is particularly valid for those European cities that, since the Middle Ages, have agglutinated in polycentric, substantially independent structures. These dynamics, which are studied in different cities in the North of Italy and in Europe have been brilliantly underlined by Jean-Claude Maire Vigueur's evocative picture of Rome during the Middle Ages, a context whose peculiarity confirms the general validity of the model⁶. Subject to different types of conditioning, the Romans gathered around heterogeneous focuses, constituting substantially autonomous communities that enjoyed a great availability of space to rebuild, in a limited spatial context, the functional complexity which was necessary to fulfill every need. The historian proved that this process of aggregation and identity reconstruction allowed the Roman population to oppose their will, often successfully, to the will of the big baronial families which ruled the cities. From the Middle Ages, suburban communities played a vital role on the development of cities, becoming resource management systems, mutual assistance societies, systems of aggregation and political pressure, and military structures. The city as a cluster of communities, as Vandana Shiva recently defined it, is not a product of post-modern fragmentation, but the habitus the European urban populations have adopted to give a shape to their own "being in the world"; the structures and dynamics produced by this habitus then and now are still evident in several European cities, and even more so in many South American metropolises, where the demographic expansion and the consequent extension of cities were not strictly regulated, but were carried out through spontaneous phenomena of bottom-up urbanization. On these themes, a scientific tradition, justified by the renewed interest in the topic of community - which had been overlooked for some decades after its renewed popularity in the Sixties and Seventies - begins to consolidate, this time in connection with environmental issues as well. It is believed that, in fact, the number of measures to face environmental issues are insufficient and that it is necessary to radically intervene on people's behaviour, beginning with the forms they can take. This evolution is perspicuous if we compare the different "State of the World" reports by the Worldwatch Institute, in which we can find a progressive rise

5 LEON KRIER, *Tradition-Modernity-Modernism: some necessary explanations*, in *Architectural Design Profile*, 65, 1987.

of issues concerning communities, new ways of living and lifestyles. The latest report questions the idea of sustainability and its achievement, and gives space largely to matters concerning the traditional diet of native populations and in particular to their sacredness; an essay by Collins, Genet and Christian calls for “a new narration in support of sustainability”; resilience and community are shown as the reference values to react against environmental crisis and natural, economic, health-related and social disasters; an interesting essay by Pat Murphy and Faith Morgan, finally, urges the world to learn from Cuba, which has to face a forced decline to which it reacted taking measures of social and value organization that meet those “survival architecture” fascinations proposed by Yona Friedman as a reference for future development.

The relevance of the community emerged strongly from the recent discussion on the environmental crisis and from the number of solutions given by different disciplines. If we do not fall into the temptation of consolatory quantitative solutions, it will be clear that the environmental crisis concerns our being there and that it comes from the same spring that fed the Greek tragedy, that is to say, from that violation of the limit called *hybris* by the ancients: in fact there is no other way to recompose the variety of phenomena through which the crisis appears. Philosophy has proposed different solutions and the one that has mostly taken into consideration is the rationalistic ethic based on Hans Jonas’s principle of responsibility, whose formulation, nevertheless, appears to be unsatisfactory and inadequate for several reasons: leaving out the eminently philosophical arguments⁷, the main flaw in Jonas’s theory consists in its weakness as a bond, because it constitutes a moral imperative – not a categorical one – whose coercive effect gets weaker and weaker according to the scale to which it is applied, that is to say, humanity.

In such a wide context, the echo of individual actions fades and then disappears, watering down the positive and negative ones inside a general perceptive indetermination; the reference to future generations, moreover, averts the time of praxis and puts the cogency of the problem back in its right perspective. Actually, Jonas’s principle of responsibility constitutes the philosophical counterpoint of the idea of sustainable development, as it is formulated by Norwegian minister Bruntland, to such an extent that the two definitions seem to be superimposable. We cannot discuss herein the contradictions and ambiguities of these principles, it will be sufficient to underline how they take away effectiveness and urgency from praxis, even from the individual one: the

7 NICOLA RUSSO, *Filosofia ed ecologia*, Guida, Napoli, 2000, pp. 374-392.

optimal scale for these interventions is made up of that *hic et nunc* of relationships called “Circumstance” by Ortega y Gasset which can be undoubtedly recognized as the Community⁸.

On a smaller scale, actions acquire an immediately perceptible relevance and their consequences immediately reflect on individuals; negative actions, moreover, are stigmatized and weakened by social control, which is poor, if not impossible, in larger contexts. After decades of studies on eusocial insects and a long time tendency towards a “familist” thesis, evolutionist biologist Edward Wilson acknowledged that the community is the result of powerful Darwinian forces and constitutes the optimal soil to achieve the best living conditions for mankind⁹. That complex balance between selfish and altruistic behaviour which has guaranteed the survival of our species and formed our culture appear to be, in fact, unfeasible outside a collective context but at the same time, restrained enough to protect the relevance of individual behaviour.

Citing another recent study, it is not by chance that, when declaring the reasons of his interest in traditional societies, geographer and anthropologist Jared Diamond first introduces a criterion of scale, proposing the obvious remark that in a more restricted context, the relationships between men and their surroundings – the Circumstance, indeed – are more perspicuous. According to Yona Friedman, the time of community is not the past at all, but the future, when the bent for flexibility and adaptability guaranteed by the soundness of personal relationships ensures that cities acquire more and more the appearance of agglomerates of constantly connected groups, arranged on non-permanent, flexible models¹⁰. The ruralist nuance we give to the idea of community is a modern distortion, easily belied by the obvious consideration that a communitarian spirit can be detected in the Greek *poleis*, therefore in eminently urban contexts: if we try to separate the definition from the semantic conditionings of the contingency, we can define the community as a network of meanings and signs which correlate a human group, that recognizes itself in that network, and its Circumstance; this network is produced by the morphogenetic relationship between its knots to such an extent that we can say that it secerns and is secerned at the same time. The community exists everywhere this

connection takes place, even in a urban quarter. Arrigo Colombo asserts that “if the community model as a universal model [...] may seem incongruous nowadays and most of all, in a future perspective, there is a diversified, well-constructed community model [...] a reduction and composition of communities which range from the family to the school community and the university [...] to the political community mostly and essentially as self-government and local assembly. The picture of a brotherly society seems to be drawn in this construction of communities”¹¹.

The quarters – or other similar divisions of the urban territory – are characterized by recognitive features, iconems, signs and traditions and most of the time they possess a strong consolidated and more or less ancient identity. Especially in the European cities, moreover, they are easily identifiable from a urbanistic point of view, since they are often aggregated around particularly relevant focuses. This constitutes an essential precondition for their rearrangement into urban communities, a process that in many cases has already begun or, more correctly, has endured preserving the vitality of the social and economic fabric¹².

The transition of territorial divisions into urban communities is, therefore, easily feasible and has several significant benefits, which can be summarized as follows.

Scale reduction: a smaller structure can be managed and controlled more easily, the interventions can be planned more clearly and better suit the users’ needs; the statistical surveys become more relevant as they represent the citizens’ behavior and give accurate information on the criticity of the management systems. Reducing the observation scale to that of a quarter-village, therefore, we would be able to accurately monitor the flows by recording, for example, the inbound and outbound resources. It is valuable information especially because it allows to modify a urban metabolism that must restore reusage and closed cycles, increasing resource exploitation and not the quantity of resources we use. Monitoring the fluxes allows us to enrich that network of exchange of people, information, goods and resources: the better it is structured, the better it works.

Bottom-up processes: in a more restricted context, less resources are needed, planning is easier and benefits are immediate and perceived straight away. Therefore, although a traditional management from above would obtain benefits from dividing the urban fabric into spontaneous villages, they constitute the ideal place to put into practice

12 LEONARDO BENEVOLO, *La città nella storia d'Europa*, Laterza, Bari, 1993.

bottom-up processes.

Social control: in a wide indistinct context social control is not required and cannot work, neighborhood relationships are weak, an individual interest limited to very restricted surroundings prevails; when the context is smaller and other people's harmful behaviour affects the individual more evidently, there is a greater interest in disciplining one's and other people's behaviour and the opinion of the community becomes a powerful weapon to stop dangerous behaviour. Social control also involves the virtuous action of neighbourhood watch, which means extending the surveillance usually carried out on somebody's property and relatives on neighbours as well; it derives from the traditional neighbourhood relationships, although it dates back to recent years in American and English quarters – where relationships between people have been damaged by modern lifestyles – in order to build relationships between neighbours. They are benefits whose effects are extremely relevant: data collected by the police have shown the effectiveness of neighbours mutual control and many recent studies, American studies in particular, show that living in a community may make people live longer, especially because depending on other people's support reduces stress and the anxieties generated by modernity.

Sustainable mobility: public transport is quite emphasized, partly because of the territorial expansion of big European metropolises and in particular, in newly industrialized countries. Compact cities are a partial answer that reduces the occupied surface, but the size of cities with a high housing density and millions of inhabitants is still unmanageable. Urban villages, instead, give a very interesting complementary solution, since they contain a series of facilities and activities which are often situated in other parts of the city and can be reached only by moving many times.

Density and functional complexity: giving back the quarters their functional complexity by transforming them into villages means to allow people to reduce their movement and use bicycle and pedestrian mobility. The more quarters convert into urban villages, the more relevant the effects: in a great cooperating context, in a urban village organized as a community which tends to self-sufficiency, citizens will be able to reach all the facilities they need near their house, as well as most of the goods and some of them are made locally. Moreover, in an advanced system even the workplace may be closer: in Europe and the US, big factories yield the ground to tertiary sector, small factories or handicraft, which are all activities that can be carried out in a urban context. Urban

communities full of facilities, goods and services are also a solution to the problem of emptying city centres, which has reached disturbing levels in many Italian cities and transformed, for example, places of deep complex anthropization into open-air playgrounds.

Self-sufficiency: a complete urban village is supposed to have at least a partial self-sufficiency and to be a place where most of goods and services for local use are produced, beginning with agricultural products. Many people have shown an increasing interest in urban agriculture recently: Bill Mc Kibben, author of *Deep Economy*, estimated that big American metropolises may be able to produce at least 50% of their own food needs by carrying out urban agriculture. Self-production, Mc Kibben added, if combined with the communitarian demands of cooperation and sharing, may have many other consequences: urban farms involve the effort of several families and allow to obtain better results with less individual effort; consuming the fruits of a teamwork – Mc Kibben underlines the drastic decrease (50%) of family lunches in the United States –allows people to build solid personal relationships and also optimize the use of resources.

The challenge in the near future, he concludes, will be to get small towns out of metropolises. Owen too considers urban agriculture as a big resource and notices its increase in many metropolises of the world: American cities, with their huge sprawls, show us a vivid picture of the space that can be used for farming and other productive activities. Yona Friedman, who refers to FAO studies as well, tried to give some figures: 40 square metres are sufficient for one's subsistence, while 100 square metres meet the total calorie needs of an adult; working 20% less and spending more time farming and doing housework would guarantee a saving which may reach 80%. This data are contained in *Alternatives Énergétiques*, whose meaningful subtitle is "*Compendium for a local self-sufficiency*", an essay that gives self-production a quantitative dimension; in *The Architecture of survival*, Friedman writes about urban villages and agriculture: the cities, the Hungarian architect underlines, are full of unused spaces which may be used for new functions. This idea combines with one of the leitmotiv of his original thought, that is mobile architecture: in Friedman's vision, the cities are light, versatile and cooperative, their inhabitants enjoy the collectivization of part of the spaces. The plots of land that can be obtained from unused spaces may not be sufficient singularly, but may produce a food surplus if connected and farmed jointly.

Agriculture is only one of the activities which can characterize the rebirth of urban

villages: craftsmanship, especially the one concerning repairing, small scale retailing, especially the local one, but also professional services. Encouraging local consuming and service fruition means to give the population large quantities of benefits. Cooperation also allows to develop advanced services without any economic burden, which work by mutual assistance, like baby sitting, kindergartens, afterschool programs and other educational experiments; there may be also comanaged activities like laundry services, a solution which may lead to a more efficient use of energy and water and a lighter individual economic burden. Many of these projects have already been feased in North European quarters, beginning with Eco Vikki in Helsinki, and are commonly carried out in many South American metropolises. The urban village, therefore, has got a number of advantages and an undeniable improvement of living conditions: it creates a network of relationships and solidarity which represents a sort of protection for its inhabitants, preserving them from many daily problems and external disturbances (a local self-producing economy is definitely immune to financial storms) and facilitates all management and control processes and also services. It is worthwhile to repeat that all these principles can be put into practice in different ways and at different paces and, above all, that a cooperative supportive economy may coexist with the traditional economic relationships: the aim of cooperation, on the other hand, is to put the free time of a community to good use by optimizing it.

A community is the result of composition and recomposition (concerning this, the fascinating discussion on utopia from Servier to Mumford is particularly interesting, see bibliographical notes), so communication has always played an essential role in it. For this reason, Mattelart focused his work *Histoire de l'utopie planétaire* on communication, suggesting interesting forerunners of modern technologies, such as the optical telegraph: in 1795 Alexandre- Théophile Vandermonde proposed to use the optical telegtaph to create a modern form of direct democracy. He was a teacher of Political Economics and claimed that this kind of technology would solve the age-old problem – as old as Plato's works at least – of community dimensions, since – as Rousseau had warned – there cannot be any democracy beyond the range of voice. A widespread network of that device, similar to the one installed earlier between Paris and Lille, would have allowed to connect directly and constantly the whole country, making collective shared decisions, a topic which is clearly similar to the contemporary discussion on Internet as instrument of participatory democracy. The scholar's proposal triggered a lively discussion but, as it

happens in every dystopia, in the end the solution was found by the army, who took upon themselves the use of the telegraph line for war purposes only. Apart from the many unsolved problems of the project, Vandermonde's proposal shows that guiding thread that connects utopic thought with the communitarian one and suits the need for integration and recomposition. ICT technologies add to ancient community dynamics, which date back to its foundation, not only a new more powerful tool nor just innovative functions, which will be analyzed later, but also different logics and even new space production systems. The datas which are transferred through new technologies, in fact, do not have only a different medium, but a peculiar, almost ontological statute, since they have all together the freedom to generate space, although immaterial. The network of relationships and exchanges between communicative subjects through ICTs, in fact, defines a metaspace and inside of it communities project themselves into metacommunities, which are generated and enriched by the contents people exchange through the net.

The contemporary historic form would not exist without the importance communication networks have gained lately, moreover, while they were contributing to the semantic demolition of the idea of place, they were producing another place, a metaplace, that is the virtual one. If a community is, by definition, a network of signs, the contemporary community cannot help but project this network to the outside, producing a metacommunity, that is the virtual counterpart of the physical one, and this metacommunity cannot help but connecting with the other ones, in a flux of signs, meanings and contents. It is important to underline that, although the vocabulary may induce to think so, this image cannot be superimposed on McLuhan's global village. McLuhan is, probably, one of the last great utopists of means, but his utopia is on a worldwide scale and cannot exist without the model indicated by Brzezinski as "global model of modernity"¹³, that is that series of issues and needs that used to be part of the American way of life exported worldwide during the Sixties and the Seventies. It is not by chance that the themes McLuhan and Brzezinski proposed are found in Al Gore's speech for the GII (Global Information Infrastructure) presentation at a meeting about telecommunications in Buenos Aires in 1994: the American vice president supports a new Athens which could be possible thanks to simultaneous real time communications, an age

¹³ ARMAND MATTELART, *Histoire de l'utopie planétaire: De la cité prophétique à la société globale, La Découverte, Paris, 1999, p. 352.*

of global harmony¹⁴. When Mattelart admits the failure of utopia he actually refers to worldwide utopia, that is the wish to recompose the human Babel in a global village which has not only the form of relationships, but also the cultural substance. This wish collides with the considerations made about the scale and, more generically, with the lack of place, of the Circumstance in which the relationships and connections that cannot be obtained elsewhere are created. It is the Circumstance that makes a global society unfeasible and draws, instead, a reticular image of interconnected groups. On a urban scale, this model expresses its potentialities to the full, reifying that continuous adaptive tension between model and praxis that is chosen by Bertelley, for instance, as a fundamental dynamic of any community, beginning with Plato's Republic. On the same line, the model of a city as a cluster of villages has a different importance: going beyond the suggestive image of a cluster, in fact, the big cities would configure as networks of communities in which a virtual network superimpose on a physical network of relationships, fluxes and exchanges. The virtual network is not only an instrument for flux control and optimization, but also a projection of the community network itself, a meta community. Such a model would allow the restitution of complex functions and services to urban subunits, by restoring quarter communities which have characterized the traditional European settlements, for the benefit of life quality and eco compatibility, with more interpersonal relationships, less movements, less transfer of materials and people: if the quarter offers advanced services, job opportunities and places for self-production, the problem of transport will drastically decrease and lose importance, as demonstrated by the experiments made in some German and North European cities. The services and facilities that need a larger scale, a urban one, would benefit from the computer control structures guaranteed by the net and already fully recognized, since the smart city model is the hub of the EU investment plan for the next six years; the same fluxes of resources may be controlled by management softwares, this would help optimize the use of inbound resources, but also self-production: a virtuous cycle of production and exchange of goods and services between communities would begin and this circuit would be more effective and immediate thanks to ITC. In addition, the reduced scale of the urban community would give back statistical surveys their own value: in fact, data would not be indefinite as for a metropolis, but would concern the citizens who live in that very community, that is, that particular human group. The most fascinating aspect of this scenario is the new

14 MATTELART, *op.cit.* p. 401.

and more radical meaning of the idea of morphogenesis in this context. It has been said that the single knots of a community network are in a mutual morphogenetic relationship, since each one of them influences the form of others and, at the same time, it is influenced by them: the use of telematics networks through computer applications, even self-produced ones, give us a new idea of morphogenesis of networks, in which the ideas of flexibility and adaptability - that according to Yona Friedman will inspire physical architecture in the near future and are already visible, in a spontaneous form, in South American metropolises – are fully put into practice¹⁵. Place of exchange, relationships, communication and hypercommunication, a metacommunity is not only a structure of management and control, but also a real community, because it creates a network of signs with users and the meta place it occupies. In an essay published in 2012 edition of *State of the World*, Diana Lind listed some of the innovations in intelligent cities management: they are proposals which have been developed mostly through a bottom-up process, often carried out by citizens, but the most important aspect is their relationship with their surroundings¹⁶. These examples, in fact, are not universal solutions to general problems, but come from an internal discussion in a group whose commitment concerns its territory, as a reaction to specific problems of the territory itself; but as they are carried out in a modular way, they can be easily adapted to other contexts, transferred through the network. It represents a new element that overtakes the *think globally, act locally* strategy; in this case, thought and action are indissolubly linked to place and are then enriched, modified and spread globally. A maybe utopic future is coming, in which behaviour and the way people use cities and parts of the urban space will be produced by citizen communities operating in a particular place; these products will derive from the relationship between human groups and Circumstance and will have a double nature: a material and an immaterial one, connected but independent. As Lind said, citing an article by Carlo Ratti and Anthony Townsend, 'we discovered that it is sociality and not efficiency the real killer of the city. Cities will be probably saved by people and not by technology, by serendipity and not by programming'¹⁷. The pair community-metacommunity relieves the tension between localism, that is a peculiar characteristic of the communitarian approach, and irenic planetarism, generally typical of utopic thought,

generating a system made of a proficuous relationship between the webknots: each knot is autonomous but in a morphogenetic relationship with the other knots. Actually it is a recomposition, that is what mankind has always looked for in utopias.

Structured Abstract

Purpose - This study presents preliminary evidence of an ongoing research project (Orchestra - ORganization of Cultural HERitage for Smart Tourism and Real-time Accessibility) on smart city platforms. Our analysis refers to smart city platforms meant to develop a set of organizational solutions to foster the sustainable compatible exploitation of cultural and touristic resources in the city of Naples. The main goal is to outline a framework able to explore participation patterns. We explain intrinsic and extrinsic motivations employed for the engagement and the retention of participants on web 2.0.

Methodology – Our empirical research follows a qualitative approach and consists of two phases. In the first one, we adopted an internet based research method, investigating four travel communities that employ incentive mechanisms to encourage the user-generated content: Tripadvisor, Travellution, AirBnB, Voglio Vivere Così. In the second phase we conducted semi-structured interviews to the administrators of these travel communities. We expanded our study in order to investigate the administrators' perceptions and the meanings attributed to motives and incentives. In particular we aim to understand which types of incentives are better employed in these communities to engage and retain users.

Originality/value – The crowdsourcing topic gained in popularity over the last decade, as more and more users have begun to flock to social communities. Our contribution is twofold. First, through an analysis of the recent literature on the crowd topic, we provide reflections on intrinsic and extrinsic motives. Second, through the case studies we shed light on a partly jagged and new topic related to the use of incentive mechanisms in order to recruit and motivate crowd. In particular, we try to explain some preliminary insights and emerging issue needed to create a model that could be applied in the ORCHESTRA platform.

Practical implications - By taking into account the incentive mechanisms and the sense of fun perceived by its users, we have reflected on the implications for the web 2.0 by looking at the mass of creative subjects that take part in crowdsourcing activities. Our argument is that the ‘architecture of participation’ surrounding the web is inextricably linked with the perception of enjoyable experiences deriving from networking activity through the mobilization of millions of voluntary actors. The inclination towards interaction would appear to be the level for motivating many web initiatives. Several communities began huge business all over the world thanks to user-generated contents.

Keywords – incentive mechanisms, participation, crowdsourcing, social communities, user-generated content.

Paper type – Academic Research Paper

1 Introduction

This study presents preliminary evidence of an ongoing research on smart city platforms. Our analysis referring to smart city platforms takes place within a research project (Orchestra - ORganization of Cultural HEritage for Smart Tourism and Real-time Accessibility) meant to develop a set of organizational solutions to foster the smart, sustainable and ecologically compatible.

The main goal of our research is to outline a framework able to explore the participation patterns. We explain motives and intrinsic and extrinsic incentives employed for the engagement, the retention and the motivation of the “crowd”, that voluntarily participate on web 2.0. In particular, the crowd is represented by the users that with different roles and tasks produce and offer contents on online social communities (user-generated content). The bottom-up participation issue and the role of the crowd in web contents production will be the focus of this paper. In particular we try to explain which tasks the crowd performs on online communities and which are the main motives intrinsically and/or extrinsically based, that lead users to participate. Our assumption is that on these motives communities administrators should invest to incentivize the users’ participation.

In light of these aims and assumptions case studies of four travel communities will be presented. We choose these travel communities because their administrators employ many incentive mechanisms to encourage the crowd participation and the user-generated content (UGC). We analyze the case studies in terms of three research questions:

- Which roles and tasks do users perform in online communities?
- Which types of contents do users generate?

- How do users perform tasks and generate contents on online communities? which are the motives and the incentives?

The paper is structured as follows. It begins with a contextualization of the crowd issue in social and managerial studies. Then we analyse roles, tasks and contributions of the crowd reflecting on the fact that many online communities, wiki -pages sites, open source projects, and social networks are based on the idea that users are key to success and that they sustain creativity, innovation and solutions. The focus then moves to a systematic review of the literature on main motives and intrinsic and extrinsic incentive mechanisms that lead the crowd's participation. Finally the case studies are described and analysed on the basis of the research questions; and the conclusions and main limitations of this study are presented.

2 Contextualizing the crowd in managerial studies

Between the late '800 and the early '900 Le Bon and Tarde (1895; 1901) introduce the concept of crowd in social studies, as an improvised aggregated of individuals, giving a purely negative meaning. In fact, the authors state that the crowd (several individuals together without a specific order) could be a threat for the civil society.

Over the years, the sociological and organizational literature has produced different meanings of the crowd concept, in some cases reducing that negative connotation before given. In particular several studies have focused on the establishment dynamics of the crowd, dimensions and the relational characteristics, therefore individuals beginning crowd acquire a new social identity (e.g. Park 1975; Diener, 1979). In this sense the thought on the crowd concept is strictly related to to the studies on the work group; then individuals as a group perform better than a single individual and it is something more than the mere sum of individuals. Over the years the crowd starts to participate not only in political and institutions events and going further the mere ideological purpose. Brabham and Page (2006; 2007) argue about the contribution the crowd coul make in terms of diversity and meanings in problem solving. The crowd participates with a process of association of ideas that rise through mutual interaction, cooperation and, critical feelings (Park, 1975, trad. italiana 1996). The crowd actively participate with different roles and tasks coming into different domains of the society and with relationship mechanisms that in the last decade strongly changed. In 2007 one of the Time cover entitles "*You*" referring to the new actors of the web 2.0: that are all the

individuals that participate on social networks, forums, blogs, virtual platforms, producing new contents and offer new meanings to the communication ways. Web platforms, blogs, online communities and other types of virtual interfaces are often defined as 'places' in which the active participation of users is clearly manifest. This new phenomenon leads to a new business model of the web based on open participations and shared relations. The roles the crowd plays in social communities and web platforms (of different sort) become the lever of competitiveness and generating new knowledge that spreads quickly and economic value.

The technological innovation and the web 2.0 become the domain for the high potential of people, for their skills, ability, ideas, through a network of not formalized social relations (Furlani and Lutman, 2012). Besana (2012) states that to be able to rapidly and immediately getting in touch seems to be the most important element.

The crowd that participates on the web 2.0 shares information, contents and data that in turn generate other new ideas, but also new and additional needs and demands to be answered. Therefore online social communities are frequently depicted as venues for users' active participation in various forms of co-production, where ideas develop and enrich thanks to new interactive experiences and the contributions of others. Moreover these ideas could "get out" of the web turn into start up, associations, etc. (Gassman, 2006).

It is clear that this massive change has an impact on the structures of several organizations, modifying their image. To face this change organizations have to re-shape their business approaching to the virtual communities world. The ability of the organizations connected to virtual reality is to engage a mass of individuals (not employees) who provide their entire subjectivity and their contributions for a new product or service in a voluntary way, just because "they like to do it" (Kodama, 2005).

In this sense, it is the whole distinction between production and consumption that is questioned; it is in the wake of the changing relationship between consumers and producers that we can find the foundations for the phenomenon of crowdsourcing, and more generally for the implementation of productive forms based on social cooperation (e.g. Howe, 2006). About this, literature is increasingly focusing on this topic, highlighting the role of the crowd participating on virtual and social communities, as a real business model creating value (Hagel and Armstrong, 1997; Lechner and Hummel, 2002; Sun et al., 2012).

As observed by Jeppesen & Lakhani (2010), even if problems can be solved through a variety of alternatives, some of these problems have no solutions if just internal resources available inside the company are used. Web 2.0 and social networks become repositories of solutions, knowledge, informations. Webb and Tohen (2010) use the concept of "Proudly Found Elsewhere" to better competitiveness and innovation.

According to some scholars (e.g. Arvidsson, 2007), the diffusion of online platforms involves a process of democratization of the economy, and this is represented by the key role of users. Following this perspective, blogs, virtual communities and other virtual interactions seem to move toward a more democratic approach of the entire society, with users' sovereignty as the key principle. A newly empowered user – whose structuring trait revolves around creative expression, cooperative activity, and a playful attitude – has arisen as the participating subject of the numerous living web platforms (Tapscott and Williams, 2006) and virtual worlds where the quality and the value of the social relations are crucial for the innovation. This seems to follow a logic based on participants as 'operant resources', where they are framed as active contributors in relational exchanges and co-production (Vargo and Lusch, 2004). Tapscott and Williams (2006) this 'participative paradigm' deriving from online collaboration. The authors account for a 'new world' of 'ever-connected people' which are the mass creativity of many 'web initiatives'. The idea of collaboration to achieve common goals is the cardinal principle. Also Van Dijck et al. (2009) critically discuss the participatory culture. They dismantle the 'rhetoric of connectivity' as a means for companies to extract value from 'networked active co-creators' (p. 863). Following this perspective, clicking, blogging and uploading videos are, among others, activities carried out by an 'army of amateurs who dedicate their time and energy to developing and sustaining a vast array of products and services'.

From this angle, the web 2.0 includes as its primary raw material users' contributions. The promise for them is receiving recognition and, potentially, to seek their sense of self-worth by marketing themselves to other virtual actors (Bauman, 2007).

3 Roles, tasks and contributions in social communities

The bottom-up process of the active crowd that participates through the web to create value also involves businesses massively, especially those that deal with innovation in a broad sense. This, together with the overbearing development of social networks are profoundly changing the way of production (Shiffman et al., 2008).

Garrigos et al. (2012) emphasize that without the participation of users on online platforms, without their contents, it would not be possible to understand what is happening outside the organizational contexts influencing the economic trend. Fuchs et al. (2010:46) state that “the user is an integral part in the production process of content, tastes, emotions, goods, contacts, relevance, reputation, feedback, storage and server capacity, connectivity, and intelligence”.

The practice of crowdsourcing – in which companies outsource a function or task to an undefined network of people — is nowadays becoming mainstream (Howe, 2008; Geiger et al., 2011).

In the social communities, crowdsourcing activity largely covers the process of creating and generating new ideas and solutions, unlike the case of the open source community where even the commercialization processes are being outsourced to the crowd (Pisano and Verganti, 2008; West and Bogers, 2010).

But then what does the crowd do, which main activities does it carry out and what are the roles that participating users hold?

In this regard, there are different types of roles within the crowdsourcing, and different types of tasks delegated (Howe, 2006). In the most recent studies and practices there are various success stories (Brabham, 2010), among others “My Starbucks Idea” which asks and rewards customers for innovative ideas for the design that could renovate the coffeehouse chain’s services; Amazon’s Mechanical Turk which acts as intermediary connecting outsourcers with the largely underutilized global workforce, letting workers accomplish different kinds of tasks. Moreover, as JetBlue Sony and Chrysler did, organizations can commit to young users user generated content (UGC) production dedicated to their social media (e.g. Facebook) (Brabham, 2008; Rieder and Voß, 2010).

A study of Von Hippel (2005) shows the advantages of the social media applications to the B-2-C communications, especially for marketing purposes. In particular, the scholar argues that a company can receive multiple benefits from innovations developed by the so-called user innovators, who are beyond the market average users, and that the proliferation of social media platforms, branded applications and widgets describe it as a booming increasing trend. In addition, other studies have shown that the crowd, as compared to professional employees of companies, is able to submit to the online platforms the best ideas in terms of quality and innovation, thanks to a process of

motivation and incentive, which will be discussed in the next section (e.g. Acar and Van den Ende, 2011).

In this context and in accordance with the paradigm of Open Innovation (Chesbrough, 2003), therefore, firms choose to cooperate with other firms, but also have the ability to connect with voluntary individuals who contribute to the innovation process (West and Lakhani 2008; Jeppesen and Lakhani 2010).). Just to give an example, at Procter&Gamble, for example, new products stemming from external ideas with the "Connect and Develop innovation model" increased from 15% in 2000 to 35% in 2006 and 45% in 2010.

In this domain, companies and practitioners commonly believe that crowd participation will solve their problems quickly and efficiently, or in a cheaper manner, but effective crowdsourcing solutions require activities that both fulfill the outsourcer's production needs and — by utilizing various motivation mechanisms — account for individual contributors' needs.

The crowdsourcing process needs a proper definition of the problem by the organization, to make it readily understandable, so to let the crowd quickly proceed to develop the solution.

Many tasks delegated to the crowd concern the production of contents that users may provide other users to help them: tips, immediate solutions to unresolved issues, reviews, experiences, activating discussions and debates, and by uploading any type of information, photos, videos, etc.. These tasks are typical of the wide plethora of online platforms in the field of travel and tourism (as Tripadvisor, Booking.com; Couchsurfing, BNB, Travellution, Gogobot, etc.), culture and publishing software (as Amazon) (Buhalis et al., 2011; Sigala, 2009). In this direction, the link between virtual communities and culture and tourism is proving to be a valuable resource, as shown in precisely the creation and the increasing number of online platforms used by tourism and cultural enterprises show in order to produce and share useful information and knowledge. In fact sharing and commission of tasks to the crowd for the production of information and knowledge is critical for those organizations that operate in highly complex and dynamic sectors, and subject to changing fashions, trends and user needs. Therefore, the participation of users facilitates the ability of these organizations to follow how the demand can evolve, potential users and customers (in terms of gender, age, preferences, requirements), types of needs they have, what they do not like (Kleemann et

al., 2008). As Micelli (2000) claims, through a system of "distributed intelligence", online communities are considered the new center of gravity around which new forms and dynamics of social innovation and competition can be built and rethought.

The growing interest in the creation of communities of practice (e.g. Wenger, 1998) allows the sharing of values and meanings that, together with the construction of a feeling of mutual trust, support and reputation, foster a strong sense of belonging to the community. Users of these platforms share goals, interests, needs, activities, and actively co-creating collective products, not only forge very strong bonds. Moreover through the reciprocity of information, they have access to shared resources (through clear and defined rules of behaviour and social filters) that without this form of participation would be limited (Whittaker et al., 1997; Spadaro, 2007).

For this reason, often travellers and tourists themselves spontaneously give rise to virtual communities in order to organize their trips and to share online their own travel experiences, providing important information to other potential travellers and tourists interested in the same goals. These new travel communities are very important also for the organizations operating in the tourism and culture sector to change their internet marketing strategies.

This aspect focuses on the fact that the participation and involvement of the crowd do not only affect the production processes of large companies and multinationals, as we talked about before. Indeed, more and more often in recent years, the phenomenon of crowdsourcing is strongly invading in the social sector and in particular the sector of culture. Focusing on the feeling of belonging of citizens, local stakeholders, tourism and cultural operators and their willingness to contribute to improve the quality of the region in which they live and work, many local virtual communities are springing up. Therefore processes of active participation, aimed mainly at creating plans for improvement, enhancement, development of the cultural and environmental heritage are arising.

In light of these assumptions several scholars (Chung et al., 2008; Acar and Van den Ende, 2011; Bakici et al., 2011; Bloodgood, 2013) highlight the ability of online communities' administrators to retain the users' participation and to motivate them in order to produce high quality contents for online communities as a very interesting research field. In other words we try to understand how to manage the crowd engagement on the online communities and which types of incentive mechanisms can motivate the crowd to participate.

The different incentive mechanisms for the engagement and the rewards that online communities put in place to retain its users are primarily used to understand how to increase their commitment, but also to control people's behaviour and their role within the community and to understand how to react to misbehaviour (Frey and Jegen, 2001; Almirall and Wareham, 2011) .

Literature on crowd incentives in online communities ranges on different fields and with several levels of analysis. The spread of these studies is mainly due to the development of virtual online communities in different areas and for multiple purposes. Thus, analyzing the incentives that spur users to contribute are critical to designing crowdsourcing applications (e.g. Shah, 2006), in order also to understand the potential related benefits and impacts on the governance of the companies themselves (O'Mahony and Ferraro, 2007; Almirall and Wareham, 2011; Acar and Van den Ende, 2011).

At a first glance there is the traditional stream of literature which link motivation and engagement to rewards and financial incentives and other aspects such as, non monetary prizes, recognition and status; thus, based on a purely extrinsic motivation. Others focus on the importance of incentives in terms of intrinsic motivation, as, belonging, identification and reputation, curiosity, play and fun (e.g. Ryan and Deci, 2000a, 200b; von Hippel and von Krogh, 2003; Kazai and Milic-Frayling, 2009; Acar and Van den ende, 2011). In the following next paragraph, we will explore the role of motivation to retain crowd on online communities. We will look at all those motives and mechanisms to incentive people's participation on on-line communities.

4 Motivation and retention of the crowd: a review of intrinsic and extrinsic incentive mechanisms

Recent studies on crowdsourcing highlight the importance of crowd motivation and incentives in participation processes on online communities, providing interesting suggestions. However, the theme still appears to be partly jagged since it is quite new and still few studies shed light on this aspect in depth (Estellés-Arolas et al., 2012). Incentives and rewards are crucial for the functioning of these virtual communities, especially since users do not receive a salary or a fixed remuneration for the services and the activities they offer.

A great part of scholars focus on this debate distinguishing two groups of motives that influence the crowd that based on intrinsic and extrinsic incentive mechanisms (Hars and Ou, 2002; Bitzer et al. 2007; Lakhani and Wolf, 2005).

As it is known, intrinsic motivation, refers do something for its inherent satisfactions rather than for some separable consequence, something you enjoy and that feeds you in a way that is not connected to external feedback (e.g. fun, pleasure, self-determination, curiosity, reputation¹, altruism, community identification, interest, involvement, feeling of challenge). In this sense, people do something, and in this particular case participate on the online communities because they want to, and feel a great personal enjoyment, without any material or monetary return. On the other hand, extrinsic motivation is based on a push that leads to a separable outcome. In the specific case, people participate on online communities because they know they can receive monetary and non-monetary rewards (money, prizes, recognition, evaluation, peer rewards, consideration, status). In light of these assumptions, an increasing numbers of scholars are focusing on the behaviours within the online social communities to understand how and to what extent intrinsic and/or extrinsic incentives can motivate users' participation (Bakici et al., 2011).

In this context, Nov et al. (2011) elaborate an interesting analysis. They distinguish between two different types of intentions that address crowd participation at different times: the intention to increase participation and the intention to maintain participation. Specific motives influence these intentions: group motives; norm-oriented motives; identification motives, intrinsic motives; reputational motives, social interaction motives.

There are also several empirical investigations that analyse the characteristics of the contents produced on online communities and the motives that address these tasks. The great part of these studies found that the main motives have a basically intrinsic nature (Hertel et al., 2003; Lakhani and Wolf; 2005). For instance, Lakhani and Wolf (2001, 2005) believe that the intrinsic motivation, based on a sense of pleasure and personal satisfaction, is one of the strongest incentive in online contents production.

Some literature argues that people like to actively participate because they feel fun and identify themselves (von Hippel and von Krogh, 2003; Torvalds and Diamond,

1 In the matter of the reputation, the literature thought is not uniform. According to some scholars (e.g. von Hippel and von Krogh, 2003; Mason and Watts, 2009) reputation is an extrinsic incentive, whereas according to other scholars e.g. Bakici et al. 2011; Bagozzi and Dholakia, 2002; Hargadon and Bechky, 2006; Lakhani and Wolf, 2005) within the specific context of online communities and web 2.0, reputation is considered an intrinsic motive. Finally according to others (e.g. Nov et al., 2011; Frey and Jegen, 2002; Benabou and Tirole, 2006) reputation is analysed as a different motive not included nor among the intrinsic, neither among the extrinsic incentives.

2001), but also some non-monetary incentives can positively influence the increase of their identification with these communities and their reputation (see, for example, the stars users earn providing the best answer to Yahoo Answer! questions; or the whole evaluation system of reviews and best profiles to award users on Tripadvisor) (Jeppesen and Frederiksen, 2006; Lerner and Tirole, 2002; Bagozzi and Dholakia, 2002; Hargadon and Bechky, 2006; Lakhani and Wolf, 2005).

In particular Kollock (1999) claims that there are five main motives that lead the crowd to participate on online communities: reputation; mutual expectations (providing information engages a feedback mechanism that facilitates the return of this information, as helping by other members or specifically, by the person who has been previously helped); the feeling of being useful for the community; commitment and the need for affiliation and belonging. Moreover Wasko and Faraj (2000) add that learning, fun, interaction with other community members, material returns (e.g. receiving useful information, personal gains), sharing interest with others members are equally important incentives to support the crowd's participation. But the intrinsic incentives seem to weigh much more than purely extrinsic ones (Ryan and Deci, 2000a).

In this sense, Bakici et al. (2011) run a study on the German community Atizo, an open innovation platform where creative people meet and submit their projects to be developed. The analysis and the interviews, including that with the CEO Christian Hirsig, show fun and personal satisfaction as important incentives to support the members' participation on the community. According to the CEO the motivation to perform an enjoyable task, the interest and the pleasure to do it are very strong incentives that involve skills, talent and intelligence of people, as compared to mere extrinsic incentives.

Extrinsic incentives, such as money, are at their best when the tasks to be performed are uninteresting, unrewarding, repetitive or in sluggish contexts, so very far from the characteristics of the web 2.0 context. In particular the challenge, the game and the voting mechanisms, characterizing the competition in creative projects, strengthen positive effects as cooperation and cheerfulness between members. This generate great awareness in the participants improving each other's ideas for their own projects. In addition, it is clear that this situation enhance the engagement of new members and new projects coming into the community. In this study the authors (Bakici et al. 2011) found that the extrinsic rewards used within the community receive very low scores, showing that they are not decisive for the members' participation.

In the same way also Lakhani et al. (2007) analyse what motivates people to produce contents on online communities of various types. The authors argue that in these specific contexts, motivation closely link to the ability to submit a winning answer to a problem or providing not ready available information to other users without any monetary incentive.

Despite these considerations, in the plethora of these studies, some still emphasize the main role of monetary and non monetary extrinsic incentives for maintaining a high motivation of the crowd to participate. According to these studies, individuals perform required tasks mainly because they know they will get money (if contents produced are judged as significantly valuable), and/or the highest recognition status within the virtual community and among other members (e.g. Antikainen and Väättäjä; 2010).

Also the literature on prosocial behaviour focuses on incentive mechanisms used in the online communities, distinguishing three types of incentives: extrinsic, intrinsic and reputational (Frey and Jegen, 2002; Benabou and Tirole, 2006; Mason and Watts, 2009). According to these scholars, people are intrinsically motivated to participate when they perform a task and reach a goal that has a high value for them. Extrinsic motivation is at the core of the rational choice theory and triggers when people are stimulated by material rewards and positive and negative reinforcements. Finally, reputational incentives, such as praises, advertising and shame motivate because of social norms and social interaction processes. These studies are very interesting because they introduce the time issue. Therefore, the crowd undoubtedly is moved by material incentives, especially in the short term, but in order to maintain a quality of participation in the long run, people need to receive what is called the "social addiction", generated by the combination of intrinsic and reputational incentives (Brabham, 2010; Liu et al., 2011).

As part of extrinsic incentive mechanisms, an aspect to highlight refers to the relationship between the characteristics of the contents produced and the size of material and monetary rewards (e.g. Terwiesch and Xu, 2008; Acar and Van den Ende, 2011). In fact the value generated within the crowdsourcing communities through the rewards is one of the few aspects that should be controlled. Given the potential impact of extrinsic rewards on motivation, a part of the literature analyse the relationship between rewards, motivation and contributions to reap the benefits of the functioning of these online communities.

In this context, if on one hand, there is a significant body of literature on incentives, on the other there are still few studies that focus on the effects produced by rewards and

incentives on performance and on individual behaviours. For example, Weiling and Ping (2010) and Acar and Van den Ende (2011) analyse how the production of contents and the motivation of the users are influenced by personality traits. Moreover they investigate how the type of personality together with the use of specific incentives can affect users' behaviour and performance. Acar and Van den Ende (2011) try to understand if and how intrinsic and extrinsic incentive mechanisms can impact on motivation and performance, measured in terms of quality, quantity, originality, innovation and usefulness of contents produced. The most important aspects that emerge is that intrinsic incentives have a high positive effect on the dimensions of quantity, innovation and originality of contents, less on the usefulness. Otherwise extrinsic incentives positively affect the time response, but not the overall quality. Regarding the effects of extrinsic incentives, the analysis model provides lower scores compared to the impact generated by intrinsic ones.

Another interesting study is that carried out by Rogstadius et al. (2011) recruiting participants for a challenge, on Amazon Mechanical Turk platform. The study partly confirms and reports the results of a similar previous study of Mason and Watts (2009). Rogstadius et al. (2011), grouping users by extrinsic and intrinsic incentives, illustrate that monetary incentives increase quantity, not necessarily the quality of the users' contents, due to the "anchoring" effect. Users who only get paid for the tasks they perform fail to perceive the significance of what they are doing, just converging on money and not to what they really can improve. Therefore, they are not motivated to do better than those who do not receive monetary incentives. In their analysis users, who get monetary rewards, provide faster feedback and solutions, but the contents are not qualitatively superior in terms of adequacy and care than users. In light of these results, authors state that the "under-contribution" is a problem for many online communities. Those who are not paid, but receive intrinsic incentives (such as the participation to new and challenging activities), although they are not as fast and timely as users receiving extrinsic ones, provide higher quality output. However, they conclude by supporting the use of both intrinsic motives and extrinsic incentive mechanisms, which would in the long run respond to both dimensions considered crucial: quality and speed of response.

Following we provide a table that summarizes the main literature regarding incentives.

Table 1 – Intrinsic and extrinsic incentive mechanisms. A summary of the main literature

	Incentive mechanisms and motives	Results
P. Kollock, 1999	Focus on five mechanisms: reputation; mutual expectations; feeling useful in the community; commitment; affiliation and membership.	Providing information led to feedback mechanisms that facilitate the information flow.
M.M. Wasko e S. Faraj, 2000	These authors add four mechanisms to the Kollock's study: learning, fun, interaction with other members of the community, material returns.	Sharing mutual interests with other members is a crucial motive to support for the crowd's participation
R.M. Ryan e E.L. Deci, 2000	Focus intrinsic motivation with the following incentive mechanisms: increase of identification, affiliation and reputation, curiosity.	The intrinsic mechanisms affect more motivation than the extrinsic ones.
K.R. Lakhan e R. Wolf, 2001; 2005	Taxonomy illustration of the two groups of mechanisms.	The intrinsic motives, based on the feeling of pleasure and personal satisfaction are the strongest ones and affect the whole motivation, increasing reputation and identification of members.
von Hippel e von Krogh, 2003	Taxonomy illustration of the two groups of mechanisms.	People like to actively participate because have fun and they identify with the community.
K.R. Lakhani, L.B. Jeppesen, P.A. Lohse, J.A. Panetta, 2007	Analysis of motives that led people to produce subjects on different kind of online community.	Motivation closely relates to the ability to submit a winning solution to a problem or to provide required not available information. The online communities analyzed members do not get any monetary reward.
M.J. Antikainen, H.K. Väättäjä, 2010	Focus on extrinsic incentive mechanisms and their effects.	The role of rewards are important to maintain high motivation and the crowd's participation in the long term.
W. Mason, D.J. Watts, 2009	Focus on extrinsic incentive mechanisms, in particular reputation on web 2.0	Incentives related to reputation: praises, advertising, shame motivate because of social norms and processes of interaction.
K. Weidung, Z. Ping, 2010	Analysis of extrinsic and intrinsic motivation, that can be influenced by personal traits and the incentives that affect organizational behaviors.	Personal traits affect content's production. Community manager should care of the members' personality and behavior in order to establish the more appropriate incentive mechanisms to motivate.
I. Borst, J. Van den Ende, 2010	Focus on extrinsic incentive mechanisms; in particular on the role of monetary rewards and the impact on members' motivation.	Authors study the effects related to the presence and absence of rewards within the community, but they do not measure them and do not analyze the impact of rewards on members' performance.
O.A. Acar J. Van den Ende, 2011	Authors analyze the main features of contents uploaded on the community and the relevance of rewards size. They try to understand if and how incentives influence members motivation and performances in terms of quality, usefulness, quantity, originality and innovation of contents produced.	Intrinsic mechanisms have a high positive effect on the quantity, innovation and originality of contents, less on the usefulness. Otherwise extrinsic incentives positively affect the time response, but not the overall quality.
T. Bakici, E. Almirall, J. Wareham, 2011	Authors analyze motives that led the crowd to participate and illustrate the most commonly used incentive mechanisms.	Authors highlight how crucial is the sense of fun among participants. Extrinsic mechanisms, such as money, are at their best when participants are asked to perform repetitive tasks in sluggish context. In particular another important point is the challenge incentive that strengthens cooperation and cheerfulness between members. Authors moreover state that extrinsic incentives are not critical mechanisms.
J. Rogstadius et al., 2011	Focus on intrinsic and extrinsic mechanisms and related effects on members' performances.	Monetary rewards increase the quantity, but not automatically the quality of contents offered by the users, because of the anchoring effects.
Nov et al. 2011	Analysis of motives that address crowd participation: group motives; norm-oriented motives; identification motives, intrinsic motives; reputational motives, social interaction motives.	Authors recognize a crucial distinction between two intentions motives, that can occur in different time periods: the intention to increase the participation and the intention to maintain the participation.

Source: our elaboration

In conclusion, literature on crowdsourcing and, in particular, studies that analyse motivation and crowd incentive mechanisms represent a new frame with a landscape that is still quite various fragmented. Therefore, it is necessary that organizational and sociological scholars deepens and focus on this topic, because without active and motivated users online crowdsourcing communities can not exist. In particular, as several studies claim, it is appropriate to dwell more on the jointly use of intrinsic and extrinsic incentives in order to maintain high and long-lasting crowd participation and to allow for ample contents production.

The next section focus on the empirical analysis we conducted on four main travel communities. In particular we will understand how the administrators of these communities use the incentive mechanisms in order to influence the users' participation and the contents production.

5 Motives and incentives for participation. Comparing four case studies in travel communities

5.1 Methodology

Our empirical research follows a qualitative approach and consists of two phases carried out between October 2013 and February 2014.

In the first phase, we adopted an internet based research method (Eysenbach and Till, 2001), investigating the online communities. Data are produced through an active involvement of the researcher, participating in communications on the following Italian and international travel communities: Tripadvisor, Travellution, AirBnB, Voglio Vivere Così (the tourism community of Tuscany Region, Italy). In this way, contents uploaded by users, such as discussion boards on websites or chat rooms, internet postings are tracked down and analysed. We observed many different types of incentive mechanisms (such as game and contests, uploading photos and videos for voting the best traveller profile, etc.) used in these communities in order to create a fun environment for users and to enable them to better participate to the production of inputs.

In the second phase we conducted semi-structured interviews to the administrators of the travel communities analysed in the first stage . We expanded our study in order to investigate the administrators' perceptions and the meanings attributed to motives and incentives. In particular we aim to understand which types of incentives are better employed in these communities to engage and retain users and to stimulate UGC. The analysis therefore combines the interpretations and perceptions of top management with the personal experience of the researchers in participation process on these communities.

The interviews took place by phone, were conducted in Italian, lasted about 50 minutes, and were recorded and fully transcribed. They were guided by a wide-ranging questionnaire including questions about basically specific roles played by the users and crucial for the community; specific tasks "outsourced" to the users, the demography of the crowd participating; the main important extrinsic and intrinsic incentives employed and their impact on the users' behaviour.

5.2 Results

Tripadvisor

TripAdvisor is one of the most popular travel communities and used back in the panorama of 2.0 travel to help travellers plan the perfect vacation with reliable advice, posted by real travellers and a wide range of information search options, with direct links to booking tools. The PhoCusWright study, conducted in December 2013 reveals the main trends of the most widely used website for reviews:

- More than 57 mln users worldwide.
- Over 80 content pieces per minute.
- More than 260 mln visitors per month.
- Over 150 mln reviews and comments.

Tripadvisor has had a growth of 140% between 2012 and 2013, and today the Italian section constitutes 26.6% of the online travel market.

Tasks and roles

Information published on TripAdvisor are generated by its users that voluntary publish reviews, comments and ratings of destinations, accommodation facilities (Hotel, B&B, Resorts), and the various tourist attractions in the cities and places of destination. The platform allows users to add multimedia contents (photos, videos), maps from previous trips or participate in discussion forums on specific goals. In order to produce contents, users must be registered on the platform and create a personal profile containing basic details.

The choice of the types of holidays and trips is therefore greatly influenced by post published data and feedback from users. In addition, they can also provide more information about a particular destination with the creation of the 'Traveller articles' (WikiPages created and edited by users describing the experiences and destinations visited). An important task delegated to the crowd is also the peer review of hotels and restaurants, commercial structures. This last aspect is particularly important, because it shows how the judgement of the crowd can determine the success and the promotion of a structure, and to create a positive word of mouth.

The platform has thus grown thanks to the user-generated contents produced by the crowd that is considered in a dual role: as the creator of inputs for the operation of the

community, and as a target for facilities that wish to sell their services to the users of the platform. Users can be divided into 3 categories:

- Reviews Readers
- Reviewers
- Managers of pages (operators that promote their structures and facilities both through free profiles and through the activation of fee-based profiles in TripAdvisor for Business).

The reviews system actually has considerable importance for the purposes of our analysis, because it is linked to a certain extent to the ability of the crowd to create an evaluation system that then has a real impact on the images of the facilities. This has important developments especially in the case of the structures through which a high rating from users can receive the so-called 'Certificate of Excellence', which is the certificate awarded to accommodations and restaurants more appreciated by users on the basis of a rating average of a score of 4 out of 5 based on TripAdvisor reviews drafted by users and the total volume of reviews received in the last 12 months. Moreover the crowd has another tool: the 'Traveller' Choice Awards, the annual ranking of the users made that aims to identify exactly the best facilities and the best destinations.

In the control systems of all of this content there are mechanisms for review and replication-mediated mechanisms filtered by a content team. The automatic ones are controlled by computer filters, such as typing criteria able to identify the veracity of contributions. For the mediated ones, in support of the platform a content team is involved with monitoring activities, leaving the online conversation or speaking, even by removing, in case of divergence from the policy that explains the rules precisely of completion of the review and usability site. The work of the content team is very important in the content management system that out of 1900 employees around 300 staff are involved in this activity. In addition, the promotion and reputation management platform are handled by a country manager.

Incentives mechanisms

In order to enhance the users' participation there are directed strategies. The only strategy that was implemented at the beginning, the birth of the platform in 2000, was a big advertising investment that has helped to create the critical mass that then has ensured the expansion of the community for content enrichment, also for indirect leverage.

In the phase of engagement of users, therefore, two were the key factors:

- The massive advertising investment;

- The right time, because the birth of Tripadvisor has filled the need to overcome the information asymmetry enhancing the exchange of content-based trust mechanisms.

In the maintenance phase, the incentives that encourage users to participate are linked with intrinsic motivation, such as a sense of belonging and collaboration with the community. One of the main intrinsic incentives is receiving recognition from other members of the community; actually, 75% of users writes reviews because they want to share their travel experience with other travellers.

Another type of incentive is the play & fun tool, in other words the ability of the operator of the platform to create a fun environment for users to enable them to participate to the production of inputs and have more fun. An example is given by the function Travel IQ, an active game on the platform by the World Travel Challenge Game where the player must identify the city and the sights on a world map.

The extrinsic incentives are, however, mostly automatic:

- For the managers of the page, the higher the reputation, the higher will be the price on the market. Actually, the relevance of the operator's response far exceeds the reliability of review: 84% of users claims the reply of the operator makes the information much more reliable and enables the consolidation of online reputation;
- For the reviewers, the incentive is also recognition of the mechanisms by management advisor through, for example, the distinction of users in different rankings according to the number of reviews published and therefore the ambition to the Expert Level.

Today the platform is much less interested in the online community growth or encourage the interaction between users and is much more focused on the evolution of business. Specifically Tripadvisor has recently adopted two strategies that leverage extrinsic motivations for participation of accommodation and insist on the Tripadvisor for Business section:

- Pay per Click: on the pages for operators, OTAs (Online Travel Agency) have a paid banner and earn with the click of the users;
- Trip connect: operators can pay an annual fee for having business profiles and compete to get reservations because this mechanism allows landlords to generate new business by addressing travellers willing to book directly on the booking page of their website. Tripconnect thus increases the visibility of the facilities and the opportunity of direct bookings.

The real reason for these strategies is to optimize the user experience that organizes the trip through the travel community. The travel user searches are never smooth or regular trend because the user considers various options going from one platform to another, and this makes it complex for the loyalty. For this Tripadvisor is trying to centralize the users' attention to start and complete their search on a single platform, with all the features needed for the planning of a journey.

Travellution

Travellution puts in touch people willing to travel to the same place, in the same period and in general, with goals, interests and travel-related style before departure with the goal of bringing together people with whom they can organize whole or part of trips. The project was realized in 2008 from an idea by Giacomo Bastianellis sometime before that had in mind to create a content aggregator that would give access to all the necessary steps in organizing a trip. In 2011 was launched the beta version of the platform that was much more oriented to be a social community pushing on the connection among travellers. Thanks to the financial support of investors, technology upgrades were implemented that ensured users good planning trips services.

Today, the platform has 14,000 registered users and 50% of them are active users because they have proceeded with the creation of their trip.

Tasks and roles

The concept of this community is clearly in line with the trend of the moment, or the idea of encouraging new encounters and experiences through travel and, at the same time encourage users to value the traditions that make every trip a unique experience. For this reason, the slogan of the community is: "*Travellution, the social network that turns strangers into fellow travellers*". Using the tourism strategy of conversational marketing you create a relationship between consumer and business useful to promote destinations using assessments and reviews of the users themselves.

The user-generated content therefore represents the main instrument for the operation of the platform that is heavily dependent on its users and what they provide. The registered user can take part in travel plans already existing or can start create his own journey becoming Tripmate. The organizer of the trip creates a proposal and invite other users through a mechanism of collaborative planning; also the operators of the platform, according to the chosen destination, create suggestions for users. When people meet and

with same needs and purpose of travel, the platform asks them to become Tripmate so that the journey can become a social network with a bulletin board, events and other social tools. The main activities of the platform, therefore, are mainly three:

1. *Useful Content*: According to the chosen destination, the user can find all the content they need (information, photos, tips, travellers to the same destination);
2. *Trip Design* the system for planning a trip with a schedule, organizing day-to-day stages and destinations, lets you see if in those days and stages there are identified potential Tripmates with whom you can get in touch, exchange information and share content;
3. *Like-Minded Travelers* This service allows you to simply get in touch with potential fellow travellers, who have the same interests and tastes, even if you do not have a precise idea of travel plans.

In terms of privacy conditions, Travellution has restrictions because the contents of the trips are only visible to registered users and subscribers to travel themselves, but proposals can be shared on major social networks in order to be able to appeal to a wider audience and create interest in individuals who then become registered users and Tripmate themselves. The travel groups also provide even greater reliability and trust, because the reviews posted are definitely more travel contextualized and truthful and therefore the risk of fake content is reduced. The team has a community manager who is engaged in the promotion and retention of users on social networks.

A final aspect to be mentioned is that of the companies section, a service offered to tour operators that on 'Travellution Advertising Platform' can get advertised to the users and promote their offers and travel plans. Specifically, Travellution offers the possibility to create business partners for the organization of travel, through a free registration for six months and a profile that will be advertised on the home page of the platform. Then, if the business partner is satisfied, it can buy space on the website to have a greater market visibility. From this point of view, Travellution also acts as an intermediary and tourism is clear that users have a dual role: the first is necessary to the survival of the platform for user generated content; the second is useful, for potential buyers of travel services of partner companies that pay advertising to Travellution.

Incentives mechanisms

The platform does not have a structured incentive system. The administrators control users' participation through monitoring the travel cycle. Moreover management controls

users' feedback through monitoring that is based on internal surveys. In light of this, they plan to launch themed routes (eg, adventure, fantasy, etc...) that might attract business relying on the interest of users.

The platform is therefore based mainly on intrinsic incentives related to the willingness to share the experience of planning the trip and the trip itself with other users. The intent of the managers of the platform, however, is pushing a lot more on extrinsic levers because they feel that the service can become more professional. Therefore they are also assuming the use of a monetary reward for creating a profile of Expert Travel is contacted and paid to support the user during the journey. Another extrinsic mechanism is activated through contests to reward the best trip; this affects appearance, but also the quality and reliability of the trip.

Finally, to recruit new members, management proceeds on two fronts:

- Partnering with other services, such as the Erasmus network technology which offer the service for planning Erasmus trips in exchange for visibility and user recruitment;
- Agreements with travel agencies, which offer the service because technology makes organizing travel certainly more fun and attractive.

Airbnb

Airbnb is a community in which people can publish, discover and book unique accommodations around the world, called hosts. It puts people in touch at affordable prices in 35,000 cities and 192 countries, with different possibilities of accommodation. A sort of low cost participatory tourism based on sharing, collaboration and exchange. If you are travelling this way it does not only save you money, but the financial motivation is not the only or the main mechanisms that pushes to travel using these new forms of tourism. The basis of this model is actually a sort of recovery of values of a generation that looks to travel as an experience, as an encounter of cultures, not only as an opportunity to relax and have fun.

The platform now has 50,000 active hosts in Italy and 12,000 travellers every day staying with the Airbnb booking system. The main host cities in Italy are Rome, Milan, Venice, Florence, Bologna, and Turin and in 2013 there was a large increase of hosts in Sardinia. Just the case of Sardinia is an example of the need that Airbnb meets, because thanks to the enormous work done to enable hosts Sardinia is able to satisfy much of

foreign tourist demand. The platform is growing exponentially and in 2012 saw an increase of 650%.

Tasks and roles

Participation is through the community that is very referenced. In the community there is no anonymity: profiles are verified as related to social networks and through email and phone numbers, so there is always a verified and traceable identity. The community activities take place:

- Online, with the reservation system for other users;
- Offline in real host-guest relationship;
- Online for later review.

The airbnb administrators greatly focusing their activities on the hosts, who are followed since registration, even with the use of a professional photo shoot free to enrich their online profiles.

The Airbnb employees are mostly hosts who were hired by the management for their passion and professionalism, among these are also the community manager.

Offline activities originally had as a main objective the creation of events to get hosts to meet up. For about two years after the Italian launch, actually, the platform has only worked on this activity; today it is run by the hosts themselves, from a community that aggregates them in every city, self-organize and plan events together to promote their business.

Incentives mechanisms

Nowadays, the platform has never made any promotion with marketing actions (the first to do so were Airbnb USA this year) but have grown increasingly through word of mouth and important press coverage that is enriched with content of the stories of users.

Motives of hosts to participate are mainly extrinsic -based. First of all there is a full monetary reward, since it has no running costs of the profile; also Airbnb's gain, indeed, happens via the guest, who pays 10% more than the base rate of the host, so the cost is included in the total room rate. And then the review system increases the social value of online reputation host and increases the economic benefit.

Other elements of incentive for the host are:

- The usability of the site;

- The confidence that is generated either by the reputation of the reviews this is by giving a guarantee in the policy that the host is covered for serious damage with a guarantee of up to € 700,000;
- The customer support (24/7 in 16 languages).

Voglio Vivere Così

Voglio Vivere Così (VVC) is a project of the “Sistema Toscana” Foundation for the tourism and cultural promotion. With this project, born in 2008 and recently ended, the Tuscany Regional Authority wanted to develop a model that can reposition and renew their tourist offer, integrating a systemic view of the area and involving a new model of tourists who are fond of personalized travel, eager to share their experiences and major user of the tools provided by web 2.0 and new digital technologies.

In this regard, MirkoLalli, who was head of marketing and communication of the Fondazione Sistema Toscana for this project, said: *"What the Region of Tuscany did is an example of the use of massive and integrated web 2.0 tools applied to promote the area and an increase in tourism. A valuable experience that shows that even in this area you can push yourself to talk about ROI. "*

Today, according to the latest report conducted in December 2013 it includes:

- 7 profiles on Facebook with 557,000 fans
- 8 profiles with 30,000 followers on Twitter
- 2,100 Instagram users
- 17,000 users on Foursquare
- A Youtube channel
- 5 Flickr accounts
- One Pinterest account

Tasks and roles

The starting idea has been converted into a large operational plan, articulated in different directions necessary to achieve its goals: technology and multimedia, accessibility, synergy between public and private actors, communication and monitoring. A campaign to collect data, information and calendars of events and initiatives of all local touristic organizations (Aziende di promozione turistica, APT) companies and consortia was initially launched to promote tourism, special offers and packages for tour operators and

they proceeded to approve all the websites of the tourism and cultural heritage operators, directing all of them to a single portal, visited by all the tourists and visitors.

The next step has been the creation of a brand, to become the Tuscan territory a brand, a symbol known and loved worldwide, aiming at a sort of "All Region Land Mark", which has its basis in the network with a slogan which has become: "From a Landmark to a Lovemark. The activity related to the project continues today at www.allthingstuscany.com in that it contains several services, such as blogs AroundTuscany 4 (general), Tuscanyicious (food), TuscanyArts (art), Diaries Toscani (travel stories); the relational service tool Talk to Tuscany, the BookinToscana App for mobile reservation.

Thanks to the web, the 2.0 tourist acquires information and buys tickets for museums, shows, events, travel packages, looking for accommodation and location suitable to his/her needs, in particular in the comments and reviews, with the same interests and priorities. They post photos and videos, review and share their experience, but also call for advice on hotels and restaurants, and come into contact with tourists from all over the world. Every traveller is an opinion leader of his own social network that influence their content with the choices of other users and their relationship with and between users takes place mainly through social networks.

Incentives mechanisms

The activities of the Sistema Toscana Foundation towards users is strongly focused on the engagement, to offer a good service, to communications and sharing information, rather than the user-generated contents.

The project mainly relies on intrinsic motivations concerning the interests and the emotional sphere: what arouses the activity of users in sharing and participation is the recognition of elite, in a quality destination like Tuscany. Identifying with the stereotype of a goal that is lifestyle, the user replaces this with a component of belonging and recognition from the cultural point of view. The belonging intrinsic mechanism enables then to feel part of the community and the sharing photos of users makes them the ambassador of the destination. Users that sees their shared photo with the hashtag #visittuscany do not feel violated in the privacy and indeed perceive an added value. In this way, users become producers of content and this happens especially on Instagram profiles where there is a strong content care.

Another intrinsic incentive on which they have worked is the sense of belonging on the site www.tuscanyfaces.com launched in 2013 on the occasion of the Tuscany Fayre. The project shows the human, man-made aspect of Tuscany in art, in nature and food. Collecting photos and disclaimers at the same time allowing the registration online through a form, have created a gallery of profiles that are both residents of Tuscany, or from Tuscany living elsewhere in the world, or foreign and now living in Tuscany. This dynamic on one side has revealed all the sense of belonging to the region and the other is part of the proactive promotion of Tuscany itself.

Administrators hardly have employed extrinsic incentives. Sometimes the administrators have launched contests with prizes of symbolic recognition, such as the publication of the photo in the cover of FB, but in general they believe that the intrinsic incentives are much more important than extrinsic factors that work in the short term but then did not follow up with significant results.

Today, starting from very large user base and the successful brand “Tuscany”, Sistema Toscana Foundation is planning a development that goes in one direction of spatial proximity marketing through the creation of a loyalty card. The intention is to transform all users collected over the years into a database of contacts to be able to offer them discounts and promotions. The card has no cost, so the entry will always be incentivized by intrinsic motivations such as membership and identification, paly and funs, but in exchange for users, once community members, receive customized information and personalized newsletters. All aimed at creating a meeting point between users and operators in order to increase tourism promotion activities that already has to its advantage a wealth of users and content.

6 Conclusive remarks

A great stream of studies on crowdsourcing highlighted the importance of crowd motivation and incentive in the participation processes of online communities, providing interesting suggestions. This topic gained in popularity over the last decade, as more and more users have begun to flock to social communities and content-based sharing collaboration. But still few studies focus in depth on the application of intrinsic and extrinsic incentives mechanisms in these new contexts.

Our contribution is twofold. First, through a careful analysis of the recent literature on the crowd topic nowadays at stake, we provide reflections on intrinsic and extrinsic

incentives. In particular this analysis lead us to explore the extent to which these incentives are able to engage and motivate users in community building processes. Second, through the case studies we shed light on a partly jagged and new topic related to the use of incentive mechanisms in order to recruit and motivate crowd. In particular, we try to explain some preliminary insights and emerging issue needed to create a model of motives and incentive mechanisms that could be applied in the ORCHESTRA platform for the city of Naples.

Findings from the case studies focus on intrinsic mechanisms that stimulate users to participate on the social communities. All the platforms analyzed, in line with the literature, make a great use of intrinsic mechanisms. They have a primary role than extrinsic motives. First of all, the users are stimulated by the mutual reciprocity that motivate to produce a content, in terms of help and/or information in the expectation of receiving other useful information. Another important incentive refers to the the reputation in the community that users get by the sharing content and marker systems. Users will be motivated if they feel useful and trustworthy for the administrators. These aspects strongly influence the feeling of belonging and identification with the community. Another motive to participate is the social interaction and the opportunity “to make yourself heard”. The more are the contacts, the most users are encouraged to participate and to produce contents, so it’s crucial enhance the connection between users and create common interests between them. In this sense, social communities follow the way that the online participation and the contents production are the results of the work of each user; therefore the term “user-generated content”.

According to the administrators that we have interviewed the intrinsic mechanisms must be included in almost all the crowdsourcing tasks in order to motivate participation and to keep up the loyalty of users. Working on intrinsic mechanisms it is therefore in the interest of the platforms, and in general of all communities of crowdsourcing. In this sense intrinsic mechanisms can be defined as "non-profit framing", and they are difficult to identify and implement but are able to increase the motivation of the crowd.

The inclination towards interaction would appear to be the level for motivating many travel and tourism web initiatives. Several communities began huge business all over the world thanks to UGCs. In fact over the years it has become clear that users handle the review tool for the destinations they visit or for commercial products and services, and for supporting or criticizing the hospitality of some structures.

In light of these results we can draw two considerations. The first is that platforms administrators must constantly strive to create dynamic environments in order to positively influence intrinsic motives to participate, maybe through a mechanism of progression: new users may start to provide input on more simple and elementary tasks, then thanks to the seniority, they can focus on the development of more sophisticated contents to support the communities functioning.

A second suggestion refers to the fact that it might be useful to make a distinction between different time situations of participation: the engagement of the crowd and the retention and the involvement increasing, differentiating the specific incentive mechanisms.

Extrinsic rewards appear to be mere component in the platforms analysed and not precisely the most important one. We can observe how intrinsic mechanisms affect the construct the participation in a more pronounced way than extrinsic incentives and in particular monetary rewards. Nevertheless it could be useful to combine rewards, motivation and performance to determine if and how users' contributions are influenced by the extent and type of reward.

By taking into account the motives and the incentive mechanisms and the sense of fun perceived by its users, we have reflected on the implications for the web 2.0 by looking at the mass of creative subjects that finally take part in crowdsourcing activities. Our argument, simply put, is that the 'architecture of participation' (O'Reilly, 2005) surrounding the web is inextricably linked with the perception of enjoyable experiences deriving from networking activity through the mobilization of millions of voluntary actors.

In conclusion, following we provide a table that summarizes the results of our case studies, in terms of tasks outsourced to users, roles played and incentives employed in the communities analysed.

Table II – Summary of results

Source: our elaboration

Finally, our study had two main limitations. In the first place, in the empirical analysis we concentrated only on the perceptions and meaning of the administrators about motives and incentives use. Future studies should focus on the users' perceptions in order to study their motivation and behavior, understanding the impact of specific incentives mechanisms. We also intend to broaden the empirical research, involving other social communities.

Structured Abstract

Purpose – In this paper we will investigate different organizational models and roles delivered by actors in smart city systems. A smart city strategy aims at using technology to increase the quality of life in urban space, both improving the environmental quality and delivering better services to the citizens. Our case study analysis referring to smart city platforms takes place within a research project (*Orchestra - ORganization of Cultural HEritage for Smart Tourism and Real-time Accessibility*) meant to develop a set of technological and organizational solutions to foster the smart, sustainable and ecologically compatible exploitation of cultural heritage and touristic resources in the city of Napoli.

Design/methodology/approach – Our research was based on a qualitative investigation. In particular we analyze a set of international cases analyzed during a research project funded by the Italian Ministry for University and Research. The selected cases are representatives of different governance structures, technologies adopted and phases of maturity in the development of integrated smart city applications. The collection of empirical data was carried out using a heterogeneous plurality of instruments. The methods include: document analysis, semi-structured interviews and participant observations. Fieldwork was carried out between September 2012 and early July 2013.

Originality/value – This research presents a preliminary view of a smart city developments. Analyzing different cases from Europe, USA and Asia we recognize common features and different characteristics in cities' smart planning and development.

The paper presents a first attempt to study different stages of maturity in the development of a smart city system.

Practical implications – First, from the analyses carried out, it would seem that models for development of integrated systems for smart city tourism-mobility are still under developed. Moreover, in many cases, "archipelago" logic of specialization seems to prevail, with the proliferation of separate and distinct applications for application domains rather than aiming towards integration. The development of inter-organisational relationships with service and technology providers by local public transport companies has proved much easier, as there is a strong *incumbent* operator with consolidated experience as a catalyst for innovation.

Keywords – smart cities, ICT, inter organizational relationships, integration

Paper type – Academic Research Paper

1 Introduction

In recent years many cities around the world are experimenting innovative ways of using digital technologies to enable competitiveness and sustainability. More generally, a smart city strategy aims at using technology to increase the quality of life in urban space, both improving the environmental quality and delivering better services to the citizens (Nam T., Pardo T., 2011). Smart cities are more and more considered as an interesting topic for organizational studies, since they bring about powerful implications in terms of issues such as coordination, incentives, design, behavior. In fact, smart city platforms typically require cooperation of a plurality of organizational actors to manage effectively collective interdependences through innovative ICT devices. They are developed on an evolving technological and economic scenario which provides at the same time an opportunity in terms of new entrepreneurial initiatives, but also constraints in terms of the availability of financial and knowledge resources needed to fully grasp their potentialities.

Our work referring to smart city systems takes place within a research project (*Orchestra - ORganization of Cultural HEritage for Smart Tourism and Real-time Accessibility*) meant to develop a set of technological and organizational solutions to foster the smart, sustainable and ecologically compatible exploitation of cultural heritage and touristic resources in the city of Napoli.

2 Inter organizational relationships and stages of development

The publications in the field of smart cities describe a richer and more complex digital space. First of all, it is worth noting how the management and competitiveness of cities does not only depend on the availability of the physical infrastructure, the "physical capital", but also and increasingly so on the availability and quality of infrastructure dedicated to ICT communication and social participation. A city can be classified as a smart city if it manages intelligently the economic flows, transport, the environmental resources, social relationships, housing choices and the administration method. In other words, a city can be defined as smart when investments in the human and social capital as well as traditional and modern infrastructures fuel a sustainable economic development and a higher quality of life. It is important to point out that not only smart features should be linked to the presence of information and communication infrastructures but also and especially to the role played by human, social and relational capital (European Smart Cities, 2012, Shapiro, 2008 Caragliu, Del Bo, Nijkamp 2009).

According to Dameri (2013): "A smart city is a well-defined geographical area, in which high technologies such as ICT, logistic, energy production, and so on, cooperate to create benefits for citizens in terms of well-being, inclusion and participation, environmental quality, intelligent development; it is governed by a well-defined pool of subjects, able to state the rules and policy for the city government and development".

Following Komminos instead (2006, p.69), the debate on smart cities belongs to the wider discourse on innovation and knowledge management; in fact, smart cities may be referred to as "territories with high capacity for learning and innovation, which is built-in the creativity of their population, their institutions of knowledge creation, and their digital infrastructure for communication and knowledge management".

Sometimes, "smart" is used interchangeably with intelligent, wired and digital. A few authors have progressively criticized this approach claiming that "the disjuncture between image and reality [. . .] the real difference between a city actually being intelligent, and it simply lauding a smart label" (Hollands RG, 2008., p.5).

As already highlighted and specified in the literature on this topic, the areas of analysis and the development aims of smart cities are different: they include the economy, mobility, the environment, people, governance, life quality (Komminos, 2002; Giffinger et al., 2007; Shapiro, 2008). Apart from the purely hard aspects tied to technology there are softer ones. In fact, the main definitions of smart city are tied together with creativity,

learning ability, innovation, knowledge and human and social capital. The technologies for information and communication integrated in the community can allow an effective use of resources by creating the conditions for the territory thanks to the interaction between citizens, institutions and businesses, so it becomes attractive from a socio-economic point of view (Berthon et al.2012)

From an economics point of view, it is important to note that the available resources should be networked so to improve economic efficiency and enable a development that is social, cultural and urban. In a broader sense, the term infrastructure includes the availability and provision of services for citizens and businesses. This is by making extensive use of information technologies, so highlighting the importance of connectivity as an important factor in development.

Similar processes take place in many cities around the world. They combine individual grass-root initiatives with investments that are the result of top-down planning. The two development processes foster the creation of a digital urban space and its integration with the pre-existing social and physical infrastructure.

In this context, integration is the driving force for development of smart cities, combining the strengths of ICT with the city community and the tools of the institutions. The applications are designed to directly complement the activities of the community, improving processes and workflows. However, we can then also observe an indirect integration of knowledge spilling over, which promotes learning and the dissemination of know-how within the city. The urban environment becomes a platform for the learning of digital skills and the creation of education systems for people living in the city.

Online transactions are reducing the need for the physical mobility of the inhabitants. Physical mobility is replaced by online transactions in the citizen's dealings with the public administration, with banks and the suppliers of recreational activities. A city that is more useful to visitors is the result of a greater information about the city and its features, monuments, and the recreational and cultural activities available online. This is particularly important for a city with great tourist potential where the employment rate in the service sector depends in large part on incoming flows. These changes however come largely from "grass root" initiatives created by small companies and individual developers. In some cases, these initiatives are then linked to aggregation systems of intermediate information at district level or that of a university campus, or other urban systems such as railway stations, ports, airports and shopping centres.

Furthermore, the development of the network economy creates new cooperation models in the production, distribution and consumption of services. On the one hand, service companies and other service providers can create different types of alliances or consortia through electronic networks with the aim of disseminating knowledge, sharing risks and reformulating value chains. On the other hand, virtual communities convey consumption patterns and user expectations, so creating opportunities to share experiences (Bessant and Tidd 2007; Furubotn and Richter 2005). Finally, with the potential liberalisation of many public utility companies (at least in some countries) a greater competitive and innovative pressure is created in terms of reconfiguring services.

Additionally, our perception of value creation has changed in the sense that service providers are not conceived to be the only parties able to create value for users. Rather, users now have a vital role in the process of value creation. In the current debate on services, an additional contextual element is featured in the design of the service system. In the new service economy, value is created not only by the service providers and customers but also as part of a broader service system of intermediaries and other stakeholders. These ideas help to redefine the organisational models for division of labour and the relationship mechanisms between public and private actors (Paton and McLaughlin 2008). The process of urban economic development that may potentially arise from a smart city perspective is not simply a model for reinforcing existing structures to achieve economies of scale and scope (range of action). The greatest benefits can actually be achieved through innovative organisation of the relations between the parties involved.

In terms of ICT, smart cities are mostly related to the applications of ICT both as infrastructure (platform) and ICT usage. Digital network infrastructures are used as a means to improve economic and political efficiency and at the same time to enable social, cultural and urban development. Such infrastructure includes mobile and landline phones, satellite TVs, and mostly the physical layer of the Internet (inter- and intra-city digital networks). The digital infrastructure with the services built upon these networks, such as electronic commerce and e-governance, are one of the main economic driving forces in cities and urban regions, producing numerous social and spatial effects.

In terms of domains of application, in the following table we put forward a tentative taxonomy of potential fields in which it is possible to deploy smart city applications, and

the levels of maturity in the development of integrated smart city applications, seen as different levels of integration of the applications, ranging from a purely informative role (diffusion of information) to a fully fledged integrated platform in which applications are mutually embedded to deliver a high level of service to citizens.

Tab. 1. A model of the phases of maturity in the development of integrated smart city applications

Field of application	Level 1 (Informative)	Level 2 (Final transaction)	Level 3 (High integration)
Orientation/location	Map	Maximizing itinerary	Comparative use of location application to decide different uses on the platform
Tourist resources	Information service about point of interest	Tickets for attractions	Enlarged fruition and augmented reality through smart city services
Public transport	Timetable and availability of transports and parking	Tickets of TPL	Planning itinerary and purchasing of integrated tickets
Public administration services	Information about potential services	Informative transactions and records on demand	Integrated access to PA information in relation to platform services
Buying goods and services	Showcase	Purchase, payment system	Integration of merchant of different types
Customer loyalty	Business proposal	Booking, discounts	Integrated access to a wide range of services
Financial services	Information related to financial service	Purchase related to specific financial services	Electronic money to buy services of the platform

3 Data Analysis

Our research was based on a qualitative investigation. As the case study approach refers to an in-depth study or investigation of a contemporary phenomenon within the real-life context, we set up six descriptive case studies, using theoretical replication logic [7]. In particular in this paper we selected six case studies, within a set of 15 international cases analyzed during a research project funded by the Italian Ministry for University and Research. We present the main evidences related to the cities of Songdo, Nice, New York, Amsterdam, Dublin and Barcelona. The selected cases are representatives of different governance structures, technologies adopted and phases of maturity in the development of integrated smart city applications.

The collection of empirical data was carried out using a heterogeneous plurality of instruments. The methods include: document analysis, semi-structured interviews and participant observations. Fieldwork was carried out between September 2012 and early July 2013. The interviews were guided by a questionnaire of wide-ranging, including questions about: the governance model, the fare structure and the fare evasion, the

transportation demand trend, the key element of the technological side, the problem of revenue distribution (clearing), the response of some managers to the application of electronic ticketing, and the socio-technical interplays within the network.

3.1 Songdo

The concept of Ubiquitous Computing Environment leads new paradigm change in urban space creation (Carvalho, L., 2011; Jang M., Suh S.T, 2010). In Korea, new concept of Ubiquitous-City (U-City) draws a lot of attentions now. It is trying to fuse high-tech infrastructure and ubiquitous information service into the urban area. It is also thought to bring innovations of urban functions, delivering information anytime, anywhere to anybody, via interconnected information systems and ubiquitous ICT solutions over the city. New Songdo is the first U-City case, where ICT are applied during urban development rather just being applied in the city, suggesting that future urban planning will possibly set ICT as an axe of precedence. In particular, Songdo International Business District is a U-City underway from scratch on 1,500 acres of reclaimed land along Incheon's waterfront, 65 km southwest of Seoul, and connected to Incheon International Airport by a 12,3 km highway bridge (Shin D.H , 2009; Shwayri S.T. 2013).

The city is planned as a hub for international business, high-education, new high tech industries, and also container port facilities: schools, hospitals, apartments, office buildings and cultural amenities are to be built in the district. Much of Songdo has still to be built, but even as it is under continuing construction, there are signs that point to its becoming an important business and residential hub. When completed in 2015, it is estimated that this \$25 billion project will be home to 65,000 people and that 300.000 will work there. It is being developed as a sustainable city with more than 40% of its area reserved for green space, including the park, 26 km of bicycling lanes, numerous charging stations for electric vehicles and a waste collection system that eliminates the need for trash trucks. The green infrastructure of the new city is to be enhanced by the provision of extra services that combine ICT as well as digital networks to ideally create harmony among the environment, society, and technology. Computers have been built into the houses, streets and offices as part of a wide area network. It can be described as a merge of information systems and social systems, where virtually every device and service is linked to an information network through wireless networking and RFID tags and sensors.

For example, crime prevention CCTV (security camera system) and CPTED operating CCTV have been installed, an Intelligence Traffic System that gives services to traffic controllers in Songdo from Incheon Traffic Information Center's Network, lower operation costs and there is also a traffic light system that uses the sensors on vehicle detectors. Moreover, Citizens will use U-mobile services to get traffic, weather and new updates through their smart-phones. The school zone safety services in particular will have a speed warning system and smart curb system in place for drivers, which use facial emoticons to send warning messages. The most eye-catching item from all these efforts has to be the U-disaster services. On top of the 68-floor Northeast Trade Tower a thermal imaging camera has been placed, in order to gather temperature, humidity, wind direction, and wind speed information all across Songdo. If there is a big fire or any pollutants being released, or significant changes to standard conditions, the system is able to sense this and alert the appropriate emergency vehicles like police cars, ambulances, fire trucks, etc.

In terms of organizational actors, relevant social groups around the development of u-city can be categorized into three groups: 1. initiators: Ministry of Information and Communication (MIC) and Ministry of Construction and Transportation (MCT); 2. industry providers of electronics conglomerates system (development companies, telecom equipment manufacturers and service providers, such as LG, KT, and Samsung) 3. host municipal authority. Along with MIC, MCT is a major initiator in u-city projects with the main responsibility of implementing the infrastructure. They have been key players in pushing ahead its nationwide u-city, coordinating the actions of both public (local) and private stakeholders.

3.2 *Nice*

Cityzi project (the integrated platform for mobile devices in use in Nice) started in 2005 in Japan with a research carried out by the third French largest mobile operator, Bouygues Telecom. At that time, in Japan, an "electronic portfolio" was already used for small payments, to buy train tickets and flights, travel titles. While the Japanese solution with proprietary technology was deemed unfit for European customers, Bouygues Telecom was convinced that the phone in the future could have been a payment instrument.

In France Bouygues Telecom had developed an interest in technology NFC in public transport (NFC cards were already in use in 35 cities) and payments (some French banks

were interested in using NFC for small amount transactions). It was clear to Bouygues Telecom that, being only the third largest telecom operator, it would not have been able to begin such a demanding initiative alone. In addition, Bouygues Telecom had understood that banks and public transport operators prefer technical solutions that can be used by all operators and on all handsets. As a result, Bouygues Telecom shared all the information in its possession with Orange, the leader in the field of mobile telephony, to convince them of the importance of undertaking the NFC initiative, but, more importantly, to emphasize the fact that, in order to be successful, would have had to work together. In addition, the president of Bouygues Telecom - having previously worked for banking groups and for Visa, was considered as the right person to convince these players that it was preferable to collaborate rather than seek each proprietary solution. Also public transport operators, manufacturers and retailers joined this collaboration that in April 2008 would have given life to AFSCM (French association for the diffusion of technology NFC). When the French mobile operators began to collaborate to develop an understanding on NFC there were no technical specifications for NFC mobile services. The first step was the creation of these specifications. Between 2006 and 2008, tests were being carried out in the cities of Paris, Caen, Grenoble and Strasbourg. In addition to testing the technology, these pilot tests served to verify the assumptions about consumer behavior. Initially, young people were seen as the target segment for services NFC mobile since they are good users of public transport, spend most of their income, rather than save, and are accustomed to electronic payments. However, during the pilot tests it became clear that the focus was too limited. Bouygues Telecom decided to extend the range of age to include older people: the objective was the segment of the population that potentially buy phones equipped with technology NFC. The collaboration within AFSCM developed in a positive way. However, some problems took place between Visa and AEPM (European Association for mobile payments), due to the potential overlap of interests between Visa and banking institutions. Only after several months of negotiations, the French banks and the telephone operators managed to convince Visa Europe of the value of the solution during implementation. After the pilot phase, the members of the AFSCM have realized that it was important to organize a final test before the launch; it was necessary to involve real customers that could have used phones to make shopping, offering them the download of real services to use.

Cityzi nowadays represents the main scheme of integrated services of mobility platform on ICT in Europe, through the use of technology NFC. Users can exploit their smart phones to access to a variety of services, including payments by credit cards, tickets of the urban network of TPL, discounts and coupons for shops, museum services, and information services on the city. The costs of the system are supported through installments paid by those who deliver a service. In particular, the actors which deliver services are charged a monthly fee. End users do not bear any charge. Veolia transdev manages the entire network of local public transport. Therefore, the revenues from public transport are transferred to the transport operator diminished of the fees needed to conclude the transaction on the smart phone platform. The system operates in a similar way as regards to the payments made toward other types of retail outlets.

3.3 New York

There is an integration system in New York that mainly concerns transport and also partly relates to tourism. It is a centralised and relatively traditional system, run by a focal organisation (a transport authority) which also makes the technological service-related decisions and develops partnerships with financial or tourism entities (in the latter case, mainly through a series of discounts and agreements).

The institutional player that governs the public transport system is the Metropolitan Transportation Authority (MTA), that operates the subway, buses and trains to Long Island and to the north (it is the biggest local transport network in North America with 16 railways lines , 24 subway lines and 338 bus lines, providing these services for a population of 15.1 million people). The MTA is governed by a board of 17 members: five members, as well as the Chairman and Chief Executive Officer, are directly appointed by the Governor of New York. All members of the Board are confirmed by the U.S. Senate.

Since 1994, the MTA has introduced a payment system called the *MetroCard*, which allows passengers to use magnetic cards which "contain" the exact value of the amount paid to the seller or electronic machine. Each Metro Card is assigned a specific serial number and transactions are recorded in the Automated Fare Collection Database: in this way the typical features of a Transaction Processing System are associated with those of a Management Information System (which acquires and processes the data collected, aggregating and compressing it and submitting it in systematic reports). In 2006, the MTA signed a deal with MasterCard to test a new payment system (*Paypass*), an

alternative to the MetroCard, with RFID technology that allows direct payment by credit card. The contactless MasterCard card has an embedded chip and antenna. Placing the card near the specific reader allows a wireless exchange of payment details without there being any need to swipe the card or insert it into a terminal. Information regarding the account is transferred from the reader and processed through the MasterCard Acceptance circuit. Starting in 2010, this solution has been extended to smart phones via an application that uses Visa pay Wave. With both methods, in order to buy a ticket for a ride you just have use the "*Slyde to pay*" method, or place your iPhone or credit card near the device, a kind of contactless reader, capable of detecting devices in relation to "non-contact" payments. The processing of the purchase is then handled in the same way as any other Visa or MasterCard transaction. The purpose is to speed-up the movement of people to the line and thus minimise payment waiting time. Despite the widespread positive response from users, the test is still being carried out for only 28 stops along the Lexington Avenue line.

The MTA has also created several smart phone applications that are freely downloadable on the App Store platform, which allow you to always have a subway map at hand and calculate the time required to move from one station to another with relative indications (iTrans NYC and NYC subway). In addition, in 2012 the MTA completed its "MTA subway time" application that allows you to check the times of all incoming and outgoing subway trains and delays.

The MTA is developing an integration system, that from 2015 that will allow users to use the MetroCard as well as the bike sharing system (Citibike), which has already been available in cities since 2012 with more than 10,000 bikes. The MTA is also developing the *Pay By Phone* system that allows citizens to pay for their parking via NFC technology. After registering your vehicle and your credit card on the service's website, you can pay for parking services by touching the relevant parking meter. This system is being developed in collaboration with the supplier of *PayByPhone* mobile payments, a *Pay By Phone* company providing a service similar to other cities in the world, such as Miami, San Francisco, Vancouver and London.

Finally, from the point of view of integration with the tourism system, it should be noted that with the purchase of a weekly or monthly MetroCard you are entitled to a discount for the New York Pass, New York City and the New York Explorer Pass. It is a magnetic card that allows discounts of up to 50% to visit the most important sights of the

city of NY (the most complete one allows visits to 80 attractions). In particular, New York Pass is a "smart card" which allows you to visit more than 80 New York attractions without having to buy a ticket. The smart card records when and where you used the pass for the first time and displays the expiry date.

3.4 Barcelona

In Barcelona the integration system concerns all transports. In late 90's, the organisation of the public transport system in the area of Barcelona required the creation of a metropolitan public transport coordinating agency, the ATM, by local government. Barcelona ATM is the governing body for integrated fare collection covering the metro system, railways, tram systems, buses, and other forms of public transport within Barcelona and the 250 towns in the surrounding area. The agency provides the system for approximately 74 transport operators in the Barcelona metropolitan region, which covers 3,240 square kilometres and serves more than five million residents. More than 70% of the journeys made by customers are with integrated tickets. In its function as regional mobility authority for the metropolitan region of Barcelona, the ATM is responsible for the following main functions: i) the drafting, processing and evaluation of the mobility steering plan; ii) issuing reports with regard to the urban mobility plans, the services plans and the evaluation studies of the mobility generated; and fostering the sustainable mobility culture among the public.

The Integrated Fare System was implemented in 2001. It is a zonal fare system (concentric crowns divided each into sectors): the fare zone is the area resulting from the intersection of crowns and sectors. In total 6 crowns and 33 sectors. Zone 1 includes the city of Barcelona and 17 other municipalities. Revenue from integrated tickets collected by ATM and paid monthly to all operators as established in the contracts. Private operators are paid according to concession contracts Renfe is paid by ATM as a result of the increase in passengers following fare integration (limited in time).

ATM is now deploying a full NFC-contactless solution for ticketing, based on open standards and ISO-CEN compliant, which is intended to be a significant step towards the deployment of contactless services across the rest of Catalonia, as well as interoperability with transport systems in other regions. ATM is also building on the momentum of Barcelona City Council's TAP@GO project, which is enabling NFC-payments and municipal services within the city.

In other words, the ticketing system the AMT is backing is based on data stored in a portable device that can be used as a bank card as well as a phone. This would mean moving beyond the ticket with a magnetic strip to employ the new contactless technology; the “the bus or train ticket” would thereby become a "transport application", which can be used in a range of bank cards and telephones.

At the moment, the only integration with the tourism system is the “Barcelona card”, developed by the Tourism de Barcelona Consortium. It is valid for unlimited journeys two, three, four or five days in the zone 1, and for free admittance in 25 touristic attractions. Furthermore the card includes many discounts in several museums, shops, restaurants.

3.5 Amsterdam

The OV-chipkaart is a contactless smart card system for all public transport in the Netherlands valid since 2011. The OV-chipkaart was first introduced to the Rotterdam Metro in April 2005. Since 2005 have been sold 6.800.000 cards on 16.500.000 people, 412 cards every 1000 people. The OV-chipkaart is a collaborative initiative of many actors. Five large public dutch transport operators: the main rail operator NS, the bus operator Connexxion and the municipal transport operators of the three largest cities (GVB, HTM, and RET). These five actors established the joint venture Trans Link System to develop and implement the card. The OV-chipkaart uses the MIFARE technology and three versions of the card are available: the disposable card, the anonymous card, and the personal one. The latter two types are valid for between five and six years, and can store credit. The disposable card, used mainly by tourist or by people who don't use often public transport, is thrown away after use. It can only be used for simple travel products and cannot be topped up with credit since it does not feature an electronic feature. The anonymous card, reusable and used by people who travel more frequently, has an electronic purse feature and the balance of the card is topped up at vending machines or at manned kiosks. The card is transferable and can not be used to hold season tickets longer than a few days in duration. Anonymous cards are obtainable from vending machines, kiosks and a special website for a fee but can be used immediately, unlike a personal OV-chipkaart. The personal OV-chipkaart used by residents, is similar to the anonymous version though it is possible to store season tickets and other travel products of a period longer than a single month. Other advantages of the

personal card are that it can be blocked if it is lost or stolen, and it can be set to automatically "top up" when the electronic purse credit drops below a certain level.

3.6 Dublin

The introduction of an integrated transport system in the Greater Dublin Area was part of a wider project. Transport 21 was an Irish infrastructure plan, announced in November 2005. Its aims to greatly expand Ireland's transport network encouraging use of public transport providing an integrated pricing system through the use of a smart card. A cost estimate of €34 billion was attached to the plan at the time. The plan includes continuing investment in Ireland's road network, along with investment in public transport in the form of buses and rail. In 2008 the Railway Procurement Agency, the State Agency of the Department of Transport charged with the development of light railway and metro infrastructure is appointed for the development of an integrated smart card system. The RPA has been a crucial role in implementing key rail elements of the Irish government initiative, Transport 21. It will be responsible for the planning, coordination and procurement through conventional means, and through Public Private Partnership. On 12 December 2011 was introduced the leap card, a form of integrated ticketing. The card can be used on DART, Dublin bus, Iarnród Éireann and Luas; minimum top up for the card is currently €5. The Leap card is the result of many years work by the Railway Procurement Agency to get an integrated ticketing-scheme for the public transport in Dublin city. Initially it only offers a pre-paid electronic wallet system to buy single trip journeys on Luas, DART / Commuter and Dublin Bus but there are plans to also offer week, month and year subscriptions on the card. It is also planned to extend the capabilities of the card. Introducing transfer rebates, monthly and yearly passes Even though the Leap card is usable on the bus, tram and local railway lines, it can only be used for single journeys within one of the systems. Any form of subscription/multi-day offerings are not (yet) possible with the Leap card: Even though tickets bought with the Leap card are cheaper than single journeys bought with cash money, using the Leap card for frequent travellers is more expensive than using the different weekly or monthly cards. There are plans however to extend the functionalities of the card, like the ability to "upload" a week, month or year-card to a Leap card.

The Leap card uses a chip inside the card then can be read from and written to without direct contact: a so-called proximity card or RFID cards. As far as concern the actors

involved in the integrated system. Several companies offer public transport in the larger Dublin area. Apart from several private companies transport is offered by Veolia Transport which operates with two tram-lines (Luas); Dublin Bus, the state owned bus service operating lines in the greater Dublin transport area, Iarnród Éireann, the national railway company (DART). In addition, Hewlett Packard Ireland/Payzone , IBM.

4 Discussion and conclusion

By presenting the cases, it is possible to make some preliminary comments about the different lines of development of the smart cities applications linked to the various spheres of citizens' lives, and more specifically, to local mobility and tourism.

In some of the world's major cities, the spread of integrated tariff schemes and mechanisms for using local public transport and having access to the city's major attractions has not yet been accompanied by a widespread use of smart city applications that employ ICT for shared and integrated access to a wide range of resources and services. However, in some cities, this potential is becoming clear, and players and services have been converging on a single platform for some time now. Finally, in other cities, the situation is at an intermediate stage and some attempts at moving toward integration of the services offered have been successful.

Table 2 summarizes the empirical findings that emerged and highlights the level of complexity and progress for each of the situations surveyed, with respect to the following aspects:

- number of services covered by the smart city application evaluated (the range of the application's portfolio of services);
- number of connections to the reference environment (the network of relationships with local stakeholders);
- number of players involved (those who have played or play a role in the application under examination);
- specificity of the inter-organisational coordination mechanisms (the establishment of site-specific, administrative and trade agreements or relationships, or agreements that can be effortlessly replicated elsewhere);
- specificity of the integrated system business model (the design of a mechanism for economic and financial equilibrium of the platform, and that relies on more or less innovative logic);

- presence of technologically relevant aspects (understood as the presence of cutting-edge technologies).

Tab. 2. The level of complexity and progress for each of the situations surveyed

Case study	Integration	Task Environment links	Number of actors	Collaborative Partnership	Governance model	Intelligent Technologies
New York	medium	medium	high	medium	low	medium
Barcelona	medium	high	high	medium	low	medium
Dublin	medium	low	medium	low	low	low
Amsterdam	medium	low	medium	medium	low	low
Nice	high	high	high	medium	high	high
Songdo	high	high	high	medium	medium	high

Figure 2, furthermore, also displays the positioning of the cases under examination in comparison to the other two key dimensions: the range of services offered by the *card* or the platform and the level of integration between the services themselves.

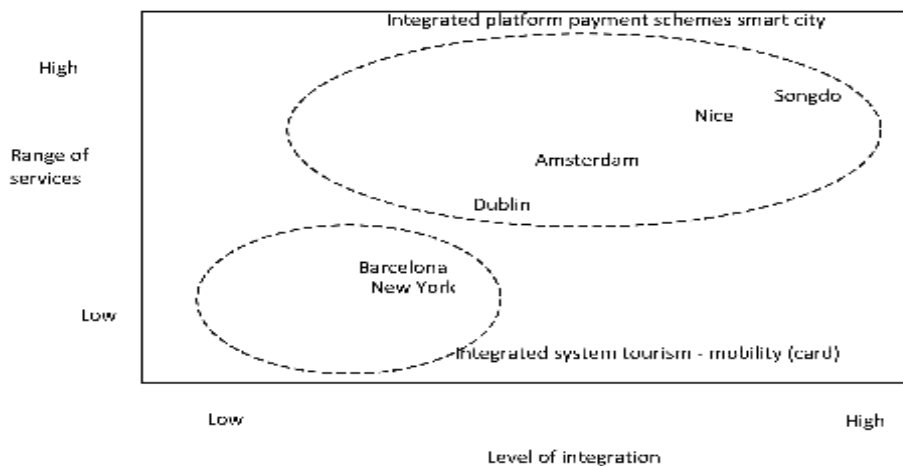

Figure 2. The positioning of the cases in comparison to the range of services and the level of integration between the services themselves.

Ultimately the level of integration (Canonicò et al., 2011), the functional and technological towards which the most advanced experiences are moving, in an attempt to

offer citizens a variety of jointly designed services equipped with commercial synergies and aimed at homogenous groups of users).

Therefore, a model of the phases of maturity in the development of integrated smart city applications could be defined as follows.

- An initial phase of basic use of the features offered by smart phone technology to facilitate a purely informative access to application domains, such as localization, access to tourism and mobility resources, public administration services, and business and financial services.
- An intermediate phase of transactions that stand alone in their respective application domains without sharing databases and information resources.
- An advanced phase represented by those integrated platforms for joint delivery of synergically designed services connected to a multitude of application fields.

The following table illustrates the levels just described, highlighting their respective potentials.

Tab. 3. The positioning of the cases in comparison to the phases of maturity

Field of application	Level 1 (Informative)	Level 2 (Final transaction)	Level 3 (High integration)
Orientation/location	Dublin, Amsterdam	New York, Barcelona	Nice, Songdo
Tourist resources	Dublin, Amsterdam, Barcelona	New York	Nice, Songdo
Public transport	-	New York, Dublin, Amsterdam, Barcelona	Nice, Songdo
Public administration services	-	-	Nice, Songdo
Buying goods and services	Dublin, Amsterdam	New York, Barcelona	Nice, Songdo
Customer loyalty	-	New York, Dublin, Amsterdam, Barcelona	Nice, Songdo
Financial services	Dublin, Amsterdam	Barcelona, New York -	Nice, Songdo

We can therefore provide a summary of useful observations for interpreting the future development paths of smart city platforms.

First, from the analyses carried out, it would seem that models for development of integrated systems for smart city tourism-mobility, while representing the frontier toward which to strive, are still under developed. In other words, the applications available in many cities are still at an embryonic stage and are not integrated schemes that are actually in use when compared to the city's mechanisms of use. Moreover, in many cases, "archipelago" logic of specialization seems to prevail, with the proliferation of separate and distinct applications for application domains rather than aiming towards integration.

In more detail, in Europe there is a prevalence of anarchistic models while in Asia, a more centralized set-up prevails (for example, Hong Kong or Songdo).

In many of the cases analyzed, we find a hurdle to spreading integrated schemes that interface with payment systems, probably due to the delay in collaboration between telephone services providers and global financial traders, still lagging behind in terms of the potential of smart city applications. The exception is France (and in particular, Nice) where the telcos have been a driving force in terms of launching platforms integrated with payment systems.

With regard to the spread of technologies, NFC, an integrated smart phone technology, is definitely the one most widely used for payments, despite discounting Apple's choice not to install NFC tags in their iPhone.

The development of inter organizational relationships (Canonico et al., 2012) with service and technology providers by local public transport companies has proved much easier, as there is a strong *incumbent* operator with consolidated experience as a catalyst for innovation.

The existing smart city applications also seem to show a very limited connection with the logic of *user generated content*. For this purpose, one of the central aspects should consist in the assumption that people should be able to participate actively in the design of the services and content that they are accessing. In fact, the delay in the synergy between *user generated content* and integrated mobility-tourism applications can essentially be explained by the limited availability of sensory, ICT and modelling infrastructures that can gather real-time input from citizens and adapt to those requests. This last point is perhaps the most challenging because it calls for flexible services, but it is the key to setting in motion the "*resource on demand*" mechanism to provide the service at the exact place in time and with the required intensity. In the early stages of application development, design tended to be self-referencing, generating a number of various initiatives with technical solutions and economic feasibility of an alternative rather than synergic nature.

Structured Abstract

Purpose – This paper tries to develop an analyzable framework of the effects of spatial knowledge spillovers on economic growth of China. Firstly, this paper investigates spatial pattern of FDI inflows in China according to the spatial neighboring effects of knowledge flow; Secondly, this paper analyses the spatial dependence process of interaction between knowledge spillovers of FDI inflows and innovative activities in China, so as to look for insights on the mechanics of knowledge interdependences across regions;; Finally, it is expected to get the practical implications about a spatial policy of driving local area success growth .

Design/methodology/approach – In accordance with the theory and method of spatial interdependence, heterogeneity, variation of knowledge spillovers involved with spatial econometrics, the paper uses Chinese provincial data to investigate the empirical evidences of the effects of knowledge flow and spatial spillovers on innovative activities of China. On the platform of GeoDa and EViews software system, the spatial econometrics models of spatial pattern and spillovers effects of FDI inflows are built so as to examine the spatial variation of knowledge flows in Chinese provinces.

Originality/value –This paper points out the ideas of spatial interdependence, heterogeneity, variability of knowledge spillovers, so as to indicate spatial association process between FDI inflows and innovative activities in China. This paper constructs the methodology of Negative binomial and Poisson probability distribution model in FDI inflows and innovative activities, and applies the methods of spatial econometrics in analyzing the mechanics of dissemination and agglomeration of innovative activities in China as well as characteristics of knowledge spillovers with distance decay effect.

Practical implications – it is expected that the studies make policymakers get a good understanding of spatial association process between FDI inflows and innovative

activities in China. In addition, this paper suggests that spatial dimension of effects of knowledge spillovers generating by FDI inflows in China on innovative activities can not be ignored. The derived suggestions and policy implications of spatial agglomeration and dissemination of innovative activities are very helpful for policymakers.

Keywords – Spatial Spillovers, Foreign Direct Investment, Innovative Activities, China.

Paper type – Academic Research Paper.

1 Introduction

Knowledge spillovers are one of the main sources and engines of sustainable innovation and economic growth (Fujita and Thisse, 2002) , and foreign direct investment (FDI) inflows are the main channels to promote knowledge spillovers and growth of productivity (Xinzhong Li and Tongsan Wang,2009)¹. In turn, FDI firms with advance technology or managerial know-how knowledge, which bring the externalities of knowledge, may enhance competitive power of local firms in China. Especially, the early encouraging FDI inflows policy has been helpful for coastal regions since China launched the “open-door” policy in 1978, which makes FDI inflows located mainly in coastal developed economic regions so as to gain agglomeration economies. As a result, FDI inflows play important role in the strong growth regions in the coastal regions, and the located regions of FDI inflows are also the most intensive regions of innovation activities in China. This shows that FDI-related technological spillovers are the sources of sustainable innovation and productivity growth in coastal areas of China.

However, most of present literatures about interaction between FDI inflows and innovation activities have gone along with the traditionally theoretical framework of knowledge production function (KPF) without considering the spatial dimension since Jaffe (1989) described the local externalities in the process of creation and diffusion of knowledge by using KPF which focus on the intra-sector dimension. Although some recent studies take into account spatial and sector dimension of knowledge spillovers of FDI inflows, the magnitude or scope and spatial variation of knowledge spillovers are not examined. The rare literature fully investigates variation of knowledge spillovers with geographical distance and spatial proximity.

¹ Li, Xinzhong, Wang, Tongsan, 2009, “*The Technological Spillovers Effects of FDI inflows in China*”, research report, Institute of Quantitative & Technical Economics (IQTE), Chinese Academy of Social Sciences (CASS).

Just as Paul Krugman (1991) shows in a theory of new economic geography, the most striking features of the geography of economic activity are notable concentration of production in space. Especially, innovation activities have even more remarkably characteristics of spatial cluster in the geography. However, Krugman (1991) argued that empirical measurement of knowledge spillovers would prove to be impossible because “knowledge flows are invisible, they leave no paper trail by which they may be measured and tracked”¹. That is, regarding knowledge spillovers, there are no reasons for a political boundary to stop the spilling and limit the spatial extent, such as city limit or province line, or national boundary. Thus, this has currently triggered a strand of new literature of understanding the spatial dimension of innovative activity.

Jovanovic and Nyarko (1995), and Glaeser (1999) argue that proximity makes worker with greater skills or knowledge helpfully acquire the skills and the exchange and diffusion of knowledge. Helsley(1990), Ota and Fujita (1993), Lucas (2001), Berliant, Peng, and Wang (2002), and Lucas and Rossi Hansberg (2002) show that cities evolve a transition from a mono center to a multi-center structure, and then to have a dispersion with spatial decay over distance, but, they don't take account of much detail of the knowledge spillovers and the spatial decay function. Helsley (1990) suggests that the knowledge spillovers are a byproduct of output, and in part of specific location. Thus, these papers can be considered as the first step towards a fully understanding knowledge spillovers and spatial cluster and decay of economic activity.

In fact, the knowledge spillovers generated by FDI inflows follow a complex diffusion process through geographic, social, institutional, and technological proximity (Jaffe and Trajtenberg, 2002). Thus, FDI inflows-related spillovers are highly likely to have a spatial dimension. That is, FDI inflows-related spillovers present the characteristics of spatial interdependence, spatial heterogeneity, and spatial variation in the spatial dimension (Xinzhong Li and Tongsan Wang, 2011)². For example, LeSage, Fisher and Scherngell (2007) attempt to incorporate spatial dimension in conjunction with KPF to demonstrate variation of spillovers with geographical distance; Blonigen and Davies et al.(2007) indicate spatial autoregressive relationships of FDI inflows based on the surrounding market potential and the spatially lagged dependent variable; Baltagi,

¹ Lucas (2001), and Lucas and Rossi-Hansberg (2002) construct a spatial structure on production externalities so as to capture the externalities of knowledge.

² Li, Xinzhong, Wang, Tongsan, 2011, “The Effects of FDI inflows on Chinese sustainable innovation”, research report, Institute of Quantitative & Technical Economics (IQTE), Chinese Academy of Social Sciences (CASS).

Egger and Pfaffermayr (2007) use spatial weight to investigate the determinants of FDI inflows; Coughlin and Segev (2000) examine the neighboring effects of FDI inflows based on database of Chinese provinces.

These studies show that ignoring spatial effects of FDI inflows likely causes the bias of model specification and unreliable estimation of externalities of FDI inflows. FDI inflows-related spillovers based on geographical proximity and spatial clustering can enhance productivity and competition of Chinese firms. Especially, location choice of FDI inflows and spatial clustering of innovation activities not only depend on characteristics of foreign or Chinese firms within regions, but also the factor characteristics of neighboring provinces or cities such as market size, relative factor endowments, and economic developing level and so on. Besides, spatial clustering and geographical proximity mean that knowledge flow increases the opportunities for face-to-face contacts among people working, and also implies that there exists the limited spatial process over geographical distance for knowledge spillovers.

Thus, in order to fully understand the role of spatial dimension of knowledge spillovers in enhancing the innovative capability across Chinese provinces, and explore mechanisms of interactions between FDI inflows and innovation activities, the paper tries to develop an analyzable framework of the dynamic spatial model of knowledge spillovers based on the methodology of spatial dependence, heterogeneity, variation of knowledge spillovers generated by FDI inflows in China according to database of Chinese provinces. Besides, the possible spatial effects such as geographical scope and spatial decay effects of knowledge spillovers as well as the limited spatial process of externalities generated by FDI inflows are examined. It is expected that the evidences can be found which FDI inflows enhance knowledge spillovers and technology diffusion.

The paper is organized as follows. Beside the section above reviews the emerging literature on the spatial effects of FDI inflows on innovation activity and spatial empirical evidences regarding FDI inflows, the subsequent section uses probability model to examine the characteristics of spatial distribution of FDI inflows and innovation activities. The third section discusses measures of spatial dependence and empirical findings and explores externalities in the process of spatial creation and dissemination of knowledge as well as the effects of proximity on knowledge spillovers. Sections four summarize some remarks and policy implications are concluded. Finally, the acknowledgments and references are given.

2 Spatial Distribution of FDI Inflows and Innovative Activities in China

In accordance with the observed spatial clustering characteristics of FDI inflows and innovative activities in coastal regions of China, the conventional linear model are not appropriate to model spatial distribution of FDI inflows and innovative activities. Therefore, Negative binomial (NB) and Poisson probability distribution models are more appropriate approaches to be superior to others for describing the characteristics of count data with cluster. Thereby, NB and Poisson model can be used to approximately simulate the spatial agglomeration of FDI inflows and innovative performance so as to understand the mechanisms of dissemination and agglomeration of innovative activities as well as the effects of technological and geographical proximities on FDI inflows and innovative activities.

2.1 Probability model of spatial distribution

In theory, when $\sigma^2(X) > E(X)$, NB distribution model may be simulated the variable X which has the characteristics of clusters; when $\sigma^2(X) = E(X)$, Poisson distribution model may be simulated the variable X which has the characteristics of clusters; when $\sigma^2(X) < E(X)$, Binomial distribution model may be simulated the variable X . In addition, NB distribution can be combined by a few Poisson distribution with the different expectations of the variable X , and the limiting distribution of NB distribution is regard as Poisson distribution.

In particular, zero-inflation probability may be present when there are frequently so low probabilities over some time period and in regions. That is, sometimes the conventional applications of NB and Poisson models don't properly address the possibility of zero-inflated counting processes. As a consequence, zero-inflated probability processes are considered as an extension of standard Poisson and negative binomial regression, such as the zero-inflated Poisson (ZIP) and zero-inflated negative binomial (ZINB) regression models have widely applied in practical frequency analysis (Shankar and Milton et al. 1997), which may generate the better results of frequency simulation.

Thus, in order to illustrate the spatial distribution characteristics of FDI inflows and innovative activities, statistical analysis is started with Poisson model in frequency analysis. When the observed data obeys $\sigma^2(X) = E(X)$, the Poisson mode is as follows:

$$P(x_{ij}) = \exp(-\lambda_{ij}) \lambda_{ij}^{x_{ij}} / x_{ij}! \quad (1) \quad E(x_{ij}) = \exp(\beta Z_{ij}) \quad (2)$$

Where $P(x_{ij})$ is the probability of spatial distribution of the variable x in region i and time period j ; x_{ij} is the grade; λ_{ij} is the expected value of the variable x_{ij} , that is, $E(x_{ij}) = \lambda_{ij}$; Z_{ij} describes the vector of grade characteristics affecting the frequency of FDI inflows and innovative; β is the vector of regression coefficients to be estimated by standard maximum likelihood methods;

However, when the observed data presents the characteristics of over-dispersion, that is, it is subject to $\sigma^2(X) > E(X)$, Poisson model may result in biased estimation of model. Thus, NB model is applied in simulation of spatial distribution. The modified equation is derived as follows:

$$\lambda_{ij} = \exp(\beta Z_{ij} + \varepsilon_{ij}) \quad (3) \quad \sigma^2(x_{ij}) = E(x_{ij}) + \alpha E(x_{ij})^2 \quad (4)$$

Where $\exp(\varepsilon_{ij})$ is a ε_{ij} error term that follows Gamma distribution, in order to allow variance ($\sigma^2(x_{ij})$) may be unequal to the mean $E(x_{ij})$, which is very different from requirement of the Poisson model; α is a adjustable parameter between Poisson and NB model. When parameter α approaches zero, Poisson model is selected, otherwise, NB model should be considered. Thus, NB model can be formed as follows:

$$P(x_{ij}) = \frac{\Gamma((1/\alpha) + x_{ij})}{\Gamma(1/\alpha) x_{ij}!} \left(\frac{1/\alpha}{(1/\alpha) + \lambda_{ij}} \right)^{1/\alpha} \left(\frac{\lambda_{ij}}{(1/\alpha) + \lambda_{ij}} \right)^{x_{ij}} \quad (5)$$

Where $P(x_{ij})$ can be estimated by moments and standard maximum likelihood methods, which can be simplified as such the forms as $P(x_{ij}) = (\hat{\kappa} + x_{ij} - 1) R(\hat{\kappa}, x_{ij}) P(x_{ij} - 1) / x_{ij}$, $R(\hat{\kappa}, x_{ij}) = E(x_{ij}) / (\hat{\kappa} + E(x_{ij}))$, $\hat{\kappa} = E(x_{ij}) / (\sigma^2(x_{ij}) - E(x_{ij}))$.

2.2 Test statistic of spatial distribution

The test of spatial distribution models are started with goodness-of-fit test of χ^2 distribution. That is, in accordance with the observed data of FDI inflows and innovative activities, the NB and Poisson model are tested respectively based on the data set of Chinese provinces and cities level. The formula for the test is as follows:

$$\chi^2 = \left(\sum_{i=1}^n x_{ij}^2 f_{ij} - \left(\sum_{i=1}^n x_{ij} f_{ij} \right)^2 / \sum_{i=1}^n f_{ij} \right) / \sum_{i=1}^n f_{ij} \quad (6)$$

Where f_{ij} is the observed frequency of variable x in region i and time period j . The test values of χ^2 distribution and test results of probability distribution model see table 2.2-1, table 2.2-2, and table 2.2-3. The test results of probability distribution model show that FDI inflows, which include number of manufacture firm, R&D firm, managing & marketing firm, and total sectors, as well as innovative activities, which include number of patent applications examined such as inventions, utility models, designs, are subject to the NB probability distribution, which is also consistent with the observation of FDI firms and innovative activities concentrated in coastal cities and provinces.

However, because probability of FDI firm distribution frequently presents so low value to approach zero in regions, ZIP or ZINB model may be developed in the observed count data of FDI firms and innovative activities, and assume that the events Y are independent. Because the NB model is favored for the observed data, rather than Poisson model, the ZINB models of the modified probabilities are only considered and are formed as follows:

$$\text{Prob}(Y_{ij} = 0) = p_0 + (1 - p_0) \left(\frac{1/\alpha}{(1/\alpha) + \lambda_{ij}} \right)^{1/\alpha} \quad (7)$$

$$\text{Prob}(Y_{ij} = c_i) = (1 - p_0) \frac{\Gamma((1/\alpha) + c_i)}{\Gamma(1/\alpha)c_i!} \left(\frac{1/\alpha}{(1/\alpha) + \lambda_{ij}} \right)^{1/\alpha} \left(\frac{\lambda_{ij}}{(1/\alpha) + \lambda_{ij}} \right)^{c_i} \quad (8)$$

Where $c_i = 1, 2, 3, \dots, n$ is the grade number of events such as FDI firms and patent applications examined; p_0 is subject to the formulas as follows:

$$E(y_{ij}) = (1 - p_0)\lambda_{ij} \quad (9) \quad \sigma^2(y_{ij}) = (1 - p_0)\lambda_{ij}(1 + (p_0 + \alpha)\lambda_{ij}) \quad (10)$$

$$\frac{\sigma^2(y_{ij})}{E(y_{ij})} = 1 + \left(\frac{p_0 + \alpha}{1 - p_0} \right) * E(y_{ij}) \quad (11)$$

Obviously, the variance is greater than the mean in ZINB model, which shows that observed data has the characteristics of clusters in ZINB model. But, because Poisson and ZIP or NB and ZINB counterparts are not nested, this test can't be conducted directly. Thus, the statistical test is critical for the selecting, ZIP, ZINB or not. According to the methodology for non-nested models developed by Vuong and Quang (1989), let random variable $Y = y_i$, and assume that the probability density functions of ZINB and

NB model are respectively the $f_1(y_i/x_i)$ and $f_2(y_i/x_i)$. As a result, the test statistic for non-nested ZINB and NB or ZIP and Poisson is as follows:

$$\eta_i = \ln\left(\frac{f_1(y_i/x_i)}{f_2(y_i/x_i)}\right) \quad (12) \quad \omega = \frac{\sqrt{n}\left(\sum_{i=1}^n \eta_i / n\right)}{\sqrt{\sum_{i=1}^n (\eta_i - \bar{\eta})^2 / n}} \quad (13)$$

Where, η_i is the logarithm of ration of NB to ZINB probability; $\bar{\eta}$ is the mean of η_i ; n is the sample size. Vuong's value obeys an asymptotical standard normally distribution, and if $|\omega|$ is less than 1.96, which is the 95% confidence level for the t-test. Thus, if the ω value is greater than 1.96, the observed data obeys the ZINB or ZIP model, while if the ω is less than 1.96, the observed data obey NB or Poisson model.

2.3 Empirical Results of Spatial Distribution

The statistical results based on Vuong's tests see table 1., table 2., and table 3.. Based on the provincial count data of such as manufacture firm, R&D firm, managing & marketing firm, and total sectors, as well as number of patent applications examined such as inventions, utility models, and designs, the results show that the ω values are less than 1.96. Thus, the observed count data obeys the NB probability distribution, rather than ZINB model, which are also consistent with the observation of FDI firms and innovative activities concentrated in coastal cities and provinces. But, based on the data of cities in China, only manufacture and managing & marketing firm obey NB model, and R&D firm and total sectors obey neither NB model nor ZINB model.

These results mean that there still exist the greater potentials for further introducing FDI inflows and sustainable innovation in China. Besides, the evidences of spatial agglomeration are helpful for further investigating the location determinants affecting innovative activities and different branches of FDI firms in global value chains. On the other hand, it is also suggested that, in accordance with the characteristics of spatial agglomeration of FDI firms in global value chains, maker of decision should preferentially support innovative activities in the advantageous location so as to boost agglomeration economies and spatial spillovers of FDI inflows.

3 Measures of Spatial Dependence

Just as is described by Tobler's first law of geography, spatial dependence means that everything is related to everything else over space, but near things are more related than distant things. Thus, spatial dependence between FDI inflows and innovative activities implies the existence of spatial process. Spatial dependence can be positive or negative, and positive spatial dependence much more common than negative. Positive

spatial dependence occurs when similar values cluster one another over space. Negative spatial dependence occurs when dissimilar values occur near one another over space.

3.1 Statistic of Spatial Dependence

Measures of spatial dependence include global and local spatial dependence based on Moran's Index (Moran 1950). Global measures indicate the same pattern or process over the entire geographic area, which are expressed by an average for the entire area. Local measures indicate different patterns or processes over different parts of the region, which have a unique number for each location. Thus, the formulas for global and local spatial dependence are described respectively as follows:

$$Moran's\ I = \frac{N \sum_{i=1}^N \sum_{j=1}^N w_{ij} (x_i - \bar{x})(x_j - \bar{x})}{\sum_{i=1}^N (x_i - \bar{x})^2 \sum_{i=1}^N \sum_{j=1}^N w_{ij}} \quad (18) \quad Z(I) = \frac{Moran's\ I - E(I)}{\sigma_I} \quad (19)$$

Where *Moran's I* is the calculated value for global spatial dependence; *N* is the number of observations such as points or polygons; w_{ij} is a weight indexing location *i* relative to the contiguous location *j*; x_i is the variable value at a particular location *i*; \bar{x} is the mean of the variable x_i ; $Z(I)$ is the standard deviation for standard normal distribution for test of statistical significance of spatial dependence; $E(I)$ is the expected value; σ_I is the standard deviation for as asymptotical normal distribution.

$$I_i = z_i \sum_{j=1}^N w_{ij} z_j \quad (20) \quad Z(I_i) = \frac{I_i - E(I_i)}{\sigma(I_i)} \quad (21)$$

Where I_i is the calculated value for local spatial dependence; z_i 、 z_j are respectively the standard values of the original variables x_i and x_j ; $E(I_i)$ is the expected value of I_i ; $\sigma(I_i)$ is the standard deviation of I_i ; $Z(I_i)$ is the standard deviation for standard normal distribution for test of statistical significance of spatial dependence.

3.2 Empirical Analysis of the Spatial Effects of FDI Inflows on Spatial Distribution of Innovative Activities in China

The derived results based on calculation of Moran index indicate the existence of strong positive spatial dependence process. That is, there are the strong patent application activities in coastal cities and provinces, which are consistent with empirical observation on FDI inflows and innovative activities clustering in coastal regions. Besides, because of existence of spatial dependence, innovative activities have also close associated with FDI inflows in contiguous regions, and the spatial effects have a highly statistical significance in the global Moran index. Thus, the spatial spillovers generated by FDI inflows have the significant influence on growth of number of patent applications examined such as inventions, utility models, designs in China.

Table 4., Table 5., Table 6., Table 7. show the significant effects of FDI inflow on spatial distribution of innovative activities in the spatial dimension. According to the evolution of innovative activities from 1999 to 2012, as a whole, the innovative activities have been spreading to middle-western regions from coastal regions, and intensity of the innovative activities have greatly increased over year although it is very different for spatial spillovers effects of FDI inflows on spatial distribution of the different type of innovative activities such as inventions, utility models, designs, and total patent applications.

For example, based on calculation of global Moran's I , global spatial dependence between FDI inflows and innovative activities such as inventions, utility models, designs, and total patent applications are respectively examined. The spatial effects of FDI inflows on designs have always held the higher values in comparison with inventions, total patent applications, and utility models, Statistical values of Moran's I on the designs have increased considerably from 0.2212 in 1999 to 0.4475 in 2007 and decreased from 0.4475 in 2007 to 0.2573 in 2012, which have the trend from agglomeration to diffusion over time with highly statistical significance. However, spatial effects of FDI inflows on inventions have always maintained the lower values in comparison with utility models, total patent applications and designs, even so, the values of Moran's I on inventions have still increased from 0.0771 in 1999 to 0.2680 in 2012, which have been the trend from agglomeration and have begun to be the statistical significance in 2003. Nevertheless, spatial effects of FDI inflows on utility models and total patent applications have always ranged between inventions and designs. In

particular, the values of Moran's I on utility models have increased from 0.0895 in 1999 to 0.3795 in 2012, which have been the strong trend of agglomeration over time and have begun to be the statistical significance in 2002. Similarly, the values of Moran's I on total patent applications have increased from 0.1409 in 1999 to 0.3520 in 2012, which also have been the strong trend of agglomeration over time and have begun to be the statistical significance in 2001.

Table 8., Table 9. respectively show the decay effects of global spatial dependence over time along with increasing orders of contiguity for total patent applications examined and FDI inflows in China. For example, with the increasing of the number of order of contiguity, in 1999, Moran index of total patent applications gradually decreases from 0.0852 at 4th-order to -0.0218 at 24th-order, and in 2012, Moran index of total patent applications gradually decreases from 0.2836 at 4th-order to -0.0233 at 24th-order. Similarly, in 1999, Moran index of FDI inflows gradually decreases from 0.0849 at 4th-order to -0.0302 at 24th-order, and in 2012, Moran index of FDI inflows gradually decreases from 0.2503 at 4th-order to -0.0212 at 24th-order. Thus, the derived results means that the spatial process of externalities generated by FDI inflows is limited and variable, that is, the scope and the extent of spatial spillovers effects generated by FDI inflows on innovative activities vary with distance, which indicates the characteristics with spatial interdependence, heterogeneity, variation of spatial effects.

Table 10. and Table 11. report the spatial variation of innovative activities and FDI inflows across Chinese provinces over year. In accordance with the evolution of innovative activities across regions from 1999 to 2012, innovative output presents the strongly increasing trend in China over the recent years. For example, the innovative output in Beijing was 6.144 patent applications examined by per ten thousand persons in 1999, and significantly reached nearly seven times higher which was 44.607 in 2012. Respectively, the average innovative output in Zhejiang gradually reached nearly twenty-five times higher from 1999 to 2012, nearly sixty times higher in Jiangsu, eleven times higher in Shanghai, and almost fourteen times in Tianjin and so on.

As a whole, the average innovative output across Chinese provinces was 0.926 patent applications examined per ten thousand persons in 1999, and gradually reached nearly thirteen times higher which was 12.232 in 2012. The Coefficient of variation and standard deviation which indicated the degree of spatial concentration and variation of innovative activities gradually decreased from 0.771 in 1999 to 0.816 in 2012, so as to

show the trend from agglomeration to diffusion. Thus, innovative activities in China present the strong characteristics of spatial variation through spatial concentration in eastern coastal regions at the beginning having spread to more regions in middle-western and northern-eastern regions later.

In contrast, the spatial variation of FDI inflows in China shows the strongly spatial disparity across provinces. Although FDI inflows in Chinese provinces have gradually increased over time, the shares of FDI inflows in middle-western regions have been still less than the shares in eastern and coastal regions. Thus, FDI inflows in China have maintained the significantly structure characteristics of spatial distribution, which have mainly concentrated in eastern and coastal regions. The Coefficient of variation which indicated the degree of spatial concentration and variation of innovative activities gradually decreased from 0.550 in 1999 to 0.681 in 2012, so as to show the trend from agglomeration and the spatial disparity of FDI inflows in China.

In conclusion, the spatial dependence described above indicates that the innovative activities are close associated with FDI inflows in contiguous regions, and there exists the pattern of decreasing dependence with increasing orders. Secondly, spatial effects present the characteristics of spatial interdependence, heterogeneity, variation with distance. Finally, FDI inflows in China have the strongest knowledge spillovers effects on the patent applications examined of designs, and have less knowledge spillovers effects on the patent applications examined of inventions in comparison with designs and utility models. Thereby, FDI inflows boost the exchange between Chinese and foreign enterprises so as to generate the demonstrating effects for Chinese enterprises.

4 Conclusions

The paper provides an analysis framework of spatial effects generated by FDI inflows on innovative activities, and illustrates the characteristics of spatial interdependence, heterogeneity, variation of spatial effects across Chinese provinces. The empirical evidences indicates that spatial agglomeration and proximity are the important factors affecting innovative activities and FDI inflows in spatial dimension, and also demonstrates that there exists the strongly positive spatial dependence process in innovative activities and FDI inflows across Chinese provinces.

The empirical evidences show that innovative activities and FDI inflows obey the probability distribution of NB model with the characteristics of spatial agglomeration, which implies that there are the greater potentials for further introducing FDI inflows and sustainable innovation across Chinese provinces. Secondly, spatial effects have the pattern of decreasing dependence with increasing orders, that is, knowledge spillovers present a decay process with increasing distance, which means that there exist the range of interaction and the limited spatial process in the analysis of spatial effects.

Thirdly, the innovative output not only depends on determinants within regions, but also is associated with FDI inflows and innovative activities in contiguous regions,

which means that the extent of spatial clustering and contiguity plays the important role in regional innovative activities. The derived results show that the innovative output in China mainly relies on human capital, international trade, FDI inflows, agglomeration economies, as well as the spatial externalities generated by these variables.

Finally, FDI inflows in China produce the different spatial effects on all the types of innovative activities, which have the strongest knowledge spillovers effects on the patent applications examined of designs, and relatively have less knowledge effects on the patent applications examined of inventions. As a consequence, FDI inflows promote knowledge spillovers and diffusion, and also boost the knowledge exchange between Chinese and foreign enterprises so as to generate the imitating and demonstrating effects for Chinese enterprises.

In conclusion, these results demonstrate that spatial clustering and contiguity can't be ignored in the analysis of externalities of knowledge, and knowledge spillovers generated by FDI inflows are one of the main sources of sustainable innovation in China. In the aspect of policy implication, in order to enhance the absorbing capacity of Chinese enterprises and promote the knowledge spillovers brought by FDI inflows, it should be encouraged that policy of introducing FDI inflows not only considers quantity of FDI inflows, but also think much of quality such as FDI inflows with advance technology. Meantime, education and training as well as R&D expenditure should be widely supported so as to enhance the human capital stock in regional economic developing.

Furthermore, it should be recognized for government agency to encourage cooperation and exchange between FDI firms and universities or research organizations, and actively embed Chinese enterprises in global value chains of FDI firms so as to promote the spatial spillovers of FDI inflows on the innovative activities in China. Besides, it is helpful for decision-maker of policy to select the advantageous location to preferentially support innovative activities for increasing the extent of agglomeration economies and spatial spillovers of FDI inflows in China.

Structured Abstract

Purpose – Small creative arts organisations are important contributors to the economy, not just in their own right, but wider. Despite the significance of such organisations in what Hearn et al (2006, 7) refers to as ‘value creating ecologies’, such organisations often struggle to survive. The study examines the pattern of order activities for a range of arts organisations and relates the outcomes of the analysis to questions of organisational growth and sustainability. The paper discusses the notion of ‘deferred value’ in relation to value creation and capture, where economic value may only be realised some time after the original creative event

Design/methodology/approach – The paper presents data from approximately 100 creative organisations for 2010 and 2011, analysing for relationships between:

- Turnover
- Size
- Revenue streams (types)
- Tangible and intangible assets

Originality/value – The paper contributes to understanding of the growth patterns and aspirations of small/medium sized arts organisations. In examining in detail the concept of deferred, the study offers new insights to the value creation literature, suggesting business models and patterns of financial support that offer a legitimate balance between the two, in relation to organisational sustainability overall. The paper is the first to look at the issue of organisational size in relation to value streams, in order to move forward from ‘one size fits all’ conceptualisations that have dominated the literature thus far.

Practical implications – From a practical point of view, the paper offers guidance to organisations in terms of addressing the very real challenges of monetising a range of revenue streams without compromising artistic integrity.

Keywords – value creation, sustainability, creative arts organisation, deferred value

Paper type – Academic Research Paper

1 Introduction

Creative arts organisations are seen as important contributors to the economy, not just in their own right, but wider, (Hearn et al, 2006, 2007) as they:

- Are a major source of innovative ideas that contribute to the development of new products and services
- Offer services that may be inputs to the innovative activities of other enterprises and organizations within and outside the creative industries
- They are intensive users of technology and often demand and create adaptations and new developments of technology, providing stimulus to technology producers.
- Realize a wide range of value, not just technical, but also social, creative, artistic, cultural, societal and of course economic

This is important economically, as the UK is renowned for its creative industries in areas as diverse as music, animation, design, gaming and the visual and creative arts. It has been estimated that the creative industries account for 7.3% of the UK economy, parallel in size therefore to the much-vaunted financial services industry (DCMS, 2007). In 2013, it was estimated that illustrates that the Gross Value Added (GVA) contribution of the arts and culture industry to the UK amounted to £5.5 billion in 2008. This actually jumped in the recession year of 2009 by 5.7 per cent to nearly £5.8 billion. Therefore, as UK GDP fell by four per cent, the arts and culture industry appears to have fared strongly in the tough economic climate. GVA fell by 2.1 per cent in 2010, but this was followed by a robust rise in 2011, when a 4.6 per cent increase saw the arts and culture industry's GVA total over £5.9 billion. Good understanding of the challenges and opportunities presented by the sector is therefore important from a regional development point of view.

The livelihood of a growing proportion of UK citizens therefore depends upon the sector maintaining its growth trajectory, particularly in the South East. Together with

London and parts of the East of England and South West, the South East region forms a "mega region" of world-class significance in relation to the creative economy. The David Powell report (2002) suggests that the creative industries employ more than half a million people in the South East and contribute more than 40 billion to the regional economy. Creative and cultural industries represent around 30 per cent of its GDP, making it our region's fastest growing sector.

Despite the significance of such organisations in what Hearn et al refers to as 'value creating ecologies', such organisations often struggle to survive, let alone grow, particularly in the current climate of austerity in the UK (and the EU more widely). Typically, multiple revenue streams are employed which span value creation and value capture (Chesbrough et al, 2006, p2). Not surprisingly, the notions of value creation and value capture are contested and open to multiple interpretations (Lepak et al, 2007), and are subject to questions of artistic legitimacy. Thelwall (2011) for example, distinguishes between 'first order activities', where endeavour is intrinsically linked to acts of artistic creation, and 'second order activities', often focussed on reproduction and scalability, rather than creative expression. The study examines the pattern of first and second order activities for a range of arts organisations and relates the outcomes of the analysis to questions of organisational growth and sustainability. Specifically, the paper discusses the notion of 'deferred value' in relation to value creation and capture, where economic value may only be realised some time after the original creative event. The paper argues that typical venture capital (VC) horizons based on high tech are too short to recognise this timing gap, which is likely to compromise sustainability and growth overall. Nor do standard funding mechanisms, which tend to focus on specific organisations, recognise the more diffuse 'organised networks' (Lovink, 2012) or 'reputational ecosystems' (Lessig, 2008) that pertain in creative milieu.

2 Background

Studying the creative industries sector presents challenges:

- Firstly, the 'creative industries' are very diverse, spanning a range of interlocking industries, including arts, culture, heritage, media, gaming, performance and occasionally sports; a wide range of organisational sizes from micro upwards; a wide range of different business models exist, spanning

different modes of funding and trading, including the production of both (aesthetic) artefacts and also surrounding services; venue and non-venue based activities.

- Secondly, developments in digital technology have stimulated new impetus for rapid change over the last decade, presenting unlimited possibilities for new resonances between social practices and values and the techno-creative milieu. For example, disintermediation in the music industry has been made possible through the internet, which allows new experiences anywhere/anytime, resulting in new behaviours in respect of the production and consumption of artistic output. Of course, this has had a profound effect on the power base in the industry, as old business models have been swept aside – at times, before new revenue streams have been established.
- Thirdly, the creative industries have a distinctive character that challenges traditional models of research into business innovation and entrepreneurship. Specifically, the creative industries revolve around entrepreneurial, innovative and often unorthodox collaborations in an ecosystem whereby numerous large, small and micro-businesses come together for the duration of a single project, then disband and form new partnerships for the next project (see Figure 1 for the arts ecosystem). This diversity, fluidity, interconnectedness and potential range of novel new combinations for which there may be currently no precedent presents a challenge for researchers, educators and policymakers who want to not only know, but explain, and further, anticipate, what is going on, so that appropriate development and support mechanisms might be put in place. This latter point is vital for sustainability and growth, particularly for small organisations, many of whom are currently struggling to realise not just social and cultural value, but economic return too.

The Art Eco-System Model

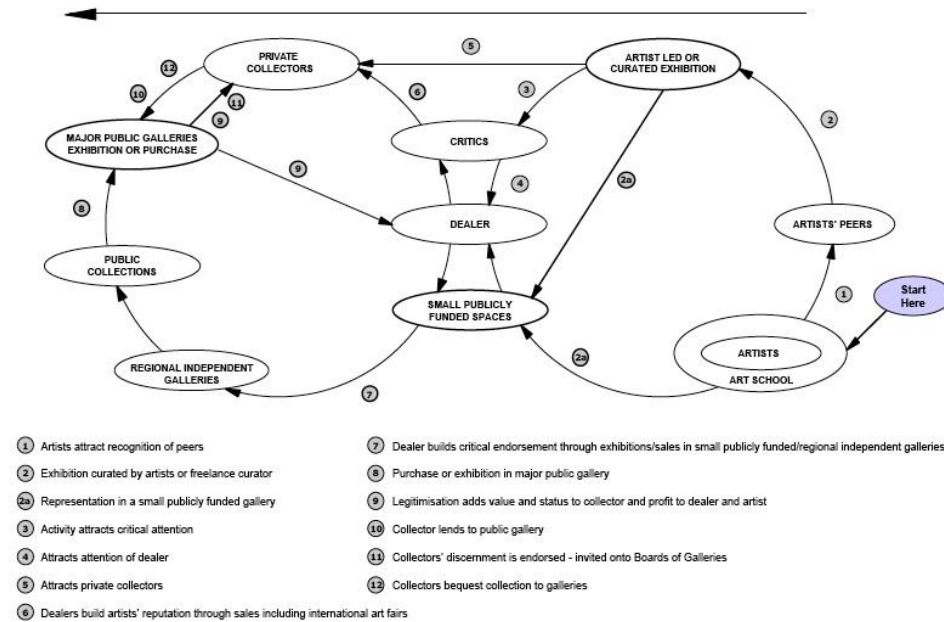

Figure 1 Arts ecosystem (Thelwall, 2011)

Fuller et al (2011) note, that to remain fit over time in the dynamic, fluid landscape of the creative industries, it is essential that creative groups constantly organise for novelty in anticipation of new collaborations, new networks and new patterns of consumer behaviour. This need is heightened by the desirable heterogeneity of actors engaged in the creative landscape, since innovation tends to spring from the fertile boundaries of previously dissociated areas of activity. Sustaining creative diversity through broad-based satisficing (Simon 1957) rather than quick-win optimisation approaches is likely to more effectively enhance the dynamics of such communities. To achieve sustainability through the creation of novelty, Fuller and Warren (2004-2008) refer to the interplay between entrepreneurial 'processes of emergence' such as experimenting (to yield new structures and practices), identity work (reputation management), organising (reflection on everyday practice), and sensitivity to conditions (anticipation of threats, knowledge and the propensity to survive). Yet to achieve sustainability without compromising artistic integrity, organisations must manage their knowledge assets, and accordingly, their business model strategies, in respect to financial realities.

Thelwall (2011) notes the difference between first and second order activities for arts organisations; first order activities are those which form the creative core of the

organisation – an exhibition for example. Typically, such activities are grant funded, as they are not expected to generate a financial return, but do deliver a cultural & social return. As they are usually intrinsically connected to the expert labour force in the organisation, they tend not to be scalable. Second order activities are those such as merchandise, that generate assets from the first order activities, and seeks to develop them into products & services that have a commercial value. As second order activities are much more disconnected from the expert labour force, they tend to be more scalable. Of course it has always been difficult to accrue funds for first order activities, and the issue today of course is that the pot of money is getting smaller all the time, with cutbacks in UK Arts Council funding leading to some groups disbanding. Organisations therefore have to manage the balance between first and second order activities very carefully in order to survive while not detracting from the creative flow.

Organisations must also balance carefully the income streams from tangible and intangible assets (Thelwall, 2011). Tangible assets include buildings, archives, collections; intangible assets individual and organisational expertise and experience, reputation, brand and goodwill, intellectual property, research skills, audience and customer base, educational reputation and resources, methods and processes, network, partnerships and people. The development of a portfolio of tangible assets generally requires substantial investment in a publicly accessible building, collection or archive. Holding tangible assets also implies significant ongoing maintenance costs, which may seem disproportionate with respect to total turnover. The challenge for small organisations is to make the best use of assets without allowing this to consume all the energy of the team, thus allowing the focus to remain on the development and delivery of projects.

The dynamics of the financial aspects of the arts ecosystem are depicted in Figure 2:

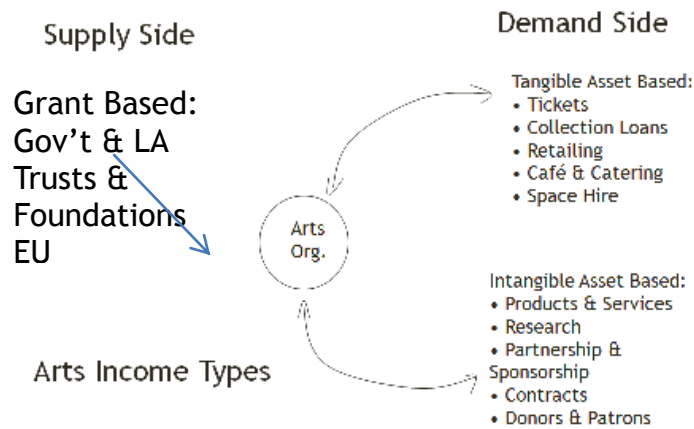

Figure 2 Arts income types

In the next section, we present an analysis of financial data gathered from Mycake.org’s Culture benchmark database, which holds data on 350 arts organisations. We analyse for Turnover/size, types of revenue streams and tangible and intangible assets. We effect comparisons on the basis of organisational size, in order gain insight into the financial profile of large versus small organisations, with a view to considering the most appropriate support mechanisms. This is important because small organisations differ from large in that they tend to be more flexible, more agile, and less risk averse, willing to take on early works and first showings, as well as playing a key role in mentoring and developing personnel.

4) Outcomes

A brief comparison of the 2010 data sliced by size of organisation – annual turnover

	2010				
	< £200k	£200-750k	£750k - £2m	£2-10m	>£10m
Sample Details:					
Sample size	21	44	15	14	5
Average turnover	approx £130k	approx £345k	approx £1.3m	approx £4.4m	approx £45.3m
Income by type as a % of turnover					
Grant Income:					
RFO	47.0%	50.1%	27.5%	38.1%	29.4%

Annual Surplus/Contribution to Reserves	0.4	4.1			2.5

Table 2 2011 data RFO = Regularly funded organisation; NPO = non-profit organisation

In the above tables, ranges have been set up in accordance with turnover, income and expenditure allocated.

- RFO funding levels – the trend here is that the smaller the total turnover of the organisation the higher the proportion of total income ACE funds (RFO or

otherwise) represents. It is only once organisations get beyond the three quarters of a million mark (total turnover) that RFO funding represents approximately a third of total income

- The trend in the Total Revenue Grant Income line is therefore as we would expect having analysed the various sources of income that are contributing to it [2010– highest in the smallest organisations (78.9% of total income for organisations <£200k) and lowest in the largest organisations (51.2% for organisations >£10m)]. [2011 highest in the smallest organisations (78.9% of total income for organisations <£200k) and lowest in the largest organisations (51.2% for organisations >£10m)]. There are clearly other income sources that come in to play as organisations grow in size and enable them to reduce dependence on grant sources.
- The most significant of these in terms of percentage of total income contribution is that from ticket sales.
- The second greatest source of earned income is that derived from café and catering activities. Clearly this income stream is only available to organisations with a public venue but nonetheless it grows with organisational size in a fairly linear manner.
- Income from a shop (or other forms of retailing) is much less linear.
- Income from the hire of space (or indeed collections) is also quite erratic and shows no clear connection to the size of the organisation.
- Income from non-venue based sources such as IP, licensing, sponsorship & donations, commissions and contracts does show a relationship to the size of the organisation in that the smaller organisations (perhaps those without a public venue) have focussed more on these areas.
- Is there a ‘sweet spot’ in terms of the size of organisation that has the most sustainable or stable financial model, that is, a size of organisation which looks to be both financially sustainable without acquiring large or long term liabilities which need to be serviced. We would suggest that the very smallest of organisations (<£200k/annum) offer examples of how, at least in the early years, staying small, leveraging the enthusiasm of a community and staying focussed on a small number of goals can enable you to deliver very effectively on small budgets. However this often leads to burn out of staff and there is a limit as to

how much an organisation can be built on volunteers and a transition in to something more stable long term is usually required if the organisation is to get beyond the 3-5 year mark. As organisations get beyond the £750k/annum level we see a different picture emerging as all the slices from £750k upwards show a more diversified income structure balancing grants, tangible assets and intangible assets.

- Is there a size of organisation that is most difficult to make sustainable? Instinctively we'd suggest that the £200-£750k small to mid-sized organisation may be one of the tougher ones in that there is still a high degree of grant dependence but typically quite a small staff base and therefore little opportunity to develop a substantial senior management team or specialist departments. Many organisations at this level do not have a publicly accessible building and therefore cannot diversify their income into café, shop and space hire and ticket income may be sporadic. Income from intangible assets is unlikely to be worth as much as those from a venue either because the organisation doesn't have the expertise or because the markets for their skills and products are not sufficiently developed. This makes growth very challenging.

As organisations get bigger so their dependence on Arts Council core funding reduces. Small organisations also rely more heavily on Trusts & Foundations & Local Authorities. Thelwall (2011) argues that through the interplays currently taking place in the arts ecosystem small organisations could be acting as an unofficial support mechanism for larger organisations because of differences in their funding and business models, as it is the small organisations that undertake the most significant role in risk-taking and the development of new work. Added to this, small organisations have consistently lacked the investment in tangible assets that has been available to larger organisations. As a result, few small organisations with a turnover of less than £1m per annum achieve any substantial income from their buildings, archive or collection. Those which do so tend to be renting out space to other organisations. They also lack income from shops or cafés and have very little access to sponsorship and donor income.

For small organisations, spending tends to be concentrated in programme and staffing costs, which are closely linked to direct, first order organisational outcomes. This leads to a lack of scope for development in small organisations, compared with large ones. This reinforces the poverty trap in which many arts workers are caught, allowing scant

possibilities for promotions and pension security. The low overheads on which these organisations are run also militate against their development in the key areas of training, marketing, research and development and the accumulation of reserves. Their main, and often unacknowledged resource is to be found in their accretion of intangible assets. With judicious investment, these hitherto assets – which organisations generate naturally as part of core activities – could be converted into earned income, offering small organisations a potential safeguard against economic uncertainty. Such ‘reputational capital’ can be realised (and valued) in the form of short-term consultancies, or research contracts that yield revenues in relation to specific requests. Thus, the creation of data that connects different business models to different size organisations may be useful in enabling arts organisations to align their knowledge assets and business models accordingly, and devise appropriate strategies for growth (or not). This is an area that would benefit from further research.

Less easy to quantify, and not captured by current metrics, is what Thelwall (2011) refers to as ‘deferred value’. Through the notion of deferred value, we recognise that value created by an initiating organisation is realised long after a commission has moved beyond its jurisdiction. Artworks accumulate value throughout their lifetimes in both the public and private sectors, but the small organisations which originated them are not usually the ultimate beneficiaries of these processes. While the intangible assets of reputation and track record are strengthened, there is often an uncoupling, at the end of a project between the originator and future tangible assets. Thus, it could be argued that a higher level of grant dependence for a small organisation is justifiable if the organisation is a ‘Deferred Value Creator’. Nor is deferred value recognised in the high tech funding discourse which has become significant in the arts with the widespread permeation of digital media and processes. The Silicon Valley ethos drives faster and faster exit strategies, with an emphasis not a growing or sustaining firm, but rather, speedily setting it on (Reis; Blank). It is time therefore for a new dialogue that recognises deferred value and the contribution that small organisations have to make.

It is not just a question of tangible returns that occur post-project. The notion of deferred value resonates with the sense of small arts organisations creating the link between the past and the future, what Warren and Fuller (2011) have termed the ‘value model’ of the organisation, where longer term value (economic, social, cultural, artistic,

technical) is realised through the identity of the firm (if it can be sustained), in terms of its :

- Past, present and future products and services
- Past, present and future technologies (perhaps supported by tangibles such as proof of concept, prototype, IP)
- Past, present and future markets or organising domains (perhaps supported by market research or constructions of future industry sectors)
- Past, present and future dominant logics (extant and potential business practices, relations with stakeholders, consumer/societal behaviours)
- Past, present and future business models, relating the creation and capture of value: (e.g. economic, technological, social, cultural, artistic, environmental)
- Past, present and future identities, expertises of those involved

The value model is not a ‘real’ entity, as might be recognised in the vocabulary of ‘incorporation’ or ‘venture creation’, but is an ontological construct that reflects not only perceptions of the identity of an organisation, but also sows seeds of anticipation for the future in terms of what future value creation might be achieved . Given the fluid nature of the arts ecosystem referred to above, when discussing sustainability, it is important to think not just of sustaining a firm economically for the short term, but also, the value model for the longer term: (Figure 3).

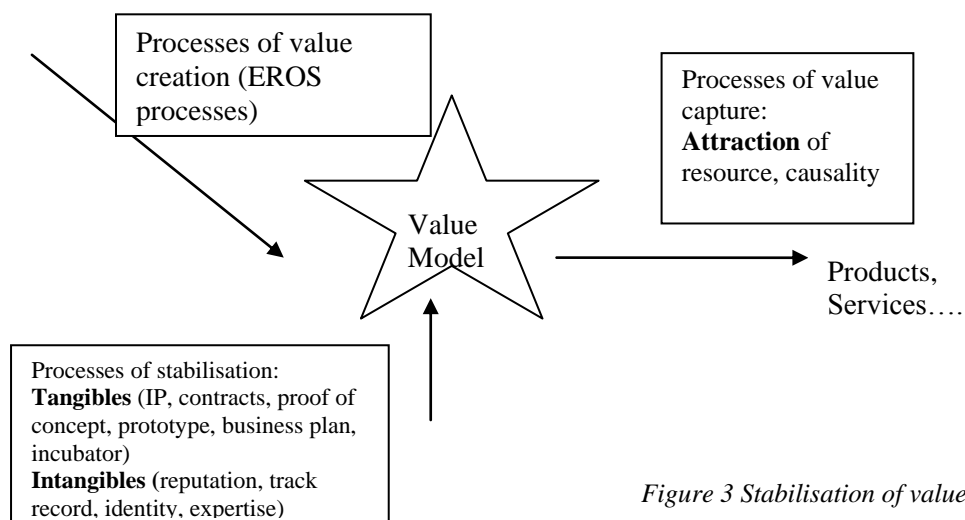

Figure 3 Stabilisation of value model

The question of how processes of stabilisation work is again, a suitable topic for further research. From the point of view of tangibles, we need to articulate funding mechanisms that relate deferred value to the creators. Considering intangibles, brand recognition, memory and inclusion in corporate, funder and societal memories is critical.

5 Conclusion

The paper contributes to understanding of the growth patterns and aspirations of small/medium sized arts organisations. In introducing the concept of deferred value, the study offers new insights to the value creation literature, suggesting business models and patterns of financial support that offer a legitimate balance between the two, in relation to organisational sustainability overall. The paper is the first to look at the issue of organisational size in relation to value streams, in order to move forward from 'one size fits all' conceptualisations that have dominated the literature thus far.

The concept of deferred value is worthy of further research because as yet, we lack the means to evaluate the relationship between the delivery approaches of small organisations, the (often intangible) assets being created in the course of their work, and the artistic, social and societal contribution they make. We also need to develop ways of measuring a wider variety of types of value being delivered by small arts organisations. We need to develop a better understanding of the variety of organisations themselves, articulating investment approaches that support them to maximise their potential within the system as a whole.

Structured Abstract

Purpose – The aim of the research is to analyse the impacts of using the Integrated Report for internal purposes: this requires, therefore, a change of perspective, that is, a transition from the external to the internal stakeholders as special players, as the reviewed players. The option to create value for investors can therefore be extended to other types of stakeholders as well, such as investor relations, senior management, corporate services, subsidiary companies, employees. Some of the new concepts introduced by the International <IR> Framework can make internal communication more transparent and can improve the effectiveness of the efforts made towards achieving the strategic goals.

Design/methodology/approach – We propose an approach based on case studies method. Case studies were selected based on the population of participants in the IIRC Pilot Programme, especially companies that expressed the will, partly through official notices, to start using IR for internal purposes. So, they were selected based on their significance, i.e. the potential contribution that each selected case study could give to the focus of the research. The following companies were thus selected: Etica SGR, Generali Group, and Vancity. The interviews concerned a number of main issues and had been designed to highlight the topics of Integrated Reporting, both external and internal. The researchers' efforts were focused on trying to find similarities and differences between the three case studies.

Originality/value – A review of the integrated reports may suggest that the companies that are pioneer in bringing to life the integrated reporting internally use such innovative tool for the following reasons: telling investors, in a more accurate and transparent way, about the value-creation process by integrating their accounting results and highlighting the creation of the value; pulling down any internal barriers between departments; responding to the increasing need for internal corporate governance and transparent external communication to the community about the actual management of intellectual capital as well; creating a consistent connection between the internal rewarding incentive

system (Performance Management), the intangible value drivers and the related performance indicators (KPIs), which provide an integrated overview of the organisation's internal and external performance.

Practical implications – The outcomes of the application could provide useful tips on how to prepare and use the internal integrated reporting since the analysis of case studies, also conducted in comparative terms, it could allow an initial outline of the framework, encourage studies on this area of interest and represent a useful empirical reference for organizations such as the International Integrated Reporting Council (IIRC), International Federation of Accountants (IFAC), Chartered Institute of Management Accountants (CIMA), the Institute of Internal Auditors (IIA), etc.

Keywords – Integrated reporting; human capital; value; internal stakeholders; sustainability

Paper type – Academic Research Paper

1. Introduction

To measure and share the “intangible assets”, where entrepreneurship means getting into the beating «heart» of a business, because this is about finding and enhancing a company's key people and processes that the creation of shared value is built upon. To do this, new and increasingly accurate analytical and reporting tools are needed, in an increasingly complex and dynamically competitive scenario.

Often, the internal measuring and management processes, as well as the external communication processes, still seem to be inadequate and unable to provide accurate, reliable information to managers and stakeholders. This means that lots of capitals are not properly reflected by traditional corporate balance sheets and reports, and even the users of such information, first and foremost investors and financial analysts, point out that the number and/or standard of the information they need and the information that is actually available in the corporate reports are remarkably different. So, a new Business Reporting structure is required (Singleton-Green, 2010).

New forms of Business Reporting are appearing, which manage to more satisfactorily and exhaustively reflect the different dimensions of a company's results, including the “intangible” ones, and to provide a wider non-financial information platform in the form of sector-specific KPIs, designed to provide more meaningful suggestions about corporate value drivers and the future financial and socio-environmental performance of an organization.

Among these, the aim of this research is the analysis of the Integrated Report, as proposed by the International Integrated Reporting Council (IIRC, 2013), of some of the companies that are regarded as the most innovative¹, as they are considered to be able to interconnect economic information and qualitative-quantitative information, mainly those related not just to economic sustainability but to environmental and social sustainability as well. The scope of the Integrated Report we analysed is to provide information about an organisation's strategy and business model, governance system and performance, while reflecting the business, political, social and environmental scenarios in which they work and providing an accurate overview of the ways they create value, both now and in the future.

The goal of such review is to consider the impacts of using such report for internal purposes: this requires, therefore, a change of perspective, that is, a transition from the external to the internal stakeholders as special players, as the reviewed players. Integrated Report definitely double up as external as well as internal reports. The option to create value for investors can therefore be extended to other types of stakeholders as well, such as investor relations, senior management, corporate services, subsidiary companies, employees. In particular, some of the new concepts that have been introduced by the International <IR> Framework, such as the option to link each kind of capital (financial, manufactured, human, intellectual, natural social and relationship capital) to a set of KPIs that provides an integrated view of performance, inside and outside of organisation, can make internal communication more transparent and can improve the effectiveness of the efforts made towards achieving the strategic goals.

Integrated reporting shifts the focus away from traditional financial reporting and looks at an organization on multiple levels. This helps to break down silos and encourages information sharing (Magarey, 2012; Holmes 2013). It also helps organizations to achieve both success and sustainability in the long term (Tilly, 2013). This approach is confirmed by the Institute of Management Accountants (IMA) which welcomed the development of the IR Framework as “an opportunity to modernize corporate reporting and corporate culture, unlock data from corporate silos and restrictive presentation formats, link operational, environmental, social and governance practices to financial performance, and make information relevant, meaningful and reliable for

¹ A listing of the IIRC pilot programme companies can be found at: <http://www.theiirc.org/companies-and-investors/pilot-programme-business-network>.

management” (IMA, 2011). As companies consider an integrated approach to reporting, their traditional performance reporting may reflect varying degrees of integration and different approaches to communicating data. Some companies have produced non-public integrated reports, which have enabled them to test systems and processes internally (PwC, 2013).

This paper is organised as follows: paragraph 2 explains the methodological approach and the design of the research, paragraph 3 provides a brief overview of earlier studies into IR, paragraph 4 is focused on the three case studies, highlighting the main topics that revolve around the internal use of IR, paragraph 5 describes the results, and finally paragraph 6 ends with some closing remarks.

2. Methodology/Design of the research

The methodology used is the case study research approach, following the methods recommended in the literature. The case study approach (Ryan, Scapens & Theobald, 2002) is, however, interesting since it may offer the option of constructing theories and generalizations based on the study of some operational cases (Mintzberg, 1979; Yin, 1981; Eisenhardt & Bourgeois, 1988; Eisenhardt, 1989). The first step in the methodological approach (Eisenhardt, 1989) identified the focus of the research, which is its most relevant aspect and has implications on data collection and the discussion of the results. Case studies were selected based on the population of participants in the IIRC Pilot Programme, especially companies that expressed the will, partly through official notices, to start using IR for internal purposes. So, they were selected based on their significance, i.e. the potential contribution that each selected case study could give to the focus of the research. The following companies were thus selected: Etica SGR, Generali Group, and Vancity

In the cases examined the benefits of such an approach can be seen in the ability to illustrate the factors that drove the companies to adopt the Integrated Report and the consequences within the planning and control function.

The research carried out features aspects of a qualitative and quantitative nature: the data examined are based on interviews, the company’s economic and financial documentation and on internal reporting documents. The interviews were conducted with the responsables and the Integrated Reporting Team: the questions were designed to explain the Internal Integrated Report design and implementation so as to illustrate the

progress achieved and the benefits in terms of company results achieved. The interview as opposed to the questionnaire approach offers greater flexibility even if the results were characterized by a certain degree of subjectivity due to the difficulties of interpreting the answers. However, this was useful for understanding the competitive context in which the company operates and the particular features of the sector to which it belongs.

The interviews concerned a number of main issues (see table below) and had been designed to highlight the topics of Integrated Reporting, both external and internal. The researchers' efforts were focused on trying to find similarities and differences between the three case studies.

The interviews were held with the managers or teams in charge of drawing up the Integrated Reports in February and March 2014: the main issues are a pattern that respondents have to adhere to, in order to have qualitatively consistent responses from the interviews. The interviews, the main tool in any qualitative survey, were quite flexible, in that the interviewees could "give priority" to some issues and discard those they regarded as unrelated to their company or the way they used the IR.

Table 1: The main issues of the interview

TOPIC	ISSUE
<i>Preliminary phase</i>	Company profile
<u>INTEGRATED REPORTING AS EXTERNAL REPORTING TOOL</u>	<ul style="list-style-type: none"> a. brief description of the drawing up of the IR as external report and indication of the reasons for the commitment to the IIRC Pilot Programme; b. comments about the <IR> Framework of the IIRC (December 2013); c. recognition of criticalities and areas for improvement within the drawing up of the IR; d. expected benefits and/or checked advantages post-adoption of the IR
<u>INTEGRATED REPORTING AS INTERNAL REPORTING TOOL</u>	<ul style="list-style-type: none"> e. motivations about the IR use also for internal purposes and the year of the IR first adoption; f. features of the design and the implementation of the IR as internal reporting tool, with particular reference to the intangible assets; g. areas of the IR use within the Human Resource Management, with particular reference to the ways of the remuneration performance; h. areas of the IR use within the process of Risk Management; i. impact of the IR on the internal process of decision-making; j. level of acceptance of the IR by the company's management and staff; k. measured and expected benefits of the IR use

	<p>for internal purposes;</p> <p>l. presence or absence of non-financial KPIs in order to measure the achievement of specific management targets and in general to determine the company's value creation;</p> <p>m. ways of the integration and/or correlation with the IR for external purposes (are there two different types of IR?);</p> <p>n. impact of the IR use on the Internal Auditing and on the Internal Auditors' assurance activity</p>

3. Background of the studies

3.1. Integrate: internal thinking in a changed world

Two parallel reporting processes are often identified within organizations. The first is a process primarily aimed at the preparation of the annual and quarterly financial statements, the sustainability report, the corporate governance report and the remuneration report and implies the collection of data that are communicated externally to a particular stakeholder group². The second is aimed at developing corporate strategy and at providing the internal management system which is used to measure, monitor and manage operations throughout the year. Sometimes the two processes are aligned and coherent, but frequently they are not.

The design of reporting systems must define precisely the qualities of both internal and external reporting, paying attention to the discrepancies that there may be between the two in relation to different goals that are pursued and necessary connections. Internal reports are prepared mainly for management objectives and internal communication; whereas, external reporting is intended primarily as a tool for disseminating information to investors, analysts and to the financial community in the broader sense of communicating corporate strategy³. In the strategic choices of the guiding principles⁴ and

² The annual report is mainly aimed at shareholders and banks: conversely the sustainability report is aimed at social and environmental stakeholders.

³ The information in one report is not usually connected to the information in other reports, or to the corporate strategy, with the consequence that each key stakeholder group sees only a different part of the company.

⁴ International Integrated Reporting Council Guiding Principles: Strategic focus and future orientations; Connectivity of information; Responsiveness and Stakeholder inclusiveness; Materiality and Conciseness; Reliability; Consistency and Comparability.

content elements⁵ it is crucial to precisely define the goals that the organizations decided to achieve in relation to the level of quality for both forms of reporting or if is possible use only “one report” (Eccles & Krzus, 2010).

Companies with low-quality systems for both internal and external reporting put themselves in an extremely critical situation since they are able neither to control the physical and intangible resources owned by or accessible to the organization, nor to communicate to the outside reliably and concisely their ability to create value in the short, medium and long term, as well as risking signalling information which is misaligned with internal reports.

Equally problematic is the situation of those companies whose external reporting quality is higher than that of their internal reporting, since they may be put in the difficult situation of not being able to substantiate the information they are disseminating to the outside world.

Those companies with high quality internal reporting are able to exploit, through their investor relations department, communication opportunities regarding value creation, and its impact both on the organization's own capital and on that of capital owned by external stakeholders. Finally, of course, those companies with high quality internal and external reporting place themselves in an optimal position

In both systems the information used internally by management, and that communicated externally, must be consistent in a way in which greater connectivity between the organizational point of view and that of the “users” of the report allows a better mutual understanding and facilitates decision making⁶.

A check of the integrated reports of organizations that are yet considering the possibility of using this tool also for internal management purposes, highlights the following main points of attention (Gasperini, 2013):

1. Breaking down any internal barriers between departments and any entrenched “silo thinking”

⁵ *International Integrated Reporting Council Content elements: Organizational overview and external environment; Governance; Business Model; Risk and opportunities; Strategy and resource allocation; Performance; Outlook; Basis of preparation and presentation; General reporting guidance.*

⁶ *EFFAS CIC - Principles for Effective Communication of Intellectual Capital n. 1 “ ... The indicators should enhance the basis for decisions of both internal and external parties. Only those indicators that are also used for internal management are relevant for investors. To that end, indicators should exhibit a clear link to the company's future value creation”.*

One of the most significant benefits obtained by companies which have successfully undertaken a journey of integrated reporting is a better cooperation between the different departments within the organization and in particular between the finance, sustainability, investor relations, corporate governance and legal departments. This is a consequence of involving the various departments in acquiring and connecting all the information necessary to achieve an Integrated Report, so helping to break down internal barriers (the “silos”) and activating cohesive communication. Identifying a new Business Report and assigning clear responsibilities for its implementation requires support from senior management and by the governance department which plays a coordination role of. Assigning the responsibility for Integrated Reporting only to the investor relations department involves the risk that the traditional view of interpreting value creation and the historical approach adopted in the preparation of the annual financial statements continue to dominate and limit the purposes of “integrated thinking” which the process of integrated reporting seeks to inspire.

In some cases, the responsibility of creating cooperation between the various departments is assigned to the sustainability department. In other cases the finance department involves the sustainability department in addressing the various socio-environmental issues from a financial point of view. In many cases an approach of top-down coordination is finally adopted with the direct involvement of senior management⁷.

2. Shared Value

Reporting is a powerful driver for the integration of corporate social priorities into business priorities and in creating shared value. Organizations must remodel business processes in relation to the needs of society and it is therefore necessary to define an innovative way of thinking and new emerging business models.

According to M.E. Porter and M.R. Kramer the solution lies in identifying the principles of “*shared value*” which implies a simultaneous value creation story for society and organizations after having accurately identified the desires and needs of each (Porter, Kramer, 2011).

The concept of shared value can be defined as policies and operating practices that increase the organization's competitiveness and at the same time improve the economic and social conditions of the communities in which it operates.

⁷ Principally to relieve strain between the department of investor relations and those of finance on the one side with the department of sustainability and corporate affairs on the other side

Shared value is not solely the value provided to the company, or even about sharing the wealth generated but value shared with the wider community as a whole. Furthermore, it must be expanded to include economic and social value for all participating in the same value chain, thereby making business competitiveness and community well-being more closely aligned.

3. Narrate a clear overview of the Business Model

The aim of the Business Model is, in a more accurate and transparent way, to integrate the accounting results and highlight the proportion of value in order to provide a more holistic view of performance; and a better insight into strategy, operating context, governance and the impact on society and the environment as following indicated:

- addressing industry-specific factors, including trends, risks and opportunities, over the long term; and consequently the company’s performance;
- indicating timeframes for key milestones and targets, looking beyond the short and medium term to longer term horizons;
- aligning integrated reports and other key disclosures, including financial statements, Management Discussion and Analysis or Management Commentary, sustainability reports, codes of conduct and policy statements.

4. Corporate Governance

Responding to the increasing need for internal corporate governance and transparent external communication to the financial community about the actual management of intellectual capital, the Board of Directors must be able to disclose information with a “forward-looking” approach that enables stakeholders to gain a more informed understanding of the market value of the organization compared to its book value.

Table 2: Governance element – Transparency and accountability

<i>Principle/s</i>	<i>Summary recommendations</i>
9.1. The board should ensure the integrity of the company’s integrated report	<p>9.1.1. A company should have controls to enable it to verify and safeguard the integrity of its integrated report.</p> <p>9.1.2. The board should delegate to the audit committee the evaluation of sustainability disclosures.</p> <p>The integrated report should:</p> <p>9.1.3. be prepared every year;</p> <p>9.1.4. convey adequate information regarding the company’s financial and sustainability performance; and</p>

	9.1.5. focus on substance over form.
9.2. Sustainability reporting and disclosure should be integrated with the company's financial reporting	<p>9.2.1. The board should include commentary on the company's financial results.</p> <p>9.2.2. The board must disclose if the company is a going concern.</p> <p>9.2.3. The integrated report should describe how the company has made its money.</p> <p>9.2.4. The board should ensure that the positive and negative impacts of the company's operations and plans to improve the positives and eradicate or ameliorate the negatives in the financial year ahead are conveyed in the integrated report.</p>
9.3. Sustainability reporting and disclosure should be independently assured	<p>9.3.1. General oversight and reporting of sustainability should be delegated by the board to the audit committee.</p> <p>9.3.2. The audit committee should assist the board by reviewing the integrated report to ensure that the information contained in it is reliable and that it does not contradict the financial aspects of the report.</p> <p>9.3.3. The audit committee should oversee the provision of assurance over sustainability issues.</p>

5. What gets measured gets done

Following a consolidated axiom proposed by Tom Peters (Peters, 1987) it is essential that all strategic operations and the supervision of economic and socio-environmental performance be focused upon the protection and development of those assets that really reflect the company's value and maybe rate as impaired those assets that are no longer considered able to generate value in the short, medium and long term.

In traditional reporting systems decision makers usually focus primarily on internal tangible assets, whereas intangibles are often overlooked in light of the fact that they can hardly be measured and checked because of the several restrictions imposed by accounting principles on the reporting of internally-generated resources, nor can they be used as collateral in funding transactions. As for the specific features of intangible assets, this kind of approach apparently prevents decision makers from identifying the most appropriate strategies to find the way out from the systemic crisis, because current measurement and assessment methods widely lack accuracy and standardization in themselves, unlike those adopted for tangible resources. It is therefore essential for what

is immeasurable to become measurable by identifying the characteristics which new metrics and KPIs should possess to be considered useful also by institutional investors and financial analysts.

6. Performance Management

To synthesise a consistent connection between the internal rewarding incentive system, the intangible value drivers, and the related key performance indicators (KPIs) it is possible to provide an integrated overview of the organisation's internal and external performance. Such connection helps avoid major risks when profit is not related to "actual economic profits" but just to standard accounting results.

The strategy to generate sustainable competitive advantages through people management practices is certainly complex, and many authors believe that the modality of remuneration referred to as "*pay for performance*" has a positive impact on business results. When companies set the remuneration system correctly, their employees increase their effort to the achievement of business objectives and, indirectly, their personal objectives⁸.

Moving from the remuneration sphere of the employee to that of managers, this issue takes on a different character partly enriched with new problems / opportunities.

If it is true that, in both cases - the intention of performance-related remuneration is to improve the productivity through the motivation, provided by business results. However, continuous dependence on the manager is not only a good practice management of Human Capital; it is a necessity in order to establish the correct balance between ownership (especially when it is very fragmented) and management. This dilemma named the "agency problem" is a concept which was defined by the Corporate Governance and Remuneration Committee, seen its most effective solution and a key strength⁹.

The remuneration issue is a complex one, rich in implications for the entire management of the company. It can even be said to be among the key determinants of success, and means the strong shifting of focus from "*what*" a manager is paid, to the real issue of "*how implicitly and explicitly*" a manager is paid (Jensen, & Murphy 1990).

⁸ Toskich B., "*The strategy of fried egg*", "...not rewarding an employee who better contributes to the company's success involves the conclusion that are paying for his time, not his effort. The result will flatten or will fall quickly. The absence of reciprocity between pay and performance discourages those who produce, encourages people demotivated and deprives the company the right gain". Itaca, 1996

⁹ Alternative solutions are represented by monitoring the rights of shareholders and the market or from the information requirements of the law such as the U.S. Sarbanes-Oxley Act (2002); Mohan S. (2004), Bonner S.E., Palmrose Z.-V., Young S.M. (1998), Grundfest J.A., Perino M.A. (1997), Hartzell J.C., Starks L.T. (2000), Strahan P.E. (1998).

7. Risk Management and internal reporting

Where possible, disclosed information on a company's capital¹⁰ must be accompanied by an assessment of the risks inherent in each indicator. This should include those possible future events and their associated probability that might endanger a company's operating performance. It is evident that these risks are also part of business processes and it is necessary to be aware of the fact that all corporate assets are subject to risks, both public and private, which sometimes make it impossible to implement them, jeopardizing future results, and these threats are most likely to occur. As for human capital, for example, a company should consider the possibility that employees may leave the company, and the higher the probability, the more it should be considered a threat. However, the degree of risk also depends on how much the person in question is crucial to the company. The risk is high if the person who may resign has knowledge/experience that is particularly significant to the entity (Gasperini, Raso, 2011).

Risk tolerance and risk appetite are not negative in themselves and a large number of risk management methods include internal management processes through which risks are accepted rather than reduced, hedged through recourse to financial markets and transferred to third parties. In particular, companies have to implement adequate strategies to reduce unnecessary risks and focus resources only on risks they deem acceptable and which determine a higher yield¹¹.

It is therefore possible to build a business model for each company by identifying its specific risk factors and by linking them to information on capital, where risks having an impact on operating profit are divided into two categories (Gasperini, 2010):

a. the first category includes "public risks", which have the same degree of impact on the competitiveness of all companies and is beyond their full control, although some risks can be mitigated by resorting to the financial market and the management may consider hedging measures based on the size of these risks and of the costs they involve;

b. the second category includes "private risks" and is applies to any company insofar as these risks are due to unavailable adequate intangible resources, rather than to poor management of those to which the company has access. These risks can be monitored directly by the company through an appropriate management and disclosing strategy.

¹⁰ *International Integrated Reporting Council Capital: Financial capital; Manufactured capital; Intellectual capital; Human capital; Social and Relationship capital; Natural capital.*

¹¹ *Yoko Ohta "Value Creation through Intellectual Asset – Based Management and Business Risk Quantification", CMA Senior Researcher Quantitative Research Department Nomura Securities co. Ltd.SAAJ may 2007*

With reference to private risks that may be associated with intangible assets, the following ones are likely to be connected with the dimension of structural capital:

- inadequate documentation on business processes;
- complex organizational structure;
- inability to identify inherent risks such as risks to the business model or reputation;
- loss of know-how;
- insufficient internal control systems;
- weak and/or insufficient corporate procedures;
- inadequate protection of intellectual property.

The following risks can instead be connected with the dimension of human capital:

- inadequate board skills and inability of non-executive directors to exercise control;
- unstable and vulnerable management and staff turnover;
- inappropriate incentives, both implicit and explicit;
- insufficient leadership on ethics and culture;
- wrong interpretation and processing of information;
- loss of know-how acquired from previous experiences;
- decisions based on personal opinions;
- dependence on key staff;
- inadequate level of competence and/or limited circulation within the company;
- failure to create an environment that accepts change.

Finally, there follow several risks connected with the dimension of relational capital:

- vulnerability related to the possible loss of customers and/or partners;
- inconsistent internal communication and information flow;
- conflicts with trade unions and non-sharing of corporate restructuring plans;
- requests by providers of guarantees and restrictive terms of payment;
- loyalty of relationships to individuals but not to the company;
- threats that may undermine the value of the brand.

3.2. Overview of the literature

An overview of earlier studies into Integrated Reporting is still quite limited, as it is still at an early stage of development, since IRs are a corporate reporting system that has recently just been launched (Eccles & Krzus, 2010). However, an extensive study has already been carried out on this topic by both academics and practitioners in the field of Intellectual Capital (Edvinson, 1997; Sveiby, 1997; Roos et al., 1997; Holland et al., 2003; Boedker et al. 2005; Marr et al., 2005) and Corporate Sustainability Reporting (Klok, 2003; Daub, 2007; Gray, 2010; Adams et al., 2011; Porter & Kramer, 2011; Fifka, Drabble, 2012; Frias-Aceituno et al., 2012; Parisi, 2012; Orth et al., 2012) in theoretical and practical terms. Above all, scholars are focusing their attention on the companies that take part in the IIRC Pilot Programme, some of which have been investigated as case studies by scholars. A non-exhaustive list of studies on companies using Integrated Reporting systems is provided below.

Table 3: Overview of case studies on Integrated Reporting (IIRC Pilot Programme)

This research may contribute to the existing literature in regard to two different fields:

1) the recent studies on the field of the integrated report are focused on issues relating to the guidelines laid down by the International <IR> Framework, recently revised (IIRC, December 2013) (Busco et al., 2013; Abeysekera, 2013), or on issues related to sustainability or intellectual capital (Branwijck, 2011; Eccles & Saltzman, 2011; Paoloni et al., 2012; Jensen & Berg 2012; Stubbs & Higgins, 2012; Parrot & Tierney, 2012; Babber, 2013; James, 2013, 2013a; Ewings, 2013) or the change made in terms of improving financial reporting and disclosure to the external stakeholders (Reid, 2012; Hickman & Tisiak, 2013). There are few studies on the use of integrated report internally and on the evaluation of the potential benefits for the internal stakeholders (Paoloni et al., 2012).

2) The integrated report could also serve as the tool to create a link between external and internal reporting in order to provide boards or senior management a realistic understanding of how to create value and to provide them with adequate information in order to facilitate the assessment of the risks and opportunities relating to the company's value creation story. This research may offer a contribution to the research area of "measuring and reporting of intellectual capital" and "managing intellectual capital and intellectual assets in the workforce" within the Knowledge Management Theory (Ross et al., 1997; Stewart, 1998; Marr & Schiuma, 2001; Bontis & Choo, 2002; Marr & Ross, 2005; Parisi, 2012).

The research could provide useful tips on how to prepare and use the internal integrated reporting since the analysis of case studies, also conducted in comparative terms, it could allow an initial outline of the framework, encourage studies on this area of interest and represent a useful empirical reference for organizations such as the IIRC, IFAC, CIMA, PwC, CPA, IA, IIA; NACD, IABC etc., (Oberholzer, 2011; Whitehouse 2013; Barry, 2013; Stefee, 2013; Gillan, 2013, IIA, 2013).

4. The case studies: ETICA SGR, GENERALI GROUP and VANCITY

4.1. ETICA SGR

Author: MARCELLO COLLA¹²

Company profile

Etica Sgr (henceforth Etica) is a Socially Responsible Investing company. Since the beginning of its activity, its aim has been finding companies and governments whose environmental, social and governance impacts were better than their peers. The whole Etica Sgr business model is based on the idea that investing in stocks and bonds issued by responsible organizations has a double benefit: improving financial return in the long term but also improving worldwide practices by actors on the markets.

On the one hand, a sustainable approach to business leads companies to a better comprehension, and as a result to a better management, of a wider set of risks, no longer limited to economic and financial ones, but including also environmental risks, social risks, and so on. In Etica Sgr view, this leads to a more sound business model, a better understanding of the context that each company faces, and in the end to better economic and financial returns.

On the other hand, investing in responsible companies can drive them more and more to comply to higher standards, in order to be able to make it into responsible investors' portfolios. Moreover, investors are increasingly engaging companies in order to improve their behavior towards different stakeholder groups.

Integrated Reporting as an external reporting tool:

Since our analysis is mainly based on data provided by companies through their sustainability reports, it has been a natural consequence for Etica to adopt the same reporting standard it asks companies to comply to. Moreover, in 2010, when we started

¹² Paragraph 4.1. has been written by Marcello Colla, Administrative Area Responsible. You can reach Marcello at mcolla@eticasgr.it.

building our CSR reporting framework, Integrated Reporting was starting to gain momentum, so we decided to go that way, even though there was not at the time any reporting framework directly related to Integrated Reporting. We decided to use GRI guidelines to outline topics and indicators, but to integrate financial, economic, environmental, social and governance data in a single document. We had the great advantage of not having issued any sustainability report in the past, so we did not have to bring together different documents, and moreover CSR is in our business model since the beginning, so it was very natural for us to treat every different information as part of the same picture.

The main idea underlying our first Integrated Report in 2010 was to be accountable especially towards companies we were investing in, but also to a wider group of stakeholders: investors, suppliers, distributors, employees, the local community. The first approach was in this sense certainly mostly an external reporting approach. And we quickly realized that Integrated Reporting was in fact not only quite new, but also that efforts made to integrate information were appreciated also by the market. Our first report was among the three finalist at “Oscar di Bilancio”, a prize promoted by FERPI that aims at finding the most transparent annual reports. The following year we were awarded the prize, and this strengthened our belief that this was a good way to communicate our results.

Something quite interesting happened on the second year of our integrated reporting experience. We decided to start engaging with stakeholders in order to define the content of our report. On the first edition we just selected the information based on our idea of what was relevant and interesting, but the following year we wanted something more. We then decided to try and get in touch with different stakeholder groups, using two different tools. First, we had a survey involving our investors, employees, suppliers. Then we organized a focus group involving representatives of other stakeholder groups, mainly NGOs, business partners, and CSR experts. Our idea was to better shape our report because we wanted it to be relevant to users, and actually read.

Integrated Reporting as an internal reporting tool

It turned out, though, that the most relevant achievement of the involvement process, more than shaping the report content itself, was to open to a dialogue with different stakeholder groups, and better understanding that:

- different stakeholders had different usage of Etica Sgr Integrated Report: some actually read it, some others honestly admitted that the focus group was the occasion for them to get to know it even existed;

- some of them were very eager to be involved, while for others it was something close to an annoyance (actually some workshop were aborted since the stakeholders didn't respond at all);

- differences in the relative importance each stakeholder group gave to different information were much less relevant than we expected.

Opening a dialogue with stakeholders was not only, not even mainly probably, about Integrated Report content, rather than about having hints about how to better meet their demands. This, in our view, was particularly true for the stakeholder group we expected to be the least interested in our report: **employees**.

In a Company like Etica Sgr, whose size is now around 20 employees, the flow of information should be quite understood, but it definitely is not. In the last 6/7 years, our size grew very fast, starting from only 5 to 20. That is four times the original size, and this changed a lot of things in terms of work flows, responsibilities, duties, but also information and participation. Only a few years ago, every piece of information was easily known by everyone, since we were working side by side in a single room, there was no need of specific tools to inform people. Now things have changed: new headquarters, every department in its own room, which is much better for concentration but of course requires tools to ensure every relevant information is known to everyone. Of course the tools were built up, but there is other information, at a higher level, that are more difficult to transmit: they are about values, mission, about why are we doing what we do. In a word, about impacts.

Surprisingly enough, involving employees into shaping the report content lead us to understand that a part, in some cases relevant, of our impacts were unknown to people working at Etica Sgr. This was more true with people who have been working for Etica Sgr for a shorter time. Questions arose about our social impact through investments, about environmental impacts and so on, and the feeling that the whole integrated reporting process was a good way of engaging people about Etica Sgr values was clear.

This, among other things, was a starting point to change our process of integrated reporting. Given our dimension, every piece of information can be found and collected by the Administration department, who is in charge of the reporting, and actually our first

report was almost entirely shaped and compiled by the Administration only. Increasingly, in the following years, we involved every other department, in order to have them providing data but also describing those impacts they were most involved in creating. This way, our Research Department became responsible for every information regarding our Socially Responsible Investing and active ownership activities, the Sales Department for information about training towards our distributors and so on.

Of course, this way of restructuring the process was the most logic and efficient, especially for a fast growing company but it also had interesting side effects, such as:

- building a “culture” of data. Every department is well aware that it will have to provide data, and in this sense is much more attentive to saving data during the year, so that it will be easier to report at the end of the period;
 - focusing more attention to activities that actually have an impact on the data provided by the department, since it became known that they will be reported on;
 - raising interest also in activities for which other departments are in charge.
- Inserting every person's activity into a “bigger picture” helped employees to better understand what happened in the Company besides the work they were directly doing, and what the social, environmental and economic impacts of the Company as a whole were.

Moreover, during the first year of integrated reporting, we worked at our employees variable remuneration. Up to that point it was only linked to two economic indicators: ROE and Cost/income. We decided to introduce environmental indicators, and ones that were under direct control of each employee: paper internally used, toners, and electricity consumption. This helped raise more awareness about environmental impact, and in the end about the Integrated Report, where that impact is described.

The report had an impact also on another internal stakeholder: the Board of Directors. Given Etica Sgr peculiarities, the integrated reporting process had a strong commitment from the board and the CEO, actually the idea was sponsored by them. But it became a sort of top-down-back to the top process, since developing this tool led the organization to engaging the board in different ways.

The first edition of the report was a mere reporting on what happened in the past, and it had no strategic perspective. Since the second edition, though, some parts were introduced that involved and engaged the board much more: a chapter about the strategies of the company for the future, and a list of improvement goals set by the company, and

against which it would report in the following editions. This evolution was due on the one hand to the shaping of Etica's first formalized strategic plan, on the other hand to best practices around the world in the field of integrated reporting.

Disclosing future strategies in a public report meant committing to reaching goals either economic, social, environmental and in the field of corporate governance. This has been, and still is, a strong commitment for the board, and it helps keeping an even stronger focus than would have otherwise been kept on both financial and non financial performances.

Year after year, the goals are becoming more specific, and now each goal is disclosed together with a time frame, one or more KPIs (if possible), a target level for the KPIs. Presently, the time frame for the goal setting is a period of three years, the same period as the strategic planning one, and each year we report against the goals we had set. This will also lead to a change in internal reporting to the board, with ESG indicators reported probably on a quarterly basis together with financial ones.

In conclusion, our Integrated Report has undergone, in only four years, a lot of development, both in the contents, and in the way it is used.

It is increasingly becoming more integrated and less combined, even though a lot of way still has to come especially concerning the intangible assets, and a real integration of information. In this sense, combining G4 and the IIRC framework, or choosing one of them, will be next year's main challenge.

Moreover, the document is becoming a tool to help manage the company, giving information but also setting goals and consequently shaping internal reporting. We strongly believe that real integration is strongly needed to help understand companies real value creation.

4.2. GENERALI GROUP

Author: MASSIMO ROMANO¹³

Company profile

Generali Group is one of the leading global insurance and financial entities, led by Assicurazioni Generali S.p.A., established in Trieste in 1831. It has always been

¹³ Paragraph 4.2. has been written by Massimo Romano, the Head of Group Integrated Reporting. You can reach Massimo at Massimo_Romano@Generali.com.

internationally oriented and is now present in more than 60 Countries. At the end of 2013 the Group's insurance turnover was over € 66 billion.

As regards its core insurance business, the life product line of Generali Group comprises savings and protection policies, which account for the majority of its portfolio, alongside the Health business and Supplementary pension policies. In the property & casualty segment the Group is currently focused on the retail market, offering coverage for the entire insurance portfolio. Furthermore, Generali is one of the world's major players in the field of assistance, through the Europ Assistance Group, which provides worldwide services in the motor, travel, health, home and family segments.

The Group has also expanded its business from insurance to a full line of asset management, properties and financial services. In particular, the Banca Generali Group is one of Italy's leaders in the personal financial services market.

Fig. 1: An overview of Generali Group

Integrated Reporting as external reporting tool¹⁴:

Generali has always supported a “one report” approach that would allow us to avoid a proliferation of reports. Following this approach - and to not create a separate integrated document as other peers do - we created a document within the Annual Report.

In line with the various alternatives envisaged by the International <IR> Framework, the Group has decided to prepare and present an integrated report in response to both this Framework and the existing compliance requirements. So, our report is made up of a

¹⁴ The Team Integrated Reporting (IR) includes Annamaria Bradamante and Nicola Padovese, who are the authors of the part focused on company profile and IR as an external reporting tool.

concise Integrated Review that becomes an Annual Integrated Report including all information (see following diagram)

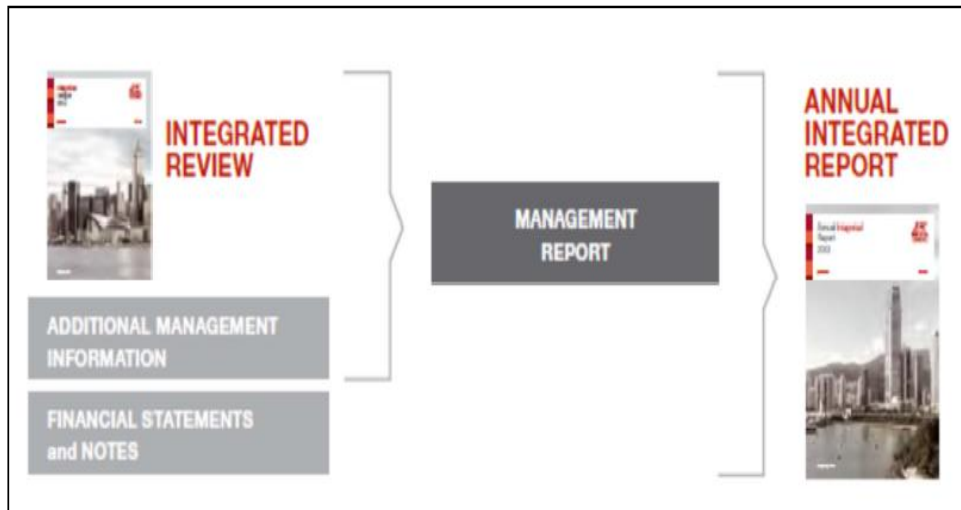

Fig. 2: Annual Integrated Report

Generali has participated in the Pilot Programme promoted by IIRC since 2012 as a result of the strong belief that this new approach to corporate reporting represents an innovative and effective way to communicate the Group’s ability to create value in a sustainable manner over time.

By participating in the pilot, Generali has contributed to the development of '<IR>' framework (see following topic), with particular reference to the principles, content and practical application of <IR>.

Among the many comments on the Consultation draft we sent to the IIRC at mid July as members of the Italian Pilot programme, in the final version was in fact welcomed the “one report” concept, very crucial for Generali.

The draft version stated that “the IR is another report”. This was considered a huge “step back” and moreover is moving to the opposite direction respect to where, through the efforts towards integration, companies are currently going and what the investors are expecting from them, when they ask for ESG information.

In addition to that, it was better specified the concept of the report audience, shifting the ‘primary’ qualifier from *report audience* to *report purpose*.

Other aspects - such as concept of value, criteria for the presentation of changes in information estimates, reporting boundaries and corrections of errors compared to previous periods - should be further improved, but the General is confident that the IIRC is in the right direction.

The most critical element in the preparation of IR has been the identification of the relevant information for our Group. At first sight, this seems to be an easy task but the real problem is that each person in the organization has its own perception “about matters that substantively affect the organization’s ability to create value over the short, medium and long term”. The topic “materiality” has long been debated and has been solved through a process which led to an identification of the main stakeholders and then the analysis for each stakeholder on which information is relevant. This process has been key to fulfill the IR framework.

Additionally, the identification of new information to be provided has led to the need to interact with different departments of the company previously not involved in the preparation of the disclosure. The organizational and communicative effort has been significant.

The IR shows more clearly what is the link between the company’s objective, governance, the remuneration policy and performance. Those elements are also better contextualized in the reference environment. The specific disclosure on main stakeholders also forced to pay greater attention to the accuracy of specific reporting and consequently a clearer focus on performance achievements.

Finally, all together the set of information provides a more forward-looking vision and elements narrated serve to provide a clearer picture of an organization in a simpler and concise way.

Integrated Reporting as internal reporting tool¹⁵

The Generali Group explore using Integrated Reporting internally

The interview with Massimo Romano who leads the Generali’s group integrated reporting team highlights the following aspects: “*The Generali Group, an international insurance company based in Italy, is a pioneer in bringing to life the Integrated Reporting “internally”*”. Indeed he discusses the benefits that they are detecting”. “*The Integrated Reporting (IR) is a process based on Integrated Thinking, focusing on the*

¹⁵ *The Team Internal Integrated Reporting (IIR) includes Massimo Romano, Barbara Sticchi and Rubens Pauluzzo, who are the authors of the part focused on IR as internal reporting tool.*

organization's value creation story over the time. An Integrated Report is a concise communication about how the organization's strategy, governance, and performance lead to creation of value in the short, medium, and long term, in the context of its external environment. The Group's Integrated Report for 2014 will be published on Thursday 13 March". "Accordingly, the Group Integrated Reporting Team have started internally this journey a couple of years ago, with the 2013 Internal IR finalized last summer while now the colleagues are working on the version for 2014 (scheduled for June 2014). The Internal IR is a report, technically a power point presentation of around 20 slides, focused on the vision, mission and business model of the Group Integrated Reporting department, its performance and the future outlook, all contents being coherent with Generali Group framework - One of the biggest benefit from Internal IR is that we have begun to break down thinking silos inside our own department -"

Generali Group has participated in the IR Pilot Programme promoted at worldwide level by the International Integrated Reporting Council (IIRC) since 2012. The Team's Internal IR tracks all the capitals (financial, human, social and organizational). Each capital has a number of KPIs, enabling to deliver **an integrated view of performance**, inside and outside the organization.

The KPIs are aligned with the **Performance Management program** to increase both the transparency of the team's internal communication and the engagement of the colleagues towards the targets (see the tables below regarding the Performance 2013).

4.3. VANCITY (Vancouver City Savings Credit Union)¹⁶

Author: JOANNE WESTWOOD

Company profile

¹⁶ Paragraph 4.3. has been written by Joanne Westwood, Management Accountability Reporting at Vancity, Canada. You can reach Joanne at Joanne_Westwood@vancity.com.

Vancity is a values-based financial co-operative serving the needs of half a million member-owners through 57 branches in British Columbia. It has a vision to Redefine Wealth by using all of its \$17.5 billion in assets to support the long-term needs of the people it serves, and their communities. Besides being a living-wage employer and carbon neutral, Vancity is a member of the Global Alliance for Banking on Values, an independent network of values-based banks using finance to deliver sustainable development for underserved people, communities and the environment. It is recognized globally for its transparent and progressive reporting practices, and was the first Canadian organization to join the International Integrated Reporting Council's (IIRC's) pilot programme.

Integrated Reporting as an external reporting tool:

Vancity's journey to integrated reporting

Vancity has voluntarily produced externally verified public reports documenting its social and environmental performance and impact since 1997. Its reporting practices are driven by the Board of Directors, who view accountability and transparency as key elements of good governance and values-based banking.

Vancity first considered producing an integrated report—an annual report that would bring together financial and sustainability information together in one document—in 2005. It commissioned research on leading practices and implications, and it began to align its financial and sustainability reporting processes and streamline sustainability data collection and verification. However, it was the launch of Vancity's vision in 2008 that was the key driver: Vancity's vision required it to integrate sustainability into its strategy and decision making, and to extend its definition of success beyond traditional metrics.

Vancity published its first integrated report in 2010. Integrated reporting provided a platform for the organization to tell its story to members in a connected, consistent and credible way, and to explain how its key activities, rather than making a profit to benefit the community, benefit the community in a profitable way.

Research has shown that Vancity's reports are highly valued by employees and members, who find them educational, comprehensive, easy to read, believable and effective in validating the reasons why they choose to bank or work at Vancity. It's reports are also a meaningful platform for ongoing communication and engagement with members, employees and others. For example, it uses the report as a tool to validate existing, or identify emerging, community or broader sustainability issues members care

about—issues that affect their personal well-being, or the communities where they live and work. It also uses the report to ignite conversations about the ways Vancity might play a role in addressing these issues.

Reporting principles and guidelines

Vancity prepares its integrated annual reports in accordance with the Global Reporting Initiative's (GRI) G4 **Sustainability Reporting Guidelines**. It also adheres to the **AA1000 principles**, and—more recently—its reporting practices are informed by the IIRC's Integrated Reporting (<IR>) Framework.

While these frameworks are often perceived as relevant to organizational disclosure, the real value is when they are applied more broadly to inform how an organization runs its business. They all speak to the importance of long-term thinking and using the results of stakeholder engagement to inform strategy and decision-making. They also emphasize the importance of understanding the organization's social, environmental and economic operating context, and having systems in place to prioritize and respond to key business and sustainability risks and opportunities, including those raised by stakeholders.

Integrated reporting as an internal reporting tool

Key changes and insights gained from integrated reporting

Arguably the most significant and positive change since it integrated its annual and sustainability reports was the alignment of its reports with its Three Year Plan (business strategy) and internal performance reports. Vancity believes the key information, measures and targets it uses internally to measure success, inform decision-making and reward its employees should be the same as those it presents to its members in its annual reports. In other words, it believes an integrated report should mirror internal reality. This is an important concept within the <IR> Framework.

To support this transition, Vancity made three important changes to its management and reporting practices. First, it consolidated two scorecards into one organizational scorecard—the scorecard that management used internally to track the organization's performance against its strategic priorities, and the scorecard that it published in its sustainability reports, which included additional non-traditional social and environmental targets. Progress against the organizational scorecard is reported to the executive team and Board of Directors quarterly; to all managers at quarterly performance updates; and—since 2011—to members in the annual report. Second, it aligned the structure of its annual reports to the framework used in its quarterly performance reports. Third, for the

first time in 2014, it made its future-looking **Three Year Plan**—the outcome of its annual strategic planning process—available to members, community partners and peers online, and invited feedback on it. It included a summary and link to the Three Year Plan in its report.

By applying the <IR> framework, Vancity also improved specific areas of its reports. It strengthened the section on external operating context, which talks about significant external trends and developments that could materially impact the organization, including stakeholder insights. It also strengthened how it communicated the linkages between governance, risk, strategy, and KPI, while recognizing it would benefit from more alignment through a common, organization-wide understanding of priority (material) issues. A further improvement was a shorter, more focused report by elevating the conversation to a more strategic level. However, it has not applied all the concepts included in the <IR> Framework. For example, Vancity's reports do not refer to the five capitals as it does not use this language internally.

Other key benefits included efficiencies and reduced costs (although this was never a key driver) as well as improved non-financial data management systems.

A commonly asked question is what comes first, integrated reporting or integrated thinking? The answer probably depends on the organization and its motivation for integrated reporting. Vancity believes it is hard to fake an integrated report, and that organizations should be aware that integrated reporting is quick to reveal if there are disconnects between an organization's business strategy and sustainability priorities. In this way the process of pulling together an integrated report can facilitate meaningful discussions where disconnects exist, and some changes will likely occur as a result.

Areas of disclosure it plans to strengthen include better articulation of its key risks and opportunities, and clearer linkages between financial and sustainability performance.

Assurance

At this time, there are no methodologies for external assurance on an integrated report. Vancity chooses to have independent assurance on key sustainability performance data and information, as well as on its adherence to the AA1000 principles of Inclusivity, Materiality and Responsiveness. In 2013, Vancity transitioned to a single assurance provider (KPMG) for both the financial statements audit and sustainability assurance engagement. As well as being more efficient than using two separate firms, this has resulted in greater collaboration across the organization and highlighted opportunities for

more ‘integrated thinking’ across Vancity. However, the outcomes of the integrated assurance process remain separate, e.g. two Management Letters, two audit opinions, due to strict rules covering financial audits as well as timing constraints. Vancity hopes it will eventually be able to include one, integrated assurance statement in its reports.

Challenges of the <IR> Framework

Vancity views the following as some of the more challenging aspects of the Framework that would benefit from further discussion and clarification.

Audience and the definition of value

Vancity believes the Framework, rather than defining the audience as ‘providers of financial capital’, should allow organizations to state who the intended audience of their integrated report is. This could allow organizations who choose to take a broader, more inclusive approach to running their business to clearly differentiate themselves from organizations who choose to focus sustainability efforts through the lens of the investor. It also believes the organization should be required to clearly state how it defines value, and who the organization is creating value for.

Materiality

The <IR> Framework, GRI Guidelines, and AA1000 principles all define materiality differently, and—while none of the frameworks appear to directly contradict each other—they have different emphases and audiences. Guidance on the key differences between the different frameworks and how they complement each other (or not), particularly when it comes to materiality, would be helpful for organizations struggling to determine the right approach for them.

Vancity believes reports need to reflect what the Board and management are strategically focused on, and so a materiality process for the purposes of report disclosure alone will no longer be sufficient and would lead to a disconnect between the information contained in the integrated report and the information used by the Board and management. One approach Vancity is considering is incorporating the principle of materiality, as defined by the GRI, into its existing enterprise risk management process, thus formally broadening the current approach to risk.

Performance indicators

An ongoing challenge for Vancity is balancing conciseness with completeness, especially when it comes to performance indicators. The <IR> Framework does not include specific performance indicators. This makes sense as material issues are

necessarily different for each organization and region, so there cannot be a set of common KPIs applicable to all organizations. In addition to using the GRI, Vancity reports additional data and information related to its co-operative nature, its business strategy and values-based banking. And it's currently working on a set of community impact metrics.

The Framework does provide guidance on performance indicators and suggests, among other things, that they be (a) consistent with information used internally by management, (b) focus on the matters identified through an organization's materiality process. If an organization is truly integrated, (a) and (b) should arguably be the same—but how often this is the case? (See also comments on materiality above).

The role of the Board vs. Management

The <IR> Framework suggests that those charged with Governance (in Vancity's case, the Board of Directors) should include in the Report a statement that sets out its responsibility for the integrated report, including an opinion on whether the integrated report is in accordance with the <IR> Framework. A challenge for Vancity, if it formally adopts the Framework, would be ensuring its Board has the capacity and knowledge to do this. It is also grappling with the role Senior Management and/or the CFO play in the preparation and presentation of the report, in general and vs. the Board. (A recent study from Deloitte in South Africa found that integrated reports were stronger when a Committee, rather than the CFO alone, oversaw its preparation. This makes sense given the collaborative nature of integrated reporting).

The benefits of an integrated approach

Vancity believes an integrated approach to management and reporting simply means a better-run business. Management and employees take a broader and longer-term view to making decisions and have a deeper understanding of the external context in which they operate, including the views of multiple stakeholders. Such an approach can lead to the early identification of emerging risks and highlight opportunities for strategic differentiation. Other key benefits include:

- breaking down operating silos across the organization (e.g. between divisions and departments);
- a complete and consistent view of the business, where external reporting reflects internal reality;

- a common understanding of priority topics and stakeholder needs and expectations, addressed through one business strategy.

Vancity anticipates its understanding of the linkages between its sustainability and financial performance and impact will evolve and ultimately demonstrate that Vancity (and other organizations) can both have a positive impact on people and communities and be profitable. Simply put, Vancity believes that if it does the right things for its members, profitability and sustainable growth will follow¹⁷.

5. Discussion of results

A review of the three case studies prompted the following considerations about the main topics listed in Table 1.

Companies profile

The three case studies are companies dealing with the financial sector: above all, they have a sustainable, transparent approach to work and are quite sensitive to the impact of their business on the local community. This is shown by their descriptions of their lines of business as well as by the presentation of their visions and missions and/or Business Models, if provided. In other words, the following topics came to the fore

- Etica points out that its core business is investing in “**responsible organisations**”, and the reasons for such choice is reaping benefits in terms of Business Model, better relations with the local community and environment, and therefore an even better financial performance;
- Generali works in insurance and personal financial services; the company’s mission is focused on integrated thinking in support of managerial decisions;
- Vancity stands out, in that it uses finance to deliver sustainable development for underserved people, communities and the environment, as well as for its transparent and progressive reporting practices.

Integrated Reporting as an external reporting tool:

In short, the topics came to the fore:

- All three case studies extensively describe the process that led to their drawing up of the IR and the improvements they got from it: above all, at first the drawing up of

¹⁷ Visit vancity.com to find out more, and to view or download a copy of Vancity’s Annual Report or Three Year Plan.

the first IIR was based on the (GRI) G4 Sustainability Reporting Guidelines (Etica SGR), G4 and AA1000 principles (Vancity) and on the IR Framework (Generali).

- Generali and Vancity have been participating in the IIRC Pilot Program since 2012, and both claim they are deeply motivated by such initiative and share the key traits that inspire the drawing up of the IR. In particular, Generali and Vancity took part in the development of the latest version of the IR Framework (December 2013) and seem to be remarkably involved in and proactively cooperating with the IIRC.

- Even if it does not participate in the IIRC Pilot Program, Etica describes the process that led it to draw up one report, i.e. the Integrated Report, as required by the sustainability reporting standards of their client companies.

- Etica drew up an IR in 2010, based on the requirements of the GRI framework, as there were no guidelines about how to draw up such document. Vancity too drew up its first Integrated Report in 2010, while Generali did it in 2012.

As to comments about the <IR> Framework of the IIRC (December 2013), a key role is played by both Generali and Vancity, while Etica thinks that the IR should be built around a combination of G4 and the IR Framework, or either one should be chosen. In particular, Generali and Vancity point to some criticalities of the IR Framework, such as:

1. audience and the definition of value;
2. materiality;
3. performance indicators;
4. the role of the Board vs. Management;
5. the six Capital contents (only for Vancity which does not adopt the IIRC definition of six Capitals);
6. criteria for the presentation of changes in information estimates;
7. reporting boundaries;
8. corrections of errors compared to previous periods.

As to expected benefits and/or checked advantages after the adoption of the IR, the following topics came to the fore:

1. more transparent disclosure;
2. better relations with different stakeholders' groups;
3. cost savings;

4. better understanding of the link between the company's target, governance, remuneration policy and performance.

Integrated Reporting for internal use

The three companies proved to be quite keen on using the IR for internal purposes, describing different uses and purposes of the IIR. The three companies widely share the Integrated Thinking concept, which the drawing up of the IIR must be based on. The following points are worth pointing out:

1. Involvement of different stakeholders' groups, both internal and external (for example, through a survey or focus group);
2. wide involvement of internal stakeholders: the employees;
3. involvement of internal stakeholders: the Board of Directors;
4. stronger strategic perspective and disclosure of future strategies;
5. link between the employees' variable remuneration, two economic indicators (ROE and Cost/income) and one environmental indicator (Etica);
6. integrated view of performance (KPIs are connected to the five capitals (Generali));
7. Performance Management program (better team's internal communication).

6. Conclusions

A review of the three case studies found the following, about the internal use of the Integrated Report:

1. alignment of the Internal Integrated Report (IIR) with the strategic plans;
2. involvement of employees and management;
3. implementation of KPIs, in keeping with the employees' remuneration;
4. high level of acceptance of the IR by the company's management and staff;
5. better deployment of the company's key risks and opportunities;
6. clearer links between financial performance and sustainability performance.

There are still a few topics that have not been clearly outlined yet and that undoubtedly still need to express their full potentials, and they will be eventually considered too, such as:

- areas of application of the IIR within the Risk Management process;

- impact of the IIR on the internal decision-making process;
- impact of the IIR use on the Internal Auditing and on the Internal Auditors' assurance activity¹⁸.

“Over the last three years, the IIRC has built consensus around the idea that the current corporate reporting model must change to meet the needs of today’s business and investment environment”, says Richard Chambers, who is the President of the Institute of Internal Auditor (IIA). However, a message of deep change is not only given by the IR as an external reporting tool, but by the IIR as well: this makes a deeply innovative business reporting tool even more revolutionary, and it is such tool that will drive a major transition to Integrated Management (Piermattei, Venturozzo, 2011).

There are the following limitations of the research carried out: the internal use of the integrated report is still at an early stage, there is lack of referral guidelines, the role of accountants in the preparation of this new report is difficult and crucial. It is also necessary to consider that companies that have joined to the Integrated Reporting Pilot Programme have different characteristics in terms of assurance, internal control framework, staff organization, performance measurement models and sustainability performance management.

Keywords – Internal Integrated reporting; case study; performance, internal stakeholders; sustainability.

Integrated Reporting for Universities? Austrian Public Universities as an Example

Otto A. Altenburger , Michaela M. Schaffhauser-Linzatti *

University of Vienna
Oskar-Morgenstern-Platz 1
A-1090 Vienna, Austria

* *Corresponding author*

Structured Abstract

Purpose - This paper discusses whether the new framework for Integrated Reporting can be applied to universities. Being a young, so far not standardized instrument, Integrated Reporting can be defined as *“a process founded on integrated thinking that results in a periodic integrated report by an organization about value creation over time and related communications regarding aspects of value creation”* (<http://theiirc.org/>).

Design - To answer the research question, we first take the basic ideas behind the International Integrated Reporting Framework released by the International Integrated Reporting Council (IIRC). The IIRC is a joint foundation of the The Prince's Accounting for Sustainability Project (A4S), the Global Reporting Initiative (GRI), and the International Federation of Accountants (IFAC) which signed a Memorandum of Understanding with the International Accounting Standards Board (IASB). We then present the framework of the annual reporting requirements for the Austrian public universities according to the Universities Act 2002: Among others, they include the financial statements and the Intellectual Capital Report which are both regulated by law and detailed by corresponding orders. The financial statements are derived from the Austrian Commercial Code and demand the publication of a balance sheet, an income statement, notes, and the audit opinion of the auditor. The Intellectual Capital Report is the first worldwide to be reported obligatorily. It follows the theoretical model of ARC Seibersdorf and consists of narratives as well as numerous ratios which shall illustrate the human capital, structural capital, and relational capital of a university. To answer the research question, we finally contrast the requirements of the International Integrated Reporting Framework and of the Universities Act 2002 and its orders to reveal similarities and differences in regard to publishing obligations. That's why we can work out the applicability and usefulness of the International Integrated Reporting Framework for universities in general and for Austrian universities in particular. Moreover, we can derive strategies to improve universities' governance by means of published information.

Originality -This research is one of the first to present the International Integrated Reporting Framework which was released on December 9th 2013 at a conference. It is also the first to discuss its relevance and applicability for reporting on universities.

Practical implications - On a national basis, the results of our research will be discussed with the Austrian Federal Ministry in charge of universities which is constantly

improving its reporting system on universities by amendments of the Universities Act 2002 and its corresponding orders. As Austria already has been the pioneer in the introduction of the Intellectual Capital Report, other European countries might follow. On an academic level, the results reveal that the International Integrated Reporting Framework cannot be implemented for universities without adaptations. However, they open a field of discussion to derive new perspectives on reporting on universities.

Keywords - International Integrated Reporting Framework, Intellectual Capital Report, financial statements, universities, Austria

Paper type - Practical paper

Introduction – Aim of the Paper

Reporting of universities to the general public beyond reporting to governmental authorities or statistical offices is a topic which gains increasing relevance. How should university reports look like? There are many different suggestions and regulations, but up to now there is no ideal concept that fulfils the needs of the stakeholders and can be implemented in a practical way.

The situation is similar to the present discussion on reporting of enterprises – with one important difference: Annual financial statements, also for groups of enterprises, are well-established and well-known reporting instruments, accepted worldwide (irrespective of details differing depending on the specific accounting standards applied). There is, however, more and more feeling of unease with these reporting instruments; they are not seen as delivering the kind of information stakeholders are demanding, namely “value reporting”. As a consequence, additional reports have been suggested or recommended, mainly social reports, environmental reports, and sustainability reports. They primarily contain non-financial information and may be very interesting for stakeholders, but due to the information overload they might lose sight of the wood for the trees.

At present, the possible solution is seen in so-called “integrated reports”. Up to now, there is no generally accepted definition; a typical example reads as follows: Integrated Reporting “is a process founded on integrated thinking that results in a periodic integrated report by an organization about value creation over time and related communications regarding aspects of value creation. An integrated report is a concise communication about how an organization’s strategy, governance, performance and prospects, in the context of its external environment, lead to the creation of value in the short, medium and long term.” (<http://www.theiirc.org/>) Financial and non-financial data shall not only be

combined in one single report, but integrated to draw an overall picture of the organization's business model and outcomes.

Integrated reporting is of utmost topicality because the International Integrated Reporting Framework (IIRF) has been launched on December 9th, 2013. It is written primarily in the context of private for-profit enterprises, but with the intention of being applicable, "adapted as necessary", to public and not-for-profit organisations as well.

This paper discusses whether this framework is applicable to universities. The analysis is undertaken from an Austrian perspective because Austrian public universities have to publish Intellectual Capital Reports annually in addition to their financial statements and these reports are somewhat comparable to such integrated reports.

The following sections 2 and 3 present the International Integrated Reporting Framework and the Intellectual Capital Reports of the Austrian universities. In section 4, the posed question "Integrated Reporting for universities?" will be answered. Finally, conclusions are drawn.

1. The International Integrated Reporting Framework

The International Integrated Reporting Framework has been developed by the International Integrated Reporting Council (IIRC) in a process of five steps:

September 2011:	Discussion Paper "Towards Integrated Reporting – Communicating Value in the 21 st Century"
July 2012:	Draft Outline of the framework
November 2012:	Prototype of the framework
April 2013:	Consultation Draft of the framework (launched for comments by the public on April 16 th , 2013; 359 comment letters were received)
December 2013:	Publication of the framework

The IIRC has been founded in August 2010 by a common initiative of

- The Prince's Accounting for Sustainability Project (A4S, The Prince is the Prince of Wales, the British successor to the throne, Prince Charles),
- The Global Reporting Initiative (GRI), and
- The International Federation of Accountants (IFAC)

and is a global coalition of investors, companies, regulators, standard setters, the accounting profession and NGOs. By means of a Memorandum of Understanding, also the International Accounting Standards Board (IASB) is involved.

To foster Integrated Reporting, the IIRC has issued the so-called “Framework” which is structured as follows:

Executive Summary

Part I – Introduction

1. *Using the Framework*
2. *Fundamental Concepts*

Part II – The Integrated Report

3. *Guiding Principles*
4. *Content Elements*

Glossary

Appendix

The **Fundamental Concepts** include value creation, the value creation process, and the so-called “capitals”:

- Financial capital
- Manufactured capital
- Intellectual capital
- Human capital
- Social and relationship capital
- Natural capital

The capitals are stocks of value that are increased, decreased, or transformed through the activities and outputs of the organization. They are the resources and relationships used and affected by the organization. The ability of an organization to create value enables financial returns to the providers of financial capital interrelated with value creation for other stakeholders and society at large.

The **Guiding Principles** for integrated reports are:

- Strategic focus and future orientation
- Connectivity of information
- Stakeholder relationships
- Materiality
- Conciseness

- Reliability and completeness
- Consistency and comparability

Most of these principles are easily understandable. “Consistency” means consistency over time, “comparability” refers to other organizations. Comparability will be difficult to achieve because the Framework does not prescribe certain specific content elements like financial reporting standards.

The **Content Elements** integrated reports shall include according to the Framework are topics to be covered:

- Organizational overview and external environment
- Governance
- Business model
- Risks and opportunities
- Strategy and resource allocation
- Performance
- Outlook
- Basis of preparation and presentation

The description of these elements is complemented by general reporting recommendations. The key statement of the Framework is that each organization is called to create its own integrated report, following the aims and guidelines laid down in the Framework.

2. The Intellectual Capital Report of the Austrian Universities

Since the fundamental Austrian university reform by the Universities Act 2002 which created autonomous corporations instead of administrative bodies appended to the responsible federal ministry, a completely new reporting system for the Austrian public universities has become effective. The universities now have to apply double-entry bookkeeping and to annually draw up financial statements similar to enterprises which have to be audited by certified public accountants (in addition to the Federal Audit Office which investigates special matters on an irregular basis).

An essential element of the reporting system is the Intellectual Capital Report. Austria has been the first country worldwide to make annual Intellectual Capital Reports obligatory, not for enterprises, but only for public universities. These universities are

mainly funded by public sources. The Intellectual Capital Reports play an important role in the budgeting process of the universities. A substantial part of public funds is assigned by performance agreements between the responsible federal ministry and the respective university. These agreements are concluded for periods of three calendar years (not academic years, the current period covers the years 2013 to 2015). The Intellectual Capital Reports have to document to which degree the goals agreed upon have been met.

Format and structure of the universities' Intellectual Capital Report are determined by a decree (order) of the responsible federal minister. At present, the Intellectual Capital Report Order from 2010 is in force which has been slightly amended in 2012 and 2013. According to this order the Intellectual Capital Report consists of three parts:

- a narrative part describing mainly the university's activities, social goals and self-imposed objectives and strategies (important topics are priorities in research and advancement of the arts respectively, study programmes and continuing education, inter-university co-operation, increasing internationalism and mobility, human resources development and promotion of women),
- a great number of numerical data, and
- a standardized report on the fulfilment of special objectives laid down in the performance agreement in force.

The numerical information is arranged according to the following classification:

1. Intellectual capital
 - 1.A. Human capital
 - 1.B. Relationship capital
 - 1.C. Structural capital
2. Core processes
 - 2.A. Teaching and continuing education
 - 2.B. Research and development / Advancement of the arts
3. Outputs and impacts of the core processes
 - 3.A. Teaching and continuing education
 - 3.B. Research and development / Advancement of the arts
4. Special data for Universities of Medicine

The current Intellectual Capital Report includes 28 ratios which are, however, further deepened by stratification factors such as gender, nation, field of studies, etc. Additional 5 ratios are demanded for universities of medicine.

3. Is the Framework Applicable to Universities?

The Austrian universities' Intellectual Capital Reports follow the Framework in several central aspects:

- identical basic concept: one report, aimed at showing the reaching of goals, presenting a great variety of mainly non-financial data
- combination of quantitative and qualitative information
- compliance with the majority of the Guiding Principles
- containing most of the Content Elements
- financial information could be integrated (e.g., the document containing the Intellectual Capital Report of the University of Vienna comprises the financial statements as well, although as a separate section)

Guiding Principles rather ignored are materiality and conciseness: As the Intellectual Capital Report has to present all data required by the order as a minimum it is not possible to concentrate on selected aspects of special importance. Connectivity of information is also reached only to a limited extent: Due to the detailed regulations it is difficult to draw a holistic picture.

Missing Content Elements are risks and opportunities as well as outlook (except for a requested outlook concerning the fulfilment of special objectives laid down in the performance agreement for the rest of the current agreement period). The “business model” is not described explicitly, but seems to be implicitly clear to a great extent.

As the universities are allowed to include additional information in the Intellectual Capital Report it would be possible to follow the Framework as far as risks and opportunities and outlook are concerned – with the reservation that the outlook might not be informative enough due to the universities' dependence of public funding which cannot be predicted reliably for years beyond the current performance agreement period. Also the organizational model (“business” is not an adequate term for universities) could be presented.

The notion of “value creation” can be applied to universities without problems because it is meant to refer to all kinds of “capitals”. As the Framework allows for an adaptation of the single capitals the concept of capitals is fully compatible with the Austrian universities' Intellectual Capital Report, especially with its classification of intellectual capital.

4. Conclusions

The International Integrated Reporting Framework is applicable to universities and could become a good basis for university reporting. The Austrian public universities' Intellectual Capital Report is following this framework to a great extent which could even be enlarged but it is impossible to comply with it completely as long as the current regulations concerning these reports are in force. Therefore, these regulations should be amended in a way which enables concise readable reports conveying value to the universities' stakeholders.

Structured Abstract

Purpose – This paper builds on Special Track No. 7 “Intellectual Capital Knowledge Management Practices and Value Creation in Different Countries and Regions” and deals with the implementation of knowledge management in Czech industrial enterprises. The paper consists of three consecutive parts – the first part presents results of research focused on the usage of knowledge management in Czech enterprises, the second consecutive part is dedicated to knowledge, which is used in the complex production process in a high-end industrial enterprise. The last part of the paper is dedicated to the usage of value management as one of the most effective methods of using intellectual capital in innovative business processes.

Design/methodology/approach – The first part of the paper presents the results of research conducted in knowledge management area in Czech industrial enterprises. The second part is an internal view of a specific high-end enterprise which is focused on machine tools – vertical turning lathes. The paper sets the knowledge which each department needs for the successful management of knowledge. The next part shows the methodology and the use of value management – as one of methods of using intellectual capital within the enterprise. This section provides a brief technical-theoretical interpretation of value management and also a concrete example of the results of its use in innovation processes in manufacturing of machine tools.

Originality/value – The paper is completely original in the context of the Czech approach to the usage of knowledge management within Czech companies and can contribute to the approach to this topic. It is hence logical that this article is consecutive to the Special Track No. 7.

Practical implications – All three interrelated parts of the paper are linked to practical implications, whether they concern a relatively general approach of the research of knowledge management usage in Czech enterprises, or defining the knowledge necessary for successful management and production of individual products in various parts of a particular Czech industrial enterprise, or in the last part is the introduction

of value management methods which have been successfully used in top rated Czech industrial enterprises for more than 40 years.

Keywords – Knowledge management in Czech enterprises, Knowledge used in industrial enterprise management, Integration of knowledge in an enterprise, Value management.

Paper type – Practical Paper

The purpose of this paper is to familiarize the forum of IFKAD 2014 Conference with the situation of the knowledge management implementation in conditions of industrial enterprises in the Czech Republic and especially with specification of this situation at one of the leading manufacturers of CNC machine tools – vertical lathes. The text of our paper deals with more complicated and sophisticated products which originate based on confrontation of a customer's wish with possibilities of the enterprise. Therefore, the paper does not deal with knowledge management at origination of products with the consumer nature made in mass production, even if the perceptions mentioned below are valid for these products in many cases too. We are aimed at markets with industrial products which are characterized by a smaller number of customers, their sizes, complexity of products, inflexibility of delivery, variation of inquiries and usually by customers having great demands.

1. Introduction

The comprehensive application of the classical knowledge management, as it is mentioned in many methodical books, can be seldom found in our industrial enterprises. As examples, it is possible to mention one of our biggest energetic giants – ČEZ (Czech energetic plants) and a rather small-sized company Darkmay.

Knowledge management is still in the background of companies' interests in the Czech Republic and it is mostly developed and applied in supranational companies or bigger enterprises, as Marešová stated [Marešová 2010]. A lot of enterprises, especially of smaller ones, do not anticipate that there is knowledge management available, but they surely uses some of its parts.

In autumn 2009 a questionnaire survey was realized on the topics "Survey of the knowledge management state at enterprises in the Czech Republic" [Marešová 2010]. The survey was performed in cooperation of University in Hradec Králové, of Per Partes Consulting, s.r.o company and of European Union. The target of this survey was to map current standpoints of enterprises with regard to knowledge management. 1 000 organizations operating in the Czech Republic were addressed, these were from all branches and the survey was focused to middle-sized and big companies. 132 questionnaires were completed (the survey was anonymous). 3 areas were investigated:

1. What leads companies to the interest in knowledge management and in which stage they are currently:

- Why have you aimed to knowledge management?
- What results do you expect?
- Which knowledge is crucial one for you?

2. Company's environment as a tool specified to support, gain and share knowledge:

- How is crucial knowledge gained and shared ?
- Which barriers and risks of knowledge management are the most topical ones for you?

3. Methods and particular procedures connected with knowledge management and applied at the company:

- Which methods do you use to assess company's performance efficiency and which could be also used to measure results of knowledge management?
- How do you use knowledge management methods for innovation processes?

The brief analysis of collected answers resulted in the following conclusions:

a) Following reasons were mentioned why to implement knowledge management:

- reduction of costs (44%),
- increase of competitiveness (42%),
- need to develop individualized "tailored" products (28%),
- utilization of information technology possibilities (27%),
- increase of the extent of artificial intelligence incorporation in a product (12%).

b) Following knowledge management benefits were mentioned:

- improvement of business strategy (59%),
- trade improvement due to better knowledge of customers' needs (54%),
- expectation of bigger team spirit at company's work (30%),
- increase of company's value (31%),
- reduction of costs (26%),
- easier discovery of new business opportunities (32%).

c) Companies mentioned the following facts regarding to their own knowledge management utilization:

- knowledge management is not introduced as a whole in most cases (34%),
- company's management leaves initiative to individuals (62%),

- projects are realized for whole-company strategy (13%),
- business has been based on knowledge management (14%).

d) Companies considered the following knowledge to be crucial:

- knowledge of customers and their needs (68%),
- knowledge of the market and market possibilities (40%),
- knowledge of competitors and their strategy (38%),
- knowledge of the potential of immaterial intellectual assets for development of company's strategy (6%).

e) Forms how to gain and share knowledge were:

- regular trainings of customers (61%),
- common informal discussions in working teams (52%),
- controlled discussion or brainstorming (33%),
- sharing of documents in the information system (30%),
- creation of knowledge database (11%).

f) Barriers at knowledge management implementation were:

- problematic evaluation of employees' knowledge (30%),
- assessment of the knowledge management contribution by the company (29%),
- unclear returnability of investments to knowledge management (25%),
- unwillingness of people to share knowledge (26%).

g) Area of knowledge utilization were:

- searching of innovation possibilities (51%),
- complying with customers' wishes (37%),
- creation of a "tailored" product for a customer (32%).

If the results of the knowledge management survey in Czech enterprises are compared, they are rather similar to the results of surveys in other countries. Nevertheless, it is typical for our survey results that few enterprises (almost the negligible number of them) have the systematically and completely implemented methodology of knowledge management available and they work only with its parts and they are probably satisfied with application of these parts.

2. Knowledge management inside enterprises

Co-authors of this paper have personal long time experience in value management utilization in our enterprises. It is possible to mention applications of value management which can be considered to be one of the most effective methods used in innovation processes aimed at development of new products or at reduction of costs, or at both matters at the same time, thus at increase of the essential parameter which value management works with and which is called "customer value". The customer value is the proportion between customer's satisfaction with product parameters and costs necessary for product utilization.

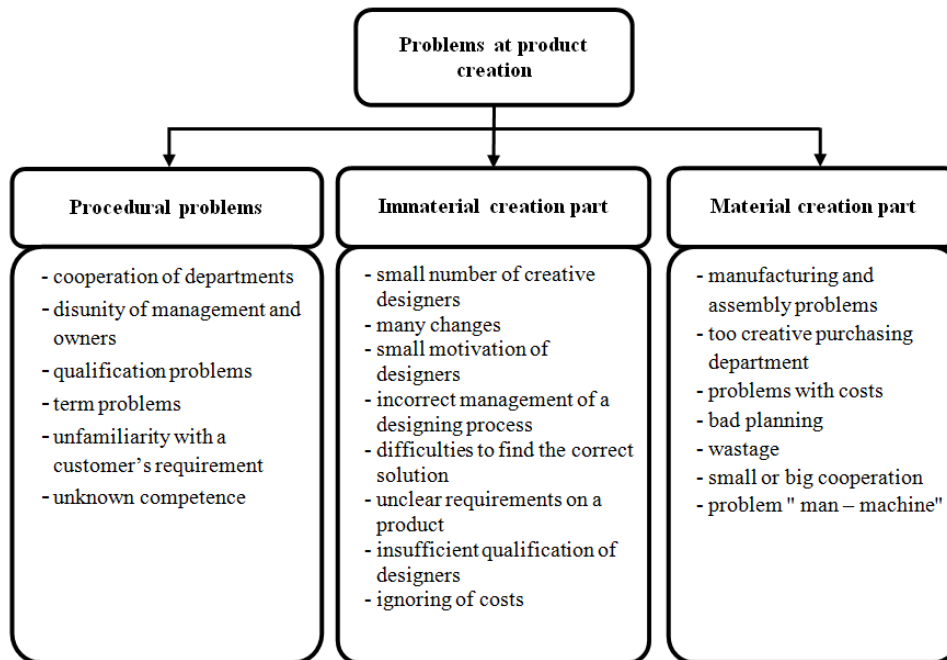

Fig. 1 Problems at product creation

Of course, it is necessary to use the system knowledge management in the whole product origination chain to obtain the high product customer value. Zelený (Zelený 2007) emphasizes "that knowledge is and it will forever remain the primary capital form and the permanent source of competitiveness. A traditional enterprise usually buys a lot of technology, it implements various functions and it collects a lot of data and information. Subsequently, the enterprise buys information systems and it fixes obtained information and information flows. Then, it borrows a lot of money ("capital"). In the

end, the enterprise finds that it has lack of knowledge and wisdom to find and reach the correct targets". There is no other possibility left that to agree to Zelený's statement. If knowledge is not managed sufficiently and if it is managed in the way described by Zelený, process problems will arise with product creation and these problems will be shown in the material part of product creation as well as in the immaterial part of product creation.

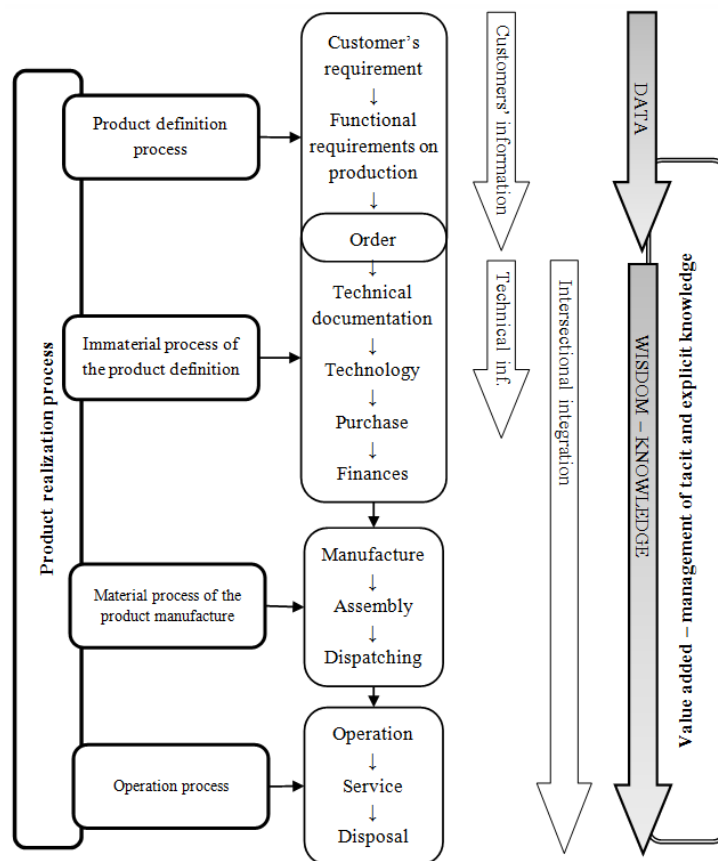

Fig. 2 Knowledge management in the product life cycle

Product creation has changed considerably at the turbulent time of current economy. Organization complexity of manufacturing companies, the demanding character of technology, integration of manufacturing technique and information technology have influenced economy and they have their considerable impacts also on product creation. The problems which can occur at product creation are given in the following Fig. 1.

The mentioned problems represent an example of those things which must be eliminated by knowledge management (Fig. 1). They are classified in three separated areas, but practice is more complicated, because these areas are interconnected together. This must be mastered by knowledge management.

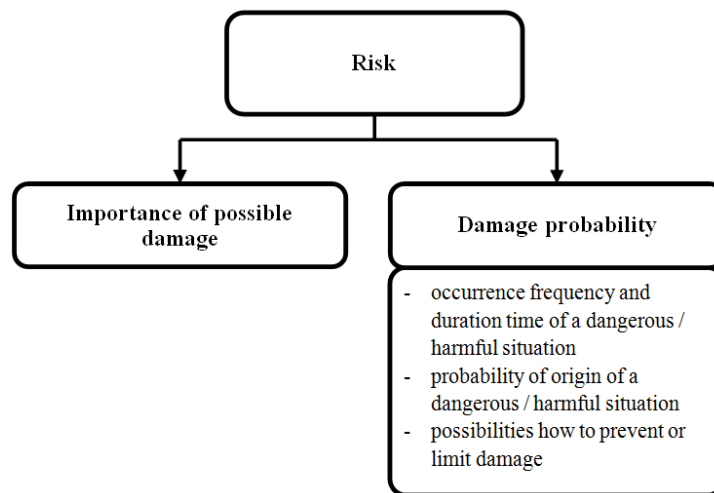

Fig. 3 Risks and possible damages

In our paper we would like to point out how a product originates in particular stages and which knowledge it is necessary to work with in these stages. We present a simplified model of product origin, beginning at expression of customer's needs, through its commercial, designing and technological processes and finishing with its delivery to the customer. This model is shown in Fig. 2.

All links of the product process mentioned in Fig. 2 are characterized by the fact that operations performed in one step (section) have smaller or bigger impacts on operations in the following section. It is important to minimize negative impacts. The negative impacts are connected with such terms as damage, damage management and probability of damage origin. Damage risk management is the essential tool of knowledge management, therefore it is necessary to mention it here. We are able to manage the damage origin risk by means of the risk analysis in each step of the product origin process. Detailed investigation of risk elements (Fig. 3) is provided by the risk analysis which is finished by the classified risk assessment and it should be also completed by damage estimation.

2.1 Knowledge and knowledge management in the commercial department

Employees of the commercial department are the first ones who are in a contact with the customer. These people define more or less customer's needs. Based on his or her knowledge and in cooperation with the technical and economical departments, the qualified employee of the commercial department informs the customer about the possibility how to fulfil the customer's wish, including the preliminary price determination. This process results in the offer elaboration and the offer must include the description of technical execution and the price. The well-elaborated offer can have a crucial impact on its profitability. When the offer is confirmed by the customer, this means in fact the end of possibilities to perform principal changes.

The following knowledge is managed in the commercial department:

- communication with commercial partners and customers,
- transfer of information about innovations in the company's production program to the customer,
- comments on impulses from commercial partners and customers and giving of these impulses,
- ability how to present the company,
- creation of new commercial contacts,
- elaboration of offers for commercial partners and customers,
- elaboration of purchase contracts,
- marketing activities,
- providing of warranty and after warranty customer care.

The followings risks are managed in the commercial department:

- incorrectly concluded contract relations and forms of their providing,
- good product calculation (profitability, loss rate),
- all other conditions connected with the product delivery (especially speed),
- unfamiliarity with customer's solvency,
- unfamiliarity with legislation in the customer's country.

All of this knowledge can be concentrated in the following formalized terms called:

- **Market intelligence** (reporting resulting from information about the particular market, its size and character, trends and directions of the future development, finding of new opportunities, detailed information about priority countries),

- **Competitor intelligence** (reporting about competitors, export strategies of other countries and manufacturers in the same branch and in the same country, etc.),
- **Product intelligence** (identification of possibilities how to improve the product quality to support export, costs, benchmarking, etc.),
- **Customer intelligence** (reporting about plans and activities of customers, exporters, associations, unions, chambers).

Note: Competitor intelligence and product intelligence are also in the focus of knowledge in the technical department (development, designing).

Unfortunately, the mentioned necessary knowledge which should be (must be) mastered by the commercial department are managed unsystematically. The appropriate attention is paid to this knowledge only in two limit cases:

- a) if an order is a great and interesting one,
- b) if there is lack of orders.

The following is necessary to manage knowledge in the commercial department successfully:

- to elaborate and maintain permanently customer databases,
- to elaborate and maintain permanently competitor databases,
- benchmarking of competitor offers,
- training of export staff about changing technical and manufacturing possibilities of the company,
- to keep databases of offers and implemented orders,
- cost analyses of profiling company's offers,
- training of staff about government export programs,
- standardization of processes for elaboration of contracts and contextual standardization of contracts,
- systematical education of people with regard to customers,
- systematical education of people with regard to offered products and their confrontation with customer's requirements,
- language education,
- to increase awareness about technical trends,
- to follow events on markets and export interests of the country.

2.2 Knowledge and knowledge management in the technical department

The technical department consists of a few sections having different contents of work. Therefore, knowledge management is very extensive in the technical department. The core of the technical department is the designing office which is clearly the base of the company's success on the market. The designing office decides up to 80 % about costs necessary for manufacture and moreover, the designing office is also responsible for product innovations which are the base of the company's competitive advantage on the globalized market. Designing can be characterized as a process where a solution of technical issues is found by means of various approaches and this solution serves to satisfy customers' needs as well as company's needs.

The designer works with the following knowledge:

- mathematics, physics and other sciences,
- customer's needs,
- limiting standards, superordinated restrictions and safety regulations,
- company's technological possibilities,
- company's assembly possibilities,
- ability of manufacturing and assembly,
- technical parameters of competitive products,
- team work,
- application of up-to-date designing support software,
- economical impacts of decision making at designing,
- economy of the future production,
- product intelligence and customer intelligence (see the previous item).

There are four essential approaches to designing available (Fig. 4). These are "attempt – error", intuitive designing (based on the existing knowledge and experience), procedural designing (based on methodical instructions) and designing based on theory (system approach).

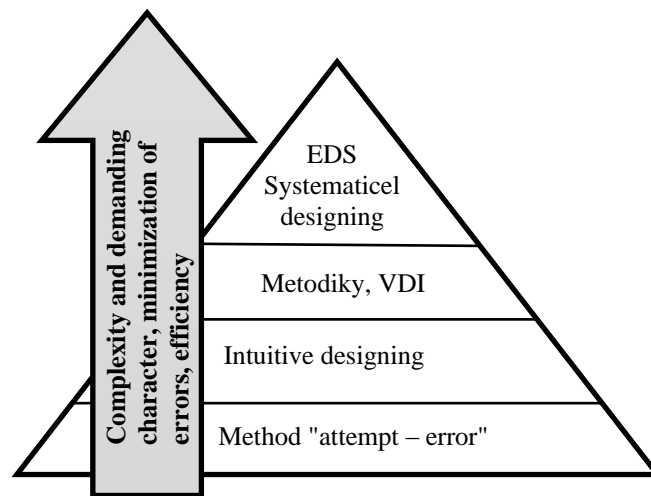

Fig. 4 Strategy of knowledge utilization at designing

When the demanding character of thinking is considered, the method "attempt – error" is the simplest method how to solve conceptual and structural designing issues. Its principle is based on a solution of the particular issue which is realized without any excessive methodical analyses, only on the base of designer's consideration.

Intuition is a higher degree how to solve conceptual and structural designing issues, applying designer's experience. Moreover, this problem solution way originates spontaneously, subconsciously, as a result of inspiration, fantasy or imaginations. The essential prerequisite for creative activity is the thorough and deep mastering of the topic, which requires intelligence as well as rich experience and education. Strong will and concentration are necessary to master the topic. Time required for preparation and collection of sources comes before a technical task is solved. The solution comes after long and exhausting work.

Methodical procedures represent the important contribution in methodology how to solve conceptual and structural designing issues. Methodical procedures originated in Germany (finally, the matter was standardized in the VDI 2221 directive called System approach to designing of technical systems and products).

Systematical approaches are called Engineering Design Science (EDS) abroad. EDS is a relatively new science branch which has been developing in the world since the forties and in our country since the sixties of the last century. After a lot of development stages,

in the last decade the development of EDS knowledge reached the qualitatively new level which can be designated as the support of knowledge integrated system designing.

The following knowledge is managed in the technical department:

- designer's creative and innovation knowledge and abilities,
- transfer of customer's requirements to a new design,
- competitors' similar solutions and patent purity connected with it,
- knowledge of simple similar designing solutions,
- comments from the service department and their inclusion to designing documentation,
- application of the maximum quantity of standard, typified and unified parts,
- consideration of operating conditions at designing (tropical climate, extreme cold, etc.),
- providing of warranty and after warranty customer care,
- application of the minimum number of non standard manufacturing procedures.

The followings risks are managed in the technical department:

- functionability of the designed solution,
- whether the new solution is really the optimum one in its technical and economical aspects,
- ability of manufacturing and assembly,
- whether the criteria selected to assess the optimum design are the same ones as customer's ideas,
- whether operation (wear of parts) does not disturb the product function during the warranty time,
- the purchasing department may not report the replacement of a prescribed part by another purchased part,
- non conforming manufacture and assembly with manufacturing documentation,
- unauthorized customer's interventions during the product warranty time.

The following is necessary to manage knowledge in the technical department successfully:

- systematical education of designers,
- to develop and build strategic knowledge management,

- elaboration and systematical maintenance of knowledge databases with internal rules, solutions already implemented, results of measuring and experiments, assembly procedures, successful and unsuccessful technical solutions, etc.,
- regular, systematical and controlled exchanges of information and designers' experience,
- to be in a contact with another company's sections, most of all with the service department,
- to keep the databasis of competitive technical solutions and parameters,
- benchmarking of competitive offers,
- to keep the databasis with realized offers,
- creation and maintenance of technical conditions of the own products,
- motivation to be creative, precise, professional, to perform radical innovations, etc.

2.3 Knowledge and knowledge management in the purchasing department

The purchasing department has the role to decide after an agreement with designers, which parts and assembly groups shall be purchased as ready-made ones (motors, bearings, hydraulic elements, etc.) and which materials shall be provided to manufacture the own parts. The purchasing department also determines which services or cooperations shall be purchased (if the cooperation department is included in the purchasing department). However, purchasing cannot be only understood as a service fulfilling the requirements given by the particular sections participating in product creation. Decision making becomes the strategic matter at purchasing and it can contribute to better quality and rapid course of creation of a new product. Decision making with regard to operative purchasing and strategic purchasing is connected with it. Strategic purchasing searches suppliers, it determines prices and elaborates contracts. Operative purchasing makes orders, provides transport, input inspection, delivery to the assembly department, etc.

The following knowledge is managed in the purchasing department:

- searching of subsuppliers and assessment of their offers,
- elaboration of high quality subdelivery contracts,
- elaboration and maintenance of the databasis with potential suppliers,
- observation and assessment of warranty claims,

- observation of the share of the target determined costs of products in subdeliveries,
- to limit the storage only to necessary items (do not bind unproductive capital).

The followings risks are managed in the purchasing department:

- well-timed delivery and its impact on the complete product delivery to the market,
- completeness of the delivery including the accompanying documentation and certificates,
- quality of subdeliveries (especially if the subsuppliers are changed to non proven ones),
- connectability of a purchased element to the assembly group.

The following is necessary to manage knowledge in the purchasing department successfully:

- systematical commercial and technical education of people in the purchasing department,
- education how to master interpersonal relations and communication,
- maintenance and renewal of the databasis with subsuppliers,
- observation of the current development work and trends in the designing and production departments and keeping of professional relations with these departments.

2.4 Knowledge and knowledge management in the production planning department and in the technology department

There is interconnection between the designing, technology and purchasing departments. Complexity and the demanding character of designing and purchasing processes results in the fact that designing solutions influence approximately 70 to 80 % of manufacturing costs, 20 to 30 % of costs are specified for technological processes. The manufacturing (technological) process consists in processing of semi products to their final shape. Two subprocesses can be distinguished here – the manufacturing process and the technological process. The manufacturing process represents all operations performed on a part and made in a particular sequence. The technological process determines how the manufacturing process shall be performed. It determines the particular machine, tools,

jigs and length of single operations. These activities are labour intensive ones and they require a lot of knowledge.

The following knowledge is managed in the technology and technological production planning department:

- creation of manufacturing procedures,
- parameters, sequence, time requirements, etc. of manufacturing operations,
- assessment of designing documentation regarding to the prescribed shape deviations, position deviations, accuracy, surface quality, etc.
- company's machinery and manufacturing capabilities with regard to the required manufacture,
- integration of changes to the technological procedures and manufacturing documentation,
- innovations on the market with tools and manufacturing technology,
- knowledge of workpiece chucking and designing of jigs,
- change procedures.

The followings risks are managed in the technology and technological production planning department:

- reality of time schedules of the production plan for manufacture of parts,
- capacity workload of the particular manufacturing centres,
- breach of technological discipline,
- unexpected outage time of machines.

The following is necessary to manage knowledge in the technology and technological production planning department successfully:

- to keep databases with technological procedures and their updating,
- solution of contradictory technical requirements and opinions of designers and technologists,
- assessment of manufacture of a single part in the complete context,
- to apply up to date software tools for automatized creation of technological procedures.

2.5 Knowledge and knowledge management in the financial department

The financial department is one of the departments which determine competitiveness of products on the global market, because it monitors costs of the product from the contract conclusion with the customer up to the product dispatching to the customer.

The following knowledge is managed in the financial department:

- real data for accounting,
- optimum company's financing,
- application of company's financial analyses.

The followings risks are managed in the financial department:

- changes of the exchange rate,
- lack of finances specified to cover orders,
- lack of finances specified to cover company's cash flow,
- unwillingness or inability to pay customer's obligations.

Knowledge management in the financial department is a very complicated and specific activity which is due to its contents beyond the possibilities and aiming of this paper. Management of the relations among the company's financial strategy, manufacture and costs, the prices and internal costs of the particular company's sections can be considered to be the crucial knowledge.

2.6 Knowledge and knowledge management in the production department

The production department has the task to manufacture the planned quantity of parts in the stated terms, to perform controlling of the manufactured assortment and operative and strategic manufacture management. The principal role in manufacture is represented by standardization and typization (standardized input sources, materials, manufacturing equipment, technological procedures, etc.). Complexity of production is conditioned by the fact, whether this is single part production, small lot production, series production or mass production. Because this paper describes single part production or small lot production of complicated manufacturing devices, our attention is aimed especially at these production types. The knowledge mentioned below must be managed at such production types.

The following knowledge is managed in the production department:

- knowledge of human and technological capacities within the enterprise,
- uniform, complete and economical utilization of manufacturing means,

- purposeful layout of manufacturing means with regard to the material flow (material, energy) and immaterial flow (information),
- profitable execution of manufacturing operations,
- searching and elimination of reasons, why non conforming parts are made,
- preventive service and maintenance.

The followings risks are managed in the production department:

- failures of manufacturing means, especially of strategic technology,
- non observance of the required quality prescribed by manufacturing documentation,
- breach of prescribed technological procedures,
- non conforming parts are not excluded from processes (and they are passed on the assembly).

The following is necessary to manage knowledge in the production department successfully:

- to build and to keep the qualified state of manufacturing technicians,
- to implement their professional and safety training,
- assessment (statistic and factual assessment) of the performed manufacture, past errors and utilization of results for training of people and to improve the quality of manufacturing processes,
- to observe accuracy and failure rate of manufacturing devices and to manage preventive service and maintenance,
- to choose and to influence purchase of new machines (based on monitoring of newly developed products which will come to manufacture).

2.7 Knowledge and knowledge management in the assembly department

Assembly is the last link in the technological chain of the material part of product realization. The assembly core is that two or more parts take a position to each other which is defined by drawings (by designing) and by technological procedures. The main operations performed during assembly are manipulation, putting together and connection.

The assembly process can be realized by various assembly types (Fig. 5). Internal assembly is performed at the manufacturer in the manufacturing enterprise on one workplace (immobile assembly) and if the particular parts are put together on various workplaces, we speak about mobile assembly. At this assembly way it is necessary

to keep the assembly cycle time between particular assembly groups and assembly subgroups. External assembly is performed at subsuppliers which supply the particular assembly subgroup to the manufacturer and the manufacturer builds this subgroup (the subgroup is integrated) to the whole unit in the own company (energetic chains including hoses and cables, gearboxes, etc.). The special kind of mobile assembly is represented by the automatic assembly line, where the band transports the particular parts to the particular assembly workplaces specified to make assembly subgroups.

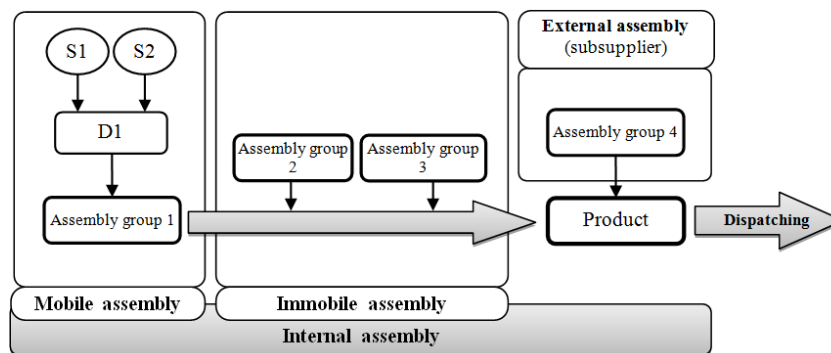

Fig. 5 Assembly types and their interconnection

The following knowledge is managed in the assembly department:

- well timed work finishing,
- uniform material delivery to the assembly workplaces,
- purposeful layout of manufacturing means with regard to the material flow (material, energy) and immaterial flow (information),
- profitable execution of manufacturing operations,
- elimination of reasons, why non conforming parts are made,
- preventive service and maintenance.

The followings risks are managed in the assembly department:

- non observance of the required quality and accuracy prescribed by manufacturing documentation,
- it is impossible to assemble the particular parts,
- delivery of a non conforming part to the assembly and its late discovery,
- breach of prescribed assembly and technological procedures,
- failures at delivery of parts to the assembly.

- The following is necessary to manage knowledge in the assembly department successfully:
- to build and to keep the team of qualified assembly technicians and their knowledge,
- to solve immediately the delivery of non conforming parts to the assembly,
- to provide the information feedback to the designing department and to the production department,
- to manage exactly relocation of people between the particular assembly workplaces,
- observance of time limits for partial assembly operations,
- to apply methodology and procedures of the final testing of the assembled product.

2.8 Knowledge and knowledge management in the dispatching and transport department

Dispatching and transport of finished products shall be performed while the product is properly fixed in a package or on a transport pallet. The package or the transport pallet must provide the protective function (to protect the product against its outside damage), the manipulation function (to provide easier manipulation with the product at its loading and unloading), the technical function (easy putting together and packing, suitability for the particular transport type and the particular region), the ecological function (recycling, no emissions of harmful substances) and the information function (information about the product and the transport destination). In the globalized world the product is delivered to the regions which are still more and more distant. Therefore, it is important to select the correct transport kind. Transport is usually included in the product acquisition price. The following transport kinds are used to transport goods: road transportation, railway transportation, river and sea transportation, air transportation and combined transportation.

The following knowledge is managed in the dispatching and transport department:

- selection of the suitable packing technique,
- volume minimization of the transported order,
- optimum transport ways,
- issue of correct documents in dependence on the customer's country type,

- determination of the suitable shipper.

The followings risks are managed in the dispatching and transport department:

- well timed product supply to the customer,
- suitable product package,
- origin of damages at loading and unloading,
- product ability to be transported
- transport insurance.

The following is necessary to manage knowledge in the dispatching and transport department successfully:

- to watch price policy of shippers and their reliability,
- to watch varying transport possibilities,
- to watch transport quality of past orders to the same region.

3. Role of knowledge management at the integrated product development

The integrated product development can be understood as a process, where a customer and particular departments of a manufacturing enterprise work together, e. g. by means of project proceedings or by means of another tool (may be using common sense). This process results in origination of a product having the optimized quality and price during the minimum time period.

The integrated product development must use company's sources, which are of course represented also by knowledge and knowledge management, to find a suitable way how to manage workers, managers and other staff in the engineering, production and marketing areas and to work together – to develop efforts throughout the whole company with the target to be competitive.

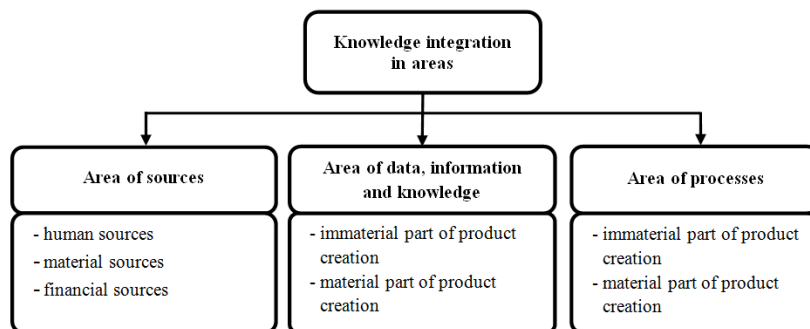

Fig. 6 Role of knowledge management in integrated production

In the first stage of attempts with "integration" the activity was aimed at integration of data which originated at designing (drawings) together with another section following with the activity, i. e. technological production preparation (technological procedures). These outputs had the character of instructions for other sections. Then, data of other company's sections started to be used (data of service and production, commercial and financial departments). The reason to do it was the reaction on often changes in creation of all documents connected with product origination. Suppliers of subdeliveries started to join too. CIM (Computer Integrated Manufacturing) – i. e. production integrated by a computer – began to come into existence.

Practical experience showed that such data integration itself does not mean achievement of competitiveness on the market. Recent approx. 20 years have confirmed that it is necessary to go one degree higher, over data integration and to start to manage knowledge – introduction of knowledge management to all enterprise management sections. This must be done with all attributes belonging to management of the knowledge enterprise (Section No. 2).

Reasons of insufficient knowledge management are shown in failures originated in the particular sections and these failures can be e. g.:

- incorrect offer and incorrectly concluded contract due to unfamiliarity with detailed customer's requirements,
- bad determination of the dispatching date due to unfamiliarity with manufacturing capacities,
- insufficient transfer of customer's requirements to the internal order in the enterprise,
- errors in technical documentation due to incorrect knowledge management in the designing department,
- changes due to unfamiliarity with exact customer's requirements,
- errors in continuity of assembly groups due to unqualified purchase of subdeliveries,
- bad manufacturing and assembly technology due to unfamiliarity with requirements of the designing department,
- unprofessional dispatching due to non-consideration of transport conditions,
- it is impossible to perform service due to incorrect designing inputs, etc.

Fig. 7 shows the idea about integrated connection of knowledge required to say about an enterprise that this enterprise is managed based on knowledge (knowledge enterprise). Cross arrows show that integrated knowledge transfer does not occur in the linear way, but this transfer is a rather complicated selection process which passes through the company's hierarchy. So, the company's management need not have all knowledge as their subordinates and staff need not have all knowledge as their management. Passing of knowledge through processes and sections and its progressive building are matters of time, finances and quality of management people. Integrated connection arises step by step and it is impossible to implement it at once en bloc. Nevertheless, it is possible to say that each partial knowledge process introduced to the enterprise can contribute to increase its competitiveness, regarding to the increase of the technical product level and especially regarding to reduction of its costs. Efforts of knowledge management are focused on these fields even at the current time.

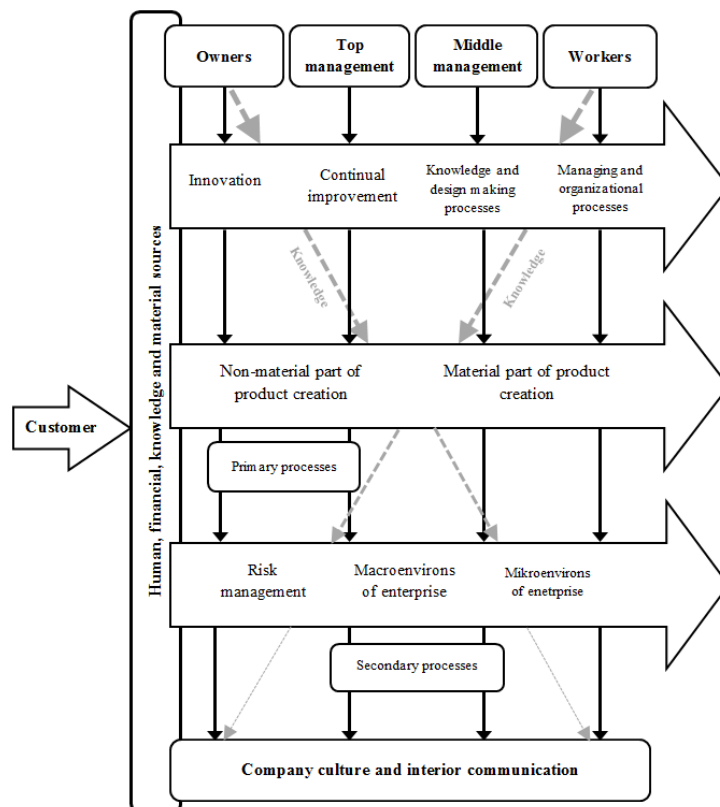

Fig. 7 Knowledge management integration in a manufacturing enterprise managed as the "knowledge" enterprise

4. Value management - one of the best tools of knowledge management

The current worldwide development trend of industrial and social processes takes place especially on the level of the development dynamics of intellectual resources and their reflection in application of knowledge management in practice. This paper does not avoid mentioning and describing shortly one of very efficient methods which use intellectual resources in companies. Ian Brinkley [Brinkley 2009] is famous due to his motto "Companies, which are able to understand how important is to know what their knowledge is, are able to use this knowledge to the maximum possible measure. These are their corporate knowledge assets." And especially the value management is one of very strong intellectual assets which companies can use very thoroughly and to a considerable extent.

Value management was formed based on war experience of American engineers – designers and businessmen who faced shortage of necessary raw materials. The solution was found by application of substitute materials and by corresponding modification of design and technologic processes which satisfied fully all needs of customers, especially from armament industry at that time. On the base of that practice in General Electric Company L. D. Miles, a young and creative supply officer was charged to implement this intention [Miles 1961]. He started to outline systematically the functional approach at reducing of costs, where the major idea was to search substitute solutions based on the fact, that the function of the explored object must remain the same one, because this function is particularly interesting for the customer. Miles called the methodology made in this way Value Analysis, because the basis for analyses of designs of substitute solutions was the ratio between Performance and Costs which was called Value by L. D. Miles, the author of this method [Miles 1971]. The methodical process was formulated in the sequence of 5 essential questions:

1. WHAT IS IT? (What object is this?)
2. WHAT DOES IT MAKE? (What does it make, which functions has the object?)
3. HOW MUCH DOES IT COST? (Which costs are necessary to provide the object function?)
4. WHAT ELSE CAN PROVIDE THESE FUNCTIONS? (Which other ideas and designs can provide these functions in a high quality?)
5. HOW MUCH DOES ANOTHER POSSIBILITY COST? (Which costs are necessary to provide the functions by new designs?)

Immediately after the war this resulted in the fact, that the approach verified in this way became one of many tools to reduce manufacturing costs also in peace-time production, and it is necessary to say that this tool was one of the most efficient tools. It spread all over the world. In 1965 this method was applied in so called socialist economy for the first time. It was in the Czechoslovak Republic, in Zetor Brno, tractor company. This essential methodical process remained unchanged for more than 60 years. However, what was successively changed in particular countries, was more precise specification of this process, usually in some more detailed years, as it is witnessed e. g. by methodology given in the Czech and European standard Value management ČSN EN 12973: 2000.

In the past years Czech professor Vlček (Vlček 2002) with the collective, created successively the comprehensive concept of the value management system based on the knowledge with classical value analysis. The value management system consisted in four types of tasks which are called application disciplines of value management and result in increasing of the product customer value. These are:

1. **Value analysis** which represents an effectively made set of methods and means, whose sense is to improve the analysed object by searching an improved solution of its functions, with the target to increase its customer value (improving its utility parameters or reducing its manufacturing costs or by the combination of both possibilities).

2. **Value designing** (value engineering) represents an application of the value approach when creating a new object (product, process, investment, organization structure) in respect to obtain a higher degree of innovations. Also here, the target is to design a new product with higher customer value.

3. **Value product strategy** is a continuous process in well managed companies, by means of which these develop their production programs. The production program set in this way must be: competitive and exportable. Product strategy has also the task to decide about attenuation programs and about modernization of current products.

4. **Inverse value** analysis is a special case of value analysis. It consists in searching a more efficient object utilization using the value approach.

The following Fig. 8 shows the position and importance of value management in the strategic management system of the enterprise and its application in value production strategy (it is necessary to begin there), through value projecting at new products up to its utilization to improve existing products.

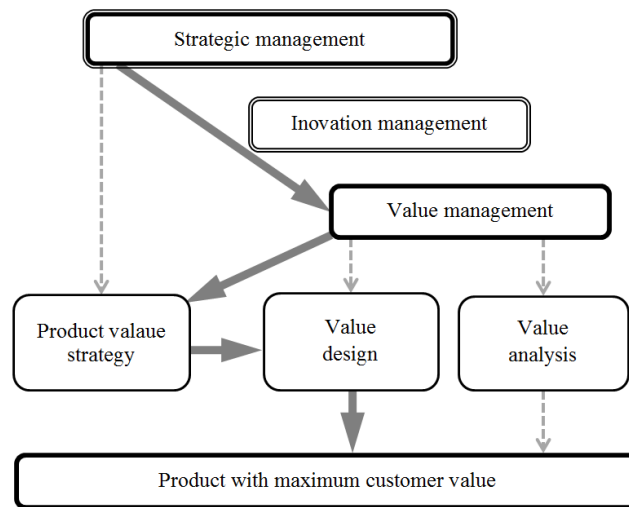

Fig. 8 Application of Value Management in the innovation structure of the enterprise

The Customer Value belongs to the key terms in market economy. Czech technical standards harmonized with EU characterize "value" or the general understanding of the customer value as "relation between satisfaction of needs and sources used to obtain this satisfaction". The mentioned relation can be described by the following formula:

$$\text{Customer value} = \frac{\text{Satisfaction of needs}}{\text{Used sources}}$$

after quantification:

$$\text{Customer value} = \frac{\text{Benefit amount}}{\text{Total customer costs}}$$

This defined value is not the absolute category but a relative one, which is conditioned by a different purchasing position of every customer. The manufacturer offering his products on the market takes into account that it is not possible to try to obtain the maximum benefit, but it is necessary to find the parameters characterizing the benefit amount on such a level which will be suitable for the particular group of customers, for that segment for which the product is intended. So, **the benefit must be optimized**, not maximized. On the other hand, total costs, i. e. manufacturing ones as well as user ones, and also the **price for the final customer must be minimalized**, which creates the premise of a commercially successful product.

Customer value will be increased (based on the previous considerations) in the following four cases:

1. when benefit increases and total costs do not change,
2. when benefit increases and total costs decrease,
3. when benefit remains the same and total costs decrease,
4. when benefit decreases more slowly than total costs.

These are four ways to company's higher prosperity, competitiveness and commercial success.

It follows logically from the above mentioned customer's and manufacturer's standpoints, that both parties must meet in the common field which is the effort to obtain the maximum customer value. The maximum customer value creates the core of commercial success and competitiveness of products and services. This maximum customer value seems to be a certain intersection point of customers' economical interests and manufacturers' economical interests. The following Fig. 9 shows all mentioned ways how to increase customer value.

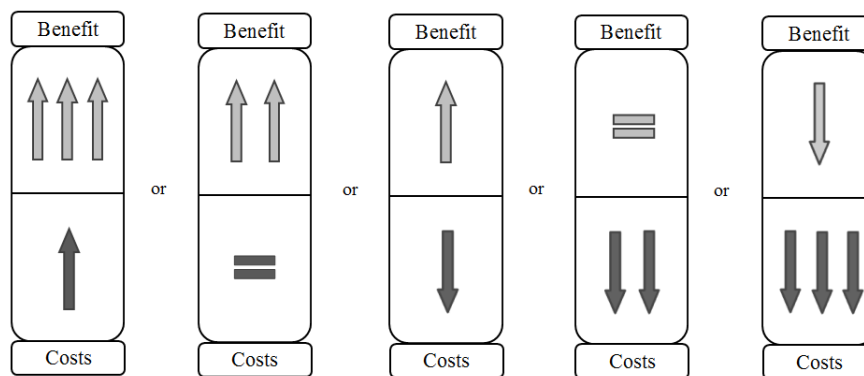

Fig. 9 Possibilities how to increase customer value

Application of value management is based on the unique organic combination of four key principles which are (Vlček 2002):

- management style (concentration on a customer, maximization of customer value),
- utilization of those terms: function, creativity, quantitative assessment of benefit and used sources,

- human dynamics (high quality communication creates environment for synergy of economical, technical and managing skills, abilities and knowledge within team work),
- respecting of environment (external environment – laws, standards and restrictions, internal environment – company’s policy, company’s organization architecture, know-how, etc.),
- methods and tools (preparation and elaboration of value management projects, methods and technique used at elaboration of value management projects).

The VUSTE research institute in Brno where the first realization of value analysis was performed was successively established as a control and development centre for implementation. It kept this task up to its end in 1990. From the seventies up to the nineties the implementation was performed on the basis of contracts with the particular plants, where the plants had about 50 designers and technologists trained at the same time. This was done in the form of work training organized in teams having 6 – 8 people who solved company’s particular smaller projects using this training form. In such a way they connected theoretical education with its immediate realization in solved projects.

After the 1989 revolution the approach of single plants was changed considerably. After the stabilization of companies, in many cases also under the influence of new owners, they started to come back to searching of methods which can be used for innovations of their products, e. g. to increase their utility value or to reduce manufacturing costs and very often to perform the both. It was done and it is still done in such a way that the companies hire an external and skilled specialist, whose priority is not to train workers in value analysis, but together with the set team of company’s specialists, to solve more complex projects having the exact innovation target. Since 1990 the co-author of this paper has solved almost 40 projects of value analysis and value engineering as a methodical leader of teams in various plants. It is necessary to say that the plants reserve very little time for the projects, so in many cases it is not possible to apply the full scope of value analysis methodology, but only its reduced form keeping all essential methodical elements, especially functional analysis, application of creative work methods, assessment of subjects, etc. In spite of that, the work results of teams working under the external specialist’s leading are very good, even excellent. It seems to be almost unbelievable that all projects showed good results in the mentioned implementation companies.

The Tab. 1 [Dobřický 2009] shows an example of the output from the value product strategy realization and from the value designing. This is only a data selection in range of machine tools because there is no room here to perform the detailed study of the particular items in the rather extensive analysis.

Conclusions

1. The presented article combines three areas of knowledge management utilization in Czech enterprises. The first deals with research and its use in Czech enterprises. The second attempts to define the knowledge used in a high-end industrial enterprise and the third part presents the use of long-term utilized innovative method - value management and its contribution to cost reduction and the finding of successful innovations on progressive machine tools.

2. Comprehensive utilization of knowledge management is not typical for Czech enterprises. Yet it is possible to find enterprises that could be labeled as learning enterprises and some even bear the label “knowledgeable”.

3. What is much more popular and has a long and successful tradition in the Czech Republic, including proved and positive results, is the theoretical development and practical utilization of value management methodology.

4. The whole article, even though it is complex, gives a relatively comprehensive picture of the real state of knowledge management in Czech industrial enterprises.

Wealth Creation in the Knowledge Economy. Reflections on the case of Spain

José María Viedma Marti

Polytechnic University of Catalonia, Barcelona, Spain.

Abstract

Purpose - After an introductory approach on the definitions and main characteristics of the knowledge economy the paper focuses on the three following purposes: 1) Discovering from the existing relevant literature on competitiveness, innovation and intellectual capital at the macro level which are the principles and theories that guide nations' wealth creation in the knowledge economy context. This part tries to answer two fundamental questions: Who creates wealth? How wealth is created? 2) Finding out the suitable methodology or framework in order to enable an in-depth diagnosis of a nation's actual knowledge driven competitiveness foundations, with the aim to aiding in the definition of the possible vision, objectives and lines of action to embrace in order to enable innovation and sustainable economic growth. 3) Applying the suitable methodology or framework for an in-depth diagnosis of the Spain crises and using the insights given by the in-depth diagnosis for having some light on the future economic development possibilities and on lines of action to be taken in order to foster innovation and sustainable economic growth.

Design/Methodology/Approach - This practical research falls among the design science research approach that tries to find out methodologies for solving practical problems. Having in mind the practical objectives of purpose 3, the methodology approach for purpose 2 will be the following: According with principles and theories of wealth creation there is a close relationship between wealth creation and competitiveness and consequently trying to find out methodologies and frameworks for an in-depth practical diagnosis of a nation's knowledge driven competitiveness foundations, leads us to the World Competitiveness Report from World Economic Forum (WEF) and World Competitiveness Yearbook from International Institute for Management Development (IMD), the two most relevant considering their up to date data bases, historical performances and scientific approach. Intellectual Capital community methodologies at the macro level are also considered as alternative approaches to the competitiveness frameworks. Finally we finish the review and valuation of competitiveness and IC macro dimension frameworks considering NICBS (Nations' Intellectual Capital Benchmarking System) and enhanced NICBS methodologies as the more suitable for the above in-depth mentioned diagnosis. In essence the approach followed in purpose 3 has been a review of scientific literature on competitiveness and IC macro dimension with the exclusive aim of finding out the practical framework that could make it possible an in depth analysis of a nation knowledge based competitiveness foundations.

Originality/Value - The paper is fully original because the in-depth economic reflection on the crisis of Spain is performed using methodologies and frameworks that consider

knowledge and other intangibles as the main foundations of competitiveness, innovation and sustainable economic growth.

Theoretical/Practice implications - The reflections arising from the paper have mainly practical implications and will guide in the decision making process not only savers and investors but also government and institutional authorities.

Keywords - Competitiveness, innovation, intellectual capital, intangibles, knowledge based development, nation.

1. Introduction

During the last fifteen years some fundamental changes have occurred in the world and more specifically in the way the world economy creates wealth.

These changes are summarised by Laurence Prusak (Neef, Dale 1998) as follows:

- A) The globalization of the economy, which is putting terrific pressure on firms for increase adaptability, innovation, and process speed.
- B) The awareness of the value of specialized knowledge, as embedded in organizational processes and routines, in coping with the pressures of globalization.
- C) The awareness of knowledge as the distinct factor of production and the role in the growing book value to marked value ratios within knowledge-based industries.
- D) Cheap networked computing, which is at last giving us a tool for working with and learning from each other.

Since 1998, when Prusak wrote about the changes, an unstoppable progress on multimedia and information and telecommunication technologies has completed the above mentioned four changes.

Reflecting on the content of the changes we arrive to the conclusion that knowledge has become the fundamental factor of wealth creation in the present economy, because there is no sustainable advantage other than what a firm knows, how it can utilize what it knows, and how fast it can learn something new.

As a consequence of such great importance of knowledge as an economic factor a new phrase or expression has become almost commonplace. It is the phrase “knowledge economy” or the equivalent “knowledge-based economy”. There are many definitions of

this phrase or combined concept and two of them have been selected for the relevance in their content. They are the following:

“... one in which the generation and exploitation of knowledge has come to play the predominant part in the creation of wealth. It is not simply about pushing back the frontiers of knowledge; it is also about the most effective use and exploitation of all types of knowledge in all manner of economic activity” (DTI Competitiveness White Paper 1998)(Brinkley, 2008)

“economic success is increasingly based on upon the effective utilisation of intangible assets such as knowledge, skills and innovative potential as the key resource for competitive advantage. The term “knowledge economy” is used to describe this emerging economic structure” (Economic & Social Research Council 2005)(Brinkley, 2008)

The purpose of the paper is double:

First finding out the suitable methodology or framework in order to enable an in-depth diagnosis of a nation’s actual knowledge driven competitiveness foundations, with the aim to aiding in the definition of the possible vision, objectives and lines of action to embrace in order to enable innovation and sustainable economic growth.

Second applying the suitable methodology or framework to the in-depth diagnosis of the Spain case and using the insights given by the in-depth diagnosis for having some light on the future economic development possibilities and on lines of action to be taken in order to foster innovation and sustainable economic growth.

2. Wealth Creation in the Knowledge Economy

Wealth creation in the knowledge economy context is closely linked with the concept of competitiveness. There are many definitions of country competitiveness. Among them one of the most cited is the OCDE official definition that follows:

“The degree to which a country can, under free and fair market conditions, produce goods and services which meet the test of international markets, while simultaneously maintaining and expanding the real incomes of its people over the long term”.(OECD “official” definition 2002)(Garelli, 2002)

At the same time relationships among country competitiveness, wealth creation and knowledge economy are stressed in the following citations:

“Nations themselves do not compete, rather, their enterprises do. There is no doubt that competitive enterprises are the main engines of a country's competitiveness”.

“The role of nations in shaping the environment in which enterprises operate influence their competitiveness”.

“Competition among nations can be seen in the areas of education and know-how. In a modern economy, nations do not rely only on products and services, they also compete with brains. The ability of a nation to develop an excellent education system and to improve knowledge in the labor force through training is vital to competitiveness”. (Garelli 2002)

“It is well understood that sound fiscal and monetary policies, a trusted and efficient legal system, a stable set of democratic institutions, and progress on social conditions contribute greatly to a healthy economy.

I have found that these factors are necessary for economic development, but far from sufficient. These broader conditions provide the opportunity to create wealth but do not themselves create wealth.

Wealth is actually created in the microeconomic level of the economy. Wealth can only be created by firms. The capacity for wealth creation is rooted in the sophistication of the operating practices and strategies of companies, as well as in the quality of the microeconomic business environment in which a nation's companies compete. More than 80 percent of the variation of GDP per capita across countries is accounted for by microeconomic fundamentals. Unless microeconomic capabilities improve, macroeconomic, political, legal, and social reforms will not bear full fruit”. (Porter 2005)

And because wealth can only be created by firms, the following Peter Drucker citations on efficiency and effectiveness will complete the landscape of wealth creation principles in the knowledge economy at nation or country level. They are:

Efficiency is the ability to get things done correctly. Managers who are able to minimize the cost of the resources they use to attain their goals, are acting efficiently.

Effectiveness, on the other hand, is the ability to choose appropriate objectives. An effective manager is one who selects the right things to get done. A manager who selects an inappropriate objective is an ineffective manager. No amount of efficiency can compensate for lack of effectiveness. The manager's need to make the most of opportunities implies that effectiveness rather than efficiency is essential to business. The pertinent question is not how to do things right, but how to find the right things to do, and to concentrate resources and efforts on them. (Drucker, 1967)

The above fundamental citations pave the way for the more systematic description of wealth creation foundations in the knowledge economy that follows:

The advent of the knowledge economy has fundamentally changed the basis of wealth creation in modern social communities and knowledge and other human based intangibles have become the fundamental resources for wealth creation.

The theoretical foundations of wealth creation in the knowledge economy are mainly found at the micro level in the modern strategic management discipline and more specifically in the three well known following perspectives: the resource based view, the dynamic capabilities based view and more recently the knowledge based view.

These theoretical foundations at the micro level have to be complemented at the macro level with recent developments on what is called strategic management of intangibles in cities, regions and nations. These recent developments are based on a complex body of principles and theories, such as institutional and evolutionary economics, cultural and social economics, systems theory, systems and innovation, triple helix, regional science and more recently knowledge based development.

Based on the above mentioned theoretical foundations some basic principles on wealth creation in the knowledge economy context can be deducted (Viedma & Cabrita, 2011). They are the following:

1. A free-market economy with inclusive democratic political institutions is the sine qua non condition for sustainable economic and social development.
2. Wealth or poverty of a specific nation is strongly dependant on the number of competitive or excellent companies that the specific nation has.
3. Government does not create wealth but contributes to facilitate or to hinder wealth creation.

4. An excellent or competitive company is the one that achieves long term extraordinary profits due to the fact that has a business model with sustainable competitive advantages.
5. In the knowledge economy sustainable competitive advantages are mainly based on intangibles. Consequently strategic management of intangibles or intellectual capital becomes a fundamental task.
6. In order to achieve business excellence strategy perspective is the key one.
7. Business excellence is always due to good strategy formulation and superior strategy implementation.
8. Good strategy formulation and superior strategy implementation is always a human task and strongly depends on the quality of the top management team and the key professional people.
9. In a continuous changing environment business models quickly get out-of-date and as a consequence of that, innovation in business models¹ becomes an urgent need.
10. In any company the essential activity to perform is always innovation in the business model so it can be converted in an excellent or competitive business model.
11. Companies alone do not create wealth. They need the collaboration of other companies, universities and research institutes, financial institutions, government and other organisations and institutions and specially the existing ones in the cluster, region or nation where the company is located. In other words they need to be active part of a territorial open innovation system and of, what some authors like to call, knowledge based ecologies.
12. When in principle 5 we state that strategic management of intangibles or intellectual capital is a fundamental task for gaining and sustaining competitive advantages we refer mainly to companies but strategic management of intangibles needs also to be applied to the government of clusters, regions or nations in order to build territorial open innovation systems or knowledge based ecologies.

¹ We consider, in this particular context, that innovation in business models, encompass all types of innovations, including products, services, processes, technical, management, etc.

Following the criteria of the above principles this paper is dealing with wealth creation at the macro level in the knowledge economy context and consequently mainly considers knowledge based ecologies that have been mentioned in principle 11. Because that reason some more details are given on these ecologies.

As it has been said before in the knowledge economy firms alone are unable to create wealth. They need to be part of a suitable micro cluster, cluster, region or nation where innovation is considered a key competitiveness factor and where knowledge and learning capabilities (i.e. technical and learning skills and capabilities, knowledge infrastructure, networking capacity, values systems and attitudes) are the main ingredients that conduce to innovation systems and innovation processes. That means that governments should play a role, not only in providing macroeconomic stability, adequate incentives, and the technology and financial infrastructure for firms to compete, but also in promoting the types of linkages (across the triple helix of industry, government and universities) and institutions and a collaborative trust-based innovative culture, that are the sine qua non conditions for a sustainable economic development.

3. Finding out methodologies and frameworks for an in-depth diagnosis of a nation's knowledge driven competitiveness foundations.

Trying to find out methodologies and frameworks for an in-depth diagnosis of a nation's knowledge driven competitiveness foundations, we quickly realize that World Competitiveness Report from World Economic Forum (WEF) and World Competitiveness Yearbook from International Institute for Management Development (IMD) are the two most relevant considering their historic performance and scientific approach. The analysis of alternative methodologies and frameworks other than the two mentioned above has not been made in this paper. More information dealing with this analysis can be found in RICBS (Viedma&Martins 2006). The criteria for selecting these methodologies have two support points. The first point concerns the scientific foundation and the second point refers to the systematic information on competitiveness of developed economies, which over a long period of time these methodologies have provided.

In section 3.1 we will note the main competitiveness methodologies and frameworks.

Next in section 3.2 we will describe the IC community frameworks or in other words the IC community contributions to enable an in-depth diagnosis of a nation's knowledge driven competitiveness foundations.

Subsequently in section 3.3 we will introduce NICBS as the methodology that synthesizes and embodies the micro and macro principles of wealth creation formulated and described in section 2.

Finally in section 3.4 we integrate the WEF competitiveness framework into the NICBS framework in order to produce the Enhanced NICBS framework, that later on will be used for reflecting on the case of Spain.

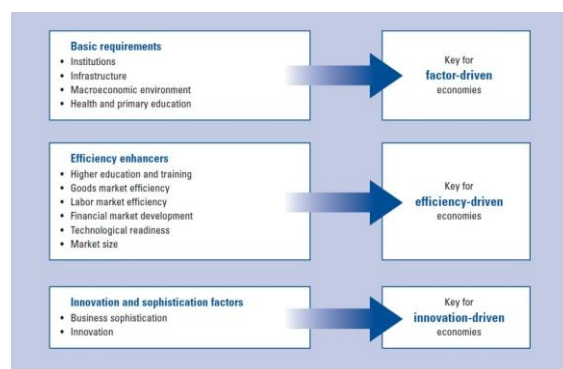

3.1 Competitiveness frameworks.

We have stated in section 3 that the two main methodologies and frameworks were the following:

World Competitiveness Report from World Economic Forum (WEF) (Schwab, *et al*, 2011) and World Competitiveness Yearbook from International Institute for Management Development (IMD 2010).

There are other methodologies such as the European Innovation Scoreboard (EIS2011) and K4D (K4D2011) World Bank that cover specific aspects and consequently are less relevant considering the specific purpose of the paper.

Following in figures 1 and 2 we illustrate the main factors or components of the two above mentioned methodologies.

3.2 IC Community frameworks

Considering that the mode of wealth creation has shifted from a mass-production economy to an economy of knowledge, where the key drivers of growth are intangible (Romer 1986; Drucker 1993), national level IC has recently emerged as a new topic of research, where the focus is on understanding intangible drivers of national wealth creation.

The IC community efforts have crystallized in a set of IC models at nation level. Some of these models are noted in figure 3 that follows.

Country	Author/year	STRUCTURE					
European Union	Bounfour, 2003	Resources, processes and outputs.					
	Andriessen y Stam, 2004	Human, structural and relational.					
Spain	Martins and Viedma, 2005	Region's Competitiveness Intellectual Capital Platform and Microcluster's Competitiveness Intellectual Capital frame.					
OECD	Hervás and Dalmau, 2007	Human and educational, technological infrastructure, linkages, firm's strategies, business policy, social block, market block, economic performance.

Figure 3. IC Community contributions. Source: Hervás-Oliver, J.L.; Rojas,R.; Martins,B.; Cervelló-Royo,R. (2011) "The overlapping of national IC and innovation systems", *Journal of Intellectual Capital*, Vol. 12 Iss: 1, 111 – 131

A more systematic approach of IC community contributions can be found in a new recently issued book on National Intellectual Capital (Yeh-Yun Lin.C, Edvinsson Leif, 2011), where National Intellectual Capital Models proposed by individual researchers are listed. An excerpt of this list with some key features is given in figure 4.

Initiatives	General Basic Model	Structure	Indicators
Sweden (Rembe, 1999)	Navigator Skandia	- Human Capital - Market Capital - Process Capital - Renewal Capital	Financial indicators Descriptive indicators
State of Israel (Edna Pasher & Associated, 1999)	Navigator Skandia	- Human Capital - Market Capital - Process Capital - Renewal & Development Capital	Financial indicators

Arab Region (Bontis, 2002)	Navigator Skandia	- Financial wealth - Human Capital - Market Capital - Process Capital - Renewal Capital	Descriptive indicators. Intangibles indicators. Financial indicators.
Malasya (Bontis, 2002)	Navigator Skandia	- Financial wealth - Human Capital - Market Capital - Process Capital - Renewal Capital	Descriptive indicators. Intangibles indicators. Financial indicators.

Figure 4. IC Comunity contributions from Yeh-Yun Lin.C and Edvinsson Leif, 2011
Source: Revised from Pomedá et al.(2002)

In addition C.Y.-Y.Lin and L. Edvinsson have proposed a new National Intellectual Capital Measurement Model that includes a carefully selection and validation of indicators. In figure 5 we include the variables in each type of capital of their model.

Variables included in National Intellectual Capital Model

Human capital index

1. Skilled labor a
2. Employee training a
3. Literacy rate
4. Higher education enrollment
5. Pupil-teacher ratio
6. Internet subscribers
7. Public expenditure on education

Market capital index

1. Corporate tax a
2. Cross-border venture a
3. Culture openness a
4. Globalization a
5. Transparency a
6. Image of country a
7. Exports and imports of services

Process capital index

1. Business competition environment a
2. Government efficiency
3. Intellectual property right protection a
4. Capital availability
5. Computers in use per capita enterprises
6. Convenience of establishing new firms a
7. Mobile phone subscribers

Renewal capital index

1. Business R&D spending
2. Basic research a
3. R&D spending/GDP
4. R&D researchers a
5. Cooperation universities and enterprises
6. Scientific articles a
7. Patents per capita (USPTO þ EPO)

Source: Yen-Yun Lin, C. and Edvinsson, L. (2008), "National intellectual capital: comparison of the Nordic countries", *Journal of Intellectual Capital*, Vol.9 No.4, pp.529-530.

Figure 5. The variables in each type of capital of C.Y.-Y.Lin and L. Edvinsson' model.

Finally we would like to stress that some researchers are discussing the IC community contributions. In that sense they are arguing:

National level IC has recently emerged as a new topic of research, where the focus is on understanding intangible drivers of national wealth creation. However, given that reporting and valuation systems for national competitiveness already exist, why is an IC perspective needed? (Stahle and Poyhonen 2005)

The IC perspective should re-focus to return to its original roots, and to concentrate on knowledge-creation and innovation. (Stahle and Poyhonen 2005)

3.3 NICBS framework.

In this section we describe the highlights of NICBS methodology and framework. NICBS is a methodology that synthesizes and embodies the micro and macro principles of wealth creation formulated and described in section 2. Some excerpts of the main features of NICBS (Viedma & Martins, 2006) are given as follows:

"NICBS was primarily conceived as a *learning strategy tool* to help nations, and the micro clusters within them, make the transition (from S_n to S_{n+1} in Fig.6) to more competitive knowledge economies by:

- 1) Enabling an *in-depth diagnosis* of the nation's actual knowledge-driven competitiveness foundations.
 - What are the resources, competencies, traditions, patterns of behaviour, etc. that act as path-dependencies in the nation's way to growth?

2) Aiding in the definition of the *possible* vision, objectives and lines of action to embrace sustainable economic growth.

- What is the model of excellence that we want for the nation?
- What competencies, values and attitudes should we promote to enable innovation and sustainable growth?

3) Developing *awareness* of a nation's potential risks and opportunities.

- How does the nation cope with change?

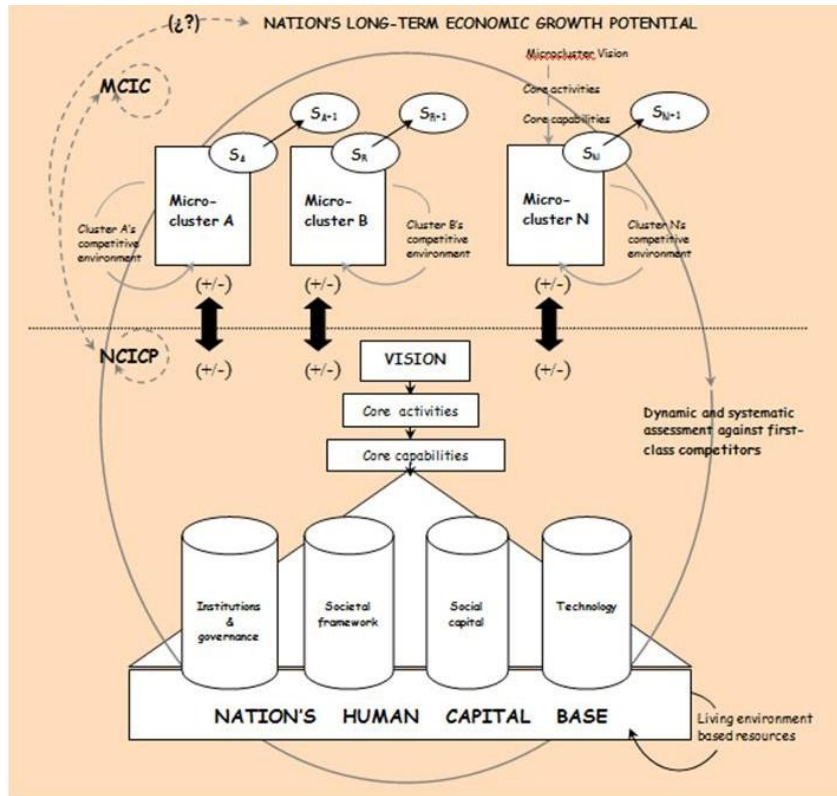

Specifically, the first two points are basically attained through disclosure skills and *competencies*; social and legal frameworks; technology upgrade and use; market access and openness; the quality of primary education, universities and research centres; industry-based collaboration, etc. for both the nation as a whole and each of the core microclusters. The third point, to which we assign the greatest importance, is the result of a dynamic and systematic assessment of the nation's innovative capacity, in the face of first-class competitors, and a process of cross-fertilised analysis. Moreover, carrying out a rigorous diagnosis (point 1) is an essential step before embarking on the definition of the vision and the objectives (point 2).

Figure 6 depicts the NICBS's main constituents and linkages, which are subsequently explained.

The general structure of the NICBS is grounded in regional innovation systems theory (Andersson and Karlsson, 2002; Carlsson et al., 2002; Enright and Roberts, 2001; Cooke and Schienstock, 2000; Cooke et al., 1997) and more specifically on the Furman et al. (2002) model for assessing a nation's innovative capacity and Viedma's (2003) Cities' Intellectual Capital Benchmarking System (CICBS), chiefly in relation to the nation's microclusters' capacity for competitiveness. It is made up of two sub-models and the linkages between them, as well as a set of indicators and extensive questionnaires to operationalise them. The nation's competitiveness intellectual capital platform (hereinafter NCICP) represents the bundle of core resources and competencies (capabilities, when tied to the vision and objectives) that are bound together by core activities. In conjunction with the norms, guides and principles set by public and private institutions (*institutions and national governance* building block); the technological skills and capabilities (*technology* block); the environmental quality of life, as determined by public services, cost of living, and other territorial endowments (*living-environment-*

based resources block); and an educated, skilled and values-nurtured human broad base with the aim of creating, sharing and using knowledge (*human capital* and *social capital* blocks), these core resources and competencies condition economic actors' patterns of behaviour, shape the nation's culture, and determine the extent to which the nation as a whole is capable of supporting and fostering an innovative and competitive productive system as displayed by the microclusters. In essence, the NCICP represents the intricacies of resources and relationships that, *assuming* macroeconomic stability (*economy performance* block), can either boost or hinder microclusters' wealth creation capacity.

However, to gain a comprehensive view of the nation's capacity to grow, we must consider the micro clusters' ecology of value chains and supportive business environment—as that is where an economy's real possibilities for growth reside—and also the quality and density of information and knowledge exchanges between the two subsystems, which is what the nation's microclusters' competitiveness intellectual capital frame (MCICF) aims for: to unveil the microeconomic environment and capacity for innovation at each of the nation's core micro clusters. The MCICF builds mainly on Porter's (1990, 1998) cluster-based theory of competition and Viedma's (2003) methodology for assessing micro clusters' core competencies. Finally, the *linkages* between the national competitiveness platform and the micro clusters account for the strength of the system as a whole. It is the density, quality and dynamism of these exchanges that grants the system the mechanisms for self-renewal and the ability to generate knowledge-driven ideas that enable long-term economic growth (see thick black arrows in Figure 6).”

Figure 6. NICBS's main components and linkages.

3.4 Integrating WEF competitiveness framework in the NICBS framework = Enhanced NICBS.

Section 3.3 has supported NICBS as the most complete methodology for an in-depth diagnosis of a nation's knowledge driven competitiveness foundations. Nevertheless and because systematic information on the indicators and factors of the different building blocks that integrate the NCICP is not available for the specific cases of Spain we considered that an imaginative solution was needed in order to make it possible an in depth diagnosis of Spain knowledge driven competitiveness foundations.

The imaginative solution comes from integrating WEF competitiveness framework in the NICBS framework or more precisely from replacing in the NICBS framework the

NCICP platform by the WEF competitiveness framework. We will call the new generated framework Enhanced NICBS and its structure is shown in figure 7.

The enhanced NICBS framework essentially improves the WEF competitiveness framework with two fundamental constructs :

The Humans Capital Base and the Microclusters' Competitiveness Intellectual Capital Frame (MCICF).

The Human Capital Base refers to what people know, what they do and what they can do. Human Capital Base it's about people Knowledge and current economic activities. What they can do in the future is strongly dependent on what they know and specially what they are doing now.

The Microclusters' Competitiveness Intellectual Capital Frame (MCICF) refers to main economic activities where people are working and are developed in the so-called clusters and microclusters'. Knowing the core activities, core competences and core capabilities on the main firms in each particular microcluster as well as the clusters' competitive environment, give as light on the nation's wealth creation potential. Special considerations deserve R+D activities because are central to the generation of new knowledge.

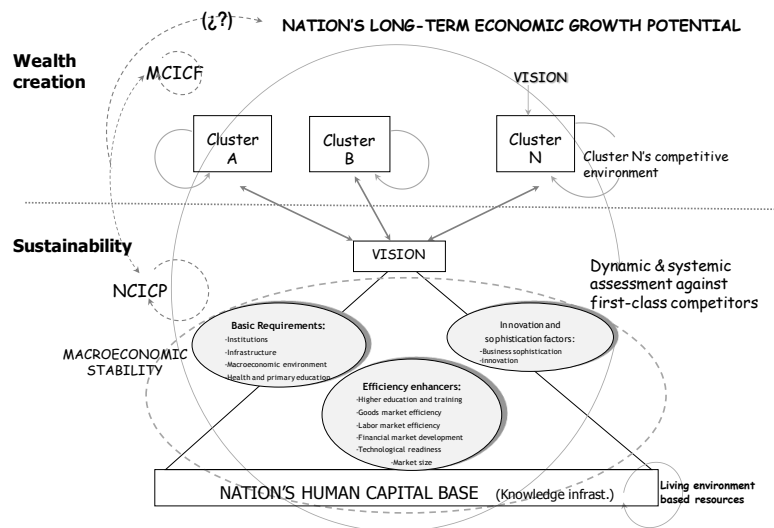

Figure 7. Enhanced NICBS: Main Structure & Key Elements

4. Using enhanced NICBS framework for reflections on the case of Spain.

The NICBS framework give us the possibility for an in depth diagnosis of a nation's knowledge driven competitive foundations.

In sections 4.1 and 4.2 some of the main features corresponding to the case of Spain are described.

4.1 Reflections on the case of Spain

Reflections on the case of Spain are mainly taken from 2.1: Country/Economy Profiles of the Global Competitiveness Report 2013-2014 (Schwab, 2013). Figures 8 and 9 show the details of Spain's Global Competitiveness Index and The most problematic factors for doing business.

Figure 8. Spain. Global Competitiveness Index.

Note: From the list of factors above, respondents were asked to select the five most problematic for doing business in their country and to rank them between 1 (most problematic) and 5. The bars in the figure show the responses weighted according to their rankings.

Figure 9. Spain. The most problematic factors for doing business.

Some comments on the content of both figures are given next:

“Despite the current difficult conditions, Spain goes up one notch in the rankings to 35th place.

The country continues to leverage its traditional competitiveness strengths in terms of a world-class transport infrastructure (6th), a good use of ICTs (23rd), and—despite the high unemployment rate—a large and skilled labor force, thanks to one of the highest tertiary education enrollment rates in the world (8th). Moreover, the country has started to address some of its most pressing challenges. In the past year, Spain undertook sharp public budget cuts that will help improve its still weak macroeconomic situation; it also implemented a series of structural reforms to improve the functioning of its goods, labor, and financial markets. The liberalization of certain services, the implementation of a labor market reform to mitigate the rigidities of a dual labor market, and the restructuring of the banking system are all measures aimed at improving the efficiency in the allocation of resources, whose full effects are likely to become more visible in the medium term. As a result of these and other measures at the European level, the country has obtained access to international financing markets at a more affordable cost than it had at the time the previous edition of this Report was released. However, this situation has not translated in an improvement in access to financing for local firms— which still suffer from an important credit crunch—to upgrade or transform their production facilities. Access to financing is regarded as the most problematic factor for doing business, and the country ranks very low in terms of the ease of accessing loans (138th) or other sources of financing, either through equity markets (101th) or venture capital (105th). In addition, the reduction of both public and private budgets for research and innovation could hamper the capacity of local firms to innovate (57th) and contribute to the economic transformation of the country. Addressing these weaknesses will be crucial in order to bridge the competitiveness gap with Northern European economies the country continues to suffer”.

The above reflections correspond with NCICP, the lower part of the NICBS model, the one that gives sustainability to the whole system.

The paper does not cover MCICF, the upper part of NICBS where the wealth is essentially created, because there is not systematic and up to date information available

on clusters, microcluster and economic sector. Same way the paper does not cover Nation`s Human Capital Base because there is not systematic and up to date information.

5. Conclusions.

After an introduction on the fundamental changes that have occurred in the world and more specifically in the way the world economy creates wealth, the paper tries, in section 2, to highlight the close relationship between wealth creation and competitiveness and to formulate the principles of wealth creation on the knowledge economy context.

Relying on the principles of wealth creation in the knowledge economy, section 3 tries to find out the suitable methodology or framework in order to enable an in-depth diagnosis of a nation`s actual knowledge driven competitiveness foundations. For achieving this specific purpose a critical review of competitiveness frameworks and IC community frameworks are carried out. Next and as a consequence of the critical review we conclude stating that probably NICBS is the most complete and comprehensive methodology. Nevertheless and for practical purposes we decided in section 3.4 to integrate WEF competitiveness framework into the NICBS framework producing what we call Enhanced NICBS framework.

Finally and in section 4 we use the Enhanced NICBS framework for reflecting on the case of Spain. Nevertheless the reflection is incomplete because the lacks of available information on micro clusters` competitiveness intellectual capital frame (MCICF), where wealth is fundamentally created. Future quality research is needed in this particular issue for achieving better results in the in-depth diagnosis and in Human Capital Base where wealth is fundamentally originated.

The paper tries to contribute in the search for methodologies and frameworks that facilitate at a nation level to an in-depth diagnosis of actual knowledge driven competitive foundations, giving at the same time some light on the future economic development possibilities and on lines of action to be taken in order to foster innovation and sustainable economic growth.

Structured Abstract

Purpose – The aim of this paper is to diagnose the intellectual capital (IC) of Spanish companies so as to provide the basis for guiding the transition from a “brick-based economy” towards a knowledge-based economy. Moreover, the interplay between IC stocks (i.e. static IC), knowledge management (KM, i.e. dynamic IC) and human resource management (HRM) policies and practices will be studied as a key determinant of value creation through innovation.

Design/methodology/approach – Setting out from the contextualization of Spanish economy in the European Union, the relevance of the research will be first justified. A theoretical model proposing the connections between IC stocks, KM practices, HRM policies and practices, and innovation performance will be then presented. Finally, the research model will be tested in a set of 101 Spanish companies using structural equation modelling (SEM) based on partial least squares (PLS). Previous to hypothesis testing, descriptive analyses will be provided that will help to identify the weaknesses and strengths of the companies analysed in terms of IC.

Originality/value –The interplay between IC stocks (i.e. static IC), KM (i.e. dynamic IC) and HRM policies and practices has been clearly neglected in previous research in the IC domain. The research reported in this paper will contribute to fill this gap by providing a comprehensive picture of these relationships vis-à-vis innovation performance.

Practical implications – The results obtained deliver useful guidance to company managers so as to how to boost their companies’ IC and enhance their innovation performance.

Keywords – Intellectual capital, Knowledge management, Human resource management, Innovation, Spain.

Paper type – Academic Research Paper

1 Introduction

As the recent economic crisis shows starkly, poor performance in the science and technology domain goes hand-in-hand with greater difficulties to cope with economic downturns and increasing pressure from emergent economies. In the European Union, all countries that have experienced a cumulative negative GDP evolution during the period 2008-2013 except Ireland are moderate or modest innovators (i.e. countries whose innovation performance is below the average of the European Union), whereas all European innovation leaders and followers (i.e. countries whose innovation performance is above the EU27 average) have experienced a positive growth. In particular, Sweden is the European absolute leader in the innovation domain and the country whose GDP has experienced the highest increase during that period: +26%.

The relevance of knowledge and technology for economic growth has been long considered in the field of Economics (Schumpeter, 1934; Solow, 1957; Augier and Teece, 2005). Technological innovation increases the amount of output achievable for a given quantity of labour and capital (Solow, 1957; Schilling, 2011) and thus boosts economic growth. However, economic history highlights the relevance of not only technological innovation, but also organizational innovation (e.g., introducing new ways of organizing production and distribution) (Fagerberg and Godinho, 2005). The development of mass production in the US and of just-in-time systems in Japan constitute clear examples of extremely relevant organizational innovations that allowed both countries to “catch-up” (i.e. to narrow the gap in productivity and income vis-à-vis leader countries) at different points in history (Fagerberg and Godinho, 2005).

The Innovation Union Scoreboard 2013 shows that Spanish economy is very far from being technology-driven. R&D expenditure in the business sector and non-R&D innovation expenditures are well below the EU27 average (47 and 32 points below, respectively), the same as PCT patents applications and patent revenues from abroad (63 and 88 points below, respectively). In the same vein, employment in knowledge intensive activities and knowledge intensive services exports are also below the EU27 average (13 points and 52 points below, respectively).

With this “brick-based profile” and huge public deficit (10.6% of GDP in 2009), the economic crisis triggered in 2008 has hit Spain dramatically. The cumulative decline in GDP from 2008 to 2013 has been 5.96% (source: INE) and the unemployment rate has risen from 11.3% to 26.4% during the same period. The largest drop in GDP has occurred

in the construction sector, where the decline rate has been 46.04% (and 54.71% in terms of employment). As a result, the weight of this sector in Spanish economy has fallen from 12.47% in 2008 to 7.16% in 2013. The services sector is the only one that shows a slightly positive evolution in GDP (+0.7%), although employment has also been destroyed there (-7.81%). In the case of agriculture and manufacturing, GDP has diminished 3.60% and 3.35%, respectively, and employment has dropped 5.01% and 22.80%, respectively.

In view of this terrible macroeconomic picture, it is clear that Spain has been completely unable so far to substitute employment in low-technology sectors showing lowering demand and/or fierce competition from emerging countries with employment and wealth creation in knowledge intensive ones. Of course, this is a long-term endeavour that requires massive investment in human capital qualification, together with a proactive industrial policy to ensure the transition towards an economy primarily based on knowledge. However, austerity measures implemented to reduce the public deficit risk curtailing capabilities for future development, as they involve important cutbacks in education and research. During the period 2008-2012, public expenditure in education has diminished 8%, whereas public expenditure in R&D has decreased 4.33%.

In this context, and considering that companies constitute the main economic agent to lead a country towards competitiveness and wellbeing, and that even low-technology sectors may be able to generate additional value through unique value propositions (Porter, 2008) based on servitization (Neely, 2008; Baines et al., 2009) and innovation, the aim of this paper is to provide a diagnosis of Spanish firms' intellectual capital (IC), as well as to shed light on the relevance of the latter on value creation (and more particularly on innovation), showing the specific elements that companies should work on to improve performance.

As Subramaniam and Youndt (2005) point out, "it is widely accepted that an organization's capability to innovate is closely related to its intellectual capital" (p. 450). In the case of this paper, the static and dynamic views of IC will be considered (Kianto, 2007; Kianto et al., 2010). Whereas the static approach of IC focuses on knowledge-related stocks controlled by the firm, the dynamic approach focuses on the activities and related behaviour through which IC stocks are managed. As a concept, IC management is very close to knowledge management (KM) (Kianto et al., 2010). Thus, activities and behaviour that allow knowledge to be created, shared, learnt, enhanced, organized and

utilized (i.e. knowledge management practices) (Abell and Oxbrow, 2001) will be studied.

Moreover, considering that knowledge management is intrinsically a human activity (although it could rely heavily on the use of information technology – IT), human resource management (HRM) policies and practices (i.e. policies and practices related to recruiting and selection, training and development, performance evaluation, compensations and job design) will also be considered. Actually, HRM policies and practices, together with organizational culture and organization structure and design constitute organization system-level determinants of organizational behaviour (i.e. what people do in organizations) (Robbins et al., 2010).

In particular, the interplay between the static and dynamic dimensions of IC together with HRM policies and practices and their influence on innovation will be analysed. More precisely, KM practices are suggested to mediate the relationship between HRM policies and IC stocks. In other words, it is believed that the influence of HRM policies and practices on IC stocks takes place mainly by means of triggering KM supportive behaviour that enables knowledge assets to be developed, used and preserved. Moreover, it is suggested that IC stocks mediate the relationship between HRM and KM practices, on the one hand, and innovation performance, on the other hand (i.e. HRM and KM practices are relevant as far as they permit knowledge assets to be developed, used and preserved).

2 Theoretical background

Although several studies have analysed the influence of IC stocks on innovation (e.g. Subramaniam and Youndt, 2005; Brookes et al., 2007; Menor et al., 2007; Wu et al., 2007; Wu et al., 2008; Delgado-Verde et al., 2011; Leitner, 2011; Carmona-Lavado et al., 2013; Castro et al., 2013), and of KM (i.e. dynamic IC) on innovation (e.g. Darroch and McNaughton, 2003; Gloet and Terziovski; Darroch, 2005; Ju et al., 2006; Palacios et al., 2009; Vaccaro et al., 2010; Kianto, 2011; Mangiarotti, 2012; Lee et al., 2013), as well of HRM policies and practices on innovation (e.g., Jiménez-Jiménez and Sanz-Valle, 2005; Li et al., 2006; Beugelsdijk, 2008; Saá-Pérez and Díaz-Díaz, 2010; Santangelo and Pini, 2011; Jiang et al., 2012; Yanadori and Cui, 2013; Zhou et al., 2013), there are very few studies that have analysed them together.

Actually, four studies have been found that analyse the interplay between HRM policies and practices and IC stocks vis-à-vis innovation (López-Cabrales et al., 2009; De Winne and Sels, 2010; Cabello-Medina et al., 2011; Wang and Chen, 2013) and one study that analyses the interplay between HRM policies and practices and KM with regard to innovation (Camelo-Ordaz et al., 2011).

In their study of companies from most innovative Spanish industries, López-Cabrales et al. (2009) found that the uniqueness of employees' knowledge (i.e. a variant of human capital) mediated the relationship between collaborative HRM practices and innovation activity. Meanwhile, De Winne and Sels (2010) found that both human capital and HRM were important determinants of innovation in small start-ups aiming at an innovation strategy. Later on, following previous research from López-Cabrales et al. (2009), Cabello-Medina and colleagues (2010) found that human capital uniqueness mediated the relationship between HRM practices such as empowerment and employee selection based on learning potential and interpersonal abilities, and firm innovativeness. Finally, Wang and Chen (2013) found that organizational and social capital in Chinese firms mediated the relationship between HRM (in particular, high-performance work systems) and incremental innovative capability, whereas social capital was the only mediator in the case of radical innovation.

As far as HRM and KM are concerned, Camelo-Ordaz et al. (2011) found that HRM practices contributed to knowledge creation and innovation through the generation of the affective commitment necessary for employees to be willing to share their knowledge.

This scarcity and specificity of studies raises the need for further research that provide a more comprehensive picture of the relationships between HRM policies and practices, KM, IC stocks and innovation performance, both in terms of the simultaneous inclusion of the three antecedents of innovation performance, and in terms of the array of HRM and KM practices considered and the variety of IC stocks included. This paper aims to fill this gap by addressing both challenges simultaneously.

Hereafter, a detailed view on IC stocks (i.e. static IC), KM practices (i.e. dynamic IC) and HRM policies and practices will be provided.

2.1 Intellectual capital stocks (static IC)

As was said in the Introduction section, IC stocks represent the static dimension of IC. In most studies IC resources have been split up into three main components: human

capital, structural capital and relational capital, based on a sufficiently established categorization (e.g. Edvinsson and Malone, 1997; Bontis, 1998). Nevertheless, the conceptualization of these categories differs depending on the IC perspective adopted: limited to knowledge or holistic (Sáenz and Aramburu, 2011).

In the first case, IC is considered to be the sum of all knowledge firms utilize for competitive advantage. This is the point of view of authors such as Stewart (1997), Nahapiet and Ghoshal (1998), Sullivan (1998), and Youndt et al. (2004). In the holistic perspective, however, IC would be conceptualized as the sum of all intangible resources companies use to compete successfully, not only knowledge. This would include employee loyalty, motivation and flexibility; leadership and management style, organizational culture and incentive schemes; brand image and corporate reputation, to name but a few (Marr, 2006). Authors such as Roos et al. (1997), Bontis (1999) and Marr (2006) are closer to this second perspective.

In both cases (knowledge and holistic perspective), human resources (i.e. human capital) are thought of as the living and thinking part of intangible resources (Marr, 2006). They do not appear on corporate balance sheets because people are not owned: they offer their services under employment contracts (Grant, 2008). In the knowledge perspective, human capital would include the knowledge, skills and abilities residing with and utilized by individuals (Schultz, 1961; Youndt et al., 2004), whereas in the holistic one additional elements such as people attitudes, motivation and commitment would also be included (Marr, 2006; Bueno et al., 2011).

Differences between the knowledge and holistic perspective are deeper when it comes to conceptualizing structural capital and relational capital. In the case of the knowledge perspective, the type of knowledge considered lies at the basis of the distinction made between organizational (i.e. structural) and social (i.e. relational) capital. The former refers to the institutionalized knowledge and codified experience (i.e. “explicit knowledge”) residing within and utilized through databases, patents, manuals, structures, systems and processes (Youndt et al., 2004), whereas social capital is the knowledge embedded within, available through and utilized by interactions among individuals and their networks of interrelationships (Nahapiet and Ghoshal, 1998). Of course, this second definition refers to “tacit knowledge” and it is important to note that the networks and interrelationships mentioned could be both internal and external to the firm.

In the case of the holistic perspective of IC, the location of knowledge and other intangible resources lies at the basis of the distinction made between structural and relational capital. In accordance with this, structural capital refers to the knowledge and other intangible resources that stay within the company when the employees have left (Bueno et al., 2011). In other words, it encompasses the organization's essential operating processes, the way it is structured, its information flows and databases, its leadership and management style, its culture and incentive schemes, as well as intellectual property rights (Marr, 2006). Conversely, relational capital refers to all resources linked to the external relationships of the firm with customers, suppliers or R&D partners (Meritum Project, 2002). Those resources could be related to knowledge, but they could refer to other intangible assets as well, such as brand image, customer satisfaction, customer loyalty, negotiating power, etc.

In the case of this paper, the knowledge perspective of IC will be adopted and human, structural and relational capital will be conceptualized accordingly. However, in the case of human capital an exception will be made and employees' motivation will also be included. The reason for that is very simple: employees' knowledge, abilities and skills are useless unless they are motivated to use them.

Beyond traditional IC components, recent studies suggest the possibility of adding new elements. Thus, we expand the focus further on renewal capital and entrepreneurial capital (Aramburu et al., 2014). "Renewal capital" refers to the capability of organizations to continuously renew its activities through learning, acquiring new skills and creatively changing its operations (see e.g. Kianto et al., 2010). "Entrepreneurial capital" can be conceptualized as the capability to develop activities of an entrepreneurial nature within organizations (see Erikson, 2002; Bueno et al, 2011). Both capabilities (as any other organizational capability) could be seen as manifestations of organizational knowledge (Grant, 2008) and therefore could be considered as part of IC.

While both concepts – renewal capital and entrepreneurial capital – have been coined earlier, they have been used very infrequently in IC research (Aramburu et al., 2014). In this study, we pursue to conceptualize and measure both of them within the broader IC framework.

2.2 Knowledge management practices (dynamic IC)

While the static approach to IC concentrates on evaluating the stocks of knowledge-related resources, the dynamic approach to IC focuses on activities (Kianto et al., 2010) that allow knowledge to be created, shared, learnt, enhanced, organized and utilized (Abell and Oxbrow, 2001). As Teece (2007, 2009) points out, the ownership of difficult-to-replicate (knowledge) assets is not enough. Purposive practices which can be harnessed to continuously create, extend, upgrade, protect and keep relevant the enterprise's unique asset base are also needed.

Unlike KM processes (which naturally exist in organizations irrespectively of managerial efforts – Demarest, 1997; Husted and Michailova, 2002; Andreeva and Kianto, 2012), KM practices refer to the aspects of the organization that are manipulable and controllable by conscious and intentional management activities (Andreeva and Kianto, 2012). In the case of this paper, the following KM practices will be considered: strategic KM, knowledge protection, learning mechanisms and IT-based knowledge search, communication, analysis and collection.

Strategic KM involves identifying key knowledge resources to be acquired or developed and establishing the right mechanisms to that end. It also involves knowledge exploitation decisions and other knowledge-related choices. Moreover, Strategic KM requires that company strategy be formulated and updated based on company knowledge and competences (Grant, 2008).

Traditionally, economics and strategy have emphasized the relevance of protecting newly generated knowledge (i.e. innovation) or strategically relevant knowledge in order to maximize the possibilities of capturing the rents derived from it (Schilling, 2011). For that purpose, formal (e.g. patents and copyrights) and informal (e.g. secrecy) mechanisms could be used.

Learning mechanisms differ depending on the nature of the knowledge to be learned (tacit or explicit). When knowledge is personal, context-specific and, therefore, hard to formalize (i.e. tacit knowledge; Nonaka and Takeuchi, 1995), learning mechanisms based on social interaction between individuals are the key. This is often compared to apprentice training. In this case, learning involves self-observation, reflection and immersion in the routines of the master (Von Krogh, 2011). However, when knowledge is transmittable in formal, systematic language (i.e. when it is explicit knowledge; Nonaka and Takeuchi, 1995) it can be easily collected, stored and retrieved. In such situation,

mechanisms based on the collection and diffusion of best practice and lessons learned could be especially relevant.

In this vein, purposive use of IT-based mechanisms for knowledge search, communication, analysis and collection is undoubtedly an important tool managers have at their disposal to increase organizational knowledge stocks. The application of IT can create an infrastructure and environment that contribute to KM by augmenting and supporting a multitude of knowledge processes (Andreeva and Kianto, 2012). Alavi and Leidner (2001) described four major contributions of IT to KM (Andreeva and Kianto, 2012). First, IT supports the creation of new knowledge by combining different sources and by facilitating “just-in-time learning” through decreasing the time delay of knowledge sharing between organizational members. Second, it facilitates the storage and retrieval of organizational memory, as it acts as a platform for valuable knowledge that has been gained by the organization. Third, it assists knowledge sharing by providing more communication channels in the organization. Fourth, IT also supports the usage of knowledge through its integration into organizational routines.

2.3 HRM policies and practices

HRM policies and practices (i.e. policies and practices related to recruiting and selection, training and development, performance evaluation, compensation and job design) constitute important determinants of organizational behaviour and organizational effectiveness (see for instance Becker and Gerhart, 1996; Delaney and Huselid, 1996; Gelade and Ivery, 2003; Bowen and Ostroff, 2004; Robbins et al., 2010). For KM to be promoted such policies and practices should be adapted accordingly.

Recruitment “includes those practices and activities carried out by the organization with the primary purpose of identifying and attracting potential employees” (Breaugh and Starke, 200: 45), while selection refers to “the task of predicting which applicant will be the most successful in meeting the demands of the job, and/or be the best fit with the work group and culture of the organization” (Torrington et al., 2011). Employees who have the required knowledge and skills should be hired (Andreeva and Kianto, 2012), but for KM to be enhanced, special attention to learning and development abilities should be paid, together to collaborative skills.

As Robbins et al., (2010) point out competent employees don’t remain competent for ever. Skills deteriorate and can become obsolete. Thus, new skills need to be learned,

which calls for training and development. Recently there has been a shift from identifying “training needs” to identifying “learning needs” (Torrington et al., 2011) which implies that development is owned by the learner with the need rather than by the trainer seeking to satisfy the need. This move also involves changes in who identifies the needs and how those needs are met. Today it is suggested that needs are best developed by a partnership between the individual and the organization, and that the methods for meeting those needs are not limited only to formal courses, but to a wide range of on-the-job development methods and distance e-learning approaches (Torrington et al., 2011). As a consequence, “self-development” becomes an important issue, which means individuals having ownership of and taking responsibility for their own development.

Performance evaluation could be an extremely relevant mechanism for guiding behaviour. It should be seen as an integrating part of the performance management system of the firm, whose aim is to direct, monitor, motivate and refine employees’ performance (Clark, 2005). For KM processes to be enhanced (i.e. knowledge sharing, knowledge creation and knowledge application) performance criteria related to them should be included.

Compensation policies could also promote KM (Andreeva and Kianto, 2012). Both tangible (e.g. bonuses or one-off rewards) and intangible incentives (e.g. status and recognition) could be used to motivate employees to share, create and apply knowledge (Scarbrough, 2003; Andreeva and Kianto, 2012).

Finally, job design is another element that could foster or on the contrary hinder desired behaviour. It refers to “the process of putting together a range of tasks, duties and responsibilities to create a composite for individuals to undertake in their work and to regard as their own” (Torrington et al., 2011: 85). One of the main contributions to job design was Hackman and Oldham’s (1976) Job Characteristics Model (JCM). This model specifies certain aspects which must be designed into a job in order to ensure the positive outcomes of meaningful work, responsibility and knowledge of the actual results of the work activity (Parker et al., 2001; Torrington et al., 2011). There were five “core job characteristics” identified by Hackman and Oldham in their model: skill variety, task identity, task significance, autonomy and feedback. Later on, with the advent of the knowledge era and the “knowledge worker”, additional extensions to this model have been proposed. Although job autonomy is expected to remain a key issue for knowledge workers (Janz et al., 1997), enabling social contact and knowledge and skill acquisition at

work are seen as two important features to be borne in mind in job design (Parker et al., 2001).

2.3 Hypothesis formulation

According to what has been explained in the previous sections, HRM policies and practices are seen as key drivers of KM, which in turn is considered the foundation for knowledge to be created, shared, learnt, enhanced, organised and utilized (Abell and Oxbrow, 2001). In other words, KM allows the IC stocks of a company to be reinforced and augmented. Thus, considering this cascading set of relationships, the following hypothesis has been formulated:

H1: KM positively mediates the relationship between HRM policies and practices and IC stocks (i.e. the influence of HRM policies and practices on IC stocks takes place mainly through the positive influence they exert on KM).

On the other hand, IC (i.e. the company knowledge base) is the foundation for innovation to occur. As Nonaka and Takeuchi (1995) point out, innovation involves the creation of new knowledge, and new knowledge emerges from the combination of existing knowledge in novel ways (Eisenhardt and Martin, 2000) or from its application to a new context.

According to Fleming and Sorenson (2001, 2004), innovation involves often a “recombinant search”. Thus, innovation comes either from combining technological components (i.e. “any fundamental bits of knowledge or matter that inventors may use to build inventions” – Fleming and Sorenson, 2004: 910) in a novel manner (Gilfillan, 1935; Schumpeter, 1939; Usher, 1954; Nelson and Winter, 1982; Basalla, 1988; Weitzman, 1996) or by reconfiguring existing combinations (Henderson and Clark, 1990). In other words, a recombinant search involves combining specialized, differentiated, yet complementary knowledge (Tell, 2011). Such recombinations may result in completely new products and services, or in the application of existing products to new markets and uses (Fleming and Sorenson, 2004; Ahuja and Novelly, 2011).

Hence, considering this line of thought and the fact that HRM policies and practices and KM have been hypothesized to influence the company’s IC stocks, the following hypothesis has been formulated:

H2: IC stocks positively mediate the relationship between HRM policies and practices and KM on the one hand, and innovation performance on the other hand (i.e. the influence of HRM policies and practices and KM on innovation performance takes place mainly through the influence they exert on IC stocks).

Figure 1 summarizes the research model that emerges from these two research hypotheses.

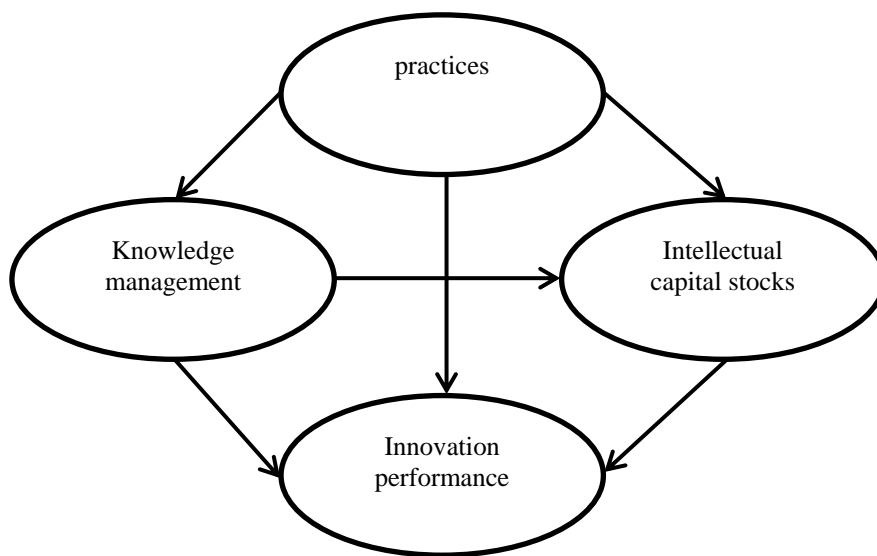

Figure 1 Research model

Although several types of HRM policies and practices will be considered, as well as different types of KM practices and IC stocks, only the results of the aggregated model will be presented (i.e. HRM policies and practices, KM and IC stocks will be modeled as second order molar constructs whose indicators will be the latent variable scores of the first order constructs considered in the research). Nevertheless, the aggregated model will allow the relevance of each first order construct to be tested when it comes to maximizing the amount of variance explained of the endogenous constructs.

3 Research methods

Research reported in this paper is part of an international project on intellectual capital and value creation led by Lappeenranta University of Technology (Finland). A common questionnaire was designed in order to gather information about the variables under study and was administered in each of the countries participating in the research. Here an exploitation of Spanish results is presented.

3.1 Sample and data collection

In the case of Spain (as in the other countries participating in the project), the target population was made up Spanish companies with at least 100 employees. To identify such companies, the SABI database was utilized. 961 firms satisfying the established criteria, together with financial and economic data availability were identified. Due to budget constraints, a junior researcher was appointed to do the data collection. 442 companies were contacted to ask their participation in the research, trying to preserve industry and size proportions in the initial population. Confidentiality was emphasized and a summary of the results was promised to the respondents. Out of the 442 companies contacted 101 responses were obtained, representing a response rate of 22.8 per cent (101/442). The questionnaires were administered through phone interviews, although some companies preferred to receive the questionnaire form by email and send their answers by means of the same mechanism. Most of the respondents held positions such as a HR director or manager (62.4 %), other director or manager (20.8 %), expert or clerical work (7.9%) or managing director (6,9 %), indicating their expertise and key position regarding the issues of intellectual capital and performance.

The sample size obtained is large enough to carry out a statistical study based on the PLS structural equation modeling approach (Chin and Frye, 2003). According to the complexity level of the model to be tested, the minimum sample size required was calculated, and this was made up of 60 firms.

3.2 Measures

The research model is made up of 15 first-order constructs or latent variables. Except innovation performance (the final endogenous construct of the research), the other latent variables are grouped into 3 sets: IC stocks, KM and HRM policies and practices. Human capital, structural capital, internal relational capital, external relational capital,

entrepreneurial capital and renewal capital form IC stocks (i.e. static IC), whereas strategic KM, knowledge protection, learning and IT-based KM form KM practices (i.e. dynamic IC). Finally, recruiting and selection, training and development, performance assessment, compensation and job design form HRM policies and practices.

These three second-order constructs have been modelled as molar constructs, as changes in one of the components making up each of them are not expected to be necessarily followed by changes in the rest of the components of the same construct. However, innovation performance and all first-order constructs except human capital have been modelled as reflective constructs, this meaning that the specific items making up each of them are expected to be highly correlated and be the representation of the same latent phenomenon. In the case of human capital, however, employees' competence and motivation are not necessarily correlated and thus it has been modelled as a formative construct.

Innovation performance measures have been adapted from Weerawardena (2003) and IC stocks have been measured using scales mostly developed for the project. The internal relational capital and human capital scales got inspiration from Yang and Lin (2009) and the scale for entrepreneurial capital is based on work by Hughes and Morgan (2007) on entrepreneurial orientation, adapted here to the specific context of IC.

In the case of KM, strategic management of knowledge has been measured combining indicators from different sources. Indicators 1 and 3 have been adapted from McKeen et al. (2005), whereas indicators 2 and 4 were inspired by Kianto et al. (2013) and indicator 5 was adapted from Boumarafi and Jabnoun (2008). Knowledge protection measures have been inspired by previous work by Levin et al. (1987), Cohen et al. (2000), Hurmelinna-Laukkanen and Puumalainen (2007), Hurmelinna-Laukkanen and Ritala (2012) and Lawson et al. (2012). The learning scale has been specifically developed for the project, with one indicator (the first one) taken from Becerra-Fernández and Sabherwal (2001). Finally, the IT-based KM scale got inspiration from previous work by Handzic (2011) (indicators 1 and 2), Negash (2004) and Pittimäki (2007) (indicators 5 and 6). Indicators 3 and 4 have been specifically developed for the project.

As far as HRM policies and practices are concerned, the indicators used for recruiting and selection have been inspired by Yang and Linb (2009) and by Cabello-Medina et al. (2009), whereas indicators for training and development have been specifically developed for the research. On the other hand, indicators for performance

assessment and compensation got inspiration from previous work by Andreeva and Kianto (2012), whereas the job design scale has been specifically created for the project.

Table 7 in the Appendix provides complete information about specific indicators used in each construct. All the items have been measured by means of 1-to-5 Likert scales.

3.3 Statistical analysis

Descriptive analyses have been first carried out in order to diagnose the IC stocks, KM practices and HRM policies and practices of Spanish companies in the sample. For that purpose, variables synthesizing each of the scales have been created by calculating the average of the items making up each of the constructs. T-tests have been then carried out in order to identify any significant difference of means between large (over 250 employees) and medium-sized (between 100 and 250 employees) companies, and between manufacturing and service companies.

Structural equation modeling (SEM) based on partial least squares (PLS) has been then applied in order to test the hypotheses put forward in the research. PLS is a common methodological approach used in management research (Bontis et al., 2007; Bontis and Serenko, 2007). It works in two stages:

- The assessment of the reliability and validity of the measurement model.
- The assessment of the structural model.

This sequence ensures that the constructs' measures are valid and reliable before attempting to draw conclusions regarding relationships among constructs (Barclay *et al.*, 1995).

As previously outlined, the research model encompasses several mediation relationships. For these to be checked, the following conditions must hold (Baron and Kenny, 1986):

- First, independent variables must have a significant effect on the dependent ones in the absence of mediators.
- Second, independent variables must affect mediating variables significantly.
- Third, in the full model (the one that encompasses all variables), mediators must have a significant effect on the dependent variables. If these conditions all hold in the predicted direction, then the effect of the independent variables on the dependent ones must be less than in the first model (the one in which mediating variables were omitted). Perfect mediation exists where in the final model the

relationship between the independent variables and the dependent ones becomes non-significant, whereas partial mediation applies when these relationships remain still significant, albeit less strong.

In our particular case, two staggered sets of mediation relationships need to be analyzed: the mediating role of KM practices in the relationship between HRM policies and practices and IC stocks, and the mediating role of IC stocks in the relationship between HRM policies and practices and KM vis-à-vis innovation performance. For this to be tested, three models have to be run:

- In the first model (see Figure 2), the relationship between HRM policies and practices and IC stocks will be tested. This will check the first condition of the first mediation relationship.
- In the second model (see Figure 3), the relationship between HRM policies and practices and KM practices vis-à-vis innovation performance will be analyzed. This will check the first condition of the second mediation relationship.
- In the third model (see Figure 1), all mediating variables will be included. This will allow the second and third conditions of each mediation relationship to be verified.

Figure 2 Preliminary research model 1

Figure 3 Preliminary research model 2

For these models to be tested, first-order models have to be run first in order to obtain the latent variable scores of the first-order constructs that make up the aggregated latent variables (HRM policies and practices, KM practices and IC stocks). These first-order models also allow us to assess the quality of the scales used in order to represent the first-order latent variables. For all first-order constructs could be included in the same model, a sample size of 160 companies would be required. Our sample being only of 101 companies, we have run three different models (one for HRM policies and practices, another one for KM practices and a last one for IC stocks), connecting each of the first-order constructs with innovation performance. In the case of reflective constructs (all but human capital), this allowed us to check for individual item reliability, construct reliability and convergent validity conveniently. However, for discriminant validity to be tested, correlations between all constructs were calculated by means of SPSS. In the case of formative constructs (i.e. human capital), multicollinearity problems were explored in order to ensure that each indicator represented a truly different characteristic.

4 Research findings

4.1 Descriptive analyses

Tables 1, 2 and 3 summarize the results of the descriptive analyses carried out.

Table 1 Descriptive analysis – IC stocks (static IC)

Constructs	Mean	SD
Human capital	3,51	0,68
Structural capital	3,63	0,72
Internal relational capital	3,59	0,73
External relational capital	3,73	0,62
Entrepreneurial capital	3,10	0,61
Renewal capital	3,44	0,78

Table 2 Descriptive analysis – KM practices (dynamic IC)

Constructs	Mean	SD
Strategic management of knowledge	3,30	0,80
Knowledge protection	3,54	1,01
Learning	3,57	0,85
IT-based knowledge management	3,72	0,81

Table 3 Descriptive analysis – HRM policies and practices

Constructs	Mean	SD
Recruiting and selection	3,79	0,73
Training and development	3,71	0,78
Performance assessment	3,38	0,94
Compensation	3,03	0,95
Job design	3,49	0,74

As far as IC stocks are concerned, the results obtained show that there is clear room for improvement, especially in the case of entrepreneurial (3.10) and renewal (3.44) capital. On the contrary, external relational capital seems to be particularly developed, its average being the highest one among IC stocks (3.73).

Moving on now to KM practices (i.e. dynamic IC), the strategic management of knowledge is the weakest component within this category (3.30), while IT-based KM seems to be fairly developed (3.72).

In the case of HRM policies and practices, although recruiting and selection (3.79) and training and development (3.71) are quite well adapted to support KM, job design (3.49), performance assessment (3.38) and compensation (3.03) are much less adapted to that end.

On the other hand, the t-tests carried out to look for statistically significant differences according to company size (large versus medium-sized firms) and industry (manufacturing versus service companies) show that there is only one aspect in which companies differ significantly: knowledge protection. The latter is significantly more difficult in service companies than in manufacturing firms.

4.2 Measurement model evaluation

Prior to testing research hypotheses, the quality of the measurement model has been assessed, both for the first-order constructs and for the second-order ones. In the case of constructs made up of reflective indicators, individual item reliability, construct reliability, convergent validity, and discriminant validity should be checked, whereas in the case of formative or molar constructs, multicollinearity problems should be explored.

Detailed results for measurement model evaluation in the case of first order constructs are provided in the Appendix (Tables 7 and 8).

Beginning with reflective constructs, and as far as individual item reliability is concerned, a rule of thumb is to accept items with loadings of 0.707 or more, which

implies more shared variance between the construct and its measures than error variance (Barclay et al., 1995; Carmines and Zeller, 1979). As can be seen in Table 7, indicator loadings are greater than 0.707, with a few exceptions: JD1 (0.6992), STRATKM3 (0.6184), STRATKM5 (0.5366), ENTCAP3 (0.6129) and ENTCAP5 (0.6001). According to Barclay et al. (1995), loadings above 0.5 and 0.6 are also acceptable in early stages of scale development as is the case for job design, strategic KM and entrepreneurial capital. Thus, all the indicators proposed have been retained in the research.

Construct reliability or internal consistency refers to the extent to which all the indicators of a specific construct measure the same latent variable. If this were to be true, all the indicators making up the construct should be highly correlated. For this to be tested, composite reliability (ρ_c) has been calculated. According to Nunnally (1978), a value of 0.70 constitutes a benchmark for modest reliability in early stages of research, whereas later on, values higher than 0.80 would be preferable. As can be observed in Table 7, all reflective constructs of the research have a composite reliability over 0.8. Hence, internal consistency is OK.

Convergent validity is assessed by means of the so-called average variance extracted (AVE). This measure was created by Fornell and Larcker in 1981 and it provides the amount of variance that a latent variable captures from its indicators, relative to the amount due to measurement error. It is recommended that AVE should be greater than 0.50, this meaning that 50% or more of the variance of the construct is due to its own indicators. As can be seen in Table 7, this is the case in all reflective constructs of the research.

Finally, discriminant validity indicates the extent to which a given construct is different from other constructs (i.e. the extent to which the constructs making up the research model really measure different things). For this to be true, a construct should share more variance with its measures than it shares with other constructs of the model (Fornell and Larcker, 1981). In other words, AVE should be greater than the variance shared between the construct and other constructs (i.e. the squared correlation between two constructs). Once the correlation matrix obtained, it is easier to calculate the root value of AVE for each construct (this would be the diagonal of the correlation matrix) and to compare it with the correlations obtained. For adequate discriminant validity, the diagonal elements (i.e. the root values of AVE) should be greater than the off-diagonal

elements in the corresponding rows and columns. This is exactly the case in our research (see Table 8).

In the case of the formative construct (human capital), the absence of multicollinearity problems has been checked by means of SPSS software. As has been summarized in Table 7, variance inflation factors (VIF) are lower than 5 in all cases (Kleinbaum et al., 1988) and condition indices (CI) lower than 30 (Belsey, 1991). Hence, multicollinearity problems have been ruled out.

Tables 4 and 5 show the results of measurement model evaluation for the aggregated constructs. In this case, all latent variables except innovation performance (whose reliability and validity have been already checked) are molar constructs (i.e. equivalent to formative constructs in first-order models). Thus, the analysis should concentrate once more on exploring multicollinearity problems.

As can be seen in Table 4, all variance inflation factors are well below 5 and condition indices well below 30. Hence, multicollinearity problems have been discarded.

Table 4 Measurement model (second-order constructs) – Part I

Constructs and measures	Item wording	Assessment parameters
HRM policies and practices (molar)		Highest VIF = 1.763 Highest CI = 2.548
		Weights
REC	Recruitment and selection	0.0991
TD	Training and development	*0.2912
PA	Performance assessment	*0.1894
COMP	Compensation	0.1607
JD	Job design	***0.4867
Knowledge management (molar)		Highest VIF = 1.565 Highest CI = 2.115
		Weights
STRATKM	Strategic management of knowledge	***0.5971
KPROT	Knowledge protection	0.1167
LEARN	Learning	*0.4444
ITKM	IT-based knowledge management	0.0424
IC stocks (molar)		Highest VIF = 1.850 Highest CI = 2.904
		Weights
HC	Human capital	0.1018
STRUTCAP	Structural capital	*0.2793
INTREL	Internal relational capital	0.1508
EXTREL	External relational capital	*0.2385

ENTCAP	Entrepreneurial capital	0.0002
RENCAP	Renewal capital	***0.5631
Innovation performance (reflective)		$\rho_c = 0.906$ AVE = 0.659
	Compared to its competitors, how successfully has your company managed to create innovations / new operating methods in the following areas?	Loadings
INNOPER1	Products and services for customers.	0.8197
INNOPER2	Production methods and processes.	0.8408
INNOPER3	Management practices.	0.8353
INNOPER4	Marketing practices.	0.7852
INNOPER5	Business models.	0.7764

Notes: ρ_c : composite reliability; AVE: average variance extracted; VIF: variance inflation factor; CI: condition index; *** $p < 0.001$, ** $p < 0.01$, * $p < 0.05$ (based on t_{499} , one-tailed test).

Table 5 Measurement model (second-order constructs) – Part II

Constructs	1	2	3	4
1. HRM policies and practices	N.A.			
2. Knowledge management	0.792	N.A.		
3. Intellectual capital stocks	0.730	0.796	N.A.	
4. Innovation performance	0.521	0.480	0.591	0.812

Notes: Diagonal elements (values in parentheses) are the square root of the variance shared between the constructs and their measures, relative to the amount due to measurement error (AVE). Off-diagonal elements are the correlations among constructs. For discriminant validity, diagonal elements should be larger than off-diagonal elements. N.A.: Not applicable (molar construct).

Table 4 also shows the weights of indicators making up molar constructs. In the case of formative and molar constructs, weights show the relevance of each indicator when it comes to calculating the score of the latent variable so as to maximize the amount of variance explained of dependent variables.

In the case of HRM policies and practices, job design is by far the most relevant element in order to enhance KM, IC stocks and innovation performance, followed at a considerable distance by training and development and by performance assessment (the influence of both elements is still significant, albeit smaller). As far as KM practices are concerned, the strategic management of knowledge and learning constitute the main aspects to work on in order to contribute to the development of IC stocks and innovation. Finally, renewal capital is the most relevant IC component when it comes to enhancing innovation performance, followed at a considerable distance by external relational capital and structural capital.

4.3 Structural model evaluation

Once the quality of the measurement model has been guaranteed (both for first- and second-order constructs), the strength of the research hypotheses and the amount of variance explained (R^2) should be assessed. For research hypotheses to be tested, path coefficient levels should be examined, as well as their degree of significance, by means of bootstrapping techniques. Table 6 and Figures 4, 5 and 6 summarize the results obtained.

Table 6 Structural models (second-order constructs)

Models	Endogenous constructs	Exogenous constructs			R ²
		HRM	KM	IC stocks	
1	IC stocks	***0.766			58.73%
2	Innovation	**0.341	*0.238		29.65%
3	KM	***0.792			62.79%
	IC stocks	*0.268	***0.583		65.98%
	Innovation	0.242	-0.114	**0.505	37.00%

Notes: ***p<0.001, **p<0.01, *p<0.05 (based on t_{499} , one-tailed test).

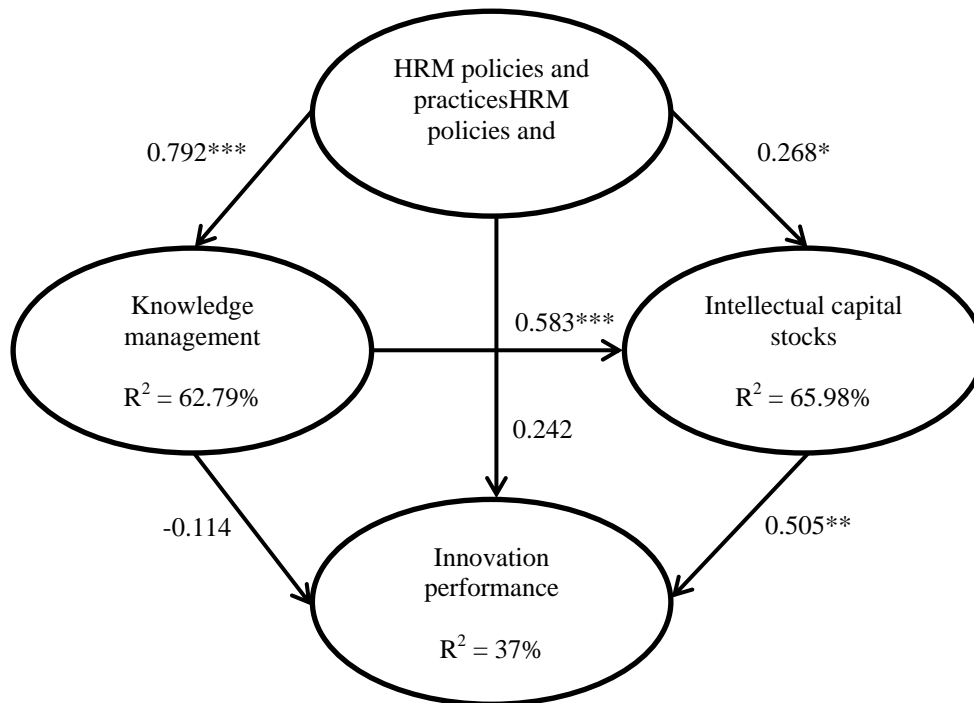

Notes: ***p<0.001 (based on t_{499} , one-tailed test).

Figure 4 Preliminary research model 1 – Structural evaluation

Notes: **p<0.01, *p<0.05 (based on t_{499} , one-tailed test).

Figure 5 Preliminary research model 2 – Structural evaluation

Notes: $***p < 0.001$, $**p < 0.01$, $*p < 0.05$ (based on t_{499} , one-tailed test).

Figure 6 Full research model – Structural evaluation

As can be seen in Table 6 and in Figures 4 and 5, the first condition for mediation to exist is fully satisfied, both for hypothesis H1 and for hypothesis H2. In the absence of KM (i.e. the mediating variable), the relationship between HRM policies and practices and IC stocks is positive and significant (amount of variance explained: 58.73%), while in the absence of IC stocks (i.e. the mediating variable), the relationship between HRM and innovation performance is also positive and significant, the same as the relationship between KM practices and innovation performance (amount of variance explained: 29.65%).

In the full model (i.e. once mediating variables have been introduced, see Figure 6), the relationship between HRM policies and practices and KM is positive and significant (thus the second condition for mediation to exist in the case of hypothesis H1 is fully satisfied), as well as the relationship between HRM policies and practices and KM vis-à-

vis IC stocks (hence, the second condition for mediation to exist in the case of hypothesis H2 is also satisfied: independent variables affect mediating variables significantly).

Moreover, the fact that the relationship between KM and IC stocks is positive and significant fulfils the third condition for the first mediation hypothesis to be accepted, while the fact that the relationship between HRM and IC stocks is still significant (albeit the path coefficient is noticeably lower than in the first model: from 0.766 it has dropped to 0.264) indicates that partial mediation applies (i.e. KM practices partially mediate the relationship between HRM policies and practices and IC stocks). In particular, the introduction of KM practices as a mediating variable has raised the amount of variance explained of IC stocks from 58.73% to 65.98%.

Finally, the fact that the relationship between IC stocks and innovation performance in the full model is positive and statistically significant fulfils the third condition for the second mediation hypothesis to be accepted, while the fact that the relationship between HRM policies and practices and innovation performance and that between KM practices and innovation performance become non-significant indicates that full mediation applies (i.e. IC stocks fully mediate the relationship between HRM policies and practices and innovation, and between KM practices and innovation). In particular, the introduction of IC stocks as a mediating variable has increased the amount of variance explained of innovation performance from 29.65% to 37%.

5 Conclusions

The research carried out contributes significantly both to academic debate and to managerial practice. From an academic perspective, it contributes to disentangle the interplay between IC stocks (i.e. static IC), KM (i.e. dynamic IC) and HRM policies and practices when it comes to enhancing innovation performance. As was noticed in the theory review, this aspect was clearly neglected in previous research, as no study was found that included the three antecedents simultaneously, and only very few studies were identified that analysed the interplay between some of the antecedents (especially between HRM policies and practices and IC stocks).

The results obtained show that KM partially mediates the relationship between HRM policies and practices and IC stocks, while IC stocks fully mediate the relationship between HRM policies and practices and innovation performance, and between KM practices and innovation. Thus, the influence of HRM policies and practices on IC stocks

takes place partly through the positive influence they exert on knowledge management and partly directly (i.e. HRM policies and practices have additional beneficial effects on the development of IC stocks beyond those related to the enhancement of the KM practices included in the research: strategic KM, knowledge protection, learning and IT-based KM). On the contrary, the influence of HRM policies and practices and KM on innovation solely takes place through the influence they exert on the development of IC stocks.

Moreover, the research highlights the specific aspects to work on in order to maximize innovation performance in the case of Spanish companies. As far as HRM policies and practices are concerned, the results obtained reveal that job design constitutes a particularly relevant aspect to consider. Guaranteeing job autonomy, social contact and the opportunity to acquire new knowledge and skills (Parker et al., 2001) should be part of the issues to be considered in work design. In the same vein, promoting training and development, together with the inclusion of assessment criteria related to employee performance in the domain of knowledge processes (i.e. knowledge sharing, knowledge creation and knowledge application), proves to be especially helpful when it comes to enhancing KM and the development of IC. On the contrary, recruitment and compensation did not prove to be relevant elements for KM practices to be encouraged and IC stocks to be enhanced.

In the case of KM practices, strategic KM (i.e. developing an explicit knowledge strategy which is consistent with the company knowledge base, and that is communicated throughout the organization), together with the use of learning mechanisms that take into account both the acquisition of tacit and explicit knowledge, are the two aspects that exert the greatest influence on the development of IC. Conversely, knowledge protection and IT-based KM have not been found to be significant.

Finally, renewal capital, structural capital and external relational capital are the IC components that exert the greatest influence on innovation performance.

Linking these results to the descriptive analysis carried out for Spanish companies, it should be noticed that some of the aspects to work on in order to make the transition from a “brick-based economy” towards a knowledge-based economy are those in which Spanish firms have shown a weaker position. This is actually the case for performance assessment and job design, as well as for strategic KM and renewal capital. Thus, the

research carried out contributes to establish attention priorities for Spanish managers in order to improve the innovation performance of the companies they run.

However, the global picture obtained may hide some relationships between specific components of HRM policies and practices, KM and IC stocks that could provide additional clues for managerial action. For instance, the non-significant role of entrepreneurial capital or human capital may be the consequence of mediation effects between IC components. Thus, further research is needed that contributes to clarify these relationships.

Appendix

Table 7 Measurement model (first order constructs) – Part I (1 of 5)

Constructs and measures	Item wording	Assessment parameters
Recruiting and selection (reflective)		$\rho_c = 0.810$ AVE = 0.587
		Loadings
REC1	When recruiting, we pay special attention to relevant expertise.	0.7657
REC2	When recruiting, we pay special attention to learning and development ability.	0.8151
REC3	When recruiting, we evaluate the candidates' ability to collaborate and work in various networks.	0.7154
Training and development (reflective)		$\rho_c = 0.910$ AVE = 0.718
		Loadings
TD1	We offer our employees opportunities to deepen and expand their expertise.	0.8325
TD2	We offer training that provides employees with up-to-date knowledge.	0.8606
TD3	Our employees have an opportunity to develop their competence through training tailored to their specific needs.	0.8490
TD4	Competence development needs of employees are discussed with them regularly.	0.8461
Performance assessment (reflective)		$\rho_c = 0.915$ AVE = 0.783
		Loadings
PA1	The sharing of knowledge is one of our criteria for work performance assessment.	0.8871
PA2	The creation of new knowledge is one of our criteria for work performance assessment.	0.9039
PA3	The ability to apply knowledge acquired from others is one of our criteria for work performance assessment.	0.8623

Table 7 Measurement model (first order constructs) – Part I (2 of 5)

Constructs and measures	Item wording	Assessment parameters
Compensation (reflective)		$\rho_c = 0.926$ AVE = 0.806
		Loadings
COMP1	Our company rewards employees for sharing knowledge.	0.8987
COMP2	Our company rewards employees for creating new knowledge.	0.8761
COMP3	Our company rewards employees for applying knowledge.	0.9173
Job design (reflective)		$\rho_c = 0.884$ AVE = 0.563
		Loadings
JD1	Our employees have an opportunity to participate in decision-making in the company.	0.6992
JD2	In our company, work duties are defined in a manner that allows for independent decision-making.	0.6300
JD3	We enable informal interaction between members in our organization.	0.7981
JD4	Our company organizes face-to-face meetings when necessary.	0.7845
JD5	When necessary, we use working groups with members who possess skills and expertise in a variety of fields.	0.8411
JD6	When needed, our company makes use of various expert communities.	0.7280
Strategic KM (reflective)		$\rho_c = 0.860$ AVE = 0.560
		Loadings
STRATKM1	Our company strategy is formulated and updated based on company knowledge and competences.	0.8341
STRATKM2	Our company strategy addresses the development of knowledge and competences.	0.8847
STRATKM3	Our company systematically compares its strategic knowledge and competence to that of competitors.	0.6184
STRATKM4	Our knowledge and competence management strategy is communicated to employees clearly and comprehensively.	0.8077
STRATKM5	In our company, the responsibility for strategic knowledge management has been clearly assigned to a specific person.	0.5366

Table 7 Measurement model (first order constructs) – Part I (3 of 5)

Constructs and measures	Item wording	Assessment parameters
Knowledge protection (reflective)		$\rho_c = 0.881$ AVE = 0.713
		Loadings
KPROT1	Our company's strategic knowledge is protected from those stakeholders to whom it is not intended.	0.7665
KPROT2	If necessary, our company uses patents, agreements, legislation and other formal means to protect its strategic knowledge.	0.8683
KPROT3	If necessary, our company uses confidentiality, employee guidance and other formal means to protect its strategic knowledge.	0.8927
Learning (reflective)		$\rho_c = 0.900$ AVE = 0.753
		Loadings

Structured Abstract

Open innovation is a new approach in innovation studies emphasize at opening the boundaries of the firm for exchanging the knowledge and R&D achievements with other enterprises, research centres and even competitors. As innovation plays a key role in achieving sustainable development goals and among them environmental sustainability, the effect of open innovation in facilitating the innovation process in transport sector will be discussed in this paper. Three indicators of open innovation have been analysed in order to identify how they can affect the number of firms which could introduce new innovations to the market in European Union countries. These indicators are: cooperation, acquisition of external resources and patents registered for electric and hybrid vehicles. The results of this study showed that while the cooperative and acquisition activities has a significant effect on the number of firms which could introduce new innovation to the market the effect of electric hybrid vehicle patents toward mitigating goals (reducing transport sector GHG emission) can't be judged using the existing data, as this indicator is related to the car manufacturers while some major manufacturing companies located in US and Japan and were outside geographical region of the study.

Purpose the study aimed at discussing how the success of firms in launching innovations to the market is affected by open innovation in road transport sector.

Design/methodology/approach– An explorative study related to the environmental innovations in transport sector has been conducted based on a mixed research approach, The data gathering methods is based on analysing data from OECD database, community innovation survey results (2010) derived from Eurostat database. Statistical analysis includes analysis of variances and regression analysis.

Originality/value – The study allows contributing to fill the gap in literature between open innovation and environmental sustainability in European Union using the network model for identifying the main players of innovative activities,

Practical implications– The results of the study shows the extent to what European firms are willing to share their innovation and how open innovation variables can affect the firm's ability in launching new innovations to the market.

Keywords –environmental innovations, transport, open innovation, R&D, sustainability

Paper type – Academic Research Paper

1 Introduction

Open innovation is relatively a new paradigm in innovation studies lying on the main idea that firms should exchange knowledge and innovation with the surrounding environment.

Traditionally, most industrial firms focused on internally developing new technologies and applying them in their own products (March, 1991; Calantone and Stanko, 2007). Since the 1990s, the frequency of various technology transactions has increased significantly due to the development of markets for technologies (Arora et al., 2001). This has led to the fact that companies have started to use external technologies and knowledge in their R&D processes to an increased extent (Granstrand et al., 1992).

Mainly large firms relied on internal R&D to create new products. In many industries, large internal R&D labs were a strategic asset and represented a considerable entry barrier for potential rivals. Extending R&D capabilities in large firms result in a gap between large firms and smaller rivals (Chesbrough, 2003). In this situation small and medium size enterprises try to increase the efficiency and reducing the costs and risks of R&D activities by sharing their knowledge and innovations. Thus, to compete, firms should share their R&D achievements and gain from the other firm achievements. Furthermore, as competitiveness increased, and the sustainable development issue started to permeate the businesses and firms strategy, the environmental sustainability has become an other perspective to challenge the firms' strategic dimension.

Ensuring environmental sustainability is the seventh goal of Millennium Development Goals (MDG) mentioned by United Nation as the issues which need to be considered urgently (UNDP, 2010). Climate change mitigation is an important goal of any environmental sustainability program, since neglecting it could result in a real threat in the near future.

Among the industrial sector, the transport sector is one of the main contributors of the GHG emissions, EU commission report (2012) states that “transport sector is responsible for the major part of CO₂ emission because it is highly depended on fossil fuels”, Transport sector has not achieved its CO₂ reduction goals yet, and the increasing demand for passenger and freight movements generates an increase of the number of road vehicles. As a consequence, it can be argued that reducing vehicle’s emissions is a key issue for economic development policies and vehicle manufacturers' business. However,

the reduction of vehicles' emission is highly depended on both the innovations in the car manufacturing industry and the public policies. While innovations in the car industry is often costly and needs a strong background of research and development, the approach of open innovation in sharing R&D achievements could be useful in progressing innovations in this sector.

This paper aims at investigating the effects of open innovation on the number of innovations introduced to the market in the transport sector. The literature analysis allowed at defining the open innovation indicators; then corresponding variables have been identified considering the data from Community Innovation Survey (2010) for 27 EU countries. Data analysis based on descriptive statistics and regressions has been conducted. The results showed that although not all variables directly affect the innovation output, the resultant indicator could predict the innovation success to a good extent. Except for patenting electric hybrid vehicles indicator that didn't show considerable effect, the indicators for cooperation and external acquisition of knowledge and R&D strongly affect the innovation output.

The paper is organized as follow: next section is related to a literature analysis about open innovation and the role of R&D to that end; the third section analyse the environmental sustainability, even with regard to the transport sector. The forth section explains the main determinants of open innovation and the correspondent measures. The fifth section describes the methodology and methods used for the study.

2 Open innovation

2.1 Defining open innovation

Chesbrough (2003) described an innovation paradigm shift from a closed to an open innovation model (which emphasize on sharing knowledge and innovation)Based on close observation of a small number of companies. He argued that firms should use external ideas as well as internal ideas, and internal and external paths to market, as they are looking to advance their technology (Chesbrough, 2003). Von Hippel (2010) comments that the open innovation which is defined by Chesbrough should be distinguished from the meaning of open in open source software as in Chesbrough's sense, the word open refers to organization permeability and is the "openness" of an organizations to the acquisition of new ideas, patents, products, etc., from outside – which

is often through licensing protected intellectual property while in open source software the word open refers to information commons that are free from intellectual property constraints and so open to all (Von Hippel, 2010).

In the context of open innovation, firms share their R&D achievements and gain from the other firm innovations. The central idea behind open innovation is that, companies cannot rely entirely on their own research, and they should gain from other firms R&D achievements by the ways such as by buying or licensing processes or inventions (i.e. patents) from other companies. In addition, internal inventions not being used in a firm's business should be taken outside the company (Chesbrough, William 2003). As Chesbrough confess, the open innovation paradigm is 'the use of purposive inflows and outflows of knowledge to accelerate internal innovation, and to expand the markets for external use of innovation, respectively' (Chesbrough et al., 2006, p.1).

West and Gallagher (2006) argue that open innovation shouldn't be considered as just using external sources of innovation such as customers, rival companies, and academic institutions, but it is also a change in using, managing, and employing of intellectual property as it is in the technical and research driven generation of intellectual property. The above mentioned authors define open innovation as the systematic encouragement and exploration of a wide range of internal and external sources for innovative opportunities, the integration of this exploration with firm capabilities and resources, and the exploitation of these opportunities through multiple channels (West, J.; Gallagher, S., 2006).

Open innovation generates benefits both from the firm and market perspective. Wallin and Von Krogh (2010) believe that open innovation can help firms by reducing the cost of product development and process improvement, accelerating time to market for new products, improving product quality, and accessing customer and supplier expertise outside the organization. Thus, open innovation paradigm would contribute to increase the level of competitiveness of the firm.

2.2 Process and activities

Chesbrough's model described the process of open innovation as inbound and outbound innovation activities or strategies. When a firm explores or commercializes external knowledge and ideas it called inbound activity; in this situation the flow of innovation is from the environment and actors which are outside the firm into the firm

boundaries. In this case firms or enterprises have the absorbent role. The other situation is when a firm out-licence or spin off internal knowledge and ideas outside organizational boundaries, the flow of knowledge and innovation in this case is from firm toward the outside environment or actors (Chesbrough, 2003a and 2003b). Enkel, Gassmann and Chesbrough (2009) added a third process to this model after analysis of in-depth case studies: the coupled process that combines the two directions. In the literature related to the management of open innovation, two main streams can be discerned: the firm perspective, and the interface between the firm and the innovation actor (Ollila and Elmquist, 2011).

Nowadays, the open innovation research is conducted through a great number of methods and tools. However, there is yet no agreement on what method is more suitable for the study of the open innovation phenomenon.

2.3 The role of R&D in open innovation models

Dahlander& Gann (2010) made an extensive literature review on open innovation and found some evidence to the concept currently used. According to their study, although in reality, not many firms followed a fully closed innovation approach; a multitude of developments within and outside the innovation arena made it necessary to make innovation processes more open. They believe that open innovation entails both exploration of external knowledge and ideas, referred to as inbound activities, as well as exploitation of internal knowledge outside organizational boundaries, referred to as outbound activities (Dahlander& Gann, 2010).

According to Vanhaverbeke, Van de Vrande and Chesbrough (2008), Chesbrough and other scholars claim that the internally oriented, centralized approach to R&D is going to be abolished in many industries. Useful knowledge is widely distributed and ideas must be used, in other case they should be sold to other organizations. R&D is going to be more costly and shorter product life cycles which is the result of increasing competition in product markets cause the reduction of R&D returns.

In the review of Chesbrough's¹ book, Faems (2008) wrote that in a closed innovation model, firms internalize their firm-specific R&D activities, and commercialize them through internal development, manufacturing and distribution processes. In contrast, an open innovation model is characterized by the use of purposive inflows and outflows of

¹ "Open innovation: researching a New paradigm", Oxford University Press, Oxford.

knowledge to accelerate internal innovation, and expand the markets for external use of innovation, respectively. While the closed innovation model considers R&D as an inherent part of a vertically integrated system within firms, the open innovation model treats R&D as an open system in which external ideas and external paths to market are placed on the same level of importance as that reserved for internal ideas and paths to market. Recently, numerous companies (e.g., IBM, Intel, P&G) have started to adopt the concept of open innovation. Nowadays, some managers even argue that open innovation is no longer a source of competitive advantage, but it has become a competitive necessity (Faems, 2008).

3 Environmental sustainability

Scholars have different definitions for environmental sustainability. Among them, Sutton (2004) defined environmental sustainability as the ability to maintain the qualities that are valued in the physical environment. Stead (2008) indicated that environmental sustainability “means maintaining the integrity, productivity, and resilience of biological and physical systems and preserving access to a healthy environment”, and Voet, Guine’e, and Udo de Haes (2000) believe that environmental sustainability “is guaranteed when environmental interventions are kept within the limits of the environmental carrying capacity”.

But one of the first and most reliable, comprehensive definition was provided by Goodland (1995). He defines environmental sustainability as “the maintenance of natural capital” and as a concept apart from, but connected to, both social sustainability and economic sustainability. He states that environmental sustainability is a source of constraints on the four major activities regulating the scale of human economic subsystem: the use of renewable and non-renewable resources on the source side, and pollution and waste assimilation on the sink side.

Environmental managers have identified environmental sustainability as a concept that has “a professional meaning for them” (Morelli and Lockwood, 2011).

Morelli (2011) believes that sustainability can be considered as a three-legged table consisting of the environment, the economy and society, while the leg for environmental sustainability is much more important than the two others; he argues that without a sustainably productive environment to provide a resource foundation, it would be difficult or impossible to imagine having a sustainable society. Similarly, a sustainable economy

depends upon a sustainable flow of material, energy, and environmental resources. A lack of achievement of sustainable goals would bring economic systems to failure. However, a sustainable environment need not be dependent on the existence of either society or economy and, as evidenced in the wild, can stand alone as a sustainable system.

According to Sutton (2004) sustainability issues arise wherever there is a risk of difficult or irreversible loss of the things or qualities of the environment that people value. Whenever there are such risks, there is a degree of urgency to take action. Greenhouse gas emission which is the main reason of climate change is an example of these issues.

Environmental sustainability is a key pillar of sustainable development and an integral component for the achievement of all other Millennium Development Goals.

3.1 Environmental sustainability in transport sector

Ensuring environmental sustainability is the seventh goal of Millennium Development Goals (MDG) mentioned by United Nation as those issues which need to be considered urgently. Under MDG 7, four global targets and ten global indicators provide a basis for monitoring progress towards environmental sustainability. The total amount of CO₂ emission per capita and per \$1 GDP (PPP) is one of these indicators (UNDG¹, 2010)

Reducing the amount of CO₂ emission is the collision point of environmental sustainability targets with transport sector. As from Szeto et al. (2012), vehicle emissions and noises damage the environment and have adverse effects on human health. It is, therefore, important to take their effect into account when designing and managing road networks (Szeto et al., 2012).

This paper focuses on the road transport vehicles' manufacturers as a main actor in transport sector. This industry is considered "the economic sector most emblematic of modern times and of the polluting consequences of modernity" (Orssatto and Clegg 1999: 264).

The international car industry is the archetypal example of an industry sector dominated by multinational corporation and is truly global in its structure and operations. It manufactures and distributes its products on an integrated global scale and today it is often taken as the paradigm case of a globalised industry (Paterson 2000: 264).

¹ United Nation Development Group (UNDG).

Vehicle production is the largest manufacturing sector in the world. In OECD countries, four to eight percent of GDP, and two to four percent of the labour force, are accounted for by the transport vehicle sector (UNEP and ACEA 2002).

Furthermore, according to Mikler (2004) environmental problems are usually characterised as cases of market failure due to environmental externalities. Environmental externalities cause market failure because the environment is often ignored by markets, so the price of goods and services does not reflect environmental aspects related to their production. This is because actors lack property rights over the environment, meaning that they can ignore the negative environmental effects of their actions (Mikler, 2004).

Ghafele and O'Brien (2012) believe that open innovation has received relatively limited attention in discussions about promoting 'green' innovation. They mention that other than Nike, only one other company – Best Buy – has agreed to place its IP assets on the green exchange, and the vast majority of the posted IP cannot be used in the creation of commercial products. Thus, the recent literature put in the research agenda the call for bridging the ability of open innovation to promote 'green innovation'.

3.2 Environmental innovation networks in transport sector

Innovation is a process. Presenting models for this process is one of the interesting topics in innovation management studies. Innovation modelling trends evolved over the years. At first, R&D was the main driver of innovation because it was the first step of technological development in technology push linear model. Then the market needs determined the direction of innovation, and after a while a combination of these two factors was proposed as the driver of innovative activities.

Since the beginning of the 21st century, the network modelling approach based on innovation systems theory emerged for defining innovation process (Pycaand Koppers, 2002; Hsu, 2005; Calia et al., 2007).

In innovation network models, innovation and technology development are results of a complex set of relationships among actors in the system. These actors are the main players of innovative activities and involve enterprises, universities and government research institutes, etc. According to European policy brief research observation (European commission, 2011), the growing intensity of innovation networks shows that firms are relying more and more on external sources of knowledge to generate innovations (Hagedoorn and Duysters, 2002; Chesbrough 2003).

Based on literature review this paper considers four groups of actors in transport sector innovation networks from the perspective of vehicle production industry. However, innovation networks can show many more relations and further actors. These groups can be introduced as:

1. **Industry partners and enterprises:** include other vehicle manufacturers and competitors or alliances in car manufacturing industry.
2. **Suppliers and distributors:** this group of actors are the partner enterprises which are completely in the industry; they may be the selling agents or may produce some parts of vehicles like seats, filters, etc.
3. **Universities, consultants and private R&D institutes:** they help manufacturers to improve their final products.
4. **Customers and end users:** they final part of a value chain who gain the innovations.

4. Measuring open innovation

4.1 Building the indicators

Many scholars tried to define indicators for measuring the openness degree of innovation in different industries. Based on the dependent variables which the effects of open innovation on it needs to be analysed, different variables and indicators could be selected. Lichtenthaler (2009) examined the effects of outbound open innovation on firm performance and showed that some factors such as high degrees of technological turbulence, transaction rate, and competitive intensity have a positive effect on firm performance. Chien (2011) declares that the open innovation performance indicators are: “the percentage of successful cross-departmental staff participation in new product development”, “the degree of incentive/reward system implementation for innovation”, and “the degree of innovation sharing among employees”.

In a report for the European Commission, Ebersberger et al. (2011) studied open innovation drivers and barriers in European countries, and described indicators for open innovation based on community innovation surveys (CIS). In that report, open innovation has been measured through: collaboration activities, searching activities, and legal protection activities, while searching activities is broken in two separate category:

searching with academic and science partners, and searching with industry and value chain partners (Ebersberger, 2011).

Another report which has been recently published by Lappeenranta University of Technology (ENPI, 2013), summarizes the indicators and variables used for measuring open innovation, after analysing a set of 507 conceptual, quantitative and qualitative papers. In this report a comprehensive set of indicators is introduced based on the reviewed papers and the data sources. Table 1 show a summary of the measures which have been introduced by Lappeenranta (2013) study.

Table 1: Indicators for measuring open innovation (adaptation from ENPI, 2013)

Author	INDEPENDENT	DEPENDENT
Czarnitzki and Thorwarth(2012)	Design activities	1) Innovation output (sales-new to market; imitation)
Ebersberger et al. (2012)	1) external sourcing 2) search (breadth and depth) 3)collaboration (breadth and depth) 4) protection (breadth) overall: open innovation (breadth/depth)	Innovation success: 1) Share of sales with market novelties 2) Share of sales with firm novelties
Köhler et al. (2012)	knowledge search: 1) science-driven knowledge search 2) supplier-driven knowledge search 3) market-driven knowledge search	Innovation success: 1) Share of sales with marketnovelties 2) Share of sales with firmnovelties
Laursen and Salter (2006)	1) external search breadth 2) external search depth (the extent to which firms draw intensively from different search channels or sources of innovative ideas) 3) Innovation collaboration	innovative performance (3 proxies): 1) radical innovation 2) incremental innovation:
Sofka and Grimpe (2010)	search strategies 2) Share of R&D expenditure of sales 3)Continuous R&D activities 4) Share of employees with college education 5) GERD as a percentage of GDP	innovation performance (the share of turnover achieved with new products (new for market, not just for the firm)
Spithoven (2013)	1) Incoming knowledge spill overs 2) Research cooperation 3) Appropriability4) Complexity of knowledge	1) research intensity (Natural log of the ratio of intramural R&D expenditure over turnover) 2) innovative sales (Natural log of the % of new or significantly improved products (goods and services) in sales)
Temel et al. (2013)	1) Cooperation-type of partner 3) Internal R&D occasional	1) Innovation

	4) Internal R&D continuous	
Tether and Abdelouahid (2008)	1) Breadth of openness 2) Commitment to R&D 3) proportion of science and engineering graduates in the workforce 4) proportion of 'other graduates' in the workforce 5) Financial commitment to 6) Radical innovations 7) External innovations	LINK SKP-links between firms and Specialist Knowledge Providers
Berchicci (2012)	1) External R&D 2) R&D capacity	Share of innovative sales
Kafouros and Forsans (2012)	1) In-house R&D 2) External scientific knowledge and technologies	firm profitability (profits before tax)
Nunez-Sanchez et al. (2012)	1) Relational assets individual level 2) Relational assets firm-level 3) Financial motives 4) Technical motives 5) Commitment of firms 6) Commitment of PRC 7) intellectual property 8) coordination in project management 9) Communication	1) Scientific impact 2) Economic impact 3) Objective impact 4) Subjective impact 5) Scientific impact - publications 6) Scientific impact-position 7) Patents 8) Technical impact
Sandulli et al.(2012)	1) Size 2) Technology 3) Leadership 4) Life-cycle 5) Concentration 6) Intensity	Open (Does the firm collaborate in product innovation with other firms or organizations? Binary variable (yes/no))
Teirlinck and Spithoven (2013)	1) research_managers (total#) 2) R&D_experts (total #) 3) PhD_holders (share) 4) R&D_training (dummy)	1) research cooperation (dummy) 2) R&D outsourcing (dummy)
Visnjic and Van Looy (2013)	1) product 2) service sales 3) Customer proximity	1) Total profit margin
Wagner (2013)	1) Innovation source (1) the use of the potential partner as a source of knowledge or information for innovation; 2) the involvement of the firm in Inter-organizational collaborations with the partners in innovation projects)	Innovation performance-new and improved services (the percentage of the firms' annual sales pertaining to services improved and services new to the firm
Waguespack and Fleming (2009)	1) Published standards 2) Working group chairs 3) Publishing attempts 4) Conference attendance	liquidity event
Wang et al. (2013)	1) licensee (dummy) 2) reference scope 3) reference time lag (average time lag for the backward citations) 4) science-based references (dummy)	innovation outcome (patent counts)

Wang et al. (2013a)	1) SLT (The total number of licences) 2) Ratio of foreign licences 3) NLT (technology newness) 4) NTS (number of different licensors used)	1) Innovative performance (patent counts) 2) Technological diversity (number of new classes in a firm's patent portfolio within five years of its in-licensing experience compared with the five years preceding the licensing year as an indicator of technological diversity)
---------------------	---	--

Following the above literature analysis of open innovation' measurement, this study's approach is based on the following three categories of indicators with regard to open innovation:

- A. Cooperation indicators: this set of measures is related to the cooperation with network actors and its effect on innovation process output.
- B. Intellectual property indicator: it includes patents registered for climate change mitigation and hybrid-electric vehicle patent, and measures the effects of patenting trends and activities on innovation process output.
- C. External innovation acquisition: this category of indicators shows the effect of acquisition external R&D, machinery and equipment, and acquisition other external knowledge in innovation process output.

5. Methodology

Based on a mixed research approach, an explorative study related to the transport sector environmental innovation networks has been conducted in order to analyze the effect of open innovation on firm innovation.

The data gathering methods is based on analysing data from OECD database community innovation survey results (2010) derived from Eurostat database, the statistical analysis include analysis of variances to see if the dependent variable changes with the independent variables or not? Then the regression analysis used for estimating the relationships among variables and the best fitting chart obtained from regression analysis.

5.1 Research propositions

Considering the literature review, enhancing open innovation affects the number of firms which introduced new product to market. Thus, the following research propositions have been formulated:

1. Does cooperation with other network actors have a reliable effect on the number of firms which introduced innovations to the market?
2. Does protecting intellectual property rights has a reliable effect on the number of firms introduced innovations to the market?
3. Does external innovation acquisition have a reliable effect on the number of firms introduced innovations to the market?

5.2 The variables

Based on the above literature review, table2 summarizes the variables which have been considered in order to measure open innovation and innovation output.

Table 2: Measures for open innovation and innovation output

Parameter	Indicator	Independent Variable	Dependent variable
Open innovation	Cooperation	with industry partners	The number of firms which introduced new innovations to the market
		with suppliers	
		with clients and customers	
		with consultants & private R&D institutes	
	IP protection	Electric and Hybrid vehicle patents	GHG emissions
			Revealed technology advantages in environmental related technologies
External acquisition		machinery, software and equipment	The number of firms which introduced new innovations to the market
		external R&D	
		other external knowledge	

5.3 Sample and data

The study steams from data related to the above indicators and environmental economic derived from different sources such as OECD¹-MSTI, CIS 2010² results from

¹ Organization for Economic Co-Operation and Development

² Community innovation survey, 2010

Eurostat (European commission) database and WIPO¹. Data related to the year 2010 was considered.

The data for 27 European Union countries obtained from the community innovation surveys, WIPO patenting data and OECD data base, although in patenting data there were some missing cases that indicated no patent registered or at least the latest updated were not available.

Secondary data sources and statistical data analysis were conducted using SPSS 18.0 software for analysing the effects of open innovation indicators on innovation output.

6. Results and discussions

6.1 Analysis of cooperation indicator

Analysing the first category of indicators, related to cooperation, the results show that the 96.8 % of the variance in innovations which are new to the market can be predicted from the variables related to cooperating activities (Table 3). Also the regression analysis coefficients showed that cooperation within enterprise group or industry and the cooperation with clients and customers have a significant effect on the introduction of innovations which are new to the market (Table 4). While the two other variables (cooperation with suppliers and with consultant and private R&D institutes), didn't show a statistically significant relation with the market new innovations. This indicates that firms preferred to cooperate with the other enterprises in their group and also with clients rather than consulting firms or suppliers,

Model summary				
	Multiple R	R Square	Adjusted R Square	Apparent Prediction Error
Standardized Data	.984	.968	.960	.032

Table 3: The model summary for cooperation indicator

coefficients

	Standardized Coefficients		df	F	Sig.
	Beta	Bootstrap (1000) Estimate of Std. Error			
Coop within enterprises' group	-.385	.171	1	5.054	.037
Coop with clients and customers	.914	.331	1	7.610	.013
Coop with suppliers	.007	.446	1	.000	.988
Coop with consultants and private R&D institutions	-.280	.331	1	.715	.409
All cooperation	.712	.256	1	7.715	.012

Table 4: The regression coefficients for the variables of cooperation indicator

As a dependent variable, the number of firms which introduced new innovations to the market can be predicted from the level of cooperation with network actors. It means that increasing the level of cooperation will intensely increase the innovations introduced to the market. Chart1 indicates that the best equation that can describe the effects of all cooperation variables on introducing new innovations to the market is a quadratic equation.

Chart1: Quadratic equation predicting the effect of all cooperation on the number of firms which have innovations new to the market

6.2 Analysis of intellectual property indicator

Although the results of covariance analysis showed a relation between the numbers of electric hybrid vehicles and transport sector greenhouse gas emissions (equivalent to tones of emitted CO₂), as in Table 5, the coefficients couldn't be computed from regression analysis. This limit resulted from a lack of availability of data with regard to some countries and from the focus of the production in a defined geographical area. Most of world automobiles are produced in the 'triad' of the US, Germany and Japan as Dicken (1998) argued. And considering the European focus of this study, it can be predicted that the 'intellectual property indicator' couldn't be a good scale for measuring open innovation, or at least it requires a wider population of car manufacturers to be investigated.

Table 5: the relation between electric hybrid vehicle patents and GHG emissions

ANOVA					
	Sum of Squares	df	Mean Square	F	Sig.
Regression	5.726	1	5.726	7.123	.015
Residual	15.274	19	.804		
Total	21.000	20			

Dependent Variable: GHG emission transport
 Predictor: electric & hybrid vehicle patents

6.3 Analysis of external acquisition activities

Based on the CIS surveys the effects of the number of firms engaged in different levels of external acquisition activities on the number of firms introduced innovations which were new to the market have been investigated. The following activities considered as the predicting variables have been considered:

- o Acquisition of machinery, equipment and software
- o Acquisition of external R&D
- o Acquisition of other external knowledge

The results showed that the set of considered variables can predict the dependent variable (number of firms that introduced new innovations to the market), with a good precision (R²=99.1 %, Error=0.9%), (Table 6).

Table 6: The relation between acquisition activities and introduction of new innovations to the market

Model Summary				
	Multiple R	R Square	Adjusted R Square	Apparent Prediction Error
Standardized Data	.996	.991	.990	.009

Analysing the effect of each variable shows that the variable for other external knowledge didn't have a statistically significant effect on the number of firms that introduced new innovations to the market (Table7). It can be argued that the number of firms which introduced new innovations to the market is highly depended on the firm's ability in acquisition of machinery, equipment, software and external R&D. Also, in order to formulate the effect of acquisition activities on the number of firms that introduced new innovations to the market, the regression chart shows the best fitting curve for the coefficients of the cubic curve (Chart2), indicating that the innovation output is the third cubic function of acquisition activities.

Table 7: The regression coefficients for the variables of acquisition activity indicator

	Standardized Coefficients		df	F	Sig.
	Beta	Bootstrap (1000) Estimate of Std. Error			
RRDEX	.372	.148	1	6.311	.021
Acquisition of machinery	.541	.114	1	22.304	.000
ROEK	.131	.127	1	1.051	.318

Dependent Variable: number of firms introduced new innovations to the market (RMAR)

Chart1: Cubic equation can be the best predictions the best predictor f for the effect of acquisition activities on the number of firms which have introduced new innovations to the market

7 Conclusions

The research aimed at discussing the effect of selected open innovation indicators on the innovation output (the number of firms which can introduce new innovations to the market). Open innovation has been measured through selected indicators: cooperating with innovation network actors, intellectual property indicator for innovation related to climate change in vehicle manufacturing industry (the number of hybrid and electric vehicle patents), and the acquisition activities which shows the firm's ability in gaining from surrounding environment. Data analysis showed that the innovation output is highly depended on the firm's ability in acquisition of resources and external R&D, and also the level of cooperation with customers and industry groups. It can be concluded that if the variables that showed a weak performance would be strengthened through appropriate strategies and policies, the number of firms which can introduce new innovations to the market could increase. This could motivate the adoption of corporate strategies and public policies, such as strengthening the link between industry and private R&D institutes and consultants. Although the study clearly pointed out that the external R&D acquisition is the most effective factor on the ability of firm in launching new innovation to the market,

the lack of information about single country profile in innovation success limited the study to the European Union countries, while country base analysis could be possible in case of update and completed database

Using a user centered methodology to drive open data initiatives. Lessons learned from the U-Home Case

Guillaume Pérocheau

ICI LAB, ISEN Toulon
Maison des Technologies
Place Georges Pompidou
83400 Toulon

Structured Abstract

Purpose – The open data movement is a global trend for the opening of governmental data and the delivery of these data onto connected internet servers. The main argument for open data is that it will enhance the governmental transparency, and will promote the creation of new services for citizens by third parts. Despite its global success, open data initiatives utilizability for end users is often questionable and limits its social impact. This paper relates the case of an open data initiative designed around a user centered methodology, and proposes operational recommendations for further open data projects.

Design/methodology/approach – During the U-Home project we used a participative design methodology, that could be described as *opened* or *participative* (Chesbrough, vanhaverbeke, West, 2006), more *horizontal* (Von Hippel, 2005) or even an *ascending* process (Cardon, 2005). The aim of this method is to imply all the stakeholders (users, partners, developers, etc.) during the innovation project to maximize the social utility and acceptability of the result.

Originality/value – This methodology is an alternative to most of the former open data initiatives, consisting in creating open data portals, and inciting independent innovators to develop third services. In this classical case, the Open Data initiative relies onto the energy and the power of entrepreneurs/developers, willing to create business from a newly appeared resource (Data).

Practical implications – Our work proposes to public agencies to play a new role in open data initiatives. They are not only data providers, but also partners that can facilitate and cooperate with data projects. Our work also insiste on the role of human sciences to imply end users at every stage of the project.

Keywords – data, end-user, innovation, process, methodology

Paper type – Practical Paper

1 Introduction

Since 2006, the opening of Open Data has become a global trend. Hundred of countries, regions or urban areas have created data portals and allow any stakeholder to re-use these data to create activities, reports, applications, etc. But, despite all its promises, the open data movement has not yet produced the awaited growth, economic activity and democratic transparency (Point 2 of this article).

An explanation often proposed by analysts and observers of this trend, is that open data initiatives do not pay a sufficient attention to the utilizability of data portals and of open data applications. For this reason, applying user centered methods to open data initiatives, could be a good solution to ensure an increasing social impact of this movement (Point 3).

Empirically, we present the case study of U-Home, a digital service, based on data sets from the urban area of Toulon in France. This project has been designed following a user centered methodology at every step of the process, implying many stakeholders. During this project, the team of scientists from ISEN used an ethnographic study, organized co-design workshops, and end users Focus Groups, and proceed to utilizability tests (with video and face to face interviews). We briefly relate this experience and try to present some preliminary results (Point 4).

From this empirical experience, we propose some recommendations for further Open Data initiatives. We insist on the complex role to be played by the public authorities, which should be only data providers, but also partners and facilitators for open data projects (Conclusion).

2 The Open Data movement, promises and critiques

2.1 Origins of the Open Data Movement

The idea that Public Data should be considered as a common good was really asserted in 2006 in Sebastopol, in the North of San Francisco, during a meeting between activists of the Internet and philosophers. For this group, governments and public authorities should promote the diffusion of open contents, defined as follow : “*A piece of data or content is open if anyone is free to use, reuse, and redistribute it – subject only, at most, to the requirement to attribute and/or share*” (Open Knowledge Foundation, 2006). This definition is highly inspired by the Open Source vision of the knowledge. Concretely

speaking, when applied to Public Data, the Open Data movement states that the public data should be available onto connected internet servers, into a re-usable and comprehensive format, with specific licences allowing the free use of those data (Berners-Lee, 2006).

2.2 The global success of Open Date Initiatives

Since then, this trend has encountered an exponential success around the world, and the concept of Open Data has inspired major governmental policies (Peugeot 2010, Chignard 2013, Davies et Al 2013). In the US, President Obama launched an initiative for “Open Government” in 2010 which led to the creation of a data portal (<https://www.data.gov/>). This portal currently proposes more than 90 000 government data sets delivered into open formats. In the UK, a comparable initiative followed quickly, with the opening of another data portal (data.gov.uk). The same year, the World Bank opened its own portal, supporting the creation of comparable initiatives in countries like Kenya, Moldova, Ghana or Chile. Open Data is not only a trend at the National level. It also concerns the opening of public data at regional level, or even at urban area level. If we take the example of France, the first Open Data initiative has been launched by the city of Rennes as soon as 2010, with the creation of a Data Portal and the launching of a competition for granting the best applications based on the re-use of this data.

2.3 The Open Date Promises

In the field, the craze for the opening of public data is clear. How can we explain this success ? Arguments for open data are numerous and have been often documented (Kitchin, 2013, Gurstein, 2011, Huijboom and Van den Broeck, 2011, Longo, 2011, Sifry, 2010). They can be categorized in three main promises. The first promise is that open data increases the accountability and the transparency of public bodies. A comparative study of recent Open data Programmes shows that the creation of government data portals often followed reports or public declarations concerning the necessity for transparency and “smarter governments” (like in UK, Australia or US.). In this case, Open Data is seen as a leverage for more participation and more democratic control, each citizen becoming *eyes and ears* for public action. The second promise is that open data will allow third parties to develop public services for citizens. In this case,

public administration will find partners / stake holders willing to extend public services through an innovative re-use of the data. For instance, in some urban areas, the opening of transportation data resulted in the creation of many applications or mobile services by third parts developers to help travellers during their trips in city. In this case, it can be seen as a free enhancement of the public services for travellers. The third promise, is that the opening of open data will create economic activity, and will enhance growth, innovation and job creation. In this case, open data is seen as a resource that can be freely used by economic agents. This resource can be used to increase efficiency of current businesses, or it can be re-used as a based for start-ups, creating apps or digital services.

2.3 Critiques to Open Data : what about the user ?

But have all those promises been fulfilled ? For Rob Kitchin (2013), despite all its promises, and obvious successes, Open Data initiatives deserve some main critiques. At first, the funding and sustainability of Open Data portals is questionable. Producing, curating, and distributing data onto connected web servers has a cost. And maintaining those servers (updates, softwares, power supply, web access, IT staff, etc.) may also be costly in years to come. But most of the time, the future of these portals is questionable, and there is no specific revenues for governments, public agencies or regional authorities freely delivering data (Pollock 2009). Another critique is that due to its complexity and its nature, Open Public data empowers the empowered. Understanding and interpreting a data requires a specific literacy. In this way, Open Data meets the famous digital divide question, and remind us that not all the citizens have the skills, knowledge and even equipments to make an effective use of the newly available data (Gurstein, 2011). But for us, **the main critique is made about the *Utility and Usability of the Open Data initiatives***. Some recent reports studying dozens of data projects (Helbig et al., 2012) point out the fact that these initiatives are often mainly driven by technological concerns, and results into collections of links pointing to structured files. In the same report, authors insist on the fact that the Open Data based services should take into account the context of use of the Data. For instance, a piece of information concerning crime rates in a city does not have the same meaning for a policeman, a neighbor, a tourist or a home seller. It can not be presented the same way. More over, most of the time, this information needs to be

enriched and mixed with other data to build a more specific signification. And finally, it will have to be presented into a readable and comprehensive way for specific users of the data. This is the meaning of this main critique about the *Open Data Usability*.

3 Open Data initiatives should be seen as an innovation process where the user has a major role

3.1 Open Data, Social Innovation and Social relevance of innovation

To better understand open data initiatives, we propose to analyze open data projects as innovation processes. Open Data initiatives are often portrayed as a Digital Social Innovations (DSI). It was even at the core of recent European Conferences dedicated to this Topic, like the Open Knowledge Conference (OKON) in September 2013 in Geneva. But the fact that Open Data - a technologically based innovation, potentially creating business innovation - may be a Social Innovation may be questionable. We believe that this is due to the difficulty to define Social Innovation, that often tends to be a buzz word, with multiple definitions, and approaches from multiple fields (Pol and Ville, 2009, Howaldt and Schwarz, 2010). Following these authors, we can remind that most of the technological and business innovations may also have social impact, whereas many current social innovations (like car sharing, crowd funding or home swapping) are based onto strong technological innovations (such as data bases, internet and mobile devices). As such, “*open data can be seen as forming the infrastructure of an Information Society, and enabling the development of social innovations*” (Poikola et Al. 2011). Finally, Howaldt and Schwarz (2010) propose to temporally close this debate, by focusing onto the social relevance of innovations.

3.2 Limits of a Schumpeterian view

Public policies to open public data often follows a three steps scenario. At first, a public agency gathers data sets from various public services into a structured format. Then (second step) this data is published with a specific license onto a public web service. Third step often consists in the launching of competitions to reward the best application based onto the re-use of these data. This scenario has often been described in recent reviews (Davies and Al., 2013, Peugeot 2010). And unfortunately, after a first and rapid emergence of concepts and proposals, it does not lead to sustainable open data solutions.

In this scenario, the main innovation driver is the entrepreneur, just like in Schumpeter theories (Hagedoorn, 1996). In this case, the Open Data initiative relies onto the energy and the power of entrepreneurs/developers, willing to create business from a newly appeared resource (Data). But, as reminded by Kitchin (2013), the entrepreneurs having the skills to understand complex sets of data are not always able to design applications for citizens, taking into account utilizability matters. And finally, the results are often technical applications offering poor user experiences.

3.3 Open Data, like any innovation, is a social process

As seen above, Open Data initiatives are innovative in many ways. And as such, they should be seen as a *social process*, as any other innovation. Open Data initiatives are *processual*, because they correspond with a phenomena where *time matters* (Abbott, 1990), where sequences of action unfold in time. And Open Data initiative are *social*, because during this innovative process, a multiplicity of actors is going to take part into action (Callon, 2003). Finally, we can remind this definition from Ven de Ven (1986) who already stated that “*innovation is defined as de development and implementation of new ideas by people who over time engage in transactions with others within an institutional order*”. With this definition of Open Data initiatives, *described as a social process where a multiplicity of actors are going to create innovative use of public data during a succession of sequences of action in time*, we can build a more complex vision of these projects.

Many various previous works have been proposed those past 20 years in the field of innovation studies in social sciences. And the good new is that the user is now having all its place during this process. We emphasis some key points of these works here under.

3.4 Innovation process : the growing role of the user (and other stake holders !)

In a traditional model, the users's only role is to have needs to be addressed by an innovative company, an innovative entrepreneur. But some recent works, based on rich empirical studies, show that many users (from 10 to 40%) are engaged into developing or modifying products (Von Hippel 2006). This point had also been underlined by works on the Open Innovation paradigm, where users are presented as key partners for innovation

processes (Chesbrough, Vanhaverbeke, West, 2006). In some areas, the users can even create communities and engage themselves into industrial projects (see the famous examples of Open Source softwares), or into controversies with scientific communities. Their role becomes so prevalent, that we some authors describe it as an ascendant innovation process (Cardon, 2005), reversing the descendant logic of innovation going from industry to customers.

3.5 Applying user centered methods to Open Data Initiatives ?

Since early 2000's, many governments or public agencies have implemented specific policies to promote the user commitment into innovation process. We usually speak of Living Labs to describe those institutional settings (Salter and White, 2013). The originality of Living Labs is to propose an extensive implication of the users, at various steps of innovation projects (ideation, design, development, tests, etc.), using scientists from Human and Social Sciences as facilitators between users, communities, SMEs, companies and research centers. Traditionally, Living Labs have been used to develop new products and services. But recent works have shown that user centered methods could also be used when designing Social Innovation (Brown and Wyatt, 2010), and that in this case, the role of social sciences could be central (Mallard, 2011, Labarthe, 2014).

By considering Open Data Initiatives as socio-technical innovation processes, and remembering that one of the main critique made to these initiatives is the lack of attention payed to final users (see previous part), it seems obvious that we should try to apply user centered methodologies to such projects. *That is why we chose to address, in this article, the following question : how can we apply a user centric methodology to open data initiatives ?*

4 The U-Home case, an open data application in Toulon urban area

4.1 An open data initiative into the Living Lab context

Provence Alpes Côte d'Azur (PACA) is a region located in the South of France. It comprises cities like Marseille, Nice or Toulon. Since 2008, PACA as launched a specific tool to support digital initiatives having an impact onto the territory. Since its origin, PACA labs is aiming at promoting user centered methodologies, by granting collaborative innovation projects melting industrials, territories, designers, users and

human sciences laboratories. U-Home project is one of these projects, supported by PACA Region. U-Home consortium is made of :

- Centr@IWeb, an IT services company, willing to develop a new application based onto public data
- ISEN Toulon, a technological graduate school, and especially its Human Sciences team, who brought the user centric methodology to drive this project.
- Toulon Provence Méditerranée (TPM), the urban area of Toulon, who provided data sets and facilitated the access to data facilities

The U-Home application concept is the following : when a person (it could be an individual or a company) wants to migrate to Toulon area or inside the urban area, he has to choose the best place for him depending on his life style : does he have children ? Is there a school nearby ? Or a doctor ? Is he far from a Judo club ? Can he park his car easily ? Potentially, all these pieces of information are disposable into various public data sets... But browsing all these data bases is a nightmare. The solution would be an interactive map of the urban area, highlighting various zones of TPM by processing a mash-up of the useful data.

The purpose of the U-Home project was double :

- 1) Centr@IWeb wanted to design a user friendly solution, by collaborating with potential end-users at each step of the project.
- 2) The TPM IT team wanted to explore the open data problematic before deciding to open (or not) its public data.

4.2 The user centered Methodology used during the project

We had the opportunity to use various tools issued from human and social sciences at each step of this project.

- From 02/2012 to 08/2012, a first team of Sociologists¹ performed a qualitative study to better understand what is the mobility process of individuals. This work was based onto ethnographic works, comprising 10 face to face interviews and on site observations.

¹ *This Ethnographic Study was performed by Voilmy D., coordinator of the ActivAgeing Living Lab of Troyes, and Karine Lan Hing Ting, Postdoctoral Researcher at Université de Technologie de Troyes, and will be documented into further articles.*

- In the same time (March 2012), we animated a Co-design workshop, joining together technical staff from TPM, developers from CentralWeb, and some professionals of property from the urban area (9 persons).
- Relying on those first works, a first version of the U-Home service was developed from 09/2012 to 02/2013. We tested this version during a Focus Group dedicated to the service utility, where 12 potential users could bring their insights concerning the current version of the project.
- A second version of the U-Home site was then developed and tested. We organized utilizability tests from 02/2013 to 06/2013 with 12 users, whose browsing sessions were recorded for further analysis².
- We finally produced new recommendations for the development of the project final version, delivered in the end of 2013.

The meta analysis of all these data is currently ongoing, and more complete results will soon be published.

4.3 First analysis of the projet results

In this article, we do not propose a complete analysis of this project research that ended just a few months ago. But we remind here the main results obtained during U-Home, regarding our initial goals. This analysis is also based onto a *post mortem* project review, organized with the various project leaders in February 2014.

- During this project, centr@lweb developed new technological skills (use of Open Street Maps, Open Data Mash Ups, etc.), but mainly discovered the importance of utilizability tests. It is now a common tool for the company project managers.
- The U-Home Web site is on line, and its technology will soon be embedded into a new portail dedicated to property market.
- TPM has decided NOT to create a data portal, as many other urban areas did before. The idea of TPM is to propose collaborations with third parts, willing to use the city data sets.
- The data sets specifically used during this project will be delivered to the PACA Regional open data portal.

² *The utilizability tests have been organized and analyzed by Alena Sjarheyeva, Researcher at ISEN Toulon.*

This first result may seem rather ambiguous : despite a succesful open data initiative, the TPM IT team decides to no create an open data portal. This shows that TPM team has clearly understood the complexity of data, and the relative inefficiency of a policies only based onto the delivery of raw material. Instead, the TMP IT managers have acquired a more complex approach of their data, and understood that opening data for third parts should imply a strong collaboration with those stake-holders.

5 Conclusion

As a Conclusion, and relying on those first empirical results, we could make some operational recommendations (R) to increase the sustainability and social impact of further open data initiatives :

- R1) Public agencies are not only data providers, but also data experts with analysis capabilities that could be useful for third parts project leaders.

In tis prospect, creating open data portals is often no more than a political gesture, but has few direct impact onto growth and welfare.

- R2) The meaning of data sets for end users often has to be explored and designed directly with users of spokespersons representing these users.

During U-Home project, we had passionating discussions concerning data representing noise. Noise at 9 PM has not the same meaning for a senior or for a student, while it is a neutral information in data. Sense making was a key result of our focus groups.

- R3) The definition of end users is a tricky question for the project designers, and should be a central task for Open Data Initiatives.

At the beguining of U-Home, we had a clear (end simplistic) vision of our service end-user. But during the project, we discovered that end users were plural, and may have very different needs and visions.

- R4) Open Data initiatives should work closely with lead users and /or user communities.

Open Data initiatives will lack appropriation as long as they will be developed only between data experts, coming from state agencies and start ups. Implication of users brings a contextual vision of problems to be solved and is a creativity resource for entrepreneurs.

By analyzing our data, we also should be able to make some theoretical proposals concerning user centric methodologies, and to better understand what may be the role of human and social sciences during social innovation processes.

Structured Abstract

Purpose – The goal of this paper is to present eco-innovation implementation in some European countries. Both current and expected government regulation is particularly important for pushing firms to reduce air and water pollution, decrease hazardous substances and increase recyclability of products. Cost savings are an important main incentive for reducing energy and material use, pointing to the role of energy and raw materials prices, as well as taxation as drivers for eco-innovation. Customer requirements are very important source for eco-innovations, particularly with regard to products with improved environmental performance and process innovations that increase material efficiency, reduce energy consumption and waste .

Design/methodology/approach – We propose an approach theoretical approach: to investigate available data concerning ecoinnovation implementation in the EU countries and case study. We review literature and analyse how different stakeholders can contribute to building a green economy through eco-innovation. Moreover, we analyze incentives and barriers of ecoinnovation development in European countries. Many companies implement eco-innovation, but the majority either still do not eco-innovate or the material savings gained due to innovation are not important. Nevertheless, there exists solid, often unrealized potential for eco-innovation in the EU. Around one fourth of innovating companies in the EU-27 countries have reported introducing eco-innovation to reduce material use between 2006 and 2008, according to the Community Innovation Survey/CIS/.

Originality/value –This methodology puts in evidence that ecoinnovations are important tool in building modern economy. It is confirmed by presented in this paper case studies.

Practical implications –The outcomes of the ecoinnovation are very important to the decision makers. Traditional environmental policies and measures focus on dealing with specific problems. Generally, this approach has been quite successful. However, since traditional problem solving begins after recognising a problem's existence, such policies

are not preventive in a general. Solving individual problems only by specialised environmental technologies can even worsen other problems, in particular those as yet undiscovered. Today, more than 95% of the resources lifted from nature are wasted before the finished goods reach the market. And many industrial products - such as cars - demand additional natural resources while being used. Sufficiently decoupling production and consumption from nature requires new systems, goods, services, processes, and procedures for meeting human needs.

Keywords – ecoinnovation, sustainable development, environment.

Paper type – Academic Research Paper

1 Introduction

Globalisation, technological progress, life cycles ever shorter, increasing pollution, and fast changing of customers demand have involved that company's competitiveness is more related to the ability to ecoinnovate. We have to underline that no fully agreed definition of eco-innovation (environmental innovation) has been emerged to date (Wozniak, 2010). Eco-innovation concept appeared in economics very late -in the 90's of XX century as response to continuously deteriorating environment and increasing interest in innovations, which contribute to the competitive growth of firms and economic development. First definition was given by Fussler and James (1996), who described them as beneficial both to producers and consumers, and simultaneously decreasing negative impact on environment. In the last years the concept is becoming more welcomed among researchers, entrepreneurs and administration. Definition of eco-innovation is continuously modified with increasing knowledge about relationships between innovation and environment.

The reason underlying is that this category is very wide and difficult to define, requiring both theoretical and practical research. In this study, we used the EIO (2010) definition of Eco-innovation. "Eco-innovation is the introduction of any new or significantly improved product (good or service), process, organizational change or marketing solution that reduces the natural resources use (including materials, energy, water and land) and decreases the release of harmful substances across the whole life-cycle". An environmental innovation creates environmental benefits compared to alternatives. The environmental benefits can be the primary objective of the innovation or the result of other objectives. This benefits can occur during the production of a good or service, or during the after sales use of a good or service by the end user." What follows is a list of environmental benefits that an environmental innovation could have produced

either with the firm or from the after sales use of a product by the user for which surveyed firms should state whether this benefit has in reality occurred or not.

Contemplated, in addition to the process of innovation is the ability to generate and absorb; eco-innovation ability is believed as one of the important attributes of the region's economy. The prefix 'eco' added to the term "innovation" enriches the positive expression. One of the main expected results of eco-innovation is the increase of environmental effectiveness, meaning reduction of energy consumption, and in this way increasing business competition (Wozniak, 2010). Still, the preparation and implementation of the eco-innovation is undertaken in order to build a sustainable competitive advantage. Another result will be in relation to the innovation perception, comprehend as the sum of the innovation capacity and synergy mechanism caused by innovation effects dispersing in the given region. The increasing efficiency of small medium enterprises enhanced thanks to those eco-innovation activity, will significantly contribute to the eco-efficiency of the region's economy.

In most conducted econometric studies to date, environmental innovations were widely analyzed while only a few papers distinguished between end - of - pipe - innovations and cleaner production ones. In the literature, there is an agreement that eco-innovations are regulation driven though significant number of studies emphasizes also cost - savings. It is especially true for cleaner production technologies, where of cost reduction is important driver of eco-innovation (Horbach, 2008; Frondel et al., 2007). However, due to deficiency of more differentiated data availability, the literature on driving forces of eco-innovations to date has ignored to analyze different areas of environmental impacts of eco-innovations such as recycling, low carbon technologies or innovations for water management (Kammerer, 2009). Kammerer also emphasizes the function of customer benefits as an important determinant for eco-innovations. Important findings were given by Popp (2006) who suggested that innovation in companies were driven rather by internal country's regulation, not by foreign regulation. Other researchers demonstrated further incentives to be very essential. Del Rio Gonzalez (2005) conducted a survey in the Spanish pulp and paper industry. He found regulation pressure and corporate image as the main drivers of cleaner technology adopting. Frondel et al. (2007) find that generally policy stringency is an increasingly important driving force for environmental innovations rather than single policy instruments. Other researchers, like Arimura et al. (2007) found similar result for the effect of regulation on green R&D.

Facilities facing very stringent environmental regulation are more likely to conduct environmental R&D. Frondel et al. (2007) point to the fact that the effects of regulation may vary with regard to different environmental technology fields.

Eco-innovation can be developed not only by firms but also by non-profit organizations. They can be traded on different kinds of innovations: “ technological, organizational, social and institutional (Rennings, 2000). There is a common agreement that eco-innovation is great chance for business. By this innovation we are able to introduce: new processes and products and changing business models to increase competitiveness in new and changing markets. We have mounting evidence that eco-innovation in companies have positive economics effect since it leads to reduced costs, improves capacity to capture new growth opportunities as well as strengthens company image in the customers view (EIO, 2012). We argue that eco-innovation in European companies is key to the constant transformation needed toward sustainable development and to meet the EU’s vision of a green economy. This transition does not have to be a burden for business, but rather a great opportunity for strategic investment. It asks how business and policy can reduce risk to ensure these opportunities are met.

Other interesting definition of eco-innovation was demonstrated by Kemp and Pearson (2008). An environmental innovation, according to them, has been defined as “a new or significantly improved product (good or service), process, organizational method or marketing method that creates environmental benefits compared to alternatives. The environmental benefits can be the primary objective of the innovation or the result of other innovation objectives. The environmental benefits of an innovation can occur during the production of a good or service, or during the after sales use of a good or service by the end user” (Kemp and Pearson, 2008). In what follows is a catalog of environmental benefits that an eco-innovation could have produced either with the firm or from the after sales use of a product by the user for which surveyed firms should say whether this benefit has occurred or not. Concerning environmental product innovations, ZEW (Zentrum für Europäische Wirtschaftsforschung -Centre for European Research) econometric results show that present regulations are only effective for reductions of air, water, soil and noise emissions but not suitable for energy consumption and recycling (Horbach, 2009). The firms expect a growing importance of future regulations for all product innovations. In all considered environmental innovation areas future regulations already trigger eco- innovations.

Environmental regulation and individual environmental policy instruments (specially, soft regulation) are important drivers particularly for eco-product innovations (Cleff and Rennings, 1999, Horbach, 2008 and Rehfeld et al., 2007). Other researchers like Green et al. (1994) imply that firms implement environmental product innovation to obey with existing and anticipated legal requirements. Horbach (2008) finds a significant positive influence of subsidies on environmental product innovation. Kammerer (2009) demonstrate that a high level of regulatory stringency incentivises companies to implement environmental product innovations which are quite novel to the firm, but this result cannot be corroborated when these innovations are new to the market. Finally, Horbach et al. (2012) confirm a high importance of expected future regulations for all environmental product innovations.

The paper consist of 4 chapters, including introduction. In second chapter we present results of ecoinnovation development in Europe, the third present case study: Poland and Spain, and forth presents conclusion.

2 Result of ecoinnovation development in Europe

Many European companies implement eco-innovation, nevertheless the majority either still do not introduce that type of innovation or the material savings gained due to innovation are insignificant. Nevertheless, there is solid, often unrealized potential for eco-innovation in the EU (EIO 2011). Around 25% innovating companies in the EU-27 have reported introducing eco-innovation to reduce material use between 2006 and 2008, according to the Community Innovation Survey/CIS/ (Eurostat, 2010). Up to 45% of EU companies in the manufacturing, construction, agriculture, water supply and food services sector reported implementing eco-innovation in the period 2009-2011. Eurobarometer survey (Flash EB No 315, 2011) showed that the majority of them achieving incremental type improvements in resource efficiency of 4. While these are positive events-seeming to indicate a greater push for material efficiency in companies—there is still a large gap between the great potential for eco-innovation and the state of eco-innovation in the EU countries (Attitudes of European entrepreneurs towards eco-innovation Summary Fieldwork, op cit.). Roughly 3 in 10 (29%) companies in the EU had introduced a new or significantly improved eco-innovative production process or method in the past two years, while roughly a quarter (24%) had introduced a new or significantly improved eco-innovative organizational method. A similar proportion (25%) had introduced a new or

significantly improved eco-innovative product or service on the market (Figure 2) (Flash EB No 315, 2011).

Source: Attitudes of European entrepreneurs towards eco-innovation Summary Fieldwork: January 2011, Publication: March 2011

Figure 1: Introduction of various eco-innovations in past 2 years

More than 4 in 10 companies in the EU reported having introduced at least one eco-innovation in the past two years (2009-2011). Surprisingly, companies in Poland were the most likely to have introduced a new or significantly improved eco-innovative product or service, production process or organizational method in the two years (63%); companies in Hungary were the least likely to have done so (27%) (Figure 2).

Source: Attitudes of European entrepreneurs towards eco-innovation Summary Fieldwork: January 2011

Figure 2: Companies that introduced at least one eco-innovation in past two years.

Medium-sized companies, companies with an annual turnover €10 -50 million and those that that increased turnover in the past two years were more likely to have introduced the types of eco-innovation listed in the Eurobarometer survey. For example, 32% of medium-sized companies had introduced a new or significantly improved eco-innovative organizational method in the past two years and 41% said the same for a new or significantly improved production method or process; the corresponding figures for small companies were 22% and 26%, respectively.

There is a large gap both in the scale of eco-innovative activities, with large differences between countries, sectors, and sizes of companies as well as a gap in the scope of eco- innovation changes, with a tendency towards more incremental rather than radical changes introduced to the market. The gap between innovators and eco-innovators is significant across the EU. In Germany around 39% of innovators are eco-innovating (Eco-innovation observatory, 2011), while only 10% in Cyprus and Bulgaria (see Figure 3). If one looked at the share of eco-innovators in total companies, only around 15% of companies across the EU have reported eco-innovative activity focused on material efficiency. In Poland there is little innovation (located on the penultimate place in the CIS ranking). Eco-innovators are about 22% of the total innovators in Poland .

Source: Eurostat (CIS)

Note: Not all countries provided data in the Community Innovation Survey on eco-innovation: data is missing for the UK, Denmark, Greece Slovenia and Spain.

Figure 3: Share of European companies implementing ecoinnovation

We argue that this share is unsatisfactory. Especially, innovative companies already have capacity to capture benefits from improved resource efficiency. Closing the

gap in the performance between countries may also add up to greater savings at the macro level. As regards the gap between incremental and radical eco-innovation, still little we know. In the past many firms have become increasingly alert of overarching environmental challenges and have begun preparing their products and services to meet the wave of “green consumption” that has swept across Europe (The Eco-Innovation observatory, 2012). While there is a general tendency towards ‘eco-friendly’ products, particularly evident in the proliferation of eco-labels over the past 5 years, the trend toward increasing consumption of natural resources in the EU has continued. This indicates that the intensity of changes have not been sufficient to counteract the overall trend (Eco Innovation Observatory, 2012, 2012). Economic growth has continued to require less additional final energy consumption within the EU-25 economy. However, this improvement has not been sufficient to prevent total final energy consumption from rising. Decoupling was most successful in the industry sector as a result of technical improvements and structural changes, while private households consumed more energy per capita due to larger and more dwellings and more electrical appliances. While energy intensity continues to decline at a faster rate in the new EU-10 Member States, it remains much higher than in the EU-15. There is not, yet, evidence of systemic change, which actually contributes to an absolute decrease of environmental pressures and impacts. This report aims to provide information about the scope of economic benefits for companies to encourage companies to grasp these opportunities and close the eco-innovation gap (Tab.1).

Table 1: Reasons of introduction of environmental innovations (eco innovations)

Environmental innovations that were introduced in response to	Yes	No	Number of firms
	In % of all firms with at least weak environmental impacts		
Existing regulations	31.5	68.5	3733
Expected regulations	27.0	73.0	3730
Financial support by governments	9.9	90.1	3733
Demand from customers	27.4	72.6	3733
Voluntary codes and industry agreements	28.0	72	3727
*only firm with environmental innovations			

Source: In SYSTEMATIC Eco-Innovation Report 2008, p. 36

The European Eco-innovation Action Plan states that European environmental legislation has been one of the most important drivers for eco-innovation. Moreover, the Plan paid attention to some aspects that should be considered in the design, revising or implementation of environmental regulation. One of these is the innovation as an

opportunity to improve the environment through flexibility in technological standards. This aspect is directly linked to IPPC Directive, also because the pollution prevention schema could be considered as organisational eco-innovation (Eco Innovation Observatory, 2012).

Just over a third of European companies reported that less than 10% of their innovation investments in the past five years were related to eco-innovation and a quarter estimated that this share was between 10% and 29% (Flash EB No 315, 2011). In just six countries, more than a fifth of respondents estimated that 30% of their innovation investments were eco-related: Sweden (21%), Greece (22%), Austria (23%), Cyprus and Luxembourg (both 24%) and Poland (30%). Companies that had made the largest share of eco-innovation investments were more likely to be found in the water supply and waste management, and agriculture sectors. Roughly 3 in 10 companies in the EU had introduced a new or significantly improved ecoinnovative production process or method in the past two years, while roughly a quarter had introduced a new or significantly improved eco-innovative organisational method. A similar proportion (25%) had introduced a new or significantly improved eco-innovative product or service on the market.

Medium-sized companies, companies with an annual turnover between €10 and €50 million and those that had grown in terms of turnover in the past two years were more likely to have introduced these types of eco-innovation. (Flash EB No 315, 2011). Among companies that had introduced at least one type of eco-innovation in the past two years, the largest share (42%) said that such eco-innovation had led to a reduction in material use of between 5% and 19% per unit of output, while roughly a third estimated that the reduction in material use had been less than 5% per unit of output.

The results also show that the attitudes of European entrepreneurs towards current high material prices have the expected impact in eco-process innovations (a positive correlation), which is consistent with previous empirical studies (Frondel et al., 2007 and Horbach, 2008). Giving importance to cost-related factors is also correlated with the implementation of EOP and cleaner production technologies. On the other hand, the variable that reflects the importance given to the maintaining or increasing market share is not statistically significant, in line with Cleff and Rennings (1999). However, similarly to what was found for environmental product innovations, giving importance to the increasing market demand for green products has also a strong positive effect on

environmental process innovation. Most probably, product eco-innovators are able to develop process eco-innovations.

2 Case study: ecoinnovation development in Poland

Poland, since its accession to the EU in 2004, enabled to utilize EU funds, reduce the backlogs in transportation infrastructure and environmental protection and at the same time build a strong and stable economy (Kassenberg et. al, 2011). The state of the natural environment has significantly improved, while the resources productivity and energy intensity unfortunately have increased. Despite that, Polish productivity indexes per Gross Domestic Product still remain below average of the EU countries (Kassenberg et. al, 2011). During the last 20 years, energy consumption remained stable in spite of significant Gross Domestic Product (GDP) growth, due to energy efficiency improvement and changing the structure of economy. Nevertheless, the energy intensity index is still 2-3 times lower than the EU-27 average. In Poland, almost half (47%) of the companies surveyed by **Eurobarometer** stated that material costs represented 50% or more of their total production value (Flash EB No 315,2011). Companies in Poland were the most likely to have introduced a new or significantly improved eco-innovative product or service, production process or organisational method in the past two years (63%); companies in Hungary were the least likely to have done so (27%). Regardless of the fact that the country policy in the area of eco-innovation misses synergy, the eco-innovations have been addressed via national policy strategies on environmental protection, product policy, energy efficiency in buildings, etc. The interest of Small Medium Enterprises (SME) in eco-innovation is slowly growing, especially in relation to cost reduction possibilities, due to notably reduction of energy consumption and decreasing expenditures related to pollutant emissions (Kassenberg et. al, 2011).

The country also has outstanding examples of eco-innovations in energy and water management, hazardous waste treatment, solar energy, green banking and coke industry and a number of eco-innovation related programs and initiatives within various clusters. On the other hand, eco-innovation does not constitute a driving force for new business opportunities in Poland. Development of eco-innovations in Poland is significantly hindered by numerous barriers. The most important is underestimation of the innovative potential as a growth driver. This innovative potential is understood here as an ability to create new technological and organizational solutions, increase labor productivity and

improve resource efficiency with relation to work, capital, energy and materials. Eco-innovations in particular, remain outside the interest of decision makers policies which determine Poland's expectations towards the EU and future Structural Fund allocations for development objectives. As a consequence, Polish policies focus on clearing infrastructural backlog and accelerating extensive economic growth, ignoring future changes in the significance of the respective sectors and the barriers that limit the current growth model, which is based strongly on price, rather than quality, competition.

Another barrier is too big focus on EU funds availability and their fast utilization. The approach that money should be utilized fast, considerably limits the debate on how to optimize EU funds absorption. Poland needs stable mechanisms (similar to Finnish solutions) that will instigate the development of new, competitive structures of the Polish economy. There should be more focus on the quality of implemented ideas, their better selection and support for truly innovative economic initiatives.

The EU funds provide new possibilities for financing various initiatives at universities and colleges. Unfortunately, due to excessive formalization, more and more often the true aim of these activities is lost, while bureaucracy is increasing. A lot of attention is provided to the accounting side of projects, although it should be focused on how to fulfill the planned objectives and ensure durable benefits.

Lack of well-qualified and skilful specialist constitutes another large barrier to development of eco-innovations in Poland. This is result of, first and foremost, from a poor and ineffective system of education. Graduates of technological studies are in minority and staff available to work on eco-innovations is limited. There is a large difference between the business sphere, which is very innovative but still on a basic, everyday level, and administration and science. Due to insufficient information, access to eco-innovative solutions developed by the academic and science sector is limited. Providing adequate support for innovations, or eco-innovations in particular, constitutes a challenge. Poland has a serious problem with innovativeness as such, in its broad meaning.

Positive, albeit slow, changes are observed in Poland in the area of eco-innovations. They do not immediately lead to a significant increase in the value of the eco-innovativeness scoreboard index. The Eco-Innovation Scoreboard (Eco-IS) is the first tool to assess and illustrate eco-innovation performance across the 27 EU Member States. The scoreboard aims at capturing the different aspects of eco-innovation by applying 16

indicators grouped into five thematic areas: eco-innovation inputs, eco-innovation activities, eco-innovation outputs, environmental outcomes and socio-economic outcomes. It thereby shows how well individual Member States perform in different dimensions of eco-innovation compared to the EU average and presents their strengths and weaknesses. The Eco-IS complements other measurement approaches of innovativeness of EU countries and aims to promote a holistic view on economic, environmental and social performance. Compared with 2011 Poland rank moved from the last place to the 25th position. The increase occurred in the area of eco-innovation output. (Eco-innovation in Poland: 2012 update)

There exist several examples of eco-innovation examples in Poland:

- Successful continuation of the program GreenEvo (Green Technologies Accelerator). This initiative of the Ministry of Environment supports Polish eco-innovators, mostly small and medium enterprises (SMEs) transferring technologies all around the world. In 2011 alone, Green Evo participants revenues increased by 31% on average, and their export revenues soared by 58%. What is more 86% of companies made a trade offer to foreign customers, and 50% of them have signed distribution agreements with foreign partners (Kassenberg et. al 2011).
- Establishing a number of eco-innovation oriented clusters e.g. Silesian Cluster of Environmental Technologies, Baltic Eco-energy cluster and Clean Energy Cluster of Małopolska and Podkarpackie (Eco-innovation in Poland: 2012 update).
- Participation of Poland in the Environmental Technologies Verification (ETV) Pilot Program of the European Union – a scheme supporting market uptake of eco-innovative technologies ((Kassenberg et. al, 2011)).

Despite these positive trends, development of eco-innovations in Poland is still hindered by a number of barriers. Eco-innovations still are giving the impression as “end of pipe, environmental protection technologies” rather than a cross-cutting innovations (Eco-innovation observatory 2012). Transition to a low-carbon economy is perceived as a threat in companies and SMEs. Implementation of stringent environmental regulations is seen solely as a cost and not as an opportunity for building an innovative and competitive economy. Awareness on the benefits resulting from implementation of eco-innovative technologies among entrepreneurs and consumers in general is relatively low. Entrepreneurs tend to invest in cheapest technologies allowing them to achieve the

commercial goal or meet the minimum legislative requirement. Many entrepreneurs and research organization fail to see benefits from cooperation.

Lack of well-qualified and experienced labor force constitutes another large barrier to development of eco-innovations in Poland. This stems, first and foremost, from a not effective system of education. Excessive number of humanists, lawyers or sociologist graduate from Polish universities each year, but there are too little engineers, biologists, etc. Staff available to work on eco-innovations is limited. There is a large difference between the business sphere, which is very innovative but still on a basic, everyday level, and administration and science. Due to insufficient information, access to eco-innovative solutions developed by the academic and science sector is limited. Providing adequate support for innovations, or eco-innovations in particular, constitutes a challenge. Poland has a serious problem with overall innovativeness as such, in its broad meaning.

The main barrier for Polish companies is lack of sufficient capital to invent and implement eco-innovation. Additionally, financial institutions face a significant risk connected with involvement in eco-innovative projects. This risk is related more to technological issues, i.e. the possibility to achieve expected parameters, than to financial ones. There are no sufficient funds to verify proposed solutions, be it in a semi-technical form or as a pilot solution. This relates especially to a project finance situation, where a company is established only to implement a particular investment. If a project has undergone preliminary verification, banks or other financial institutions are more likely to provide a loan, as such verification reduces their risk. Venture capital funds are also lacking. Establishment of the National Centre for Research and Development and development of clusters should improve that situation.

Eco-innovation needs and challenges in Spain are associated with the economic crisis. Primary energy intensity and greenhouse gas emissions (GHG) have declined in Spain since 1999, reflecting the decoupling of economic growth from primary energy consumption (Sorli M.,2011). Many enterprises and technology providers are emerging in the sector of renewable energy. However, a large potential rests in the eco-innovations involving low energy consuming in industry and housing, ICT solutions, etc., (Sorli M.,2011).. One of the limits is a high imported of fossil fuels from non-EU countries, in particular natural gas. Construction is the most energy consuming sector in Spain, and therefore eco-innovation is of the utmost importance in the introduction of renewable energy sources and energy saving materials in buildings. There is a challenge for eco-

innovations that will enable transform the Spanish building sector towards less materially intensive practices (EIO Country Brief: Spain 2011). Spain faces a number of serious environmental problems that would need addressing through eco-innovative solutions. Despite water efficiency progress the country still faces ever increasing water shortage which poses the must in water efficiency innovations. There are emerging problem with solid wastes, while the resource efficiency and consumption needs improvements towards sustainable patterns; the growing number of cars in fact, cancelled out the improved energy and environmental efficiency achieved in other sectors. Industries and agriculture sector are increasingly contributing to the nation's water pollution problem (EIO Country Brief: Spain 2011). In comparison to 2010, the Spain country's eco-innovation performance has changed significantly. In 2010, Spain's overall eco-innovation performance was even 5% above the EU average and it lay within a group of countries with a medium-high eco-innovation performance. The 2011 Eco-Innovation Scoreboard places Spain high in the EU27 ranking of eco-innovative countries (fifth). It is positioned particularly well in eco-innovation inputs (due to its strong performance for environmental and energy R&D appropriations and outlays), eco-innovation activities (due to its high number 14001 registered organizations) and eco-innovation outputs (due to its strong performance in eco-innovation related media coverage) ((Sorli M.,2011). The country's leading areas are water efficiency, sustainable construction and waste treatment. Many initiatives have been taken in reuse of water, proper management of water resources, water collecting and purification systems, water quality control, etc.), waste management (energetic waste recovery) and sustainable construction¹

Current strengths of Spain in the promotion of eco-innovation include the high number of EMAS (Eco-Management and Audit Scheme) certificated organizations. Spain has 1,235 Eco-Management and Audit Scheme certified workplaces, which means the country is one of the leaders in Europe. Most of the certificates are issued in the service and hospitality sectors, and in the Autonomous Communities of Catalonia and Madrid. In addition to this, Spain has the sixth highest number of certified eco-labeled products (51) in the EU. Furthermore, Spain is for the fourth consecutive year, the third country in the world and first in Europe in number of Environmental Management Systems certified ISO 14001, 16,443 certificates (Eco-innovation observatory, Country profile Spain, 2011).

¹ <http://www.eco-innovation.eu/>

Current weaknesses of the country can be found in the limited participation of the private sector in the funding of environmental R&D. This is despite the substantial outlays effort of recent years and a reduction in Spain's "environmental deficit" thanks to the application of environmental regulations and the progressive compliance with objectives (Sorli M., 2011). Another weakness is the lack of organization at an institutional level. This involves many entities, organizations, programs and funds over a wide geographical area (European, Spanish, and Regional) for eco-Innovation and Environmental Technologies. The lack of collaboration between research centers and companies in Spain makes technology transfer and RTD difficult (Eco-innovation observatory, Country profile Spain, 2011 op.cit.).

One of the main causes revolves around limited knowledge and lack of assessment from technology transfer offices. In addition, RTD (Research and Technical Development) from universities and public research centers is not oriented to corporate technological needs. These agents are not used to applying for patents and setting up companies. Spain has an excessive dependence on grants and subsidies. The public sector through its grants and subsidies is another important financial source (Eco-innovation observatory, Country profile Spain, op cit.). Moreover, poor consumer awareness regarding eco-innovation advantages exists. Market prices do not reflect the ecological advantages and so there is a very low demand for eco-innovation both among consumers and businesses exists. Although the Future Sustainable study shows that 43% of consumers are aware of the environment and consider environmental aspects to be important, they do not understand eco-innovation and what type of measures are available to help the environment (Sorli M., 2011).

7 Conclusions

There are considerable concerns related to the development of eco-innovativeness in some European countries including Poland and Spain. First, politicians do not recognize the significance of eco-innovations, or more generally speaking – innovations. There is a strong lobby supporting obsolete industries and it is not interested in development of eco-innovations. On the one hand, there is no pressure on research in new eco-innovative solutions. On the other, academic and R&D centers are unable to satisfy the demands of the industry. It is of key importance that eco-innovations are perceived as the driving factor of the third transformation in Poland and other EU members (following system

transformation and the EU accession). The state should play the key role in this process – on the one hand it should inspire the demand for eco-innovations and on the other it should assure conditions for increasing interest in such solutions. Despite significant progress, the Polish economy has low productivity and high GHG emission intensity. Poland still has a lot to do to become an economy of high material and energy efficiency. This includes development of a necessary legal and institutional background. Such a transformation also requires fundamental changes in education and the behavioral patterns of citizens and companies so that we become a society of sustainable material consumption and move toward a green economy, where development is decoupled from material and energy use (Szpor, Sniegocki, 2012).

Cooperation between research institution and companies is not satisfactory in some European countries. Poland and Spain indicate stringent environmental regulation as main driver of eco-innovation. Those countries experience limited interest, lack of collaboration between business and research institutions, and limited budget for research at this area.

Structured Abstract

Purpose – The Project Management body of studies has represented a catalyst of research, contributing to the development of effective theories and models, enabling to manage project's results achievement. From another point of view, instead, it appears necessary, and still lacking, an higher attention towards theories and models that support the management of stakeholders' value achievement. Of a fundamental importance in order to support the management of a program/project with the aim of value matching, is evaluation activity.

A variety of evaluation approaches and models exist. Existent literature suggests that no one approach is best for all situations. Rather, the best approach varies according to many different factors. This paper collects, classifies and compares several project/program evaluation models, addressing insights on the selection of the proper evaluation model.

Design/methodology/approach – Through a literature review several models addressing a program or project evaluation have been selected. They have been analysed in terms of characteristics, approach (qualitative vs. quantitative), field of application, pros and cons. A summative critical analysis compares the models and suggests implementation insights, depending on the evaluation scope and/or project's field.

Originality/value – The research contributes in the defining of a holistic framework of project/program evaluation models, that overcomes existent limitations: overall collection and comparison of evaluation models, critical analysis for an effective selection of the model.

Practical implications – Evaluation of results and impacts of programs and projects is even more fundamental in turbulent and high competitive environments. The assessment and selection of the evaluation model is a crucial activity for many different purpose: finance of a project, assessment of a project's efficacy, improvement of a program's performance. Any project's/program's stakeholder should consider evaluation models characteristics, as a rationale for an effective and efficient evaluation process.

Keywords – Program, Project, Planning and Evaluation, Evaluation models.

Paper type – Research Paper

1 Introduction

In the last decades there has been a wide diffusion of Project Management (PM) approach in all the fields of human life. The scientific community is paying attention to the research and the studies focusing on PM; companies and public administrations works even more by projects applying PM's models and techniques.

The PM approach implies planning the achievement of a given objective, on the base of project's activities planning. According to this approach the management by activities secure an effective management of the whole project, with respect of expected time and cost.

The PM approach, indeed, recognizes as driver for customers' value creation, the respect of planned time, cost, quality of delivered product/service. It is not comprised, among the management drivers, the stakeholders' value, that is all the benefits that arise in the mid and long term because of the project's results.

In today's economic, political, social context the measurement of the value generated in the mid term (effects) and in the long term (impacts) by projects and programs is not circumventable in order to actually boost companies, public administrations, politics, third sector, a whole country.

If on one hand PM has represented a catalyst for research, largely contributing to the development of effective theories and models enabling the management of projects, on the other hand an higher attention needs to be addressed to theories and models enabling

the management of the value that spin-off from the project or program. The management perspective changes from PM: the project/program is not the goal, but the mean to impact on stakeholder's value.

A step in order to support the management of project's and program's impacts, in the perspective of stakeholder's value creation, is the modelling of relations between project/program and created (or induced) changes on stakeholders in the mid and long term.

This paper aims to identify and frame the models that play a role in the measurement and analysis of effects/impacts produced by projects and programs. These models are identified as evaluation models. The terms project and program are used interchangeably.

The paper is organized as follows. Section 2 provides the background of the research, section 3 reports the research results, section 4 outlines the conclusions.

2 Program and Project evaluation: definitions and concepts.

Notably higher than the past is the variety of projects and programs that the manager faces today: local development programs, social innovation projects, poverty reduction programs, politic programs, cooperation projects, research projects, are just few of the wide range of today's project typologies.

Global dimension, intangible nature of the objectives, wideness of target beneficiaries, are just few of new emerging characteristics of a program. They call to a re-examination of the models of project management, according to new management drivers, like mid and long term impacts, stakeholders' value.

Those last critical drivers of a project have been adopted by the European Community under the European planning programs, with the name of Project Cycle Management (PCM) (European Commission, 1993). The management approach focuses on wider effects and impacts of a project or program, and becomes critical for many reasons: the funding, the management, the communication.

A different approach to planning, distinguishes the traditional PM from the management of impacts: management of impacts is based on the "planning by objectives", while PM is based on "planning by activities". In the "planning by objectives" it is first identified the ultimate objective of project, that is the impact, then afterward the sub-objectives, that are the effects, necessary preconditions to generate impacts.

Project evaluation, that means exactly measurement of the created value, allows to evaluate the actual impact produced on a project's stakeholders, to assess ex-ante the coherence of a project, to provide feedbacks to managers and policy makers against the quality of management process, to improve/innovate the management.

Any framework designed to promote an understanding of evaluation should include a common conception of what evaluation is (Saskatchewan Minister's Advisory Committee on Evaluation and Monitoring, 1989).

Evaluation concepts are understood in very different ways. For this reason it is important to define them so everyone will attach the same meaning to them, or know what the differences are, thereby improving communication. Most definitions refer to program evaluation; some refer to project or policy evaluation. Some definitions use one term to refer to all types of evaluation, for example including policy and program evaluation under the umbrella label of 'policy evaluation'.

The concept of evaluation is wide and requires a focus against the context, the field of study. In management and economics evaluation is the assessment and the analysis of the effectiveness and the route of an activity, it involves the formulation of judgements about the impact and progress. "Evaluation is the comparison of the actual effects of a project, against the agreed planned ones. Evaluation looks to what is planned to do, what has been achieved, how it has been achieved" (Shapiro J., 1996; Archibald R., 2012).

Many different definitions of Evaluation can be found in the management literature. Evaluation is often as an activity that judges worth. Valutazione è spesso definita come l'attività che giudica il valore. For example, evaluation is "...the determination of merit, worth, or significance..." (Scriven, 2007), or "a course of action used to assess the value or worth of a program" (Farell et al., 2002). Policy evaluation is a family of research methods that are used to systematically investigate the effectiveness of policies, programs, projects and other types of social intervention, with the aim of achieving improvement in the social, economic and everyday conditions of people's lives (Government Social Research Unit, 2007).

This last definition highlights the need of measuring the change produced by a project, and not just limit to the output. The change should be measured in terms of improvement (value creation) or worsening (value destruction). The produced change takes different forms and dimensions, not always measurable and comparable.

Program and project evaluation models are approaches and techniques aimed at evaluate and/or measure one or more dimensions of change, like social, economic, cultural, technological, determined by actions taken in one or more contexts.

Most of the definitions of evaluation are linked to concept of improvement. As Kahan e Goodstadt (2005) argue, evaluation is a set of research questions and methods properly articulated to review processes, activities and strategies, with the aim of improve and achieve better results.

The strategic importance of evaluation for the project management is given by the need of do it so along the whole project life cycle. So according to this need, it can be effectively divided into ex-ante, interim, ex-post evaluation. The first applies in order to compare, select, finance alternative projects. The second one applies along the project development in order to improve the strategy, or the processes. The third applies to completed projects, in order to take lessons, insights, judgement and awareness about taken decisions and projects.

The real purpose of an evaluation is not just to find out what happened, but to use the information to make the project better. Different project evaluation 'process models' can be found in the management literature. Darabi (2002) proposes a systemic model of 5 phases:

1. program analysis and evaluability assessment
2. evaluation design
3. evaluation methodology development
4. implementation and administration
5. communication of evaluation findings

The statement that many programs and projects for social and economic development have not determined tangible and durable changes to target of stakeholders, induced the main international organizations for development (United Nations, World Bank, European Union) to give themselves frameworks and tools able to secure higher project efficacy, overall improvement of program management .

As the motto '*you cannot manage what you cannot measure*' sounds appropriate to stress the importance of the performance measurement and management in companies, the one '*you cannot change what you cannot evaluate*' appears equally appropriate to stress the importance of evaluation in the management of project and programs. A fundamental role in performing evaluations play the evaluation models.

3 Program and Project Evaluation Models: a literature review.

3.1 A collection from the literature

Many evaluation approaches and models exist. The literature suggests that no one approach is best for all situations. Rather, the best approach varies according to factors such as fit with basic values, the intent of the evaluation, the nature of key stakeholders, and available resources. In addition, it is not necessary to stick strictly to one approach: evaluations “might quite reasonably combine elements of different approaches or adapt to local conditions.” (Rogers and Fraser 2003) . A variety of approaches exists (Kahan, 2008): goal based, goal free, theory based (logic model), utilization, collaborative, balanced scorecard, appreciative inquiry, external, CIPP. The Logical Framework Approach (LFA) is probably the widely used to support planning, evaluation and management of a project (Practical Concepts Incorporated per US Agency of International Development, USAID, 1969).

Tab. 1 - Summary table of Program/Project Evaluation models literature review.

Approaches vary on the basis of what is evaluated, who participates in the evaluation, evaluation purpose, and how the evaluation is conducted. In practice, approaches are often combined.

Despite the large number of evaluation models, their heterogeneity in nature, field of application, phase of application, make the selection of the suited model(s) a strategic decision for the evaluation. In order to decide which model/approach best suites, a literature collection of evaluation models has been carried out. The collection results in 41 frameworks and/or models, some of them have common subjects, context/field of application, evaluation or measure approach. These commonalities allows to group in typologies. Besides they have been labelled by 'source' and 'nature' (qualitative vs. quantitative).

4 Conclusions

The collection of models/approaches for program and project evaluation purposes, represents the first step of a research project aimed to define a wider, prescriptive framework addressing support for the models selection. A suitable characterization should take into account some program's variables like phase and field/context, and some evaluation's variables like purpose.

The research contribute also to understand how important is the adoption of evaluation's model, in the management of impacts of programs and projects, in the perspective of stakeholders' value creation. Particularly important is the selection of the approaches and techniques in order to support ex-ante, ad interim, ex-post program evaluation. Useful implications arises as spin-off from the research, for practitioners such

as managers, policy-makers, public decision makers, that have to perform project and programs in ages of even higher expectations and needs coming from stakeholders.

A management model for sustainable SMEs marketing networks: it's all about knowledge

Lara Agostini *

Department of Management and Engineering (DTG)
University of Padua
Stradella San Nicola, 3 - 36100 Vicenza (Italy)

Structured Abstract

Purpose – This paper has two main aims: the first is to explore the development process of marketing networks, which are much less studied than R&D networks; the second is to identify those organizational and managerial factors that are supposed to have an influence on the success of a SMEs marketing network, given that the phenomenon has attracted much attention, but a high percentage of networks still fail. This allows to design a model for the sustainability of SMEs marketing networks.

Design/methodology/approach – To address the aim of the paper, a qualitative approach based on multiple case studies was used. Four SMEs marketing networks having a different level of success were selected so as to have a base of comparison. The analysis of cases is based on a framework of analysis developed on the grounds of the literature review, which represents the guide for the within- and cross-case analysis and the basis for the design of the final management model.

Originality/value – The study makes a noteworthy academic contribution to theory concerning marketing networks, since it allows to design a management model representing the development process of SME marketing networks, encompassing organizational and managerial factors involved in the process, as well as elements of contingency. Moreover, this study lays the grounds for future research in this field and gives rise to a new stream of research considering the specific role played by knowledge in networks.

Practical implications – This study provides managers with a model for the development and management of SMEs marketing networks and a series of guidelines for success. The most relevant recommendation is that an network needs to be managed, and to this purpose specific network-related skills and know-how are required. Moreover, the paper contains insights relevant also for public policy. Indeed, high investment in order to foster collaboration need to be sustained by strong campaign of awareness of these topics.

Keywords – Management model, Marketing network, Knowledge, SME

Paper type – Academic Research Paper

1 Introduction

The theme of inter-organizational relationships (IORs) draws the attention of both representatives of the economic life, because IORs may provide firms with significant benefits they would not reach by their own (O'Dwyer *et al.*, 2011), and the academic world, since networks are addressed by different disciplinary specializations (Dennis, 2000).

By now, literature has much more focused on networks established with the aim of cooperating in upstream value chain activities, such as R&D, engineering and manufacturing, with respect to downstream value chain activities, such as marketing, sales, distribution, and customer service (Teng and Das, 2008). Actually, given that recent IORs have developed with internationalization and market competitiveness enhancement as their main drivers (Yu *et al.*, 2011), this aspect is worth considering. IORs, despite being potentially relevant for all types of firm, seem to be particularly suited for small- and medium-sized enterprises (SMEs) which may need to look outside of their boundaries in order to overcome constraints related to their lack of all the required resources and competences needed to enhance their competitiveness (Colombo *et al.*, 2012). Therefore, if a SME is not obliged to grow dimensionally in order to survive, its survival cannot leave its development inclination, regarded as its ability to offer suitable strategic answers to the quali-quantitative changes of the socio-economic context it belongs to, out of consideration (Gianfelici, 2012).

Furthermore, the literature about this topic presents two main shortcomings: the first refers to the lack of a comprehensive analysis of the development process and management of networks; the second regards the issue related to network success, since previous research noted the high failure rate of networks (Hyder and Eriksson, 2005), as well as a lack of studies describing how success (or failure) has been achieved specifically (Reid *et al.*, 2008).

On these grounds, the purpose of this paper is to explore the development process of marketing networks and the organizational and managerial factors that are supposed to have an influence on the success of SME marketing networks, which allows to design a management model for the sustainability of SME marketing networks.

To reach this aim, a qualitative approach based on multiple case studies was selected since it proved to be particularly useful for network dynamics (Halinen and Törnroos, 2005).

The main contributions of the paper consist of a comprehensive framework representing the development process of marketing networks which has been designed on the basis of the literature and then tested through the case analysis, as well as a series of guidelines for firms willing to undertake a marketing network, which rises the issue of the importance of knowledge within the context of the development process of networks. In particular, results demonstrate that most of the critical factors leading to the successful formation and development of a marketing network are related to knowledge.

The setting of this study is the Italian context which is characterized by a high presence of SMEs which are at the backbone of the Italian economy. While on the one hand, their structure allows flexibility (Schumacher, 1973), on the other hand the limits related to their dimension constrain their ability to internationalize and face competitive and environmental pressures. For this reason, from the beginning of 1960s, different forms of collaboration, initiated by the phenomenon of the industrial districts, started to gain pace in many areas of Italy. More recently, the most relevant action is represented by the draft of the Network Contract Law in 2009, the first European law which aimed to formalize and regulate the issue related to collaborations; however, this is only one of the recent government actions, both national or regional, favoring firm collaboration. Therefore, within this context, this paper assumes a high relevance.

The remainder of the paper is organized as follows: firstly, a literature overview about marketing networks is outlined, before entering into the details of the design of the theoretical model of the marketing network development process; secondly, the methodology is described in deep details; thirdly, data analysis and results are illustrated; lastly, results are discussed in order to draw the conclusions, identify the theoretical and practical contributions of the paper and open new paths for future research.

2 Theoretical background

2.1 Literature overview about marketing networks

Marketing networks may be defined as formalized collaborative arrangements between two or more organizations focused on downstream value chain activities (Swaminathan and Moorman, 2009). The literature about marketing networks is not very broad, indeed few and sporadic publications in this area appeared before 2003 and most contributions date back to the period between 2007 and 2010 when the body of literature started to grow. The first papers (e.g. Eyuboglu and Buja, 2007; Mouzas et al., 2007) are mainly theoretical and have a broad scope aimed to describe the emerging phenomenon, as well as to identify the theories on which basis this new topic has developed (i.e. transactional cost economics theory, resource based theory, real options theory). Then, authors have started to restrict the scope of analysis, focusing on precise aspects related to marketing networks, such as drivers to network formation (Palmer and Bejou, 1995), governance (Bucklin and Sengupta, 1993), partner selection (Spekman *et al.*, 1996; Pansiri, 2005) and social elements like trust (Mehta *et al.*, 2005, Mouzas, 2007), commitment (Mehta *et al.*, 2005). Most of these studies are quantitative and aim to determine whether these factors may have an impact on network success or firm performance. Within this context, the main shortcoming concerns the development process of marketing networks, taking a process perspective and thus investigating the sequence of events leading to an outcome. Indeed, most papers adopt a cross-sectional approach and even those papers carrying out a longitudinal analysis, which would be supposed to adopt a dynamic perspective, investigate the relationship among the independent and dependent variables considering what is in between these variables as a black box. There is only one theoretical paper (Wang and Xiang, 2007) which aims at designing a theoretical framework meant to explain an observed sequence of events in terms of some underlying generative mechanisms or laws, particular circumstances or contingencies (Van de Ven and Huber, 1990) and it focuses on a service industry, as most papers do. Moreover, previous research also noted the high failure rate of networks (Hyder and Eriksson, 2005), as well as a lack of studies describing how success (or failure) has been achieved specifically (Reid *et al.*, 2008). In this regard, the extant research has tended to focus on networks and their success or failure rates, but has not looked at them in comparative terms (Ring, 2000). Regarding firm size, the literature has dealt both with SMEs and large firms. However, the SME context was preferred because

SMEs are at the backbone of the Italian economy, as anticipated, and networks are thought to be a concrete possibility SMEs have in order to overcome resource constraints in order to enhance their competitiveness (e.g., Colombo et al., 2012).

On these basis, the present paper aims to answer to the following questions: *how is the development process of SMEs marketing networks carried out?*, and *how do the organizational and managerial factors involved in the development process of successful SMEs marketing networks differentiate from those involved in the development process of unsuccessful ones?*.

2.2 The design of the theoretical framework

In order to design a theoretical model for the development process of networks, previous papers containing a model of network development process were identified and analysed in order to integrate different models within this stream of research. Organizational and managerial factors included in all papers were organized in order to categorize and include them in the model.

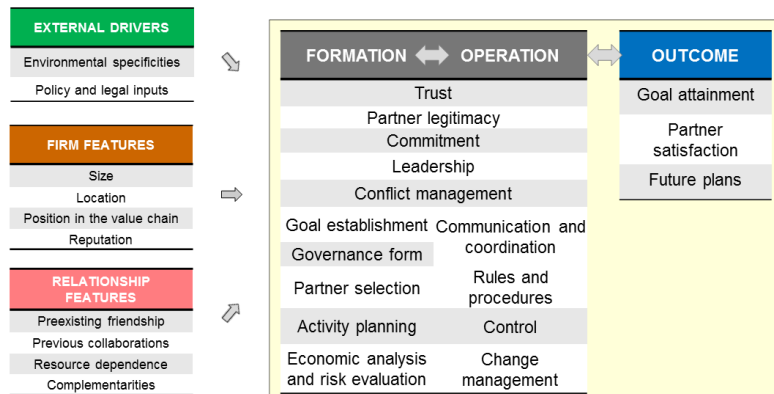

Most papers (e.g., Das and Teng, 2002; Batonda and Perry, 2003) describe the process of network development in terms of stages or phases. Even if different authors call them with different names, most of them agree on the main phases of network development. In particular, the process appears to be made up of three main moments: when the network starts to arise and partners decide how to integrate, which has been called network design (e.g., Doz, 1996); when the network begins operating and conducting its activity at full, which has been called network operation (e.g., Das and Teng, 2002); and when at a certain point partners need to evaluate the activity of the network, its costs and benefits, and decide what to do with the network, whether to continue, making some changes or not, or terminate, which has been called network evaluation (e.g., Wohlstetter *et al.*, 2005). Each of these phases includes different organizational and managerial factors. There are some factors which seem to influence both the design and operation phases and they are mostly “social” aspects related to trust (Hyder and Eriksson, 2005; Todeva and Knoke, 2005), commitment (Das and Kumar, 2011; Gebert-Persson *et al.*, 2011), legitimacy (Das and Kumar, 2011), leadership (Wohlstetter *et al.*, 2005) and conflicts (Todeva and Knoke, 2005; Wohlstetter *et al.*, 2005), which may take different connotations but are relevant throughout the whole process of network development. Instead, some factors interest only the formation phase and others only the operation

phase. In the design phase there are those factors which are needed to establish the network, that are goal establishment (e.g. Batonda and Perry, 2003; Hyder and Eriksson, 2005), partner selection (Doz *et al.*, 2000; Reid *et al.*, 2001), governance (Pansiri, 2005; Konsti-Laako *et al.*, 2012), activity planning (Gebert-Persson *et al.*, 2011) and economic and risk evaluation (Spekman *et al.*, 1998). Instead in the operation phase there are those factors meant to maintain the network, that are communication and coordination mechanisms (Wohlstetter *et al.*, 2005; Wigley and Provelengiou, 2011), rules and procedures (Larson, 1992; Reid *et al.*, 2001), control (Spekman *et al.*, 1998; Das and Kumar, 2011) and change management (Halinen *et al.*, 1999; Batonda and Perry, 2003). It could be argued that in the design phase there are more organizational factors, while in the operation phase more managerial factors, which reflect the type of decisions which are taken in the two phases respectively. In the outcome phase, managerial factors and decisions are present, as the evaluation of performance and impacts (Hyder and Eriksson, 2005; Todeva and Knoke, 2005), possible improvements (Wohlstetter *et al.*, 2005; Konsti-Laako *et al.*, 2012), and the decision whether to continue or terminate the network (Das and Teng, 2002; Das and Kumar, 2011).

The process of network development is not a stand-alone process, in the sense that there are a number of affecting factors. There are a few authors (Das and Teng, 2002; Pansiri, 2005) explicitly dealing with these factors; instead, many authors cite them without giving them a precise positioning within the context of network development. After analyzing papers in deep details, three main categories could be identified: external drivers which include those socio-economic conditions and specific policies or regulation that can push the development process of an network (Ring, 2000; Lapiedra *et al.*, 2004; Pansiri, 2005); firm features which refer to the distinctive characteristics of a partner, such as size, location, position along the value chain and reputation (Das and Teng, 2002; Pansiri, 2005); and relationship features which is not explicitly dealt with in the literature, but items like preexisting friendship of partners or complementarities are frequently cite and seem to have an influence on the development process (Das and Teng, 2002; Todeva and Knoke, 2005).

Figure 1 depicts the framework designed taking the macro-stages theory (Batonda and Perry, 2003) as a reference point, but considering also possible dynamic changes, which implies a not strictly sequence of stages and, thus the possibility to go back to a previous stage in order to make some changes.

Figure 1: The theoretical model for the development process of networks

3 Methodology

A qualitative methodology based on multiple case studies has been selected for three main motives (Yin, 2009): firstly, “why” and “how” questions are likely to favor the use of case studies, experiments or histories; secondly, the case study is preferred in examining recent or contemporary events, but when the relevant behaviors cannot be manipulated, as in the case of networks; lastly the case study method should be used when the researcher wants to understand a real-life phenomenon in depth, but such understanding encompasses important contextual conditions because they are highly pertinent the phenomenon of study. Along this vein, cases are analysed combining a retrospective and real time temporal orientation. Furthermore, Halinen and Thoroos (2005) explicitly assert that “it is obvious that case strategy is more suitable for the study of business networks”.

3.1 Case selection

This study analyses four cases of marketing networks among partners from different Italian industries. Several factors were considered in selecting the cases. First, the study is limited to manufacturing networks not only to bridge a gap in the literature, as previously explained, but also to minimize extraneous variation (Eisenhardt, 1989) that might be derived from differences between the service and manufacturing sectors (Yan and Gray, 1994). Second, since the issue related to success is worth investigating, two successful (S&S and RAB) and two unsuccessful (CDP and CEV) marketing networks were

selected. In this study, the level of success reflects the level of goal attainment (Arino, 2003). In so doing, also the maximum variation sampling principle (Patton, 2005) is respected. Lastly, case studies are particularly useful when investigating recent or contemporary events (Eisenhardt, 1989), hence we opted for choosing recent networks.

Table 1 summarizes the major characteristics of the selected networks. The companies and individuals are disguised to ensure confidentiality.

Table 1: Summary of major characteristics of selected cases and data collection

<i>Network pseudonym</i>	<i>Industry</i>	<i>Year of foundation</i>	<i>N° of partners</i>	<i>Aim</i>	<i>N° of interviewees/ interviews</i>
S&S	Ho.Re.Ca.	2006	9	Participate to trade fairs together, get information about potential clients and markets, provide clients with complete solutions	4 interviewees 8 interviews
CDP	Shoe	2009	4	Clients' fidelity through the collection of unsold goods to be sold directly through outlets	3 interviewees 6 interviews
RAB	Automotive	2009	12	Participate to trade fairs, candidate to large clients, provide them with finished products and services	4 interviewees 7 interviews
CEV	Construction	2010	16	Participate to public offerings, provide clients with full solutions	4 interviewees 7 interviews

Table 2 contains comparative data instances for each case relative to each of the key constructs in the theoretical framework that are developed in this article.

3.2 Data collection

Data for this study were collected from both interviews and secondary sources, such as company briefings, press releases and internal reports, such as to provide data

triangulation (Patton, 2002). Interviews were carried out following a semi-structured protocol which was developed on the basis of the literature review and our research questions and then shared with key informants during some preliminary interviews before applying it to a pilot case. This helped identify the most significant aspects, those aspects that, indeed, were not so relevant and those that needed to be investigated in further detail. Moreover, the pilot data provided considerable insights into the basic issues being studied, so that the final research design was informed both by prevailing theories and by a set of empirical observations.

Based on the data collection protocol, 28 in-depth interviews with actors involved in the selected networks (i.e. network partners CEO, consultants and external brokers) have been carried out. Since the unit of analysis is the network, respondents were summoned to answer in name of the network and keeping in mind that the object of study is the network and not themselves. More than one informant for each network was interviewed (see Table 1), so as to respect investigator triangulation (Patton, 2002). Furthermore, some informants were interviewed more than once, with a period of time passing between the two sittings, so as to capture aspects related to network dynamics over time. To this regard, apart from scheduled interviews, I had regular contact with informants over a period of two and a half years, which allowed me to track the development of each marketing network over time. The duration of each interview was between thirty minutes and two hours, according to the time the interviewee had available, and all interviews were recorded. All the interviews were conducted during the period between March 2011 and November 2013. A complete database containing all required information about all cases was created, which is recommended in order to allow personal inspection and following examination (Yin, 2009).

3.3 Data analysis and coding

We structured our methodology according to established procedures for theory-building inductive research (Miles and Huberman, 1994; Voss, 2002), working recursively between our multiple cases (Eisenhardt, 1989; Yin, 2009) and the theory we were developing. Following Eisenhardt (1989), I carried out data analysis in two macro-steps: the within-case analysis, in which each single case is treated as a stand-alone entity, and the cross-case analysis, whose main aim is to examine these cases comparatively using different techniques.

In this research study, due to the fact that this is not a totally unexplored field, the coding process is mainly “theory-driven” (Ryan and Bernard, 2000) since many categories already existed in previous literature as explained in the framework of analysis. However, also new categories have been identified following the classical open coding technique (Corbin and Strauss, 1990). Data were coded manually, including as many potential themes as possible, coding extracts of data inclusively, so as not to lose the context (Bryman, 2001). In so doing, it was possible to build the book of codes for the present study. The subsequent step consisted in the axial coding (Corbin and Strauss, 1990) which aims to make connections between categories, thus identifying a set of relationships using visual representation, as for example schemes and tables (Miles and Huberman, 1994), which facilitates the identification of patterns.

While documenting patterns in the data and constructing tentative theoretical explanations, data were used to challenge and extend our theory (Strauss and Corbin, 1998). During the repeated process of interrogating the data, revising the theory, and returning to the data, the themes presented in this paper eventually emerged. In the presentation of the results, the use of a combination of tables describing the data from which inferences were drawn (Miles and Huberman, 1994) proved useful.

4 Results

In this study, there are two key themes which make reference to the two research questions: the development process of marketing networks and the organizational and managerial factors that are supposed to have an influence on the success of a marketing network. The output of the former is the management model for the development process of marketing network; instead, the output of the latter contains a series of propositions dealing with those organizational and managerial aspects influencing the success of the development process of marketing networks. Next paragraphs deal with them separately. In the presentation of the results, I make use of a combination of illustrative examples and tables describing the data, as well as interviewees’ quotes from which inferences were drawn (Miles and Huberman, 1994). Moreover, here cases are dealt with one by one and in comparative terms, thus expanding on data presented in Tables 1 and 2.

Table 2: Comparative data from case studies

GENERAL ASPECTS				
Case study	S&S	CDP	RAB	CEV
Drivers	Acquire new clients, increase their marketing activities, take advantage of a chance offered by Unindustria (both internal and external drivers)	Enhance competitiveness, improve client fidelity	Overcome the crisis of the sector and reach new clients; take advantage of a chance offered by the Union of Industrials	Crisis of the industry, lack of orders, need to create synergies and gain contracts otherwise unattainable singularly
Responsible of the network business idea	Union of Industrials of the province, helped by a partner CEO	A partner CEO, supported by the shoe trade association	A partner CEO, helped by the Union of Industrials of the province	Union of Small Firms of the province
Criteria for partner selection	Companies belonging to the same industry and territory, manufacturing complementary products, potentially interested in the project; later on, no competitors are accepted	Shoe makers belonging to the district realizing complementary product, not competitors	Firms of the same industry, with process complementarities (not competitors), willing to invest some money in projects	Firms of the same industry, mainly associated to Apindustria, willing to take part to the project, not competitors
Partner entering/exiting	Two competitors and another firm exit	One firm exited and a bank entered	One partner exited and two entered	Some entered and some exited
Partner core business	Appliances producers (e.g., kitchens, ovens, food processing equipment, laundry solutions)	Shoe makers (assemblers)	Components production and assembling	Different specialization in the construction industry (e.g. hydraulic, architecture)
Partner business model	Firms selling products with their brand in the B2B industry	Shoe makers selling with company brand, only one is also a subcontractor (B2C)	Firms selling products without brand (suppliers) in the B2B	Firms selling in Italy, only one also abroad
Market position of partners	In the same market segment, at the same level of the value chain	In the same market segment, at the same level of the value chain	In the same market segment, at different levels of the value chain	In different market segments, at different levels of the value chain
Partner reputation	Same level of reputation	Almost same reputation	Different level of reputation	Different level of reputation
Previous knowledge of partners	Yes	Yes	Almost all	Almost all
Previous collaborations together	No	No	Yes, some of them	No
Other previous collaborative projects	Not partners, but the Union of Industrials	No	Yes, they are used to collaboration, even if not formalized	No

ORGANIZATIONAL AND MANAGERIAL FACTORS								
	Design	Operatio n	Design	Operatio n	Design	Operatio n	Design	Operatio n
Business plan	Activity planning, not economic analysis	Activity planning	The minimum required by the contract, not economic analysis	Totally informal activity planning	The minimum required by the contract, not economic analysis	Activity planning	Not really	
Governance form	Consortium		Network contract	Consortium (selling product with the NC was a problem)	Network contract		Consortium	
President and/or bodies	President: Union of Industrial s		President: a partner CEO Bodies: internal board		President: a partner firm Bodies: internal board		President: external manager Bodies: internal board	
Communication, coordination and decisional process	Periodical meetings	Periodical meetings	Periodical meetings	Informal meetings	Periodical meetings	Periodical meetings	Periodical meetings	Periodical meetings
Existence of shared norms and rules	Yes	Yes	Yes	Informal rules	Yes	Specific rules to manage orders	Yes	nr
Control of activities	Periodicaly by the Union of Industrial s	Periodicaly by the Union of Industrial s	No	Sales through the shop (planned)	Periodicaly	Periodicaly	No	Informal
Conflicts	Among two competitors	No	Not with partners, but with external entities	Not with partners, but with external entities	No	No	No	No
Change management	Regarding criteria for partner selection	Evolution of goals	Regarding governanc e (network form) and goals		No	Evolution of goals		The president is going to change
Commitment to the network	Same level by all partners		One partner is more committed	Not relevant difference among partners	Three firms are more committed	Some firms are more committed	Low level of commitment, equal among partners	Low level of commitment, equal among partners

Level of trust	Good level of trust	Good level of trust	High level of trust	High level of trust	High level of trust	Very high level of trust	Good level of trust	Decrease in the level of trust
EVALUATION								
Partner satisfaction	Medium-high		Low		High		Very low	
Main difficulties	Relationships, trust building; some of them overcome some not		Bureaucracy, not able to solve them, they are the real obstacles		A company which did not want to invest some money (then it exited); not equal benefits		Partners with different size and thus with different facilities and inclination to investment; aptitude towards collaboration; lack of planning	
Plans for the future	Terminate		Continue		Continue		Uncertain	
Aspects to be modified or re-evaluated	nr		Yes, common brand, other outlets		None		Yes the planning phase which is now absent but required	

* nr = not relevant

4.1 The development process of marketing networks

The analysis of cases shows that marketing networks develop through a process made up of four phases pushed by an initial input which consists of an idea of business involving different actors. At the beginning, this input is just a concept which can be used for commercial purposes prior to its transformation into a viable business. For this reason, the input to the process has been called *network business idea*. Secondly, the first activity carried out after the network business idea is always partner selection which happens before any other plan is made or decision is taken, so as a stand-alone phase. To support this evidence, a representative of the association supporting CEV pointed out:

“Without partners, any decision can be taken and any activity can be started. Thus, this is the first step to be carried out.”

This is quite logical, since an network implies more partners working together, so the first decision to be taken is to whom collaborating with. This step may be carried out by a firm in first person, more probably when one of its members is responsible for the network business idea, as in the case of CDP, by a firm helped by an external association, as in the case of RAB and S&S, which are supported by Union of Industrials of their province during the start-up of the network, or totally by an external association, when it is responsible for the network business idea, as in the case CEV which is created by the Union of Small Firms of the province.

When partner selection has been carried out, since partners are not familiar with the project and they do not figure out how precisely it could develop, they are used to meet all together in different sessions in order to design the network. To this regard, the association supporting S&S asserted:

“The network needs to be ideated and shaped, therefore all partners should start collaborating since the beginning in order to make the network start.”

This phase may include various activities, but the three points that are always dealt with are the governance form of the marketing network, goal establishment, and activity planning which allows to reach objectives. The governance includes the designation of the president and internal committees or bodies, or any other requirement of the contract which is always present in the analyzed cases, either being a network contract, as in the case of CDP and RAB, or a consortium, as in the case of S&S and CEV. These preliminary decisions, in particular activity planning, may be more or less formalized, at the point that they can be developed in the context of a real business plan or only drafted, also depending on what the contract requires. In particular, firms signing a network contract (i.e. CDP and RAB) are obliged to write in the contract the network program. Another factor which assumes particular relevance in all investigated cases is the choice of the network brand. Actually, on the one hand, marketing networks are supposed to be directly visible by clients and, on the other hand, since their aim is mainly to increase competitiveness, even though in different forms and with different specific objectives, the intangible component related to emotions and suggestion created by a brand is highly important (He and Balmer, 2006).

In those networks where the activities in the development process are carried out in a more formal way, partners also establish specific rules and procedures for the going on of activities. They more often regard how to deal with orders and involve different partners in different requests from clients; otherwise, they may also concern what partners can or cannot do in name of the network. For example, in the case of RAB, firms which are positioned at different levels of the value chain, partners agreed on designating the final assembler to maintain the relationship with clients, since it is the closest to the market. Then, for each order, partners realizing the requested products or manufacturing phase are selected. Instead, in the case of S&S, rules and procedures were established regarding the selection of trade fairs where to participate jointly and the sharing of information about markets gathered during these fairs and other specific actions.

The operation phase starts when the network begins to function and some activities are effectively put in practice. Owing to many partners and activities being involved in the network, the communication and coordination process seems to be unavoidable. It often consists of periodical meetings where partners talk about what to do and take decisions. Face-to-face meetings and verbal communication are preferred in all cases. Meetings may also represent a moment of control of activities by partners or by external entities which play a role in the network, as well as a situation when discussing possible conflicts emerged among partners. As the literature indicates (Batonda and Perry, 2003; Todeva and Knoke, 2005), conflicts are functional when more people work together, so they are not always negative; however, it is important that they are treated as any other issue regarding the network and that they are dedicated the attention they deserve. For example, in the case of S&S there were some conflicts inside the network due to the presence of three competitor partners which were not able to find their way through collaboration. Instead, in the case of CDP, conflicts rose with external entities. In any case, as the CEO of one of RAB partners asserted:

“Conflicts are ordinary events when collaborating, overall at the beginning, hence they need to be treated as any other shortcoming in the development process.”

On the contrary, in the case of RAB and CEV, no conflicts emerged, hence this activity has not been carried out. Since cases proved that conflicts may arise in any step of the network development process, this activity has a cross-sectional dimension.

Another relevant matter which needs to be taken into account is change. Due to an infinite number of circumstances, every aspect of the network may change with the passing of time, so change management represents something partners face day by day. This last element makes us understand that there may be a return to previous phases which leads to a change of initial settings. The most relevant change happened in CDP which had to change their governance form since the network contract did not result the appropriate tool for partners' specific activities and goals. Hence, they reconsidered the whole project and established a consortium supporting the network contract. Other relevant changes regard the reconsideration or evolution of goals, as in the cases of S&S and RAB which, once reached the first goals, started setting new ones, which obviously caused the need to re-plan activities.

In the design phase, the economic evaluation, which was present in the framework of analysis based on the literature review, is never mentioned in the case analysis. Actually, this element is never carried out, despite its potential importance was highlighted during two interviews. To this regard, the CEO of one of RAB partners asserted:

“Realizing a complete and accurate business plan including a detailed economic analysis would be useful for partners who may have a concrete description of all the aspects related to the project they are participating in.”

As a consequence, it has been included in the final framework (see Figure 2), since the fact that the economic evaluation is not carried out seems to be a shortcoming of the analyzed cases, rather than an aspect which is not worth considering.

Other than all these practical and tangible factors, there are other aspects which deserve to be considered due to their high level of importance for marketing networks. Since many people are involved in an network, it is impossible to overlook those intangible elements regarding personal relationships and attitudes. Indeed, during the design and operation phase of the development process, three main elements intervene throughout the development process of all cases, that are trust, commitment and leadership. Due to their nature, they do not take place in a precise moment, instead they go hand in hand with the going on of activities and are shaped during the process. They need to be taken into account in the development process of marketing networks since they may influence and be influenced by all the above mentioned elements.

The last phase of the process is the evaluation. After the network has operated for a certain period, it arrives a moment when partners take stock of what they have done and the results they have obtained. They mainly evaluate whether goals have been attained or not, if partners are satisfied with their participation to the network and think about future plans, in case they decide to continue with the marketing network. This is the case of RAB whose partners have reached predetermined goals and are going to continue their network. Also CDP partners have decided to go on with the network, despite they have not reached their objectives yet, but feel confident that they can improve the network success. Of course, this may also represent the moment in which partners decide to interrupt the network both because they have reached their goals or because they realize it is not worth doing. This happened in the case of S&S partners which have reached their goals, but then decided to interrupt the network. Due to the standstill, CEV partners are still evaluating whether to continue or not. The fact that at this point partners may think

about future plans implies that there might be the need to go back to the design phase to establish new goals or plan different types of activities, as anticipated. This confirms the fact that the development process of marketing networks is not strictly sequential, but it encompasses the possibility of passing from one phase to the subsequent one and then again to the previous ones.

As far as elements of contingency are concerned, many different elements emerging from each single case have been taken into consideration, so as to provide a picture as complete as possible. Furthermore, cases proved that contingency factors related to external factors are more likely to make the development process of marketing network start up, while firm and relationship features intervene later on during the partner selection phase. Next paragraph expands on this issue.

Evidences emerging from cases are in line with the framework of analysis presented in paragraph 2.2, with the exception of some elements that has been modified or added. More specifically, for first, the partner selection phase has been isolated as a stand-alone phase; second, leadership and conflict management have assumed a cross-sectional dimension throughout the design and operation phases.

The factors that has been added concern the network business idea, branding and previous experience of partners in other collaborative projects, not necessarily with the same partners. To this regard, a key informant asserted:

“Having participated to previous collaborative projects makes each partner more prepared towards the new network, hence this aspect may play a significant role in its development process.”

Being related only to each firm, it has been included in elements of contingency related to firm feature.

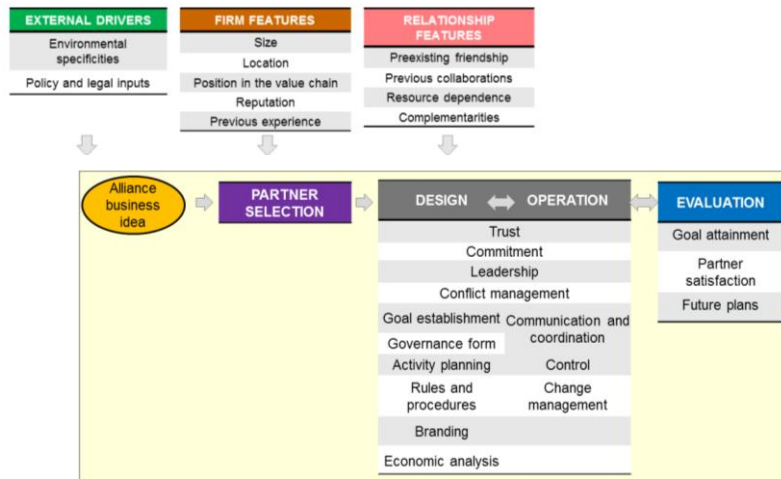

Figure 2 summarizes the proposed version of the management model for the development process of SME marketing networks.

4.2 Organizational and managerial factors and marketing network success

This paragraph is intended to shed light on the second research question investigating the organizational and managerial factors that may have an influence on the successful development process of marketing networks. Organizational and managerial factors, taking into account also contingency factors, are analyzed and compared among cases so

as to identify patterns leading to the discovery of key success factors for the development process of marketing networks.

Figure 2: Model for the development process of SME marketing networks

Partner selection presents similarities among all cases, indeed the same criteria for partner selection are used. SMEs seem to privilege collaborations with partners located in the same industry and geographical area, because this entails partners share the same problems and values. A partner CEO asserts:

“Belonging to the same industry, we already know the environment we operate in and we share difficulties; as a consequence it is easier to communicate and look for collaborative solutions.”

Another partner CEO gives another point of view:

“I prefer to make affairs with someone who I know shares my ideas and values, and I can be aware of this only if it is quite close to me.”

This last quote introduces another important element for partner selection, that is previous knowledge of partners. Indeed, SMEs tend to search for partners among people they already know, which reflects a precautionary attitude of Italian entrepreneurs. Proven that, in general, they have difficulties in collaborating with other entrepreneurs, if they manage to do so, at least they do it with someone they already know, which gives them a higher sense of confidence.

Secondly, product complementarity seems to be essential for collaboration. In particular, SMEs willing to be part of a marketing network look for partners offering products or services they cannot provide singularly, thus becoming more attractive to clients. This is in line with previous literature asserting that one of the main drivers to collaboration for SMEs is to overcome resource constraints (Lorenzoni, 1990). Related to this issue is the fact that SMEs do not want any competitor to be part of the same marketing network. Whilst in some R&D networks collaboration among competitors may happen (Gnyawali and Park, 2009), in marketing networks they seem absolutely undesired. Indeed, in CDP, RAB and CEV no competitors were accepted during the partner selection phase. Indeed, in the case of S&S at the beginning there were two or three competitors in the marketing network, but this caused conflicts leading to competitors exit from the network. As a consequence, also in the case where this was not a selection criterion since the beginning, it became later on. This may be due to the fact that clients have a direct visibility on marketing networks, so balancing the dichotomy cooperation-competition becomes much more demanding. Based on these evidences, the first proposition is shaped.

P1: When firms are close one another, in terms of location, production and culture, already know each other and realize complementary products, they are more likely to undertake and maintain a marketing network.

The suggestion from cases is that these criteria are supposed to increase the level of initial trust among partners. To this regard, the association supporting S&S asserted:

“Italian entrepreneurs, who are distrustful in nature, feel more relaxed if they know other managers they collaborate with. [...] We also realized that suspicion increases sharply if competitors are involved in the same network, overall in case of marketing networks which have a direct visibility towards clients.”

Always referring to competitiveness inside the network, the CEO of one of RAB partners explicitly confirmed:

“I felt comfortable and confident because no competitors were involved in the project.”

The CEO of one of CDP partners completed the picture by stating:

“I prefer to choose partners in my district since I know they share my values and my problems, which increases the initial level of trust towards them.”

These evidences lead to the second proposition exposed below.

P2: In SMEs marketing networks, selecting not competitor known partners which manufacture complementary products and with a high level of proximity increases the level of initial trust among partners.

Always talking about partner selection, the initiator of RAB explicitly asserted:

“When selecting partners, it is fundamental that they are willing to invest some money in the network; for this reason, doing a due diligence before starting the marketing network could be a useful practice.”

Indeed, not only in RAB, but also in CDP, those firms which were not inclined to investments, despite modest, ended in exiting the network. Accordingly, the following proposition has been developed.

P3: In SMEs marketing networks, selecting partners prepared to invest money in the network decreases the probability that those partners exit the network.

Focusing on goal establishment, we can notice that the main difference emerging from cases concerns the way they are established, that is whether the macro-objective is set and then separated into more detailed sub-objectives, so as to reach the macro-objective step-by-step, or the macro-objective remains the only established goal without any intermediate step. In the two cases of success (i.e. S&S and RAB) the macro-objective is divided into more concrete and simpler sub-objectives before going on with more challenging goals. Before S&S partners started to realize finished solutions, they participated to trade fairs together, gathered information about potential interesting markets and clients. Similarly, RAB partners, before approaching large clients, went to trade fairs in order to promote their network brand and acquire some smaller clients. Instead in the two unsuccessful cases, partners start with a very ambitious goal since the beginning, as Table 3 shows.

Table 3: Goal establishment and previous experience

<i>Level of success</i>	<i>Cases</i>	<i>Goal establishment</i>	<i>Previous experience</i>
High	S&S	Start with few and concrete goals	High
	RAB	Go on with more ambitious goals	High
Medium-low	CDP	Start with ambitious goals	Low
	CEV		None

In particular, CDP goal was to collect unsold products from their clients, which represents a very complex and ambitious goal, as well as CEV goal whose partners aimed to realize complete solutions for clients. They did not think about any way to make their network gain consensus and visibility, nor any intermediate goal so as to make trust and commitment among partners increase.

Since we guessed one possible explanation could be the level of experience of collaborative projects of actors involved in the network, we checked this element of contingency and find interesting evidences. Indeed, in the two cases of success, there are at least one actor that has a high level of experience of collaborative projects. In S&S, the external entity, which supported the network throughout the whole network development process, is a body of the Union of Industrials which was born with this precise mission; hence, it had already supported the design and operation of other networks before S&S. To this regard, the responsible of the Union of industrials asserted:

“We noticed that proceeding step-by-step enhances the chance the network is successful, firstly because it entails a more precise activity planning and control, secondly because in so doing partners are more likely to perceive they are reaching established goals, hence the level of trust and commitment increase.”

Instead, in the case of RAB, partners are already used to collaboration, in the sense that they previously collaborated either with some of the same partners or with other firms. This different attitude with respect to partners of other networks seems to be related to the location of partners. Actually, the Emilia Romagna region is particularly active in promoting collaborative projects, even before the establishment of the network contract. The CEO of a partner affirmed:

“Having experienced other collaboration projects, we know it is better to set minor objectives and then go on with more ambitious ones. In this way, the macro objective has more chances to be reached.”

Based on these evidences, the following two propositions are presented.

P4: If involved actors have a high previous experience of collaboration, they are likely to follow a step-by-step approach in goal establishment.

P5: Having a step-by-step approach in goal establishment increases the probability of a successful SME marketing network.

The issue related to governance deserves particular attention. Among the four selected cases, S&S and CEV are consortia, while CDP and RAB are network contracts. While in the case of the two consortia, the governance form does not play a significant role in determining the success of the network, in the two cases of network contract, the governance is partially responsible for the failure. Indeed, since the network contract does not establish a new legal entity, partners can't sell products through the network contract, so they have to establish specific rules and procedure to deal with this issue, otherwise potential conflicts or barriers may arise. This aspect is particularly delicate in the case of horizontal marketing networks where all partners are positioned at the same level of the value chain and, potentially, any partner could be the head of the network and have direct contacts with clients, as in the case of CDP (see Table 4). Indeed, CDP partners were not able to establish specific procedures so as to overcome this "problem", so they had to establish also a consortium which could act as a separate legal entity in name of the network partners. Instead in the case of a mixed network, like RAB, it is easier that the head is naturally selected (i.e. the one closest to the client which is used to maintain the relationship with it). As a consequence, a mixed position of partners along the value chain facilitates the positive impact of rules and procedures on network success.

Table 4: Rules and procedures and position along the value chain in network contracts

<i>Level of success</i>	<i>Cases</i>	<i>Governance form</i>	<i>Rules and procedures</i>	<i>Position of partners in the value chain</i>
High	RAB	Network contract	Well established	Mixed (vertical + horizontal)
Medium-low	CDP	Network contract	Informal	Horizontal

As a consequence, the following two propositions are outlined.

P6: The presence of well-established rules and procedures has a greater impact on the success of a SMEs marketing network governed by the network contract, than on the success of an SMEs marketing network governed by the consortium.

P7: In SMEs marketing networks governed by the network contract, a mixed position of firms along the value chain moderates the impact of rules and procedures on network success.

Always referring to the network contract, being a new and specific tool, also the presence of someone who is familiar with the principles of the network contract is fundamental for the successful starting up of a marketing network governed by the network contract. Indeed, the sustenance of the Union of Industrials of its region during the draft of the contract and the initial settings of RAB was essential since the law had just been approved and it was one of the first network contracts to be signed. Some people in the Union of Industrials had studied the network contract law in details, so it had a good knowledge of this new tool. On the contrary, in the case of CDP, which is also one of the first network contracts, the shoe trade association supported the network at the very beginning, but since it was not so skilled in matter of network contracts, it asked for an accountant's assistance; however, he had never heard about the network contract hence he had any knowledge of the network contract (see Table 5).

Table 5: Level of knowledge of the network contract of involved actors

<i>Level of success</i>	<i>Cases</i>	<i>Governance form</i>	<i>Network contract experts</i>	<i>Knowledge of the network contract</i>
High	RAB	Network contract	Unindustria	Medium-high
Medium-low	CDP	Network contract	Accountant, Acrib	Low

As a consequence, we hypothesize that the presence of an actor having a good knowledge of the network contract is relevant for the successful starting up of a marketing network.

P8: In SMEs marketing networks governed by the network contract, being supported by an entity with a good knowledge of the network contract is fundamental for the success of the starting up of the network.

Different actors involved in the network development process have been mentioned. One having a main role is the network manager who is responsible of the going on of activities, their coordination and control, and who maintains the leadership of the network. The network manager can be both internal to the network or external. In the case of CDP and RAB the network manager is the CEO of one of the partners of the network; instead, in the case of S&S the network manager is the responsible of the body of the Union of Industrials. The case of CEV is atypical since the trade association supporting the network formally nominated an external person as the president of the network, hence the tasks of the network manager are deployed by both actors. What emerges from the cases is that in the case of S&S and CEV, that are the two successful cases, there is a network manager with both network-related skills and a strong leadership. On the contrary, in the case of CEV there is not a strong referential figure, the management of the network is in the hand of one formal president, who limits to head meetings, and the trade association whose representatives do not possess neither leadership characteristics or specific skills in matter of networks. Instead, the case of CDP is in the middle of the other cases because the network manager is a moral leader, despite not possessing all necessary skills and know-how required to manage a marketing network. These evidences suggest that it seems not important whether the network manager are inside or outside the network, the relevant issue for success is that he has certain features. On these ground, the following hypothesis is formulated.

P9: The higher the leadership attitude and the network-related skills of the network manager, the higher the probability that a SME marketing network is successful.

Cases show that different organizational and managerial activities may be carried out in a more or less formalized way. In particular, activity planning may consist of a detailed medium-term plan including different activities and actions the network partners arrange to carry out with a precise scheduling, including also a moment of control over the

established scheduling, as in the case of S&S and RAB where there is a proactive attitude. Oppositely, activities may be planned day-by-day with a short-term orientation, as in the case of CDP and CEV which have a reactive approach. Following the same vein, communication and coordination processes can follow a regular pattern of meetings to which all partners participate and tasks are divided among members so as to know who does what, as in the case of S&S and RAB; otherwise they can be managed informally, as in the case of CDP and CEV in which informal communication is preferred and there is not a precise coordination of partners and activities. These opposed situations suggest that on the one hand there may be a context in which everything is formally planned and controlled, and partners follow specific rules and established procedures, while on the other hand a context in which there is not a comprehensive vision and control of the whole network and everything result less formalized. On these grounds, the following proposition is articulated.

P10: A higher degree of formalization of activity planning and control, communication and coordination mechanisms leads to a successful SMEs marketing network.

The last issue is related to the network brand. In three of the analyzed cases, this topic is given particular attention, in the sense that partners of these marketing networks demonstrated high consideration of this theme. The CEO of one of S&S partners asserted:

“For our network, we wanted a brand recalling our specific activity which also highlighted our Italian character. Hence, we opted for S&S since the steel is the main material we work with and one of the main feature associated with the made in Italy is style. Moreover, at the same time, we opted for an English brand in order to be more internationally oriented.”

Also RAB partners chose an English brand:

“A marketing network needs to have a short and effective brand evoking internationalization.”

Instead, partners of CDP relied on different arguments:

“CDP is the name of the confraternity of shoe producers which was born in 1268. It seemed to us an appropriate name for our network contract since it evokes our origins.”

Both successful cases have a short brand, easy to remember because somehow related to the products realized by partners, and very effective. Instead, CDP and CEV opted for a long network brand which is the result of a reasoning favoring the roots of the network and no particular consideration towards this element, respectively. This evidence inspired the last proposition.

P11: A short, effective and easy to remember brand contributes to the success of a marketing network.

5 Discussion and conclusions

The study examined the development process of marketing networks, with a particular focus on organizational and managerial factors involved in the process and having an influence over marketing network success. Investigating these aspects related to marketing networks provides an important contribution as on the one hand prior studies have tended to disregard them, dedicating much more attention to R&D networks (i.e. Hagedoorn, 1993; Belderbos *et al.*, 2003), and on the other hand, despite the high failure rate of networks (Hyder and Eriksson, 2005), the extant research has not looked at successful and unsuccessful in comparative terms (Ring, 2000). Moreover, Italy represents a fertile field for research in this field since the first European law dealing with the topic of formal collaborations has been approved in 2009, which is the most relevant but also one of the policy actions favoring firm collaboration.

The first main finding consists of a scheme representing the development process of marketing networks. It includes the phases of the process, that are the network business idea, partner selection, the network design, operation and evaluation, all pushed by the initial network business idea. The concept of the network business idea is new in the literature about marketing network, but actually it is the element which makes the process start, thus its characteristics, meaning its clarity, its feasibility, the person who is the creator, may shape how the process is then carried out. Also the fact of moving partner selection out of the design phase is a novelty, indeed previous literature consider this element inside of the formation process (e.g. Reid *et al.*, 2001). Instead, we guess it comes before any other phase, since it is a prerequisite for networks. In the network design, operation and evaluation all relevant organizational and managerial factors are highlighted. They represent the link between the first and the second research questions.

Indeed, the second finding deals with those organizational and managerial factors having an influence on network success. Previous paragraphs have dealt with each of them in deep detail, hence here the discussion aims to provide an interpretation of the above-discussed results. Table 6 provides an overview of the most significant findings, highlighting those aspects that have some relationship with knowledge in its broader meaning. Cases prove that the partner selection phase is mainly based on previous knowledge, in the sense that Italian managers, characterized by a skeptical attitude towards collaboration, prefer to collaborate with someone they already know, someone who is next to them, and of course who is not a direct competitor. Hence interpersonal knowledge makes manager be more confident about the collaboration and trustful of their partners, which enhances the probability of a successful marketing network. During the network design and operation, more technical elements seem to play the main role, that are previous experience of collaboration, which entails that involved actors have developed network-related know-how, knowledge of the possible contractual forms, including the regulations of the recent network contract, and the skills of the network manager. These elements may be categorized as network-related know-how and skills.

Table 6: Interpretation of results assuming a knowledge perspective

<i>Phase</i>	<i>Relevant factor</i>	<i>Knowledge perspective</i>
Partner selection	Previous knowledge of partners Proximity Non competitors	Interpersonal knowledge
Network design	Previous experience of collaboration Knowledge of the network contract Formalization	Network-related know-how and skills
Network operation	Leadership and know-how of the network manager Formalization	Network-related know-how and skills

5.1 Theoretical and practical implications

The study makes a noteworthy academic contribution through the development of theory concerning marketing networks. Generally speaking, being completely dedicated to marketing networks, it enriches and enlarges the knowledge about this topic which has

been under-investigated until now. In this context, this research addresses one specific issue, that is the development process, which are supposed to contribute significantly to the literature. Previous contributions have been integrate in a systematic way, which makes it possible to design a comprehensive framework representing the development process of marketing networks, which encompasses organizational and managerial factors involved in the process, as well as elements of contingency. This framework responds to the call for a deeper understanding of how marketing networks are formed and what are the dynamics that bring to their creation and development (Veilleux et al., 2012). This aspect has not been given much attention in previous literature not only about marketing networks, but also about networks in general. As a consequence, it could represent a good basis for the development of theory concerning the development process of different types of network. With respect to previous literature investigating aspects related to marketing network development process (e.g. Batonda and Perry, 2003; Hyder and Eriksson, 2005; Wang and Xiang, 2007), this framework maintains the approach based on phases (Das and Teng, 2002), despite highlighting that those phases are not strictly sequential. On the contrary, it provides a more focused, even though detailed and comprehensive, picture of the process, rationalizing and giving an order to previous contributions coming from different areas of research. Moreover, it adds an analysis of elements of contingencies which may influence the development process. Moreover, this study proposes a number of factors which seem to impact on network success, hence providing the basis for the identification of key success factors for marketing networks. This study could also represent a starting point for the comparative analysis of different types of networks which are supposed to have different peculiarities and thus different dynamics leading to success. With respect to previous literature, all relevant organizational and managerial factors are considered, as well as their potential interrelations. Beyond the scope of networks, considering the touching point with the theme of knowledge, in some of its different facets, the present research may also contribute to the theory of knowledge management within the context of networks.

This study has a relevant managerial component, since marketing networks are a very practical subject which has immediate implications for managers. Indeed, evidences emerging from cases suggest a series of recommendations which may reveal convenient for those firms involved in or willing to undertake a marketing network. In particular, they need to take into account that managing an network is not like managing a firm,

meaning that specific skills and know-how are required, which becomes even more important when dealing with the network contract.

Furthermore, this study contains insights relevant also for public policy. Indeed, governments throughout the world, primarily in Italy, are investing more and more funds for the creation of networks and the signing of network contracts. Therefore, it is important to assess the efficiency and returns of these millionaire investments of public money and to provide assistance to firms willing to start a collaborative project. Actually, a fundamental prerequisite is a strong campaign of awareness of these topics. All analyzed cases show that Italian entrepreneurs and managers are still skeptics about collaborating with other firms, due to their individualist aptitude. There are some Italian regions where firms have a greater inclination towards collaborations, as for example Emilia Romagna, than others, as Veneto. Indeed, none partner belonging to the marketing networks in the Veneto region has previous experience of collaboration, whilst partners belonging to the case in Emilia Romagna were more familiar and, thus, more comfortable with collaboration. Indeed, in this region, there have been many public and private measures laying the foundations for the development of collaborations, resulting in a high number of projects involving many firms, far before the draft of the network contract law. As a consequence, following the steps of these pioneer regions is of great importance, because if firms are not educated in matter of collaboration, it is more difficult that they succeed. In his case, educating means illustrating the different forms of collaborations, because the network contract is only one of the different possibilities to govern an network, but it is not suitable for all necessities. It also means presenting potential benefits, but also the commitment, responsibilities and technical skills and know-how an network requires. To this purpose, it is important to accept an external support in case partners do not possess all necessary skills and know-how.

As far as the network contract is concerned, legal issues should be integrated with managerial requirements. Moreover, a good base on knowledge should include the awareness that the main driver for signing a network contract should not be fiscal subsidies. The president of Retimpresa asserted:

“If a group of firms want to sign a network contract with the main purpose of receiving some subsidies, then it is better for them not to do it.”

5.2 Limitations and future research

Despite the above-discussed implications, this paper has some limitations. In particular, data were gathered from four cases, which is the minimum number of cases suggested by Eisenhardt (1989) to carry out a qualitative research based on multiple case studies. In marketing networks, but actually in networks in general, there could be endless elements of contingency, hence four cases cannot provide full evidence of how all marketing networks develop, despite networks in different industries have been considered. To this regard, only the Italian context has been considered, which limits the scope of validity of the study. For these reasons, evidences should not be treated as generalizable findings, rather findings that lay the foundations for further investigation.

Considering opportunities for future research, marketing networks are an emerging area of research interest and the study of networks themselves presents a complex methodological problem. Hence further research is needed to address the complexity of networks by investigating them over time, in order to capture in greater details their dynamic aspect, and at more than one level. A more precise operationalization of the concept of network success also needs to be defined, which calls for future research in this domain. The framework representing the development process of marketing network and propositions developed from the present study provide the basis for this further investigation. In particular, the framework could be used in order to understand whether other types of networks follow the same pattern or, instead, there are different organizational and managerial factors entering the process and determining success. A more detailed in-depth study of marketing networks which combines both qualitative and quantitative methods in which data is gathered from all actors in the network is called for. Such a study would also allow for a rigorous testing of the propositions developed in the present study. Moreover, a comparison with cases in other countries may represent an interesting path for future research in order to establish a set of good practices within the context of SME marketing networks. Moreover, further investigation is required regarding specific organizational and managerial factors which have not received specific attention by now. For example, branding seems to be particularly relevant in marketing networks, despite this issue is highly under-investigated in previous literature. Understanding the dynamics occurring between the network brand and partner company brands may be an interesting issue, as well as the role played by trust in the different phases of the marketing network development process. In addition, due to the apparently

fundamental role he plays, the figure of the network manager needs to be defined better, specifying his duties and responsibilities, as well as his scope of action, so as to maximize their effectiveness for the network. Also the relationship between these emerging concepts with the concept of leadership in the network literature could represent an interesting area for future research. Lastly, the findings highlighting the importance of knowledge, in its different meanings, gives rise to a new stream of research considering the specific role played by knowledge in networks.

Structured Abstract

Purpose – This study investigates the importance of networking for enhancing companies innovation capabilities and facilitate internationalization, especially for resource restricted companies (like SMEs). Collaboration is regarded as an important factor for the success of SMEs, especially as technology becomes complex, and where knowledge is distributed across various firms (Lee et al., 2010; Bianchi et al., 2010). The Contratto di Rete -CR- (literally translated as “Network Contract”) is a key solution, enhancing growth and increasing innovation capacity and internationalization of SMEs. This is made possible through knowledge sharing leading to higher outcomes (Hau-Siu Chow; 2012). In fact, sharing contributes to knowledge, skill, and ability that is vital to enhance performance. After grounding the Contratto di Rete in the general theory of networking, we propose a model based on Ring and Van de Ven theory (1994) in order to describe how a Contratto di Rete is established and performs.

Design/methodology/approach – We propose a deductive approach through a multiple-case study design. After having selected multiple Italian CRs (through a specified protocol) we make an in depth investigation with recorded semi-structured interviews (Yin, 1989), triangulating data with other relevant sources: internal documents, acts, presentations and the CRs. More in detail, we will answer to the following research question: Is the Contratto di Rete providing competitive support for the Italian SMEs? Outcomes will be compared to theory understanding case-specific patterns, similarities and differences among the case selected.

Originality/value – This methodology puts in evidence if and how – thanks to linkages and knowledge sharing – CR is proving to be effective for Italian SMEs. Additionally, we address to Hofstede’s national culture dimensions to explain further in which ways the Contratto di Rete fits Italian entrepreneurship culture. Since 2009, year when the instrument was introduced, not enough time went by in order to make relevant quantitative studies (Bank of Italy, February 2013). For this reason, we will adopt a qualitative approach, based on interviews and, more specifically, with a multiple case study design.

Practical implications – The outcomes of the study will shed light on this emerging networking phenomenon that is becoming widely applied in Italian SMEs. In particular, entrepreneurs and network managers will find which elements and practices drives the performance of the network. Our original approach links networks structure (nature of network ties, typology of involved firms), networks knowledge (in terms of competences and capabilities) and network performances in terms of innovation and internationalization.

Keywords – SMEs network, knowledge, formal contract, innovation, internationalization

Paper type – Academic Research Paper

1 Introduction

The Contratto di Rete (CR), literally translated as Network Contract, is a new kind of legal contract available for Italian companies to create networks. The EU, considering the principles of the Small Business Act, defines this tool innovative. Indeed, Italian SMEs are widely adopting the CR. In particular, Italian businesses, especially smaller ones, need to develop stable and manageable networks, in addition to the typical Italian “natural” ones (such as the Industrial Districts). Innovation and internationalization processes request shared projects and high investments in new knowledge and sharing resources. SMEs, through trans-sectorial and trans-regional networks, can participate to global dynamics, especially in terms of knowledge exchange.

This study grounds in the social network theory and aims to show the validity of the CR as a tool enabling the creation and the development of networks with the above-cited features.

First, we observe the convenience of the CR with the Italian entrepreneurial culture, as it is a tool available for national firms. For these firms, networking is related to the social capital entrenched in the local contexts. National culture is central in describing the nature of this kind of capital.

Second, we empirically verify whether the CR is creating networks raising the competitive performance of Italian SMEs. Through a multiple case-study methodology, we show how the CR is providing to contract members competitive advantage, in terms of innovation and internationalization.

Our results suggest that the CR is an important support for creating competitive networks and an essential element for the resumption of Italian SMEs.

2 Literature Review

2.1 *Networks and Competitive Advantage*

Network has gathered a significant share of scholarly attention in the last decades, giving birth to a rich and varied stream of study. Authors focused on its organizational nature (Powell, 1990; Larson, 1992), considering its features compared to the traditional organizational forms, market and hierarchy (Coase, 1937). Previously transactions were often concluded through either market transactions (primarily controlled by price) or internal hierarchical arrangements (primarily controlled by administrative authority). Recently firms have been engaging forms of collaboration that resemble neither the familiar alternative of arms' length market contracting nor the former ideal of vertical integration (Powell, 1990; Ring & Van De Ven, 1994).

Some scholars affirm that in between the two poles of market and hierarchical arrangements, we find various intermediate or hybrid forms of organization. At first, the network was depicted as one of the many hybrid organizational forms along the market-hierarchy continuum (Thorelli, 1986). Today the idea that economic exchange is arrayed along a continuum is too quiescent and mechanical and the familiar market-hierarchy continuum does not do justice to the notion of network (Powell, 1990; Larson 1992). So, the three modes of organization – market, hierarchy, and network – need distinct research approaches and theories.

In this paper, we consider networks as a distinctly different organization of coordinating economic activity, separate from market and hierarchy (Powell, 1990) as they are endowed with a set of social dimensions, such as trust, reliability and reputation (Larson, 1992). A network structure avoids the hierarchy and market problems, institutionalizing collaboration, shared information, and assured results (Larson, 1992).

Others researcher observed in which ways a network is born, evolves and dissolves, building networking life-cycle models (Ring & Van de Ven, 1994; Onetti & Zucchella, 2012). Other authors linked networking to firms' performances, in general competitive advantage terms (Dyer & Singh, 1998), or considering specific performance, such as innovation (Gulati 1998; Kogut, 2000; Ahuja, 2000; Gulati et al., 2000) or internationalization processes (McDougall et al. 1994; Oviatt et al., 1994; Coviello et al., 1995; Johanson and Vahlne, 2009). In this section we give a comprehensive overview of this literature, with the aim of creating a sound and complete theoretical ground for the new italian networking tool, the Contratto di Rete.

In the past few years there have been many empirical studies, aiming to understand how economic activities occur in a Network Structure (Gulati 1998; Kogut, 2000; Ahuja, 2000; Gulati et al., 2000; Dyer and Singh 1998) and foster firms' development and success. These analyses provided a significant contribution to the broader strategic field of research, addressing the traditional research question "why firms differ in their conduct and profitability?". According to Gulati, Nohria, & Zaheer (2000), it is necessary to analyze the network of relationships in which companies are included, overcoming the "atomistic" idea of strategic analysis towards a "relational model", in order to explain further differential firm performance. This is a very important contribution, as allows strategy research to overcome the classical juxtaposition (Hoskisson, Hitt, Wan, & Yiu, 1999) between the resource-based view (Penrose, 1959) and the positioning school (Porter M. , 1996). Today, firms are embedded in networks of social, professional, personal, and exchange relationships with other organizational actors (Gulati, 1998). Dyer & Singh (1998) claim that these relationships play a key role in explaining firms advantages and disadvantages. In particular they advance that the source of relational rents are not in simple market relationships, where the exchange between the partners is based on trade transactions, but lie in more deep and idiosyncratic ties. "Relational rents are possible when alliance partners combine, exchange, or invest in idiosyncratic assets, knowledge, and resources/capabilities, and/or they employ effective governance mechanisms that lower transaction costs or permit the realization of rents through the synergetic combination of assets, knowledge, or capabilities." (Dyer & Singh, 1998, p. 662). Relational rents exist in two forms (Kogut, 2000). Burt rents are typical of hierarchical networks, where participating entities competitively struggle to occupy powerful brokerage positions (the s.c. "structural holes") and arbitrate the knowledge and information flows (Burt R. , 1992). Coleman rents characterize flatter networks, and are originated by coordination, repeated exchanges among the members and collective resolutions of problems (Coleman J. , 1990). Accordingly, four elements drive the competitive advantage in network relationships: investments in relation-specific assets; substantial knowledge exchange, which leads to "joint learning"; the combination of complementary and scarce resource and capabilities, which drives the creation of new products and technologies; lower transaction costs than competitor alliances, guaranteed by effective governance. This last element, in particular, has a central role triggering investments in relation-specific assets, sharing knowledge and combining complementary

resources. Indeed, governance has not only a role in setting the rules for the appropriation of network's outcomes, but especially in coordinating the activity (Gulati & Singh, 1998) and creating the so called social capital (Burt R. , 2000; Nahapiet & Ghoshal, 1998). For this to happen, a significant presence of trust, reputation and reliability is required among partners (Larson, *Network Dyads in Entrepreneurial Settings: A Study of the Governance of Exchange*, 1992), as there is "widespread preference for transacting with individuals of known reputation" (Granovetter, 1985, p. 490).

Literature provides many definitions of trust. In broad terms, trust is the common expectation between the parties involved in a deal that the counterpart acts in good faith and behaves in accordance with explicit and implicit commitments, is honest in the negotiations, does not take excessive advantage of another if there is opportunity to (Kassicieh, et al., 2002). Considering the governance of risk point of view, trust is the confidence in the predictability of one's expectations and in another's goodwill (Ring & Van de Ven, 1994). From the knowledge perspective, trust can be defined as "cognitive coordination mechanism" (Lorenzen, 2001, p. 16), and it can be declined in many forms. First, it can be distinguished as dyadic networked trust, featuring strong mutual interest and shared values among partners in small networks, or as social trust, developed in larger industrial clusters through social learning processes. Second, Ettliger (2003) defines emotive trust, developed positive personal feelings about others, and capacity trust, based on the competences of partners in professional contexts. Trust, in all these forms, is involved in networking, as network relations are both professional, interorganizational and personal (Ceci & Iubatti, 2012).

Building such trust requires time, efforts and resources, as well as the integration and interaction of various forms of formal and informal governance tools (Dyer & Singh, 1998). Indeed, succesful alliances use multiple governance mechanisms simultaneously (Borch, *The process of relational contracting: Developing trust-based strategic alliances among small business enterprises*, 1994). Informal sensemaking and formal bargaining are the processes that characterize the negotiations on which a cooperative relationship is created, institutionalized in a formal relational contract (like the *Contratto di Rete*) and informally understood in a psychological contract (Ring & Van de Ven, 1994). Formal governance mechanisms act, on one hand, as a safeguard from opportunistic behaviors when trust is not consolidated, and, as a consequence, its use fades over time, as trust raises and more informal tools are preferred by partners (Gulati, 1995). However, recent

research developments argue against this view, indicating that formal contracts and relational governance are complementary rather than substitutes (Poppo & Zenger, 2002). Mellewigt, Madhok, & Weibel (2007, p. 842) suggest that “trust serves as a moderating variable that influences the direct relationship between control and coordination concerns and contract complexity. Thereby, trust will be at once a substitute of contractual complexity (regarding control concerns) and a complement of contractual complexity (regarding coordination concerns)”. On the other hand, formal governance transforms instrumental transactions into a socially embedded relationship, endowed with norms and values which guarantee the existence and prolonging of the ties over time. This process is called institutionalization under a social-psychological perspective (Ring & Van de Ven, 1994).

Networks of exchange relationships contribute to competence development, thanks to knowledge sharing fostered by trust. An important competence for an organization is the ability to maintain close relationships with partners and customers. “Relational competences” or “network competences” are essential for business innovation as well as business internationalization enhancing the competitiveness of a firm. From this point of view, the creation of new value through alliances is a learning process, as it deals with contracts which cannot prespecify all the interactions among the partners (Anand & Khanna, 2000). Large part of literature addressed to the field of organizational learning (Argyris & Schon, 1978), showing its important contribution in explaining the existence of resource of competences that are inaccessible to competitors. In networks, learning exist *within* the alliance and *across* the alliance too, originating a double-cycle process (Anand & Khanna, 2000).

The first type of learning is based on the transfert of knowledge among the partners. In this sense, the relative positioning of a partner (an “ego”) and the other members (the “alters”) plays a central role in determining the access to new and distinctive knowledge. Egos situated nearby knowledge brokerage positions (s.c. “structural holes”) have greater chance to excel in innovation races (Ahuja, 2000). Russo (2011), in his empirical study, based on a sample of 214 organizations operating in the fuel cell industry, showed that the centrality of a firm in a specific network influences the success of an alliance. Moreover, firms acquire new knowledge through multi-sectoral relations. Therefore, enterprises must be able to handle new relationships, involving organizations operating in several sectors, such as public, private, non-profit (Selski & Parker, 2005) and also coming from

different geographical contexts. With a networking orientation companies adopt a global direction in searching for new opportunities, ideas and resources - especially when networks are activated inside multi-sectoral and multi-territorial dynamics - looking for new markets and develop international strategies, and consolidate their presence on existing markets. As a consequence, learning *within* alliances has a strong tension between competition and cooperation, as confirmed by the existence of internal learning races (Gulati, Nohria, & Zaheer, 2000). The second kind of learning, that is *across* alliances, refers to the “processes by which a firm can systematize the acquisition or development of an alliance capability” (Anand & Khanna, 2000, p. 298). A long history of networking experiences builds up a specific knowledge about “learning through networks” skills, in a typical “learning to learn” phenomenon (Estes, 1970).

Allowing the sharing and creation of new and idiosyncratic knowledge, networking enhances specific performances in terms of innovation and internationalization. Operating in a network triggers a set of strategic and organizational advantages: 1) it is possible to take benefit of external specializations and focus more on what you excel. 2) Take advantage of various types of economies and cost reductions. 3) Introduce new ideas and different views that reduce complexity and develop innovation. 4) Reduce risks, which are shared among several participants. 5) Promote new standards and introduce new technologies in the market. 6) Acquire a global orientation in searching for new opportunities and resources (Gulati, 1998; Kogut, 2000). In particular, networking is beneficial for resource-constrained firms, who can enjoy relationships and resources typical of more established ones (Powell, Koput, & Smith-Doerr, 1996). Strategic alliances with other SMEs, big companies or other individuals, bring positive influences for SMEs, since they can access to resource difficult to develop on their own, guaranteeing at the same time, a high flexibility and enhancing their growth capacity (Powell, Koput, & Smith-Doerr, 1996) enhancing innovation and internationalization. Network relations brings different benefits and opportunities for SMEs: 1) provides value-added services through a well-connected network of different knowledge sources, overcoming some of their barriers related to the limited information sources, knowledge, and financial resources. 2) Helps SMEs specialize and focus on particular functions where they have competitive advantages and access a wide availability of knowledge throughout the establishment of contract of mutual trust (Lee, Park, Yoon, & Park, 2010). 3) Allows them to distribute the costs and risks of the innovation process with a larger basis of

actors by reinforcing firms' positioning in the challenge for the competitiveness (Gronum, Verreyne, & Kastle, 2012). 4) Helps them develop "international networks" which allows them to overcome size constraints on internationalization, provide additional resources needed in the route for internationalization and facilitate product commercialization across international markets (Valsilenko & Morrish, 2011).

2.2 Networks and the Competitiveness of Italian SMEs

We have seen so far how networking is important for enhancing companies competitiveness. This is true especially for resource restricted companies (like SMEs).

Many Italian SMEs were unable to implement innovation strategies and least of all to take full advantage of development opportunities that despite the crisis have emerged in the last decade. Italy, compared to other European competitors, has been highly exposed to competition coming from new emerging countries. According to most scholars and analysts, this is related to the size issue. In fact, the Italian productive system for more than 99.7%, is made up of SMEs (the EU average is 99.1%). However SMEs are the backbone of the Italian economy and the engine of the European one. The Italian SMEs perform at least the 80% of the GDP making a substantial contribution to economic development and growth (OECD, 2009).

Italian SMEs make "innovation without research" (Hall, Lotti, & Mairesse, 2009), investing less in R&D activities. Italian firms are highly focused on traditional productions with a low technological content. In fact, most of the Italian SMEs operate in traditional sectors with a labour-intensive orientation. Furthermore partnerships are restricted to traditional partners such as suppliers and cannot easily find the financial resources (both public and private) to allocate for innovation. SMEs have difficult relationship with the banking system, and while in other countries there are specialized agents (e.g. venture capitalist) that are able to intercept, evaluate, and finance R&D projects, in Italy the rarity of these figures generates less opportunities of investing in research (Hall, Lotti, & Mairesse, 2009). With regard to distribution, marketing and general relational competence SMEs act as large workers strongly oriented "to the task, and less to relations" (Ghiringhelli & Pero, 2010). There are a small number of collaborations with universities and national and international research centres.

Other important reasons are related to socio-cultural factors (on which we will focus in the next pages), with a governance focused on the family control (Van de Vrande, De

Jong, & Vanhaverbeke, 2009; Hall, Lotti, & Mairesse, 2009; Lee, Park, Yoon, & Park, 2010; Bianchi, Campodall'Orto, Frattini, & Vercesi, 2010) with a pyramidal structure, and a governance focused on family control.

As Furlan and Grandinetti (2011) suggest, SMEs growth is not related only to the increase in size. They need to integrate the relationship growth and the capability growth. Concerning the first notion, “the extent of external resources can grow both as a result of an increase in the number of relationships and as a result of an increase of the value of existing relationships. In the former case, the firm extends its value network, namely the set of relationships that the firm uses to get access to external resources. In the latter case, the firm keeps its network stable, but evolves its existing relationships towards more valuable configurations” (Furlan & Grandinetti, 2011, p. 198). The capability growth regards the systematic accrual of specific capabilities (such as functional, market related, etc.), organizational and learning routines helping firms to continuously innovate and to be competitive (Verona, 2000; Grant, 1996)

The above mentioned factors limit investments in innovation and restrict the internationalization activities. Nevertheless, the Italian SMEs can count on strong points: the entrepreneurial brilliance in pursuing niche strategies joined to the ability of developing tailored products or original solutions; the ability to benefit from the division of labour and from knowledge sharing, mediated by interpersonal relationships and the social capital settled in the territory, last but not least, the capacity of adaptability, daughter of “diversity” (in knowledge and skills at regional level, in forms of specialization, in local manufacturing systems, etc..) that is peculiar to the Italian context.

The creation of new dynamics that boost the competitiveness of Italian SMEs is necessarily the inclination and the ability to work in a network. The type of network that has beneficial for the success of the Italian industry on the international scale, studied at the international level (Porter M., 1990, 1998; Powell, 1990; Gulati, 1995) is the industrial district. It is defined as: “a socio- territorial entity characterized by the active presence of a group of persons and a population of firms in a given historical and geographical dimension” (Becattini, 1990). Currently, 40% of the Italian manufacturing firms is located in the districts, and achieves the 27.2% of GDP and the 37.2% of exports. In the industrial districts, interactions in the local social collectivity produce “intellectual capital” (Nahapiet & Ghoshal, 1998). As Camuffo and Grandinetti (2012, p.826) advance, “the community dimension works like an immaterial resource, being both collective and

district specific. First, its presence facilitates the establishment of inter-firm (inter-organizational and interpersonal) relations within the local cluster, cutting down on barriers to communication. Second, it increases the ‘average’ level of trust in local relationships. Both these effects can be regarded as cognitive premises of cognitive interaction”. Industrial experience, technical expertise and knowledge specific to manufacturing are closely connected to the district’s social capital. So these competitive elements are created and available for local businesses in an exclusive way and with lower costs compared to non-district firms (Ricciardi, *Strategie di cooperazione tra aziende e mitigazione del rischio operativo: i vantaggi competitivi delle reti di imprese*, 2010). District’s social capital system will also allow to apply sanctions for opportunistic behavior carried out from individual entrepreneurs and reward favorable ones. Consequently, transaction costs are reduced, since many agreements may also be informal.

With the changing of environmental dynamics, the district is losing its competitive advantage, even though it is still important for the Italian productive system (Ricciardi, 2013; Palmieri, 2009).

Italians industrial districts cannot remain geographically and culturally embedded, they need to spread all over the world, including regions of Italy itself (Zeleney, 1999).

Rullani argues that there are two characteristics of the district that need to be called into question: 1) it is a form of voluntary cooperation (between the customer and the supplier in the supply chain), but more an involuntary form; 2) the network of collaboration is a “natural” network, not designed but emerging from the individual units, mostly supported by the social capital of the area (trust, social and cultural proximity, etc.).

Among other things, the most popular model of SMEs inside the districts is the one of “traditional local enterprise” which has a low coverage in end markets; a low (or no) international projection of production and a reactive attitude towards innovation.

Nowadays, innovation and internationalization processes require shared projects by stakeholders and substantial investments in new knowledge and resources. This is the “cognitive” meaning of internationalization, that makes it increasingly interconnected with innovation. “Knowledge moves with great ease and speed from one corner to another of the ‘global village’, moving along networks of science and technology, beside the lines of long distance communication (which moves goods, people and information).

The internationalization becomes a process of transnational spread of knowledge from one firm to another, from one country to another. In other words, since several years the real internationalization process has become invisible” (Rullani, 2006). Therefore, in addition to district networks, Italian SMEs need network that are more stable and better governed, in which autonomy and realizable synergies need to coexist. At the same time it is necessary to extend the old short networks which are a characteristic of districts, making them more cross-sectorial and cross-territorial. In short, we need networks that have to facilitate global participation.

2.3 The Italian “Contratto di rete”: a new instrument for competitiveness?

Introduced in 2009 by the Law Decree 5/2009¹, the CR has certainly raised the qualitative and quantitative development of networks which are suitable for the modern internationalization and innovation processes.

In particular, the Law Decree (and its subsequent modifications and integrations) states that with the CR a group of entrepreneurs aims to accrue, individually and collectively, their innovative capacity and their competitiveness on the market. In order to fulfil their aim, they commit themselves to: 1) cooperate in forms and fields fitting their business activities. 2) Sharing industrial, commercial, technical or technologic information or services. 3) Carry out together one or more activities convenient with their business activities.

The essential elements of the CR are 1) the group of participants: Italian single entrepreneurs, companies, cooperatives and Consortiums can participate to the CR. 2) The strategic goals and their assessment system. 3) The CR Program, specifying rights and duties of the members and the planning to fulfil the aim of the CR. 4) The length of the partnership: an analysis by Unioncamere shows that more than one third of the CRs plan to last more than 10 years. 5) The enter conditions for new members. 6) Decision making rules on topics of common interest.

The CR can include the creation of a common fund and the establishment of a governance body, which manages the execution of the Contract in behalf of the members. Although these last elements are voluntary, most of the CR includes them.

¹ For further information regarding the law regulating the CRs:
<http://www.retimpresa.it/index.php/it/documenti>

The attribution of legal subjectivity (which creates the s.c. “Rete Soggetto” in opposition to the CR without legal subjectivity, called “Rete Contratto”) is recognized drawing up the contract referred to art. 3, co. 4-tert ss., L.D. n. 5/2009 and is, according to the present law, “optional and contingent” to the registration in the Business Register in which it is located. For the purposes of such registration it is required: setting up a common fund, and drawing up the contract through public deed, private writing, or digital signing ex-art. 25 L.D. n. 82/2005.

The CR is spreading rapidly: as of 1st March 2014, there were 1.344 CRs, involving about 6.500 firms. In September 2012, there were 458 CRs, counting 2.400 companies (Unioncamere).

The European Commission, found this tool very innovative and in line with the principles contained in the Small Business Act (SBA)². Collaboration in fact is considered an effective solution and is mentioned among the practical measures to implement the SBA. EU is also considering an European version of the CR.

In this paper, our aim is to ground the CR phenomenon in the general network theory, understanding and explaining its idiosyncrasies. In particular, we advance the following propositions:

1. *The CR is an innovative networking tool convenient with the cultural characteristics of the Italian entrepreneur;*
2. *The CR allows the creation of networks that drives superior competitive performance for the Italian SMEs*

3 Methodology

Since 2009, year when the instrument was introduced, not enough time went by in order to make relevant quantitative studies.

For this reason, we will adopt a qualitative approach, more specifically a multiple case study design (Yin, 2003), based on interviews and company visits to the three networks under investigation.

² *The ten key principles are the following: create a “friendly environment” for entrepreneur and family businesses; support honest entrepreneurs who faced bankruptcy, providing them a “second chance”; design rules according to the “Think Small First” principle; adapt public administration to the needs of SMEs, removing administrative barriers; adapt public policy tools to the needs of SMEs, in particular in terms of awarding public procurement contracts and allocating State aid; facilitate SMEs’ access to different types of finance; ensure that SMEs benefit from the opportunities offered by the Single Market; promote SMEs’ potentials for innovation, research, and development; foster the turning of environmental challenges into opportunities for SMEs; support SMEs in opening towards external markets*

We selected three CRs following a specified protocol: first we analyzed CRs that have at least one year of operation in order to obtain more reliable results (data were obtained by the Italian Chamber of Commerce, section Info Camere, November 2013). After an initial phase of contact, where companies have been submitted to a brief informative telephone interview (reaching 200 companies of 52 CRs), we selected those cases whose experience has shown higher managerial and organizational implications, following a technique of theoretical sampling indicated by Eisenhardt and Graebner (2007).

Once having obtained their availability, we selected and interviewed them. For the purpose of this study, we selected three cases particularly suitable for illuminating relationships and logic among construct (Eisenhardt & Graebner, 2007). These three case studies will be called with fantasy names to avoid social-desirability answers issues: Alfa-net, Beta-net and Gamma-net (also, companies participating to the networks will have fantasy names).

Details of the Italian CRs and the companies involved inside the network are set out in Table 1 (*Summary of Case Details*).

Table 1 - “*Summary of Case Details*”

CR	YEAR	REGION	INTERVIEWED COMPANIES	FOCUS OF THE NETORK CONTRACT	ACTIVITY
<i>ALFA-NET</i>	2011	Emilia Romagna	<ul style="list-style-type: none"> • Circle Ltd • Square Ltd • Triangle Ltd 	Innovation	development of an experimental waste collection system
<i>BETA-NET</i>	2013	Puglia	<ul style="list-style-type: none"> • One Ltd • Two Ltd • Network Manager (external) 	Internationalization	Commercialization of innovative products in the field of precision mechanics
<i>GAMMA-NET</i>	2011	Puglia Toscana Veneto	<ul style="list-style-type: none"> • Sun Ltd • Moon Ltd • Cloud Inc (external) 	Marketing	promotion, workshops, events, trade fairs

As guided by Yin (2003), we collected the main data through recorded semi-structured interviews, ensuring for all similar procedures, for a total of 8 interviews. These interviews were conducted mainly to the responsible for decisions related to the CR (e.g. President or Representative/Responsible of the CR). For each case, at least two interviews were made, this in order to guarantee the validity and coherence of information, collected from different point of views.

Considering the roles of the respondents, together with the president³ of the network, for each case study it was interviewed a representative (owner or manager) of at least two of the member companies: this because we wanted to listen to the experience and the voice of the companies involved in the network. In addition, the analysis developed for each case was submitted to the interviewees, so that they would guarantee the correct and faithful data retrieval of the information collected through the testimonies.

It was satisfied the criteria that the informant must be a prominent and well-informed person in the case selected, on the basis of his/her expertise in the areas relevant for our research (Yin, 1989).

Each interview lasted on average 45 minutes, covering the following topics:

- The role of the interviewed inside the network and free description of the CR;
- The motivation that led to the entrance/foundation of the network and the main objective in stipulating the contract;
- The outputs achieved in terms of innovation/internationalization/competitiveness;
- Organizational dynamics of the network: structure, relationships between members and third parties;

To supplement to the interview material, we collected secondary data, both internal material and published material, that were relevant for the study. To have a clear overview of the supplemental material collected, see Table 2.

Where possible, we examined websites of the CRs/Companies, before the interview this in order to gain background information and identify specific issues useful for the interview.

We also collected internal documents, like the certificate of incorporation of the CR, where we found a better definition of the network program specifying the common

³ *In his absence or unavailability, it was interviewed the subject referred to as representative or responsible for the network contract*

purpose together with strategic goals and economic activities implemented by the network.

Table 2: Summary of supplemental documents

Italian CR	Internal Documents	Published materials (quantity)
<i>ALFA-NET</i>	Certificate of incorporation Internal presentations notes and slides	Companies websites (4) Press release/media statements (2)
<i>BETA-NET</i>	Certificate of incorporation Internal Report Internal presentations notes and slides	Companies websites (5) Press release/media statements (14) Public presentations (1)
<i>GAMMA-NET</i>	Certificate of incorporation Internal presentations notes and slides	Companies websites (5) Brochures

Following Yin's (2003) suggestions, we maintained a database of all the recorded interviews, transcripts and notes.

Here we provide a brief description of the analyzed CRs:

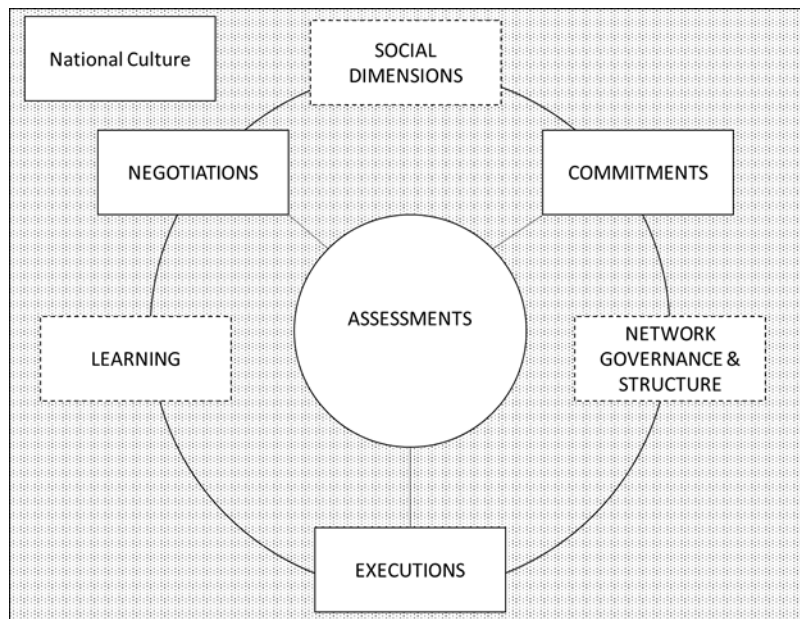

- *Alfa-Net* was founded on August 4, 2011 and is composed by three SMEs all coming from Emilia Romagna (Circle Ltd, Square Ltd and Triangle Ltd). The aim of the relationship is to develop a new project through the commercialization of a new technologically advanced product in the field of urban solid waste. It is, in particular, an electronic system able to monitor users refuse in normal waste bins, distributed throughout the area. In addition, the technology allows you to tighten up the bins when not in use. Thanks to an electronic key, it is possible to unlock them and record data access. The development of the product has been possible thanks to the participation of a large multi utility, H-Group, which holds 40% of its patent (external to the network). The remainder is equally distributed among the three members of the CR. The President is responsible for business relationships with customers, and a Technical Manager, acting as a Project Manager, follows the technical and electronic part for the development of the hardware at the base of the new product.
- *Beta-Net* was founded on January 24, 2013 and is composed by seven SMEs operating in the field of the precision mechanic, located between Bisceglie and Molfetta (Puglia). The participants have years of experience, also international,

within the industry. With this agreement, their intent was to strengthen their planning capacity in innovation and internationalization activities. The purpose of the network is strengthening *Beta-Net* competitive advantage, and so of their group members. This is done through: the development of their value proposition brought to the market, the introduction of products and services with higher added value and the strong orientation towards internationalization. The President has the function of management representative of the network guiding the activities of the common body. *Beta-Net* is a “Rete Soggetto”, as it has legal subjectivity.

- *Gamma-Net* was founded on July 7, 2011 and is composed by eleven companies coming from Puglia, Toscana and Veneto, which operate in the context of alternative energy sources. The members differ in size, as *Gamma-Net* includes large firms and micro firms too. The purpose of the network is “the creation of an innovative organizational model designed to create strategic and operational synergies between the members”. Under a common brand, the participating companies are aiming to increase their competitiveness through the development of communicative activities, capturing potential business opportunities. Cloud Inc. an external company that operates in the consultancy field supports this network. Therefore, while the strategic and operational decisions are the responsibilities of the common body and the President, the external support deals with the administration of the network. After the creation of the website and the development of promotional activities, *Gamma-Net* has entered in a stalling situation, continuing up to now. Some companies, in fact, do not adhere anymore to the CR.

4 Findings and Discussion

We introduce a revised version of a model originally introduced by Ring and Van de Ven (1994) in order to validate our propositions.

Source: Authors' elaboration on Ring & Van de Ven, 1994

Figure 1: Development of cooperative inter-organizational relationships within the CRs

The proposed model is cyclical and features overlapping stages in recurring sequences that are separated for analytical purposes. The whole model is embedded in the Italian national culture, as the CR is available only for Italian companies. We found culture significant to explain the adoption of the CR.

In order to understand the relationship between national culture and network dynamics, we propose to integrate Hofstede's studies with the findings of a more specific cross-cultural analysis by Del Junco & Bràs-dos-Santos, 2009 regarding cultural and social values of owner-managers of SMEs from different countries (Italy, Germany, and Spain).

Hofstede model (1983), which is one of the most established tool of analysis and reviewed in the organizational literature, highlights the culturally determined values of people from a particular country or region. From this perspective the scholar arrives to the definition of four dimensions of national culture⁴:

⁴ There is also a fifth dimension independent of the four others and is called "confucian dynamism" opposing a long-term or short-term orientation in life and work (Hofstede; 1990). Each dimension has an index value between 0 – 100. These dimensions were found through multivariate statistics and theoretical reasoning. The value for each nation helps compare with other national cultures.

- “Individualism versus Collectivism (IDV)”, explains the relationship between the individual and the group. The degree of Individualism in a country is statistically related to that country’s wealth⁵.
- “Large or Small Power Distance (PDI)”, it can be defined as the extent to which the less powerful members of institutions and organizations within a country expect and accept that power is distributed unequally. In other terms, in societies where this index is high, it is expected that everyone accepts the authority of those with a higher power.
- “Strong or Weak Uncertainty Avoidance (UAI)”, society deals with the fact that the future can never be known. This ambiguity brings with it anxiety and different cultures have learnt to deal with this anxiety in different ways. We have cultures that wish to avoid any form of ambiguity and uncertainty, and those where this need is felt less.
- “Masculinity versus Femininity (MAS)”, are the social implications of having been born as a boy or a girl. A high score (masculine) on this dimension indicates that the society will be driven by competition, achievement and success. A low score (feminine) on the dimension means that the dominant values in society are caring for others and quality of life⁶.

These dimensions are relative, do not change over time and express a dominant culture (Hofstede, 1983).

If we explore the Italian dominant culture through the lens of the Hofstede’s four dimension model, we can get a good overview of the deep drivers of Italian culture⁷. Italy, in common with other southern European countries and some countries in Central Europe where the Roman Empire has left its mark, has a relatively high index in the hierarchical distance.

Integrating Hofstede’s model information with the findings of Junco et.. analysis, it’s possible to note that:

- at a score of 76 Italy is an Individualistic culture, “me” centered, especially in the big and rich cities of the North. Individualism reflects the desire to be free to plan one’s

⁵ *Wealth countries (like USA, Great Britain, etc.) are more Individualist and poor countries (like Colombia, Taiwan, etc.) are more Collectivist.*

⁶ *The fundamental issue here is what motivates people, wanting to be the best (masculine) or liking what you do (feminine).*

⁷ *These information were taken from Hofstede’s web site www.geert-hofstede.com.*

own work (Hofstede, 1990). This dimension does vary in Southern Italy where less individualistic behavior can be observed: the family network and the group one belongs to are important social aspects. People going from Southern Italy to the North say that they feel cold not only for the different climate but for the less “warm” approach in relationships. With regard to Italian entrepreneurs, the IDV index is twenty points lower than Hofstede’s results (56 instead of 76). This implies that Italian entrepreneurs are roughly half-way between Individualism and Collectivism. Moreover, in business, a friend is reputed “someone that you know and can be useful for introducing you to the important or powerful people” (Hofstede, Hofstede, & Minkov, 2010);

- considering the Power Distance dimension, with a score of 50, specially Northern Italy tends to prefer equality and a decentralization of power and decision-making. Control and formal supervision is generally disliked among the younger generation, who demonstrate a preference for teamwork and an open management style. With regard to Italian entrepreneurs, the results show a very low value compared to Hofstede’s study (3 instead of 50). Therefore, Italian entrepreneurs have a strong need for independence. The high score on Individualism accentuates this aversion of being controlled and told what to do;
- at 75 Italy has a high score on Uncertainty Avoidance, which means that as a nation Italians are not comfortable in ambiguous situations. Formality is important and Italians wish to avoid ways of dealing with uncertainty. Laws, rules, and regulations are seen as ways in which a society tries to prevent uncertainties in the behavior of people (Hofstede, Hofstede, & Minkov, 2010). In societies where this index is high, we have more formal laws and informal rules controlling the rights and duties of people. With regard to Italian entrepreneurs, the value is lower than Hofstede’s study (38 instead of 75), showing that they do not show much concern for uncertainty avoidance;
- at 70 Italy is a considered masculine society – highly success oriented and driven (Hofstede, 1983). Therefore, competition can be very strong. With regard to Italian entrepreneurs, the value is twenty-two points lower (48 instead of 70) than the one found in Hofstede model. The presence of a more feminine culture indicates that entrepreneurs prefer to resolve their conflicts via compromise and negotiation.

Developing feminine value in organizations is very important for improving business strategies (Chorn, 1995).

Typically, when the Italian SMEs have decided to connect themselves, the tendency towards individualism and autonomy of the Italian capitalism, has led them to prefer “natural” networks (like industrial districts) with respect to mergers or acquisitions.

However, nowadays we increasingly need to create more stable and better governed networks. Unlike what happens into the “district”, nowadays, innovation needs a project shared by the various stakeholders and significant common investments in knowledge and resources. “When you begin to explore new lands which require substantial investments, being unconsciously in a network, as in the case of the district, is not enough. Being in a network with identified partners requires a conscious choice and a strategic plan” (Rullani, 2008).

The CR is a key solution in responding to Italian SMEs needs. As it was possible to note, the tool is marked by a broad concept but also from a meagre discipline: the rules are both dictated by the legislator and especially decided by the firms’ own autonomy (Cafaggi, 2010). Therefore, the legislation, is incomplete in the sense that the legislature intended to draw only a frame, giving the possibility to the companies to complete it with contents and details in accordance to their needs. For this reason it is a new instrument compared to other tools that had little or no success, since they ignored the practical needs of entrepreneurs. Alternatively, the CR is shaped step by step, giving the possibility to maintain a high autonomy, important for many small and medium entrepreneurs (Preti & Vignali, 2013).

The CR raises from trust and commitment.

In order to develop an efficient CR you need to know each other. Trust between people is essential, as well as their capabilities and their reliability. With Triangle Ltd, it is 20 years that we collaborate together, and with Circle Ltd it is already 5 years. We also have relationship with the H-Group, our direct client. We have been taking care of all their optical fibre networks that they have in our region, for almost more than 10 years. (Alfa-Net, Owner Square Ltd).

You cannot make a CR without knowing already each other. This tool helped formalizing a temporary relationships, in order to create a stronger one in the future (Beta-Net, Owner of One Ltd)

Compared to other traditional aggregations - like Temporary Joint Ventures (A.T.I), Consortium etc. - which are more focused on specific and short-medium term goals, the CR places itself as an open, volunteer and convinced aggregation between entrepreneurs with the aim of increasing their potential for innovation and internationalization (Di Seri, 2012). Compared to other types of collaboration, it has a greater flexibility in defining scope and boundaries of the network, and degree of participation of the partners (Cafaggi, 2010). Both the Consortium and the Temporary Joint venture have a definite function, limited to the fulfillment of a specific business or at the execution of certain phases of the activity of the companies; what is missing to both is “the purse of a durable common program”.

We have created a CR with as much flexibility as possible. The CR shows a great flexibility and helps SMEs overcoming dimensional limitations and difficult economic conditions. We prefer growth strategies that do not imply the creation of a separate entity, and so the loss of independence, setting up a new organization could be more costly and generate greater rigidity. (Alfa-Net, Owner Circle Ltd).

I believe that the CR has a big advantage: the flexibility (Beta-Net, Network Manager).

We chose the CR, compared to an ATI or a Consortium because it is much more flexible. If there is the need of other participants, they can enter and we avoid the too much bureaucracy. It's much more slim (Gamma-Net, Manager Sun Ltd).

The “network program” is a key element of the CR, and can be seen as a platform for the dialogue among the participating companies. Other important elements are: the strategic objectives; the rights and duties of each participant; the definition of roles and conducts and programming tools and checking the obtained results.

The CR is designed in order to help businesses work in the medium-long term, without having to give up their independence. The discipline regulates a form of inter-entrepreneurial collaboration in a contractual nature promoting new forms of cooperation, supporting and increasing in the business's competitive capacity.

This tool is not specifically targeted to SMEs, but it is a general tool of collaboration to be used by enterprises of any dimension. However the law is suited for SMEs, in fact helps them overcoming limitations due to their dimensions without causing them to lose independence, while also enabling them to collaborate with firms of different dimensions (Ferrari, 2010).

Thanks to this tool SMEs can cooperate on a specific project, focus on a specific task, improve efficiency, organize innovation activities held by actors from several knowledge fields, improve relation with clients, suppliers, research institutes, and share economic and financial capacity.

Last but not least, the CR continuously enhances and valorizes “territories”, especially for the Italian context, where social capital is located, in terms of production and knowledge sharing (Rullani, 2013). For example, the CR both integrates positives district logics and eliminates some important limitations of the same, re-launching it towards a new modernity.

As stated by Ricciardi (2013), “collaborative networks should be a key priority for the districts: ‘overflowing the boundaries of localism and broadening the vision has to be an important target for growth’. The district, can be the basis through which new and wide networks are created”.

Stable networks, arising from a CR can transform the industrial districts in open systems to non-local processes and skills. It opens the district to external expertise, often integrated to those available in the territory, reorganizing them and meeting the challenges of globalization. District firms have the opportunity to implement networks that are more stable, better governed and more extended (more cross-sectorial and more cross-territorial).

In turn, districts give to the “new” networks (formalized by contracts) their precious heritage of social capital (trust, commitment, learning) and specific synergies and skills.

Currently, one-fifth of the manufacturing firms participating to CR comes from a district unit (Centro Studi Unioncamere, 2013). In addition, the CR arising from the districts shows a greater commitment for “cross-sectoriality”: 64.4% of them are made up of companies that are specialized in different macro-economic sectors (2nd Observatory Intesa Sanpaolo).

Negotiations

During the negotiations stage, “the parties develop joint (not individual) expectations about their motivations, possible investments, and perceived uncertainties of a business deal that they are exploring to undertake jointly.” (Ring & Van de Ven, 1994, p.97). This stage creates the antecedents and sets the ground for the subsequent commitment in a shared initiative. Parties argue and debate over the possible terms and conditions of the potential relationship, understanding opportunities and assessing risks. Formal bargaining

is sided by socio-psychological sense making. In this process, social dimensions like trustworthiness, reputation, reliability play an important role moderating the relationship between the negotiation stage and the commitment one. As seen before, national culture is one of the most important antecedents of these social dimensions.

Through the dialogue, then you realize that there are real opportunities that can be managed together, and which otherwise could not be managed, and so in this way you start to have an inclination towards collaboration (Beta-Net, Owner Two Ltd).

Not by chance, most CRs are born within existing systems of relationship, such as industrial districts, industrial associations, other groupings (Gretzinger & Hinz, 2010).

Existing relationships in the Apulia Mechanical District and in the local industrial association helped the creation of the network and its formalization through the CR. (Beta-Net, Network Manager)

Commitments

At this stage, we see how a collaboration is institutionalized, trying to achieve the most appropriate balance between formal and informal processes (Ring & Van de Ven, 1994).

Formalizing a collaboration is important, first for the purpose of enforceability against third parties and also for the recognition of the network by the various stakeholders who contribute to the creation of knowledge and its transformation into value.

With regards to internal relationships, the contract acts as a control function. In this case, the contract complexity must take into account the level of confidence (and, therefore of commitment) that has developed between the parties.

Normally the trust has been seen as a substitute for formal contracts, able to gradually reduce opportunistic behaviour making collaborative processes (Gulati, 1995) faster and more flexible (sometimes via a “handshake”).

In addition, trust helps reducing the costs related to contracts that, may give rise to mistrust and even the fear of preserving their independence and their competences (Macaulay, 1963). All these aspects are carefully taken into account by the Italian SMEs.

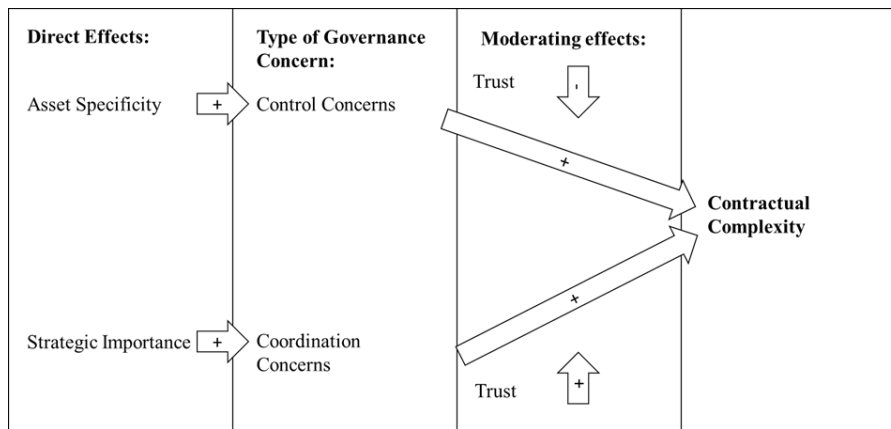

However other scholars, have pointed out that such substitution is not possible at all. With their study, Poppo and Zenger have shown that as the collaboration takes place and the investment in assets become more specific (Asset Specificity), the degree of complexity and level of detail in the contract tends to increase.

Though, for other scholars (Loasby, 1998; Foss, 1997) considering the internal and external complexity of enterprises, the coordination would assume even greater importance for the control: “while opportunism is significant, the problems and opportunities of developing and coordinating knowledge deserve priority” (Loasby, 1998).

Gulati, Wohlgezogen and Zhelyazkov (2012, p.537) define the coordination as the “the deliberate and orderly alignment or adjustment of partners’ actions to achieve jointly determined goals. Coordination is an outcome that can be characterized by efficiency, the relative cost of designing and operating coordination mechanisms and, by effectiveness, the degree to which coordination efforts actually produce the desired alignment or adjustment of action. Coordination typically involves the specification and operation of information-sharing, decision-making, and feedback mechanisms in the relationship to unify and bring order to partners’ efforts, and to combine partners’ resources in productive ways”.

As stated by Mellewigt, Madhok, and Weibel (2007), the contract can be a strategic tool for coordination, that if coherently used with the need of control, it can produce a competitive advantage for the firms. According to these scholars, its clauses can precisely enumerate the tasks to be accomplished, define procedures to be used and lay out quality standards to be fulfilled. On the other hand, contracts can specify the decision rights in IORs and may structure communication flows in a decisive way. For example, contracts may prescribe information duties, conflict resolution procedures and boundary departments.

Trust is itself an important resource of coordination, especially when in time it develops a strong collective identity. On the other hand, relations supported by a growing confidence, will evolve becoming more interdependent and intricate, and there will be a greater need for coordination. As a result, it will increase the complexity of the contract (see figure below).

Source: Mellewigt, Madhok, & Weibel, 2007

Figure 2 Trust and Contractual Complexity

The issues previously discussed are fully reflected in the high level of functionality and flexibility of the CR that for the latter can be considered as a “work in progress” supporting various networking needs.

The formalization through the agreement is important for the visibility and collaboration with those third parties that are essential in achieving the network objective: business partners, customers, suppliers, consumers, citizens with whom it is possible to co-produce value; trade associations, chambers of commerce and districts that are real incubators of relationships needed for signing the CR, as well as a key factor for dialoguing with other actors (Gretzinger & Hinz, 2010). Universities, fundamental supporting institution, with their training activities, research centres and technology transfer; banks and venture capital funds, which act as financial advisors for the internal network projects and accessible solutions for customers; public administrations, who have an burning duty of encouraging this tool in an innovative way.

As already noted, the CR was born as a free, voluntary and convinced aggregation among entrepreneurs. Therefore, the network will continue to grow when there will be a high level of confidence and commitment. Thanks to its flexibility, the tool allows to quickly fulfil the changing control needs of occurred in the network. The participating companies will be able to easily modify it by inserting new references to clauses or regulations governing the internal conduct.

The CR assumes a significant strategic value when it is framed as an instrument of coordination. Through the objectives and the program, the cooperation between the

parties is institutionalized. In fact it makes the relationships socially embedded by infusing them with norms and values that permit them to be reproduced and perpetuated (Ring and Van De Ven, 1994; Berger and Luckmann, 1966). In this way, in a sensemaking view, it will foster a higher sense of belonging and the network will become increasingly seen as a collective construct, result of an intended action from the participants.

The companies knew each other before the CR: the tool did not bring to the collaboration. Rather, the collaboration has led to the CR, proving to be an effective way to formalize the existing relationships. To this day the contract has worked in giving a unified vision for this project and to the members who participated in the development (Alfa-Net, President of the CR).

Apart from outlining a vision useful for commitment, the contents of the CR specify and explain firms what these are: the objectives; the roles and responsibilities for each in relation to the objects; mechanisms of integration; mutual expectations; standards and languages required in order to best operate; the communication channels available, etc. (Mayer & Argyres, 2004).

Feedback transparent channels and the concept of the CR as a “repository of knowledge” will be useful for understanding the possible errors and, through the learning process, from start to redesign themselves to better understand the dynamics of the network (Argyres & Mayer, 2007).

The CR needs to be focused on a strategic focus, along with a clearly defined program.

The specific aim of the CR in terms of waste collection system, is focused on the “supply, installation, maintenance of an experimental monitoring system for the waste collection system, and supply of electronic keys that are attached to this experimental system” (Alfa-Net, President of the CR).

The aim of Gamma-Net is in the creation of an innovative organizational model designed to create strategic and operational synergies between the members. The participating companies intention is to increase their competitiveness through the development of communicative activities, capturing potential business opportunities (Gamma-Net, Cloud Inc.).

In accordance with its competences, each participating company must keep in mind its tasks, rights and obligations within the network.

Therefore, institutionalization is also used to “transform informal commitments into organizational routine” (Ring and Van De Ven, 1994; Berger and Luckmann, 1966; Zucker, 1977). Other critical points regard the identification of the structure and governance, and the choice of its members. For the latter, the match of skills and knowledge coming from different sectors can promote the development of technological innovations in totally new areas (Russo, 2011). In this sense, the present discipline of the CR allows the participation of companies that have different but complementary skills within the same industry or firms coming from different industrial sectors. As already mentioned, it is expected the participation of cooperatives and academic spin-offs. On the other hand, if not properly managed, belonging to different sectors and regions can represent a major obstacle for the network activities.

The crucial point is to put together the right companies in order to collaborate in an efficient way. (Alfa-Net, Owner Triangle Ltd).

Probably one of the errors of setting up the CR was to involve firms of different sizes. Large companies already carry out most or part of the typical activities of the sector. So it becomes difficult for other smaller businesses to make a significant contribution. We also had problems in relation to the willingness to cooperate from the most large companies. On the other hand, however, there were also small companies that were not structured: they were simple engineering consultants. Other realities instead had a purely speculative philosophy. The network would have had different perspectives if it had put together companies of the same size but s aimed at specific segments of the industry and market (Gamma-Net, Manager of Moon Ltd).

The actors who formed the network were overly presumptuous: no one has taken the lead or involved the partners in projects going beyond the first steps taken (Gamma-Net, Manager of Moon Ltd).

In structural terms, the relations must be based considering that the “tie strength ensures social capital and solidarity benefits that are important for the tacit characteristics of innovations, that is, knowledge recognition and realization” (Rost, 1994; Coleman, 1990). At the same time, the inclusion of “broker” companies will be important to access information and new opportunities also distant from each other (Burt, 2000; Ahuja, 2000; Rost, 1994; Capaldo, 2007).

However given that the contract is primarily based on trust, commitment and independence, governance mechanisms should be appropriately set in order to ensure a

democratic participation for network choices and to limit the authoritarian pressures of those firms that, over time will take on a leadership role or they will ensure rent due to property rights or bottleneck resources (Kogut, 2000). On the other hand, leadership is important for guiding complex networks (Muller-Seitz, 2012).

However, the network has come to face a difficult situation. But it was not an issue of trust. It was due to the lack of an “enabling force”, someone who would bring the network to meet and manage opportunities. From what our experience shows, networks that are able to overcome these difficulties are those that have a leader. There must be a person who drives the activity of the network. From the operational point of view, being able to coordinate all of these companies, even geographically distant, was a huge obstacle. I can affirm then that the presence of a strong leader, makes the network work better, especially in networks like this, that bring together 11 different realities, including Ltd, Inc., Lp.(Gamma-Net, Manager of Sun Ltd)

For innovative purposes the network’s governance structure for selecting problems and solutions could be flat or hierarchical. Following the approach of Pisano and Verganti, (2008), you will have networks associated to “innovation Consortiums”, which operate like a private club, with participants jointly selecting problems, deciding how to conduct work, and choosing solutions. In this clubs, the expertise of all participants is needed and firms can share the resulting intellectual property with the other participants. Other networks, could be organized as “innovation Elite circle” in which one company selects the participants, defines the problem, and chooses the solutions.

Executions

In the executions stage, “the commitments and rules of action are carried into effect” (Ring & Van de Ven, 1994, p.98). SMEs can go beyond the simple dyadic relation and experience the importance of synergies, achieved within the CR and with external partners too. Indeed, “a firm grows by being a player; it does not become a player by growing” (Powell, Kogut and Smith-Doerr 1996).

The CR provide SMEs with a set of opportunities that they would not have if taken individually. They can manage an higher complexity in terms of activities and knowledge. In particular, the competitive advantage fostered by the CR consist in the following elements:

1) Breaking the “size issue”, that chokes Italian SMEs development. Small businesses can grow (especially in qualitative terms) and follow development paths that were inaccessible before because of their size limits. This growth happens without takeovers or mergers, which are far from the Italian entrepreneurial culture. Firms’ independence is safe, and the relational and social capital accrue.

2) Synergies in the use of resources reduce costs. SMEs can adopt technological solutions (e.g. advanced ICT systems of “social enterprise”), that were too costly for a single business.

3) SMEs can take internationalization paths. They can enter in touch with internationalized partners and take advantage of established global relations to build new ones (Johanson & Vahlne, 2009). The CR acts in global markets as a unique player, with an increased bargaining and competitive power. Moreover, it enables processes of cognitive internationalization (Rullani, 2006), raising the exchange of flows of knowledge and resources with international firms.

4) It promotes trans-sectorial and trans-territorial dynamics, which drive innovation processes. Firms can identify and create new opportunities in emergent industries and/or markets. They can innovate in an open way, or following design-driven logics, creative new meanings for their products (Verganti, 2009). Today design does not concern only the physical requirements of products, but it becomes “a creative conciliation of functionality and form, a tool to communicate values and contents, esthetic element and brand” (Baglieri & Loiacono, 2009)

5) Increased bargaining power and better relationships with stakeholders eventually determine a better relationship with the local context. This creates new social capital. In particular, the CRs ease access to financial resources and credit, allowing SMEs to invest in their regions.

6) CRs overcome some well-known limitations of the district-based networking model, allowing a modernization of this traditional dimension.

7) CRs have access to fiscal benefits and incentives, and institutions at regional, national and European level give financial support to firms adopting this new tool.

Working through a network you can do something that alone you could not afford. We do not have expertise in the field of electronics, software, or plant design. The network is the only way for small companies like us to work not only on behalf of third parties, but to

develop a new product and have direct contact with the market” (Alfa-Net, Owner of Triangle Ltd).

The network allows us to do things that otherwise we could not do that alone. We believe the combination of our competences must be greater than the sum of our know-how, thanks to a multiplier effect. The shared competences are the basis to find our points of contact. On the competences you optimize business opportunities, investment evaluations and internationalization strategies” (Beta-Net, President of the CR).

Thanks to the network we can have various specializations that otherwise would be impossible to have. (Alfa Net, Manager of Circle Ltd)

Being part of a network is the only way to approach certain customers, even if we make innovation since 8 years, we would never be able to create our system without being an enterprise network. This because the mechanical and business skills that were necessary would have been unknown to our reality, so being in a network was an imperative. (Alfa-Net, Owner of Square Ltd)

We made an initial agreement as a network with a Swiss multinational, which operates worldwide in Spain, Singapore, United Arab Emirates. (Alfa-Net, President of the CR)

The CR is a tool that allows us to operate on international markets. If we go abroad as a company with ten employees has an effect, but if we go as a group with two-hundred employees has another effect since we have a business plan of relations that none of the companies pursued before entering in the CR, such as relations with trade associations.(Beta-Net, President of the CR)

If you have a small size company, you are seen as a simple supplier and you find yourself at the bottom of the chain. (Beta-Net, Owner of Two Ltd)

We can obtain higher results thanks to knowledge sharing. We reach this thanks to research and development. The CR is essential for attracting other actors like Universities, think tanks, and to enter into new and high-tech industries like aerospace, defence, oil&gas and energy. (Beta-Net, Manager of the CR)

From the point of view of appearance, the network has guaranteed a greater visibility, both in institutional terms and media.(Gamma-Net, Manager of Sun Ltd)

Assessments

As stated before, the proposed adaptation of Ring and Van de Ven's model follows a cyclical logic, depicting a looping process of network creation and enactment. Such circuit triggers a process of learning *within* and *across* the Contratto di Rete (Anand & Khanna, 2000). The first type of learning directly depends on the access to new knowledge: multi-sectoral CRs have amplified chances to increase their innovative capacity, as they can combine and coordinate diverse sets of capabilities and skills. This learning have a significant impact on competitive performance.

The Contratto di Rete importance is related to the second type of learning too. "In order to carry out a business deal, a cooperative inter-organizational relationship may need to remain in effect for a long term. With time, misunderstandings, conflicts, and changing expectations among the parties are inevitable, and these factors can provide cause for rethinking the terms of the relationship" (Ring and Van de Ven, 1994., p.98). Once negotiated the conditions of the partnership and committed formally, partners execute the program shared in the CR. During all these overlapping stages, a continuous process of assessment evaluates the transactions and the relationships built and enacted in the CR. If they are not carried out in an equitable and efficient manner, partners will take corrective measures by re-negotiating the terms of their alliance, and/or reducing their formal commitment through less demanding requirements of their Contratto di Rete. If their alliance provides good performances, proving its effectiveness (Snow, Miles, & Coleman, 1993), enhancing partners' competitiveness, innovation capacity and internationalization processes, they may decide to improve their commitment, establishing, as an example, the so called "Rete Soggetto".

This continuous progression of assessment and adjustment is essential for the *across* alliances learning process, which accrues the networking or relational capability of the firm (Anand & Khanna, 2000). Contratto di Rete's flexible nature is convenient with this meta-learning dimension, encouraging the individualistic or family-centered Italian entrepreneur to learn how to open his business to partners, how to manage relationships, how to build his own social capital (Nahapiet & Ghoshal, 1998). The accrual of the relational capability is obviously a process that goes by during the whole networking activity, but we decided to put it after the execution stage and before the new negotiation stage in our model because that is the moment where all the new knowledge resulting from the networking activity is gathered and systematized in new relational capability.

5 Conclusion

Our study addresses a new pattern of networking for Italian SMEs that goes beyond the quantitative increase in size. They need to integrate the relationship growth and the capability growth, adopting an holistic approach that is focused on networking.

The inclination and the ability of networking is influenced by entrepreneurs' national culture and social values.

For the Italian case, many studies (Hofstede, Hofstede, & Minkov, 2010; Del Junco & Bràs-dos-Santos, 2009) show that Italian entrepreneurs are individualistic and prone to autonomy. Collaboration occurs when negotiated and when is able to create relationships which can be useful for business purposes. As a consequence, Italian entrepreneurs prefer local "natural" networks rather than mergers or acquisitions. These "natural" networks produce operative flexibility and knowledge sharing related to the local social capital. Many SMEs (including the 40% of Italian manufacturing companies) raise from industrial districts, which has always been significant for their international competitive success.

Notwithstanding, current innovation and internationalization processes are more and more at the crossroad of diverse forms of knowledge. So, they require the development of networks which are highly designed, governed, large, cross-sectorial and stable.

In the Italian context, we advance that the CR can create networks with the above mentioned features, considering at the same time the idiosyncrasies of the Italian entrepreneurs. The law regulates only the essential frame, giving the possibility to the companies to complete it with contents and details in accordance to strategic and operative needs, maintaining their autonomy.

Moreover, our findings show that the CR is effective for the competitive performance of the involved firms. Considering innovation, the tool allows firms to integrate their competences (as showed by Alfa-Net and Beta-Net cases) and connects technology development to market needs (Alfa-Net case). In terms of internationalization, the CR provides the participation in international networks, and speeds up the global relational growth (Beta-Net case). Nevertheless, when the strategic focus is missing or is not well defined, and the partners are not selected in a proper way, the CR fails to deliver results (Gamma-Net case).

The CR was born to support in a long term perspective cohesion, coordination and learning among the partners in terms of innovation, internationalization and marketing, fulfilling goals difficult to achieve alone. Our contribution is twofold: first, we show that

CR is an innovative networking tool convenient with the cultural characteristics of the Italian entrepreneur; second, the CR allows the creation of networks that drives superior competitive performances for the Italian SMEs.

Our study is exploratory and calls for an empirical and quantitative deepening. This is because the CR is still a recent tool and not enough time went by since its introduction in order to make relevant quantitative studies, especially in financial terms. In particular, it would be of interest to study the use of this tool in various industries, focusing on cross-sectorial and cross-territorial dynamics, as well as collecting more quantitative data.

We provide implications for both academia and practitioners (managers, entrepreneurs, public administrators) showing that there is a new way for networking in Italy, driven by the Contratto di Rete.

Structured Abstract

Purpose – Organizational performance is increasingly grounded on knowledge-related issues. The seminal academic discussions addressing this phenomenon revolve around the concept of Intellectual Capital (IC) (e.g. Edvinsson & Malone, 1997; Sullivan, 1998). IC is typically divided to human, structural and relational capital assets possessed by an organization (e.g. Bontis, 2001; Guthrie, 2001). We expand this focus further on renewal capital (e.g. Kianto et al., 2010) entrepreneurial capital (e.g. Erikson, 2002) and trust capital (Mayer et al., 1995). There has been inconclusive evidence on the performance outcomes of possessing IC in firms. In general, IC has been seen to increase firm's performance in various aspects, but the evidence is mixed and based on various types of measures (e.g. Bontis, 1998; Chen et al., 2006; Subramanian and Youndt, 2005; Tovstiga and Tulugurova, 2007). Therefore, to understand better the role of IC in firms' value creation, we will analyze here empirically the effect of different IC categories on performance measures using psychometrically robust scales developed to capture the whole essence of the phenomenon. Our purpose is to provide detailed evidence on the different performance implications of IC categories in firms, and thus bring about new knowledge to the field.

Design/methodology/approach – Our results are based on a survey data, collected in Finland during 2013. The data consist of 262 responses from firms with at least 100 people employed. We analyze seven different categories of intellectual capital, and examine their influence on various market and innovation performance measures. The used measures are based on multiple-item scales, developed on basis of earlier research, as well as including new measures developed by the authors. The Partial Least Squares (PLS) was used for the analyses by first assessing the reliability and validity of the measurement models and then the structural models to test our hypotheses.

Originality/value – In this study, we examine the firm-level performance outcomes of intellectual capital. We utilize a broad set of measures for IC, including six categories of human, relational, structural, renewal, entrepreneurial, and trust capital. The first three categories are well-established and often utilized conceptualizations, while we suggest here that the latter three cover important facets of IC that should also be analyzed to get

an overarching picture of the phenomenon. Our results show that the various IC categories have different implications for firms in terms of their performance.

Practical implications – The results of this study help managers in firms to better understand the potentially best-performing categories of IC. Moreover, the results provide key performance outcomes for IC, which can be utilized to measure the return-on-investment of IC initiatives accurately and reliably. Thus, our findings provide the managers with a sound decision making tool regarding the investments on IC.

Keywords – Intellectual Capital, Knowledge Management, Value Creation, Organizational Performance

Paper type – Academic Research Paper

1 Introduction

Organizational performance is nowadays grounded largely on intangible assets, i.e. intellectual capital (IC) (Drucker, 1993; Grant, 1996; Edvinsson and Malone, 1997; Stewart, 1997; Sveiby, 1997). Edvinsson and Malone (1997) suggested already more than fifteen years ago that corporate intellectual assets clearly outweigh the tangible value, and a study by the World Bank (2005) found that intangible capital accounts as much as 77% of total wealth worldwide. Knowledge assets have also been linked to companies' ability to innovate (Subramaniam and Youndt, 2005; Youndt et al., 2004), and to compete (Stewart, 1997; Teece et al., 1997; Zack, 1999) in the modern knowledge economy.

Early conceptualizations in the late 1990s divided IC mainly into human-centred, organization-centred and relationship-centred assets (Edvinsson and Malone, 1997; Nahapiet and Ghoshal, 1998; Roos and Roos, 1997; Stewart, 1997; Sullivan, 1998; Sveiby, 1997; Bontis, 1998). Accordingly, the majority of studies consider that IC consists of three elements, i.e. IC stocks: human capital, structural capital and relational capital. However, we consider that there are further dimensions of IC that have not been generally addressed – renewal capital (e.g. Kianto et al., 2010), entrepreneurial capital (e.g. Erikson, 2002) and trust capital (Mayer et al., 1995). We also suggest that these IC stocks that can be utilized to measure organizations' IC and thus help us to gain more holistic understanding of the phenomenon.

Generally speaking, the research suggests that IC has a positive and significant influence on firm performance, but the evidence is mixed and based on various types of measures (e.g. Bontis, 1998; Chen et al., 2006; Subramaniam and Youndt, 2005; Tovstiga

and Tulugurova, 2007). Thus, the purpose of this paper is to shed more light on the phenomenon by empirically analyzing the effect of different IC stocks on firm performance in terms of market and innovation performance.

2 Intellectual capital stocks

IC can be defined as "the possession of the knowledge, applied experience, organizational technology, customer relationships and professional skills that provide a company with a competitive edge in the market" (Edvinsson and Malone, 1997). According to other definition by Stewart (1997), IC stands for the information, intellectual property, intellectual material, knowledge, core technique, customer relationship and experience that can be utilized to make company rich. Further, Sullivan (1998) considers that IC consists of "knowledge-based resources that contribute to the sustained competitive advantage of the firm".

The majority of studies in the field consider that IC consists of three elements: human capital, structural capital and relational capital. Thus it has been seen to include the human skills, expertise and motivation; the structural features of production embedded in organizational processes, systems, solutions, databases, patents and IPs; and the value embedded in the network of relationships. In addition, we suggest that there are also four other elements that could be seen as parts of IC: "renewal capital" in terms of innovative solutions, products and services available for the firm (e.g. Kianto, 2008) "trust capital", i.e. the trust embedded in its internal and external relationships (e.g. Mayer et al., 1995); and "entrepreneurial capital" i.e. the competence and commitment related to entrepreneurial activities in the organization (e.g. Erikson, 2002). Moreover, we decided to split relational capital into "internal" and "external" categories, because the two categories relate to relationships with different stakeholders. Traditionally relational capital only refers to an organization's relationships with external parties, but in our model, we separate intra-organizational relationships as a facet of IC of its own. This broad 7-partite definition of intellectual is based upon a wide understanding of knowledge, as not only the explicit outcomes of knowledge-intensive work such as patents, formulae and actualized products, but also as the tacit potential of organizational actors to e.g. flexibly react to unexpected situations and rapidly changing customer demands.

3 Intellectual capital as a firm performance driver

The majority of the empirical literature seems to agree that the IC stocks are interlinked by nature and influence firm performance the most when combined. Thus, it is seen that the firms which possess high overall IC gain also better results in terms of financial performance (Youndt et al., 2004); new product development performance (Chen et al., 2006); new product sales performance (Chien and Chao, 2011); knowledge productivity (Huang and Wu, 2010); amount of intellectual property and related firm performance (Namvar, 2010); process flexibility (Menor et al., 2007); and innovation (Wu et al., 2008).

The relative impact of various IC stocks on company performance has been addressed in a number of studies. The results gained have not been unanimous. There are some studies that have found human capital to be the most important performance driver. It has been found that organizations with high amounts of human capital tend to achieve also higher export intensity (Bontis et al., 2007); innovation performance (Cabello-Medina et al., 2011); and competitiveness (Tovstiga and Tulugurova, 2007). In addition, Hormiga et al., (2011) noticed that human capital was a powerful predictor of the success of young enterprises.

According to some other studies, the relationship between structural capital and firm performance is the most significant among all of the IC stocks. It is stated that structural capital has a positive influence on new product development (Aramburu and Saenz, 2011) and innovation performance (Delgado-Verde et al., 2011a). Furthermore, Yang and Lin (2009) studied IC in the Taiwanese healthcare industry, and found that organizational (structural) capital had almost two times the explanatory power over firm performance compared to human and relational capital.

Relational capital has also been touted as a crucial factor that influences firm performance. Bozbura (2004) found that relation(al) capital of firms was positively and significantly related to the market-to-book value of firms. In addition, relational capital has been discovered to positively affect also cost-leadership and differentiation advantage (Čater and Čater); radical innovations (Delgado-Verde et al., 2011b); and financial and operating performance (Huang and Hsueh, 2010).

In addition to the three traditionally considered IC stocks, we suggest that also renewal capital, entrepreneurial capital and trust capital are likely to function as important assets of the firm that increase its performance.

Renewal capital represents the resources of the firm for renewing what it knows and can do. It consists of the ability of the firm to acquire new information, develop skills and to learn. An organization with high renewal capital, sometimes also called innovation capital (Chen et al., 2004), is able to build on previous knowledge and to generate new knowledge (Madinios et al., 2010), as well as to develop new products, services and innovative ideas on a continuous basis (Tseng and Goo, 2005). The organizational learning literature underlines that the main mechanism for building new knowledge assets is learning (Argyris, 2002), and from this perspective renewal capital as an intangible resource can be characterized as the actualized learning capability of the firm. It has been found that the capacity to learn and to acquire new knowledge by a firm is strongly related with several aspects of firm performance. E.g. Nonaka and Takeuchi (1995) have argued that knowledge creation is a key factor in enabling company competitiveness and sustained performance. Andreeva and Kianto (2011) found that knowledge creation was the key explanatory of firms' innovation performance. In a similar vein, the dynamic capabilities approach (Teece et al., 1997; Eisenhardt and Martin, 2000) argues that the ability of a firm to update and modify its knowledge and capabilities is important for sustaining competitiveness, especially for in conditions of turbulent and hyper-competitive market environments. Edvinsson (2002) has even argued that as organizations have to survive in turbulently and unexpectedly changing environments, renewal capital has become the most important facet of IC (Edvinsson, 2002).

Whereas renewal capital is about the firm's ability to learn and to acquire new knowledge and skills, entrepreneurial capital is related with the entrepreneurial behavior exerted by organizational actors. Concerning entrepreneurial capital, i.e. the courage, initiative-taking and pro-activeness in an organization, there is some evidence from previous research that these qualities increase organizational performance (Hughes and Morgan, 2007). E.g. this kind of orientation is likely to increase innovation performance by allowing more self-directed development activities in the firm. Risk-taking, recognizing new business opportunities and ability to make bold decisions will also help the organization to produce and to prototype innovative ideas. An organization with high entrepreneurial capital will be more competitive through having employees that are willing and empowered to make fast localized decisions and to show initiative in solving problems.

On trust capital side, there is evidence among literature that it has powerful explanatory power over organizational performance. Mayer et al. (1995) stated that trust contributes to organizational cooperation and collaboration; Costigan et al. (1998) found out that high trust among colleagues generated an environment that supported calculated risk-taking and entrepreneurial orientation; Blomqvist (2002) wrote that trust increased the efficiency and effectiveness of communication and knowledge-creation processes; Zeffane and Connell (2003) concluded that organizational efficiency is possible only when the actors work together in a climate of positive trust; Ellonen et al., (2008) noted that trust added to the efficiency, effectiveness and innovation performance of organizations which rely heavily on their interpersonal and intra-organizational collaboration; and Chen and Hung (2010) established that trust generated improved resource exchange and production innovation.

Based on the preceding argumentation, we posit the following sets of hypotheses concerning the performance impacts of the various types of IC stocks:

- H1: Renewal capital → Market performance
- H2: Entrepreneurial capital → Market performance
- H3: Human capital → Market performance
- H4: Structural capital → Market performance
- H5: Internal relational capital → Market performance
- H6 : External relational capital → Market performance
- H7: Trust capital → Market performance

- H8: Renewal capital → Innovation performance
- H9: Entrepreneurial capital → Innovation performance
- H10: Human capital → Innovation performance
- H11: Structural capital → Innovation performance
- H12: Internal relational capital → Innovation performance
- H13: External relational capital → Innovation performance
- H14: Trust capital → Innovation performance

4 Research design

4.1 Sample and data collection

We tested the hypotheses with a survey data that was collected in Finland in 2013 by means of a structured questionnaire, using key-informant technique. The initial population comprised a cross-industry sample of Finnish companies that included all firms with at least 100 employees. The Intellia database was utilized in identifying the

companies. A total of 1523 companies were considered suitable for the initial sample. All the eligible firms were contacted by external research company by telephone and the person in charge of the human resources were asked to respond to the questionnaire. Confidentiality was emphasized and a summary of the results was promised to the respondents. Out of the 1523 companies 262 responses were received, representing a response rate of 17.2 per cent (262/1523). Most of the respondents held position such as a HR director or manager (77.9 %), other director or manager (8.8 %) or managing director (6,9 %), indicating their sufficient expertise and key position regarding the issues of intellectual capital and performance.

4.2 Measures

Independent variables. IC stocks were measured by scales developed mostly by the authors. The internal relational capital and human capital scales got inspiration from Yang and Lin (2009) and the scale for entrepreneurial capital is based on work by Hughes and Morgan (2007). The 23 items covered seven IC stocks: renewal capital (3 items), entrepreneurial capital (4 items), human capital (2 items), structural capital (3 items), internal (3 items) and external (3 items) relational capital, and trust capital (5 items). All of the measures were based on a five-point Likert scale (1-strongly disagree, 5-strongly agree). See Appendix 1 for the measures and the wording of the items.

Dependent variables. Market performance was measured on a scale developed by Delaney and Huselid (1996) and a scale for innovation performance relied on work by Weerawardena (2003). Market performance (3 items) was covered by asking respondents to compare their company's success against other companies in its sector. For the innovation performance (5 items) respondents compared their company's success to the competitors' in terms of creating innovations or new operating methods. For both scales a list of different areas of performance were listed and the respondents rated these on a five-point Likert scale (1-very poorly, 5-very well). See Appendix 1 for the measures and the wording of the items.

Control variables. Three variables (firm age, sales and industry) were used as control variables to eliminate whatever effects might have had on market and innovation performance. Firm age was measured in terms of years since establishment. Sales was measured in 1000 euros, and industry was classified to eight categories.

4.3 Assessment of bias

The data relied on self-report measures, and therefore common method variance might have biased the findings. Common method bias is of particular concern when survey respondents are asked to fill out items covering both independent and dependent variables. We used Harman's one-factor test (Podsakoff et al., 2003) in order to assess the risk of such bias, and conducted a principal component analysis that incorporated all the items from all of the constructs. We investigated the solution in order to determine the number of factors required to account for the variance in all the items. The largest factor accounted for 28.3 per cent, which suggests that common method bias was not a concern.

5 Results

We used Partial Least Squares (PLS) for the analyses (version 2.0M3 of SmartPLS). The first step was to assess the reliability and validity of the measurement models. We then used the structural models to test our hypotheses.

5.1 Correlation analysis

Table 1 and 2 present the means and standard deviations, and provides correlation matrixes.

Table 1 Correlation matrix for market performance model

	Mean	SD	1	2	3	4	5	6	7
1. Market performance	3.46	0.64							
2. Renewal capital	3.52	0.66	0.291**						
3. Entrepreneurial capital	3.29	0.66	0.125*	0.572**					
4. Human capital	4.01	0.54	0.115**	0.466**	0.410**				
5. Structural capital	3.54	0.78	0.035	0.407**	0.282**	0.385**			
6. Internal relational capital	3.50	0.63	0.212**	0.432**	0.390**	0.376**	0.400**		
7. External relational capital	3.56	0.57	0.215**	0.353**	0.333**	0.221**	0.238**	0.274**	
8. Trust capital	3.96	0.51	0.372**	0.546**	0.481**	0.470**	0.372**	0.507**	0.468**

Notes: ** Correlation is significant at the 0.01 level; * Correlation is significant at the 0.05 level

Table 2 Correlation matrix for innovation performance model

	Mean	SD	1	2	3	4	5	6	7
1. Innovation performance	3.32	0.55							
2. Renewal capital	3.52	0.66	0.468**						
3. Entrepreneurial capital	3.29	0.66	0.330**	0.572**					
4. Human capital	4.01	0.54	0.200**	0.466**	0.410**				
5. Structural capital	3.34	0.78	0.164**	0.363**	0.307**	0.326**			
6. Internal relational capital	3.40	0.62	0.268**	0.339**	0.287**	0.274**	0.339**		
7. External relational capital	3.56	0.57	0.266**	0.353**	0.333**	0.221**	0.225**	0.273**	
8. Trust capital	3.96	0.51	0.383**	0.546**	0.481**	0.470**	0.315**	0.439**	0.468**

Notes: ** Correlation is significant at the 0.01 level; * Correlation is significant at the 0.05 level

As the matrixes show, there are significant correlations between the independent variables (i.e. IC stocks) and the dependent variables (i.e. market and innovation performance). This indicates and supports our expectations of interconnectedness between IC stocks and these two types of firm performance.

5.2 Measurement models

In order to test the measurement models we assessed the internal consistency as well as the discriminant validity.

Internal consistency. Measures of construct reliability (CR) and convergent validity represent internal consistency. According to the CR test, all the constructs showed a value above the threshold (0.7, adopted by Bagozzi and Yi, 1988) (see Appendix 1). In order to test for convergent validity we examined CR, the factor loading and Average Variance Extracted (AVE). Firstly, the loadings of all the items were high and statistically significant (see Appendix 1). This means that they were all related to their specific constructs, verifying the posited relationships among the indicators and constructs. Secondly, the AVE measure exceeded the cut-off (0.50, see e.g., Fornell and Larcker, 1981) for all of our constructs.

Discriminant validity. This indicates the extent to which any one construct differs from the others, and in assessing it the AVE should be greater than the variance shared between that construct and the other constructs in the model (i.e. the squared correlation between two constructs) (Fornell and Larcker, 1981). The constructs of our study fulfil this condition: in our two models (see Tables 3-4) the diagonal elements (AVEs) are greater than the off-diagonal elements in the corresponding rows and columns.

In sum, the model assessments gave good evidence of validity and reliability for the operationalization of the concepts.

Table 3 Discriminant validity for the market performance model

	1	2	3	4	5	6	7	8
1. Market performance	0.77							
2. Renewal capital	0.08	0.68						
3. Entrepreneurial capital	0.02	0.33	0.64					
4. Human capital	0.01	0.22	0.17	0.64				
5. Structural capital	0.00	0.17	0.08	0.15	0.70			
6. Internal relational capital	0.04	0.19	0.15	0.14	0.16	0.76		
7. External relational capital	0.05	0.12	0.11	0.05	0.06	0.07	0.80	
8. Trust capital	0.14	0.30	0.23	0.22	0.14	0.19	0.26	0.64

Notes: AVE associated with the construct is presented diagonally.
The squared correlations between constructs are presented in the lower left triangle.

Table 4 Discriminant validity for the innovation performance model

	1	2	3	4	5	6	7	8
1. Innovation performance	0.74							
2. Renewal capital	0.22	0.72						
3. Entrepreneurial capital	0.11	0.33	0.60					
4. Human capital	0.04	0.22	0.17	0.64				
5. Structural capital	0.03	0.13	0.09	0.11	0.65			
6. Internal relational capital	0.07	0.11	0.08	0.08	0.11	0.58		
7. External relational capital	0.07	0.12	0.11	0.05	0.05	0.07	0.80	
8. Trust capital	0.15	0.30	0.23	0.22	0.10	0.19	0.26	0.54

Notes: AVE associated with the construct is presented diagonally.

The squared correlations between constructs are presented in the lower left triangle.

5.3 Testing the research models

As Tables 5 and 6 shows, our research models could explain 20.5 and 18.5 per cent of the variance in market and innovation performance, respectively.

We estimated path models reflecting the posited relationships between IC stocks and both market and innovation performance in order to test the hypotheses.

In market performance model (see Table 5) only path estimates from both internal (H5) and external (H6) relational capital as well as from trust capital (H7) to market performance were as hypothesized. Internal relational capital ($B=0.165$, $p < 0.05$), external relational capital ($B=0.125$, $p < 0.10$), and trust capital ($B=0.211$, $p < 0.05$) each had a significant, positive impact on the market performance. Contrary to our hypotheses, renewal capital ($B=-0.145$, $p < 0.05$), human capital ($B=-0.111$, $p < 0.05$) and structural capital ($B=-0.111$, $p < 0.05$) had a negative impact on market performance.

Table 5 Results of testing the market performance model

Path	Path coefficient	t-value
<i>Path</i>		
Renewal capital → Market performance	-0.145*	1.762
Entrepreneurial capital → Market performance	0.05 n.s.	0.840
Human capital → Market performance	-0.111*	2.113
Structural capital → Market performance	-0.111*	1.801
Internal relational capital → Market performance	0.165**	2.446
External relational capital → Market performance	0.125 ^a	1.584
Trust capital → Market performance	0.211*	1.900
R^2		.205

Notes: *** Significance < 0.005; ** Significance < 0.01; * Significance < 0.05; ^a Significance < 0.10

For the clarity reasons results for the control variables are not presented

In innovation performance model (see Table 6) both internal (H12) as well as external (H13) relational capital were as hypothesized. As expected, the effects of internal ($B=0.123$, $p < 0.05$) and external ($B=0.280$, $p < 0.05$) relational capital on innovation

performance were significant and in the predicted direction. Again some of the paths were contrary to our hypotheses. Human capital ($B=-0.134$, $p < 0.05$) had a negative effect on innovation performance. In addition, for structural capital there was a statistically significant (at 10% level) impact to innovation performance, but the strength of that was so low ($B=-0.086$) that in practice it has no effect.

Table 6 Results of testing the innovation performance model

Path	Path coefficient	t-value
<i>Path</i>		
Renewal capital → Innovation performance	-0.034 n.s.	0.466
Entrepreneurial capital → Innovation performance	0.052 n.s.	0.683
Human capital → Innovation performance	-0.134*	2.290
Structural capital → Innovation performance	-0.086 ^a	1.544
Internal relational capital → Innovation performance	0.123*	2.013
External relational capital → Innovation performance	0.280*	2.270
Trust capital → Innovation performance	0.087 n.s.	1.104
R^2		.185

Notes: *** Significance < 0.005; ** Significance < 0.01; * Significance < 0.05; ^a Significance < 0.10
For the clarity reasons results for the control variables are not presented

6 Conclusions

This paper examined the impact of intellectual capital on the organizations' market and innovation performance. Especially, this study concentrated to evaluate the performance enhancing influence of the three traditional IC stocks, namely human, structural and relational capital, as well as four IC stocks that the authors considered as important additions to achieve an overarching measurement model of the phenomenon. In contrast with the majority of the existing IC literature, our results demonstrated that most of the IC stocks are not directly related to organizations' market and innovation performance.

However, the results were mixed. As hypothesized both internal and external relational capital had a positive and significant influence on firms' market and innovation performance. Thus, it can be stated that both internal and external collaboration and understanding between the stakeholders are able to generate value to the companies. This result follows the findings from Delgado-Verde et al. (2011b), who found out in their study that both external relational capital and internal social collaboration had a positive influence on radical innovations, with external relation capital being more significant of the two. Similarly, Čater and Čater (2009) established that firms with more relational

capital were more competitive than those with less relational capital, and Huang and Hsueh (2010) accompanied that relational capital not only had a direct influence on firm performance but it also mediated the influence of other IC stocks. Relationships function as channels for flows of intangible and tangible resources. Especially relationships with extra-firm parties can bring new knowledge and insights into the firm, allowing for novel constellations of ideas and collaborations, as argued by the literature on open innovation (e.g. Chesbrough, 2003; Huizingh, 2011).

Contrary to our hypotheses, renewal capital, human capital, and structural capital had negative impacts on market performance, and human capital had a further negative effect also on innovation performance. According to Kianto (2007), possessing intellectual assets does not singlehandedly facilitate improved organizational performance, but the other equally important factor is what the organization does with it. In other words, organizations should use proper management methods, i.e. knowledge management practices, to leverage on the IC stocks. For instance, good supervisory work boosts the employees' willingness to share knowledge and innovate risks, whereas bad management can leave the employees ineffective and without aspiration. Therefore, we suggest that comprehensive understanding of IC stocks' influence on firm performance requires that knowledge management practices are also analyzed.

One limitation of this study is that the data was collected only from Finland. Another limitation is that we only examined the direct singular impacts of the IC stocks on performance. It may well be that IC stocks function in interaction with each other to produce performance outcomes. The further examination of the IC asset bundles in terms of their optimal combinations is a task that is left for future research endeavors. Finally, the performance metrics used were based on self-evaluation by company executives, leaving space for doubt in terms of their validity. This calls for further studies utilizing objective performance assessments as dependent variables.

This paper contributes to the theoretical discussion by identifying and demonstrating the viability of three novel types of IC, which have been relatively neglected by the emerging standard in the field to divide IC into the three elements of human, structural and relational capital. In addition, renewal capital was divided into two distinct aspects, addressing firm-internal and firm-external relationships separately. This kind of a classification was supported by the inspection of the measurement model.

From a managerial perspective, our results demonstrate that “more IC is better” may not be a valid assumption. It seems that different facets of organizational overall performance have various supporting IC categories. Specifically, for ensuring market performance, investments on building functional intra-firm collaboration and a climate of trust are especially relevant. Relationships with extra-firm partners on the other hand seem to be the best bet for investments for improving innovation performance.

Appendix 1. Measurement items

<i>Concept</i>	<i>Item</i>	<i>Factor loading</i>	<i>CR</i>	<i>AVE</i>
Market performance	Compared to other companies in its sector, how do you think your company has succeeded in the following areas over the past year?		.91	.77
	Net sales growth	.913***		
	Profitability	.909***		
	Market share	.798***		
Innovation performance	Compared to its competitors, how successfully has your company managed to create innovations/new operating methods in the following areas over the past year?		.94	.74
	Products and services for customers	.883***		
	Production methods and processes	.793***		
	Management practices	.900***		
	Marketing practices	.855***		
Business models	.869***			
Renewal capital	Our company has acquired a great deal of new and important information	.818***	.88	.68
	Our employees have acquired a great deal of important skills and abilities	.855***		
	Our company can be described as a learning organisation.	.808***		
	Our employees take considered risks related to new ideas.	.849***		
Entrepreneurial capital	Our employees show initiative.	.734***	.86	.60
	The operations of our company are defined by independence and freedom in performing duties.	.924***		
	Our employees have the courage to make bold and difficult decisions.	.722***		
	Our employees are highly skilled at their jobs.	.818***		
Human capital	Our employees have a high level of expertise.	.787***	.78	.64
Structural capital	Our company has efficient and relevant information systems to support business operations. (B)	.752***	.78	.65
	Our company has a great deal of useful information in documents and databases. (A)	.684***		
	Older documents and solutions are easily accessible. (A)			
	(B)	.961***		
Internal relational capital	Different units and functions within our company – such as R&D, marketing and production – understand each other well. (B)	.481***	.71	.58
	Our employees frequently collaborate to solve problems. (A)	.931***		
	Internal cooperation in our company runs smoothly. (A)			
	(B)	.808***		
External relational capital	Our company and its external stakeholders – such as customers, suppliers and partners – understand each other well.	.924***	.92	.80
	Our company and its external stakeholders frequently collaborate to solve problems.	.864***		
	Cooperation between our company and its external stakeholders runs smoothly.	.892***		
	The operations of our company are defined by an atmosphere of trust.	.573***		
Trust capital	We keep our promises and agreements.	.548***	.83	.54
	Our company seeks to take the interests of its stakeholders into account in its operations.	.936***		
	The expertise of our company inspires trust in stakeholders.	.899***		
	The image and reputation of our company inspire trust in stakeholders.	.953***		

Notes: *** Statistically significant at a 0.005 significance level.

Structured Abstract

Purpose – This study examines how intellectual capital can affect firms' value creation. The aim is to investigate the effects of the best practices' adopted in this field on shareholders value and sustainability results, considering the human factor as the part of intellectual capital filled from the rising of the knowledge. For this reason managers should maintain skilled people inside the firm, considering a new respect for people.

Is analysed the relationship between people management best practices and shareholder value creation. By the other side, the notion of the production of economic and financial value for shareholders is, though, ever more broadened to also take in the social shared "value". So, in conclusion and for a broader qualitative and quantitative analysis, is also analysed the relationship with sustainability results.

Design/methodology/approach – We propose an approach based on the analysis of the largest companies in Europe according to 2013 rankings. The qualitative and quantitative analysis is based on the comparison of accounting/market based value measures and social/environmental performance indicators, together with the analysis of best practices on human resources management which are possible to underline with the case analysis methodology.

Originality/value – This methodology puts in evidence the strong link between people capital strategies and firm value creation and sustainability results. As we aim to prove, companies giving greater attention to the working conditions of their own workforce not only make people working inside more faithful and involved, but also handle a strategic lever able to create value for shareholders.

Practical implications – The outcomes of the application could be a suggestion method for managers who want to find new opportunities in managing intangibles inside their organization and recognise their effects on shareholder value and sustainability results.

Keywords – people capital, intellectual capital, shareholder value creation, sustainability results, performance measures.

Paper type – Academic Research Paper¹

1 Introduction

From the mid-eighties until 2000 the United States experienced a period of economic growth at rates higher than those of the other main industrial countries, in particular Germany and Japan. Other economic indicators also gave clearly superior results: lower unemployment and inflation rates and a higher capital productivity. In a dynamic economy new opportunities continually arise. Under such a stimulus to growth – according to Copeland, Koller and Murrin (2000), managing consultants for research undertaken by McKinsey – management is constantly searching for new capital to finance its latest investment, and this leads to continuous pressure to come up with strategies that give value to the invested capital. Since there is competition for capital and capital flows toward those investment projects that guarantee the highest return, the management of growing companies select strategies and investment projects on the basis of the differential between return and cost of capital.

Following the acceptance of the principle that management must aim toward the production of shareholder value, much has been written about the advantages and operating policies in order to obtain shareholder value (Rappaport, 1998; Hennel, Warner, 1998; Cornelius, Davies, 1997). “Shareholder value is therefore defined as the difference between corporate value and debt, where corporate value is the sum of the future (or free) cash flows discounted at the WACC” (Black, Wright, Davies, 2001). “To maximize shareholder wealth, management must generate, evaluate, and select business strategies that will increase the corporate value” (Morin, Jarrel, 2001).

Most of researches studies have shown that the human factor makes organizations able to face markets in which they are competing and the competitive advantage has been the most important factor in changing the labour market and the people management (Pfeffer, 1999; Caudron, 1994; Armstrong, 2006; Kaplan, Norton 2004). For instance, Jac Fitz-Enz (2001), pioneer of human capital impact valuation, gave the bases for empiric

¹ Abstract and introduction are co-written by the authors. Sections 3, 5 are written by Pellicelli M. Sections 2, 4 and conclusions are written by Casalegno C.

support of theories that claim how workforce is strategic to obtain great financial results. In other words, organizations can measure and maximize the value of their investment in employees.

Previous researches (Casalegno, Pellicelli, 2008; Casalegno, Cerruti, Pellicelli, 2009) have demonstrated that companies with superior human capital practices can create substantially more shareholder value than companies with average human capital practices and that great human capital practices prevail, regardless of the economy; the same key practices that are associated with higher value show up in bull, bear and flat markets.

The aim of this paper is to investigate the effects of the best practices' adopted in this field on shareholders value and sustainability results, considering the human factor as the part of intellectual capital filled from the rising of the knowledge. It analysed the relationship between people management best practices and the relationship with shareholder value creation and sustainability results.

2 The people capital as intellectual capital chest and value driver asset

According to authors as De Cenzo and Robbins (1996), Armstrong (2006), it is possible to say that hierarchy has been substituted by networks in the last years and the best performers on markets show more flexible processes. The control-based management has been evolving in a more friendly approach in which the communication is the most important tool (Malone, 2004).

Barlett e Ghoshal (2002) try to identify changes managers should lead in this war of talent era. Above all is important to work on the hardest mind-set to alter, deeply embedded belief, that capital is the critical strategic resource to be managed and that senior managers' key responsibilities should centre around its acquisition, allocation and effective use. It is not to deny the need of the use of financial resources, but for most companies today capital is not the resource that constrains growth; human, not financial, capital must be the starting point and ongoing foundation of a successful strategy (Casalegno, Pellicelli, 2008). Kiessling and Harvey (2006) recognize that when a company is acquired, the amount of money paid for the company is normally some multiple of earnings. The assumption is that the purchase price is higher than the tangible assets of the company. Frequently, some percentage of the 'premium' paid by the acquiring company is for the top management team and/or key managers.

People detain human capital, intellectual capital; this is considered and valued by Fitz-Enz (2001) as a profit lever in the knowledge economy. People are knowledge lever (Bahra 2001); they represent that part of intellectual capital following the individuals when the employees leave. According to Fitz-Enz, this asset can and should be measured as a fundamental asset for achieving competitive advantage. This is a precious resource, a lever to create organization value.

Accordingly, human resources represent the first source for starting and promoting innovation. An innovation-oriented culture can be considered part of the Total Responsibility Management (Gorenak and Bobek, 2010), by leveraging on the part of intellectual capital is detained by people. This is fundamental even if for most of the time it is difficult for firms to care about the ‘human factor’, since they always have to think about costs reduction and employees are often perceived only as costs in small or medium realities (Pellicelli *et al.*, 2014). But if a firm wants to overcome the competition leveraging on technology and innovation, employees must be motivate so to feel themselves as part of the whole organisation. Indeed, competitive advantages are earned when it is possible to build a link between employees’ and company’s goals (Pellicelli *et al.*, 2014).

The sharing of common goals first, together with the values sharing concerning corporate social responsibility and ethics can be a mean of creating this positive connection (Casalegno, 2008) and a way for increasing employees’ satisfaction and commitment (Bevan and Wilmott, 2002).

As intangible asset, people and their management in firm can impact on firms’ value creation (Casalegno, Pellicelli, 2008; Casalegno, Cerruti and Pellicelli, 2009). If we consider Fitz-Enz (1978; 2001; 2010), for example, people and human capital inside the company must be measured: he talks about *human capital return on investments* (HCROI), the *human economic value added* (HEVA), the *human capital market value* (HCMV). We can talk about two levels of human capital; one refers to the single employee, while the second one is about the firm community and represents the whole organizational knowledge (Casalegno, Cerruti and Pellicelli, 2009). Again, Barber (2005) argues that capital-oriented measures are not valid to evaluate “people business”, because they cover weaknesses and show volatility where it does not exist. So he suggests a people-oriented equation which uses employee productivity instead of capital productivity

(ROI); he talks about the human capital economic profit which considers the employee productivity and the average cost per person, as well as the number of employed people.

3 New intangible frontiers: sustainability and shared value creation

The idea that corporations has a responsibility that extends beyond their shareholders is not new. Many companies in the 19th century built special housing for their employees in the belief that a well-housed employee was more productive than one living in a dump (The Economist, 2009). But it was in the early years of the 20th century that this idea started to be discussed to great extent and to be translated into concrete actions.

The debate, from the very beginning, arose between what was known as Anglo-Saxon shareholder capitalism, which portrays that companies should pursue exclusively the interests of their shareholders from one side, and stakeholder capitalism, which claims that companies are also responsible to their workers and communities from the other.

In past decades the economic interests of firms and production organizations of all kinds prevailed over any possible social disadvantages; the search for the creation of value was directed mainly at achieving short-term financial results, based on a near-sighted perspective that ignored the needs of clients and of the collectivity in general. However, stakeholders, in particular governments and local communities, have become aware of the problem of sustainability and now demand greater attention to the environment, economic growth and the condition of workers, while customers are increasingly more demanding in terms of quality and innovation.

In recent years firms have been subject to increasing pressure in terms of sustainability – defined as follows by the World Commission on Environment and Development (Brundtland Commission, 1987): “Sustainable development is development that meets the needs of the present without compromising the ability of future generations to meet their own needs” – as regards both current processes as well as those being developed.

There have thus followed many definitions of sustainability with regard to the economic sphere. We can mention several recurring aspects of the definition of this term (Vos, 2007):

1. it refers to a way of observing environmental problems in relation to the economy and society;

2. the interconnections are usually described as a triangle, a ‘three-legged stool’; or overlapping circles in a Venn diagram, where the three elements can be diversely described as the economy, environment and society or equity, ecology and the economy;

3. despite the fact the specific elements and their relevance can change, what distinguishes sustainability is the observation of the systemic connections and the idea that the constituent elements should be mutually sustaining and reinforcing;

4. the focus on intergenerational equity; that is, guaranteeing to future generations the same conditions available to the present generation;

5. a final aspect shared by the various definitions, and which differs from the traditional way of observing the environment, the economy and society, is the need to go beyond the mere compatibility of existing laws and regulations.

In order to increase the dissemination of sustainable objectives, numerous international, national, state and local government protocols and policies, as well as the ‘mission statements’ of corporations and NGOs, include a commitment to sustainable development.

Based on the guidelines of the “Brundtland Commission” (1987), the United Nations has defined a series of Millennium Development Goals (MDGs) to be achieved by 2015. These goals aim at economic development and the elimination of poverty, and the objectives include human rights, health, education and environmental questions. In this context the: “efficiencies of markets, combined with the resources and managerial expertise of large multinationals, are considered crucial success factors in achieving these goals” (Seelos and Mair, 2005).

In addition, the United Nations Secretary-General, Kofi Annan (2002), challenged business leaders to join an international initiative, the Global Compact, that would bring companies together with UN agencies, labor and civil society to embrace a set of shared values and principles in the areas of human rights and labor and environmental standards.

Along with this process to involve firms in promoting sustainable growth, and thanks in part to the publication of Elkington (1997), the Triple Bottom Line (TBL) has gained acceptance as a new instrument to measure company performance in line with three approaches: economic, environmental and social (Hubbard, 2009).

The positive aspect of the TBL is that it focuses the attention of companies not only on the economic value they achieve through their business activities, but also on the environmental and social value they produce or possibly destroy (Elkington, 2004).

This emphasis has led, at the international level, to a considerable effort to define the common standards for the drafting of sustainability reports and to identify performance indicators that could highlight the value created in the social and environmental areas as well. There have been a large number of proposed guidelines for sustainability reporting.

At present the most complete and adopted guidelines are the “Sustainability Reporting Guidelines on Economic, Environmental and Social Performance” (2000), published by the Global Reporting Initiative (GRI), a joint project promoted by research institutes, international bodies, environmental and social associations, business coalitions, and certification institutes.

The GRI guidelines indicate the main topics firms should particularly focus on in their sustainability reports and propose performance indicators to communicate the impact of business activity based on three areas:

- economic, which refers to general aspects regarding the sustainability of corporate business in the long run;
- social, which refers to the impact of corporate activity on the firm’s stakeholders;
- environmental, which includes the evaluation of the impact of processes, products and services on natural resources (air, water and soil), biodiversity and human health.

Thus today “there is wide consensus that the idea of sustainability figures as one of the leading models for societal development by indicating the direction in which societies ought to develop” (Christen and Schmidt, 2012).

Also Baumgartner and Ebner (2010) point out, management should pay more attention to several aspects that are indispensable for achieving business sustainability, such as: ‘innovation and technology’, in order to reduce environmental impacts from new products and from business activities; ‘collaboration’ with the various business partners (for example, suppliers, R&D institutions, universities); ‘knowledge management’, in order to implement the organizational knowledge base; ‘processes’ that must be planned and roles assigned in order to integrate sustainability into daily business life; ‘purchasing’, and thus relations with suppliers, in order to improve business sustainability; ‘sustainability reporting’, in order to evidence the results achieved.

Therefore, corporate policies for growth that respect environmental sustainability cannot be left to the discretion of entrepreneurs but must be guided and, where necessary, imposed. There are now specific regulations that oblige firms to provide information to the public regarding their actions in favour of sustainability. In particular, larger, publicly-

quoted firms are asked to increase their sustainability and to publish their results in the economic, environmental and social domains. The Communication on the EU Strategy for Sustainable Development (2001) invited all publicly-quoted companies with at least 500 staff to publish a “triple bottom line” in their annual reports to shareholders that measures their performance against economic, environmental and social criteria.

According to Nidumolu, Prahalad, and Rangaswami (2009): “In the future, only companies that make sustainability a goal will achieve competitive advantage. That means rethinking business models as well as products, technologies, and processes”.

The authors propose a five-stage process needed to emerge from the recession and make the firm sustainable:

Stage 1: Viewing Compliance as an Opportunity

Stage 2: Making Value Chains Sustainable

Stage 3: Designing Sustainable Products and Services

Stage 4: Developing New Business Models.

Porter and Kramer (2011), on the other hand, emphasize the importance of redefining the purpose of the corporation in order to orient it toward the creation of shared value. “The purpose of the corporation must be redefined as creating shared value, not just profit per se. This will drive the next wave of innovation and productivity growth in the global economy. It will also reshape capitalism and its relationship to society” (Porter & Kramer, 2011). Therefore, the authors propose a model illustrating three key ways that companies can take to create shared value opportunities: 1) reconceiving products and markets; 2) redefining productivity in the value chain; 3) enabling local cluster development.

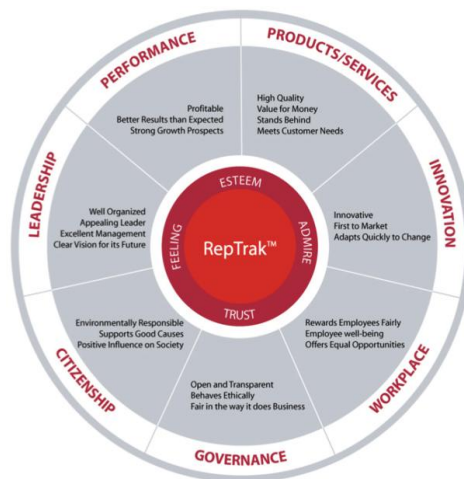

Thus firms should “look at decisions and opportunities through the lens of shared value. This will lead to new approaches that generate greater innovation and growth for companies—and also greater benefits for society” (Porter, Kramer, 2011).

4 Values, people, society and firm reputation

The importance and impact that the people management and corporate social responsibility have on the reputation and the sustainability of the company is also shown by the Reputation Institute¹, which annually publishes the ranking of firms, globally, have the highest degree of reputation. The Reputation Institute has over the years refined an

¹ *The Reputation Institute is a company specialized in management and strategic consulting. The topic in question is related to the company's reputation. This organization consists of members and offices in over thirty countries worldwide. Source: Romoli Venturi et al., 2014.*

instrument, the RepTrak, in order to give a measure to the business reputation. This tool is also useful for identifying areas of risk and reputational risk. The model analyses 23 indicators are grouped into seven dimensions that, according to the Reputation Institute, are precisely the dimensions of corporate reputation. This can result (Romoli Venturi *et al.*, 2014) considering at the same time the financial results and future projections (*Performance*), the degree of quality of firm's products and how they meet the needs of the target reference (*Goods/Services*), the degree of product and process innovation (*Innovation*), methods used in order to develop human resources skills and talents (*Workplace*), the degree of business transparency and related communications (*Governance*), company inclination to support causes related to the environment the firm itself is in (*Social Responsibility*), resources organization and the managerial ability to lead people in order to reach common goals (*leadership*). The result that comes from the joint analysis of these dimensions lead to the definition of the so called *Pulse*. Various firms' stakeholder are annually asked to answer an online survey in order to give, for every dimension, their perception in terms of sustainability. The sum of the seven dimension scores gives the *Pulse*.

Source: Reputation Institute, 2013.

Figure 1 – Reputation Institute RapTrak

Figure 1 shows the Reputation Institute model. Since the reputation is an important asset in order to create value (Reputation Institute documents show that customers are more prone to buy products of those firms on the top of the reputation ranking - 71% of

them – and more ready to suggest their products to other people), is interesting to understand that intangibles are, nowadays, representing the assets through them a firm can reach a useful degree of it.

Starting from the RapTrak model, the purpose of the present research is to empirically understand the kind of link can be present between people management and sustainability, since it has been already proven that people management, on one side, and sustainability (the kind of sustainability coming from social concerns, environmental and economical ones) on the other side can impact on value creation.

5 Research design and methodology

In order to understand the link between human capital productivity indexes and value creation, on one hand, and corporate social responsibility and value creation, on the other hand, a sample of European biggest companies (chosen by using Amadeus dataset) has been analysed. We considered the European largest public companies in terms of revenues (with a revenue turnover equal or major than 50 million euros) and we focused our attention on the first 10 (data available for the following companies: Royal Dutch Shell, BP, Volkswagen, E.On.Se, Eni, Daimler AG, Enel), in order to calculate for fiscal years 2012, 2011 and 2010:

- Costs of employees/operating revenue (%) and Human capital return on investments (HCROI) as significant indicators for human capital;

and their correlation with:

- Total shareholder return and Earning per share as significant shareholder value creation's performance indicators;
- Sustainability companies activities in terms of corporate sustainability results, with particular reference to the awards earned by the firms in the sample.

5.1 Human Capital performance indicators

In the empirical analysis we've considered the average Costs of employees / Operating revenue (%) for the years 2012-2011-2010 and the average HCROI for the years 2012-2011-2010.

Regarding the HCROI, the decision to consider this index, rather than the others Fitz-Enz indexes, has been taken because the formula is easily applicable to all analysed companies.

Figure 2 – Human Capital performance indicators

The other indexes considered by Fitz-Enz are based on the number of full-time employees (for example, the HEVA is reachable by using the formula: net operating profit after tax minus the cost of capital and the result is to be divided by the full time employees), but our data did not allowed us to figure out who among the employees in question, who was part-time and full-time. HCROI is calculated with the following the formula:

$$HCROI = \frac{\text{Revenues} - \text{Costs} + \text{employees costs}}{\text{employees costs}}$$

This performance indicator is easier to calculate. However, it is not significant in the event you need to compare different firms in which the number of employees is very different. In fact, as we can see in Figure 3, while the average Costs of employees / Operating Revenue (%) for the years 2012-2011-2010 is very high for Volkswagen and Daimler AG compared to other analyzed companies, HCROI turns out to be insignificant for Volkswagen and Daimler AG. In this case, the number of employees, for example considering the year 2012, are much higher than the other companies: they are respectively equal to 469.497 and 274.605 in 2012 against 87.000 for Royal Dutch Shell, BP for 85.700, 74.811 for E.On.Se, 75.206 for Eni, 74.610 for Enel.

5.2 Shareholder value performance indicators

Regarding shareholder value results we have to considerate that value creation is based on two fundamental postulates: 1) the objective of management is to maximize the return for the shareholders. Management is an “agent” whose task is to manage shareholder interests; 2) stock markets give a value to the company's shares based on investor expectations regarding the present value of the cash flow, which will be generated by the firm itself. A company creates value for investors in a certain period of time when the increase in the value of capital is greater than what the investor would have had with an alternative investment of equal risk.

In the empirical analysis we've considered two shareholder value performance indicators: Total shareholder return (TSR) and Earnings per Share (EPS).

Total shareholder return (TSR) determines how much shareholders have received over a certain period of time (dividends) plus the appreciation of share values. TSR is important because it expresses what is of most interest to investors. It is easy to calculate and interpret; it is not based on accounting data, and thus is not subject to distortions due to valuation criteria; and it is not affected by the size of the company. TSR is the sum of the increase in share prices and the distributed dividends over a given period of time (usually less than three years).

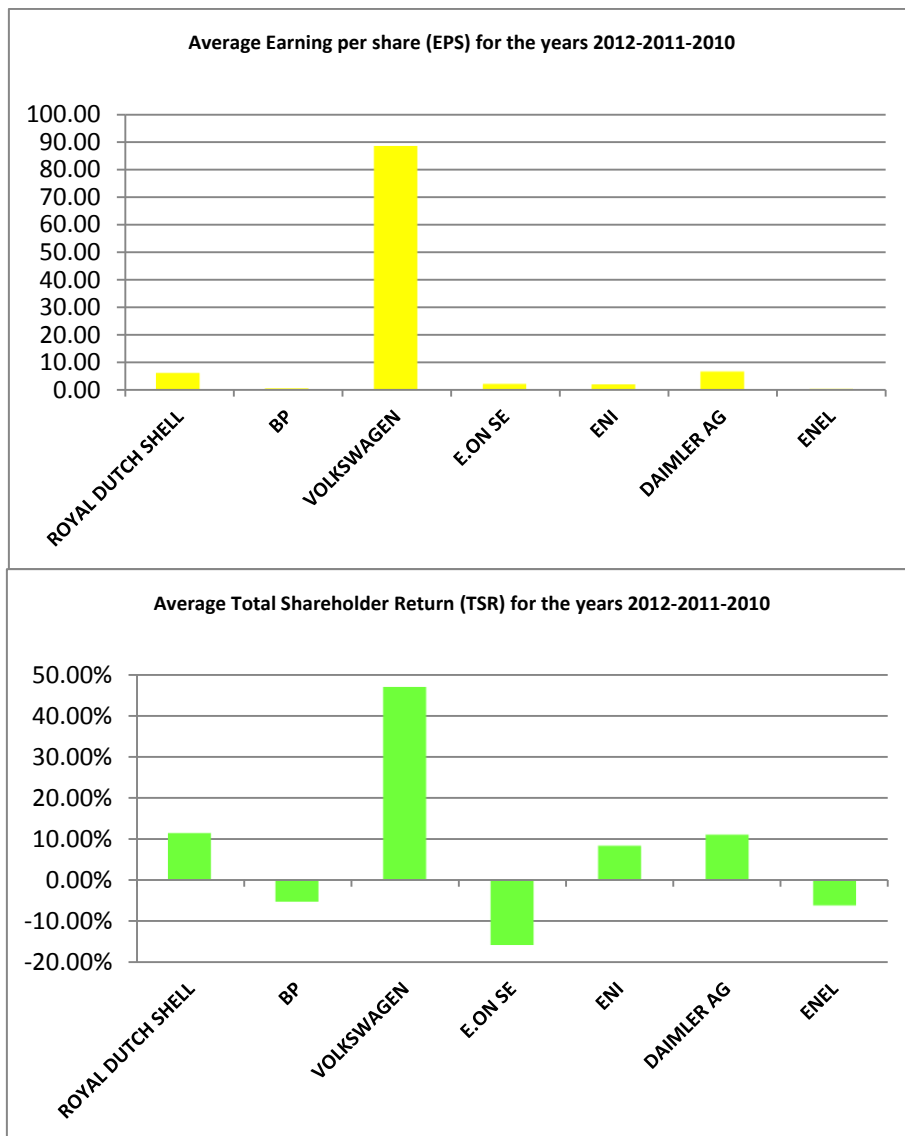

Figure 3 – Shareholder value performance indicators

The TSR formula, as presented by Cornelius e Davies (1997, p.113), is:

$$TSR = \frac{\text{Dividend per share} + (\text{Share price at period end} - \text{Original share price})}{\text{Share price at start of period}} \times 100$$

In the empirical analysis we've also considered EPS that is the most common index, although sometimes is less significant for evaluating results and the expectations of investors.

The results in terms of shareholder value creation of analysed sample are in line with the average Costs of employees / Operating Revenue (%) for the years 2012-2011-2010: Volkswagen and Daimler AG have in fact achieved the best results in terms of the average Total Shareholder Return (TSR) and the average earnings per share (EPS) for the years 2012-2011-2010.

5.3 Sustainability results

In order to highlight the results obtained in terms of sustainability we felt it appropriate to consider the rankings and awards received by the companies analyzed for the years beyond 2010.

From the conducted analysis we've found that all the firms in the sample have a sustainability report and are indexed in the most important Sustainability Index, as: ASPI Advanced Sustainability Performance Index, Dow Jones Sustainability Index (DJSI) World, ECPI Ethical Index, ESI Excellence, FTSE4Good, Dow Jones STOXX ® Global ESG Leaders indexes and are all actively engaged in social responsibility and the shared value creation.

From the analysis on the rankings and awards received, Volkswagen and Daimler AG are found to be the most active active. Eni has been awarded with CSR Online Awards Italy and is also very active in sustainability reporting.

Volkswagen has received the following significant rankings: Carbon Disclosure Project (93%); Oekom Research (Prime Status); Environmental Management (ranked 2nd); Reputation Institute DAX 30 (ranked 2nd) and the Following Awards: Ethics in Business Award in the category "Outstanding Corporation" (winner 2012); Automotive Award - Media & Publications in the category "Digital Media" (winner 2012); SAM Sustainability Awards (finalist 2012).

And Daimler AG was rated as "Prime Investment", receiving a very good (for the automotive industry) overall rating of B-. Daimler Also Scored impressively in the Carbon Disclosure Project rankings, receiving the highest rating in the categories of reporting, transparency and performance.

Also Daimler AG received very important awards, as: GreenIT Best Practice Award (2012 winner in the category "Green through IT"); EcoGlobe (winner 2012 in the category "Concept vehicles"); Automotive Environmental List (winner 2012 in the "Manufacturers" category of the VCD Automotive Environmental List); IAHE Sir

William Grove Award 2012 and received a lot of awards in the year 2011 for its environmental innovations.

So we can conclude that Volkswagen and Daimler AG have received important results also in terms of sustainability.

5.4 Human Capital investments and the correlation with value creation

From the results of the above analysis it is possible to highlight a positive correlation between investments in human capital and the creation of value, in terms of shareholder value creation and sustainability results. These results are evident for companies Volkswagen and Daimler AG, as we can see in the Figure 4.

Figure 4 – Human Capital and the correlation with Shareholder value performance indicators

6 Key findings, managerial implications and conclusions

The results obtained have allowed us to establish not only that there is a strong link between the management of human resources within an enterprise and the creation of value, but that there is an equally strong bond between the results in terms of sustainability of the undertakings concerned and their market capitalization. Although the number of companies considered not to have statistical significance, the results also

indicate that there is a link between the proper management of human resources and corporate sustainability. The model is possible to define is represented below (figure 2). As is possible to underline, people can represent an interesting lever when we talk about responsibility; the more the internal communication works, the more employees are told about corporate goals and values the company itself wants to share with stakeholders, the more the employees themselves can be an effective tool to augment the communication and the sentiment around the concept of corporate social responsibility.

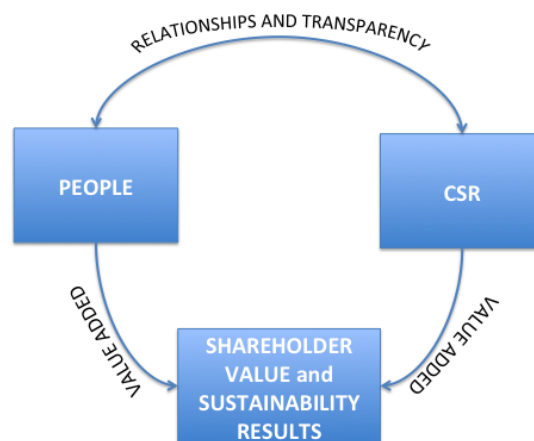

Figure 5 - The relationships model

Although the present study present limitations in terms of number of cases and indicators considered, the results clearly lead to the conclusion that greater interaction between managers and employees can be of impact not only on the creation of value, but the sustainability of the enterprise. Why human resources of a firm perceive a greater involvement of business activity that is necessary to set up a communication plan that considers not only how the company intends to communicate to the outside, but the values and goals that must be communicated to 'internal structure.

The communication plan can follow the following structure, planning borrowed from that relating to integrated marketing communication. Rules to consider can be defined following Duncan and Ouwersloot (2007) communication planning steps:

- Follow analysis results directions;
- Convert them in destination objectives. Main goals must be quantitative and valuable; they must be specific, on one hand, challenging, on the other hand;
- Develop strategies and use benchmarking to do that;
- Define the right budget for communication spending.

The last step is about the evaluation of communication strategy effects; even if we are talking about an internal kind of communication, since it represent an investment, it will be useful to understand quantitative effects of it in advance.

An exploratory study on an Intellectual Capital eco-system

Structred Abstract

Purpose – The purpose of this paper is to explore the fourth stage of IC sociology development, In which, the good quality of a person’s life and the a environment are added to economic development. In an organization, Human beings are treated as social citizens rather than simply organizational employees. However, the relevance of IC beyond the organizational dimension is still hidden as the lack of research techniques and practical application.

Design/methodology/approach – Institutional ethnography (IE), a sociological method of inquiry, is being used to explore employees’ everyday life in both internal and external organizations. With the use of IE as a methodological framework, the relevance of IC in the whole social system can be critically visualized. In the process of using IE, autoethnography is used as the entry point.

Originality/value – Through our research, the critical role IC plays in the 4th stage of IC sociology development is virtualized. The eco-system of IC is drawing organizations into the whole social system to share part of human beings’ life equally and suitably. The stage is coming in which organizations should balance employees’ role through leveraging good IC to fulfil the requirements of a healthy society.

Practical implications – The methodology used in our research creates path for the researchers to be involved in the actual life of employees and offers a real life application of IC at the individual, organizational and societal levels. Hence, the empirical evidence of IC research which originates from the actual experience is not just a “new language” of the research. Meanwhile, the skills needed for operating IE also demonstrates that potential for IC management lies in the practical world.

Keywords – Intellectual capital; Eco-system; Human beings; Institutional ethnography; Autoethnography;

Paper type –Practical Paper

1. Introduction

Since intellectual capital (IC) was first proposed by some visionary practitioners (Allee, 2000; Edvinsson, 1997), IC research has had 4 stages of development. The first stage accomplished the important mission of raising the awareness of IC in the knowledge era (Richard Petty & Guthrie, 2000). However, IC was misunderstood as there was a lack of empirical studies at that stage. The second stage of IC research mainly focused on the management, measurement and reporting IC (Bernard Marr, 2004). However, the problem of this stage was that IC research was mostly involving accounting issues and all kinds of IC frameworks, which in turn has weakened IC's relevance to management. The third stage of IC research began by the examined the role of IC in a critical way (Guthrie, Ricceri, & Dumay, 2012). Undoubtedly, IC is the key driver of value creation in the organization. However, not all aspects of IC can create values.

In recent years, more and more emphasis has been given to the importance of the products and services to customers (Dumay & Garanina, 2013). The disadvantage of the third stage IC research was that intellectual capital (IC) is only seen as a tool to develop strong organizations but, as a result, the sustainable development of the organization is often ignored (Dumay, 2013). The advent of the fourth stage of IC research which is described as IC eco-system attempts to redress this gap (Dumay, 2013; Edvinsson, 2013; Wasiluk, 2013). In this stage, the concept of an IC eco-system has been proposed. IC research is attached to the social eco-system in which good quality of human life and a healthy environment are added to the economic development. Human beings are treated as social citizens (Allee, 2000; Wasiluk, 2013) rather than simply organizational employees. However, the role of IC in the IC eco-system and the relevance of IC beyond the organizational dimension are still under-explored due to a lack of research techniques and practical applications of IC in relation to - eco-systems.

Having identified such a research gap, two research questions are proposed below,

RQ1. What is the role of IC in a social eco-system?

RQ2. What are ways to visualize an IC eco-system?

In this research, institutional ethnography (IE), a sociological method of inquiry, is used to explore employees' everyday lives in both internal and external organizations (Smith, 2006). With the use of IE as a methodological framework, the relevance of IC in the whole social system can be critically visualized (Breitkreuz & Williamson, 2012). In the process of using IE, autoethnography is used as the entry point (Taber, 2010). The

“web of life” (Allee, 2000) is mapped based on the IE frameworks;. It is found that IC is indeed playing a critical role in terms of coordinating these statuses. The eco-system of IC is weaving organizations into the whole social system to share part of human life equally and suitably. The stage is coming when organizations should change through leveraging IC to fulfill the requirements of a healthy society.

The methodology used in our research creates a path for researchers to be involved in the actual life of employees, and offers a real life application of IC at the individual, organizational and societal levels. Hence, the empirical evidence of IC research which originates from actual experiences (Smith, 2006) is merely the actual language of the daily life of employees. Thus, IC is never only stays at the academic Ivory Towers (Dumay, 2012). Meanwhile, the skills needed for operating IE also demonstrates that the potential for IC management is vested in the actual world.

2. Literature review

In the early stage of IC research, Petty and Guthrie (2000) expressed that “intellectual capital is implicated in recent economic, managerial, technological, and sociological developments in a manner previously unknown and largely unforeseen.” However, much IC research focuses on the economic (e.g. Abdolmohammadi, 2005; Kristandl & Bontis, 2007), managerial (e.g. Dumay & Roslender, 2013; Sveiby, 2010) as well as technological development (e.g. Lock Lee & Guthrie, 2010). On the other hand, IC implication on sociological developments has not received much attention in both the academic and practical worlds. Recently, Edvinsson (2013) and Dumay (2013) formally proposed the concept of an IC eco-system which hails the beginning of the stage of IC sociological development. In this stage, Edvinsson (2013) emphasized that human capital plays a vital role. Dumay (2013) illustrates that the good quality of human beings’ life and the healthy environment are added to the economic development. However, the empirical evidence offered motives us to explore what the system consists of and how it works. Firstly, we need to trace back to the path of IC sociological development even though this stream had not received much attention in the past.

It is encouraging that Allee (2000) studied IC from the perspective of how an employee can live a good life, which is different from the conventional top-down managerial perspective that is mainly concerned about how organizations can enable people to work at high efficiency. Allee (2000) stresses that enterprises and organizations need to depend

on social system in which people are seen as the social citizens. Thus, a sustainable enterprises and organizations depend on the good quality of life of its people. For example, people who work in the Silicon Valley companies leave their employer because they do not want to raise their children there as the living environment is not good reveal the importance of a social system in people's mind. However, this example shows only the "tip of the iceberg" of this complex system. But the data which Allee (2000) collected only from the annual reports cannot fully represent people's actual lives and requirements of a good quality of life.

Bontis and Fitz-Enz (2002) presented one of a few papers which pay special attention to human capital. They draw a causal map of human capital antecedents and consequents by integrating the results collected by using both quantitative and qualitative research methods. Bontis and Fitz-Enz (2002) state that this model "allows participating organizations and researchers to gauge the effectiveness of an organization's human capital capabilities." Meanwhile, Bontis and Fitz-Enz (2002) stress that this model also "allows practitioners and researchers to more efficiently allocate resources with regard to human capital management." However, this model is biased as it only covers the managerial perspectives of senior executives; the attributes which considering the common employee are ignored. What is more, the 15 latent constructs presented in the paper are all from academic papers rather than the actual life and requirements of people themselves.

It is encouraging that Roslender, Stevenson, and Kahn (2006) propose a the "employee-centered" perspective on intellectual capital based on adding the employee wellness to intellectual capital. From the perspective of how physical and psychological healthy issues affect the employee working status and organization development, the attributes of human capital which cover individual wellness are shown more comprehensively. Meanwhile, aiming at studying the new dimension of IC, Roslender et al. (2006) propose to develop metrics and deploy self-accounts to fulfil the purpose of communicating useful information to a variety of stakeholders. However, regardless of the rational methods being used, the purpose is confused, as Roslender et al. (2006) themselves argue that increasingly employers pay more attention to the employees' experience and expertise than the individual health issues. Therefore, the first step in studying should investigate the requirement and conditions of employee wellness rather

than to develop metrics to measure them. A new method is much needed which would help to understand the healthy situation of actual people.

Fritzsche (2012) investigates the implicit evaluations of IC in practical decision making by conducting interviews with experts from different multinational companies. He found that “despite a growing awareness of the necessity to bind promising employees to the company, talent management is still mainly concerned with filling concrete positions in the company according to specific job descriptions”. Unfortunately, the experts concerned did not pay attention to other attributes of human capital except the experience and expertise of employees. People there are just regarded as the “instruments”. This finding reminds us to reflect on practical management lacks the knowledge of IC sociological implication. Meanwhile, the academic world also needs to reflect that the IC sociological implication for the organization cannot be just a slogan and fashionable concept. How can we bridge the two worlds?

Wasiluk (2013)’s paper is one of the seminal papers in terms of studying IC sociological developments. In the paper, she illustrates that “IC and corporate sustainability (CS) have a mutually beneficial working relationship”. Hence, Wasiluk (2013) point out that the critical approach in studying IC should also reflect on the practice of CS in the organization. However, more empirical evidence is needed to bridge this gap. Meanwhile, Wasiluk (2013) highlight the vital importance of human capital. She specially proposes the “spiritual approach” which is focused on more than a human being’s technical expertise. However, the spiritual approach is not clearly illustrated in the paper. Besides, all the empirical evidence is from senior management. These views can only represent the “top-down” management perspective. The spiritual requirements of employees are still scanty. Furthermore, there is also the need for a methodology to guide the study of employees’ actual spiritual requirements.

To sum up, the IC ecosystem (Dumay, 2013; Edvinsson, 2013) proposed motivates us to uncover the mysterious veil of IC sociological developments. Through tracing back through the history of IC sociological development, it is revealed that some research has paid attention to this perspective, but the problem is that much of the current research up to now has not progressed beyond the stage of concept development (Allee, 2000; Roslender et al., 2006). For those where empirical data have been collected, they are dominated by top-down management methodology (Bontis & Fitz-Enz, 2002; Fritzsche, 2012; Wasiluk, 2013). Besides, those studies whose empirical data were collected in the

annual reports already have lost the relevance (Dumay & Cai, 2014). Thus we argued that there is an opportunity continuing to virtualize the IC eco-system by collecting empirical data from the actual experience of common employees. The next four sections describe one of the author's experiences in immersing herself in a real workplace and apply institutional ethnography to collect empirical data to explore IC's role in an eco-system.

3. Research site

The research site is the Information Technology Services (ITS) sector of a public organization in HK. The role of ITS is to facilitate, foster and support the organization's vision through providing the up-to-date, efficient and cost-effective information technology environment. In the research site, there are 5 sections consisting systems infrastructure services (SIS), network & communications services (NCS), user services (US), administrative applications services (AAS) as well as administrative & general services (AGS).. Under these sections, teams are formed based on the different nature of the projects.

The working time in the ITS varies across the service support areas. For example, a few staff have to come to work at 08:15 am for some special services/scheduled activities and they are on shift. This working model applies to staff who may have to leave after 10:30 pm. The organization specifies the normal working hours which will not violate the Hong Kong Employment Ordinance. It is however in operation staff may have a more flexible working time by arranging the working time according to their own work schedule. Sometimes, they could even work from home. The number of days of the staff's annual leave depends on the level of the position. Some special positions which have to cope with urgent work at mid-night are given compensation leave. Reporting line is assigned when they enter into this working environment.

4. Framework

An institutional ethnography is a research methodology that begins "in the actualities of the lives of some of those involved in the institutional process and focuses on how these actualities are embedded in social relations, both those of ruling and those of the economy" (Smith, 2005). Besides, Smith (2005) presented that IE "is a method of inquiry into the social that proposes to enlarge the scope of what was visible from that site, mapping the relations that connect one local site to another. Like a map, it aims to be

through and through indexical to the local sites of people's experience, making visible how we are connected into the extended social relations of ruling and economy and their intersections." Moreover, Smith (2005, p. 32) proposed that "institutional ethnographies produce a kind of knowledge that is made visible to activists or others directly involved the order they both participate in and confront". In this research, institutional ethnography (IE) provides a methodological framework to examine critically what the role - a company is playing in the daily life of employees and how IC in the work affect the links between the work and other social relations. Two key notions from institutional ethnography support this analysis (Breitkreuz & Williamson, 2012, p. 665): work (Smith, 1987, p. 165) and rule of relations (Smith, 2005, p. 10).

The notion of work (Smith, 1987, p. 165) "directs us to its anchorage in material conditions and means and that it is done in "real time"- all of which are consequential for how the individual can proceed." Breitkreuz and Williamson (2012) further illustrate that the "concept" of work "captures the day-to-day activities people engage in , the material conditions of their lives, and is conducted in "real time", referring to the details of the mundane practices of everyday life when they occur. " The reason that we highlight- the concept of work is that we would like to study the impact of "work" in the company on the actual experience of people's daily lives. The concept of work (Smith, 1987, p. 165) here which Smith (1987, p. 10) specially stressed that there is no boundary to the work that is related to actualities of daily life, which exactly weakens dominated role of the work in the conventional IC research. Thus, this new perspective can bring us into the wider domain of people's lives. This approach helps to reveal how the work affects the good quality of life.

Smith (2005, p. 10) referred to the rule of relations as "extraordinary yet ordinary complex of relations that are textually mediated, that connect us across space and time and organize our everyday lives-the corporations, government bureaucracies, academic and professional discourses, mass media, and the complex of relations that interconnect them. " The analytical interest here is how the IC that exists in the narratives (Dumay, 2009; Dumay & Cuganesan, 2011; Dumay & Roslender, 2013) in daily life is connected with these institutions. Thus, it is about how IC coordinates these people's statuses.

Smith (2005, p. 32) argues that "institutional ethnography begins by locating a standpoint in an institutional order that provides the guiding perspective from which that order will be explored. It begins with some issues, concerns, or problems that are real for

people and that situated in their relationship to an institutional order”. Therefore, this research utilizes autoethnography and narrative as methods to obtain entry-level IE data

5. Data collection

Firstly, the first author goes to the sector to work as a common employee to experience the same things that the common employee experience every day. The period is one week. The purpose of autoethnography is not to fully understand what the common employees really do, but, as mentioned in the framework, the purpose here is to get the IE entry point to critically explore what a common employees’ experience. Autoethnography shows one common employee’s web of life as shown in Table I. The topics and questions of interview originate from the web of life as shown in Table I. In the web of life, not only the first author serves as the common employee, but also a daughter, a girlfriend, a friend as well as a Christian. However, the web of life index is not a restraint for exploring interviews rather it just offers a point to open up the conversation and guarantees the relevance of conversation.

To guarantee the comprehensive perspective for the whole organization, 10 employees from the 5 different sections were selected through snowball sampling as shown in Table II. Among the 10 participants, there were 3 senior staff and 5 junior staff, respectively. The purpose of choosing the senior staffs was not to investigate how they managed teams but rather to investigate the actual experience of work and life as one of the employees. 7 males and 3 females are included. Two of the chosen staff need to take the “support mobile phone” once a month to provide 24 hours standby support in case of any problem in the IT services.

Table I Web of life index

Social relations	Good	Bad	IC related concept
Personal issues	<ul style="list-style-type: none"> • I like the kitchen which is integrated into the workplace • I gave up the Canteen in the same building. I went to another canteen • I have enough time to sleep 	<ul style="list-style-type: none"> • The air conditioner is too cold • I would like to take some fruit in the next meeting 	Workplace design
Family/ho	I have to change the time to	<ul style="list-style-type: none"> • My parents like my working 	Routine;

me	call my mum as morning is busier than before I can go back to change my clothes as the office is quite near to the place that I live	place now. • I don't have time to chat with boyfriend.	Goodwill; location of office
Boss	<ul style="list-style-type: none"> The manager treated me as an old friends. Feel very warm, as Manager remembers my habit 	• I feel a little nervous that my "boss" was looking for me as I was late for work due to paying bank bills; feel good to come to work on time. Can't be fully flexible.	Hierarchy, Culture
Colleague	My colleague invites me to join their badminton team One of the colleagues passes me a cup of water during the meeting, I am very happy.	<ul style="list-style-type: none"> Feel not good as my new colleague refuses to have lunch with me Feel not very happy after I wake up as there is no friend in the office. 	Culture
Friends	My colleague invites me to join their badminton team	• I don't have time to do lunch with my friends	Routine & Culture
Community	I am happy to join in the bible reading time in the morning	• I can't go to work so late every day.	Routine
Shopping, bank	I bought a laptop bag during my lunch time I go to the bank to pay the bill in the morning on my way to the office	• Feel not good to arrive back at the office too late.	Routine

Table II Investigation targets

Name	Position	Gender	Other attributes
K1	management staff	Male	
H	administration staff	Female	
R	management staff	Male	
P	support staff	Male	Alert call
E	support staff	Male

N	support staff	Female	
G	support staff	Male	Alert call

*Support phone is a kind of cell phone you need to take back home and wait for the urgent call during a 24 hours period.

6. Findings

6.1 IC plays a critical role in social eco-system.

Guthrie et al. (2012) emphasize that the third stage of IC research is still seeking critical views. Wasiluk (2013) further supports that “if the critical approach to practice is the way forward for the field of IC research, then people must also critically examine the rationale for studying the practice of corporate sustainability in organizations”. From the empirical data collected as shown in Table III, they clearly show that IC in the organization plays a critical role in offering good quality in an employee’s life.

A very interesting example is that the modern technology sometimes increases the working efficiency but sometimes, it can also be a kind of barriers that obstructs the enjoyment of life.

One employee said this,

“Actually, there is no broadband in my home (smile herself), you know, I am an IT staff, I don’t have the Internet in my home. But now you can still check the Email at home. It is fine if I receive a normal working email, but if I receive an urgent one, my quiet life in home is destroyed. (see more examples in Table III)”

Meanwhile, the critical perspective makes invisible IC visible. For instance, different employees have different requirements and views for the workplace location.

P said that *“One of the reasons to work here is that it is very convenient to go many places, like shopping”*. However, R said that *“the office is far from my home but the environment around my flat is good, of course, it is cheaper than the flat near to the office”*. K argued that *“it takes so much time on the way to office, so work at home will be better”*.

From these seemingly conflicting, the role of IC in the individual, enterprise as well as society level (Chatzkel, 2004; Edvinsson, 2013) is presented clearly. IC not only has the impact on the organization (Guthrie et al., 2012), but also has effect on the healthy development of the whole social system (Edvinsson, 2013)

6.2 IE can be used as a strategy making invisible visible

In this research, institutional ethnography (IE), a sociological method of inquiry, is first being used to explore the role IC plays in the employees’ everyday life in both internal and external organization (Smith, 2006). Interview is the main inquiry technique for the people’s daily life. In the process of using IE, autoethnography is used as the

entry point (Taber, 2010). This innovative design moderates the problem of conventional qualitative research methodology such as questionnaires (Alvesson & Deetz, 2000, pp. 55-56), which ignore the “specific case” and interview (Krippendorff, 2012) through which the interviewees may merely say what the investigators would like to hear. Meanwhile, this design bridges academic and practice by sharing the same experience.

Furthermore, this strategy can also facilitate the research more sustainably and deeply. For example, after the 2nd interview with R, the author shared that her hobby is playing badminton. Accidentally, R organizes the colleague’s badminton team. So R invited her to join in their Badminton gathering next week. Then she has the opportunity to explore more related to the actual experience of their life.

Another interesting example, E is a busy programmer. But after I shared with him about her research and, he said to me that:

“If you can speak Cantonese, I can tell you more. “

Obviously, if she can speak Cantonese, she can get more data.

K2 is quite stressed in the new team, as both of us are Christian, so we have some topics with common interest. At the end of interview, he said that:

“I am quite grateful for your listening to my stories. “

After she shared the travelling experience with H, She said that:

“I admire your travelling experience greatly, I also would like to travel, you know, I like travel very much, but I don’t have much annual leave.

Thus people know that, if there is more annual leave, H can have more opportunities to travel.

On the other hand, this strategy is a good strategy for IC management. Chatzkel (2004) argues that “continuing dialogue between practitioners and academics” is needed to help IC move through the crossroads of relevance. Dumay and Rooney (2011) and Dumay and Cuganesan (2011) proposed the function of narrative in terms of improving the relevance of IC. The autoethnography which weaves narrative helps the seniors to get the employees’ actual experience of IC in the organization. Then with the utilization of IE as a methodological framework, the relevance of IC in the whole social system can be critically visualized (Breitkreuz & Williamson, 2012).

At the end of research, the managers communicated with the author that,

“We hope can get some data from you to understand our employee’s working status and requirements, as they may like to talk with you about some issues, but they may not

like to talk with us. Even though, we don't have the hierarchy concept in our seniors' mind. We hope to listen to them and help them. "

Thus, it can be seen that the strategy of this research can also be used as a kind of IC management technique rather than merely a research strategy.

Table III Web of life index in ITS

Social relations	Good	Bad	IC related concept
Personal issues	<ul style="list-style-type: none"> I can eat breakfast in the canteen in the same building There are very good equipment you can use to play sports 	<ul style="list-style-type: none"> The pantry is dirty, as everyone can enter and use it. As too many people use pantry in the morning, I have to come to the office a little earlier. The air-conditioner is too cold The coffee machine is for customers not for us (staff). 	Workplace design
Family/home	<ul style="list-style-type: none"> The office is near to my home The office is far from my home but the environment is nice Both my sister and I study IT; sometimes we discuss work in home; we can help each other The technology is so easy that you can check email at home 	<ul style="list-style-type: none"> The office is far from my home There is no Broadband in my home as I don't want to work at home The technology is so easy that you can check email at home but it will affect my relaxed lifestyle if I receive a urgent work email I hope I can work at home when my family is ill. It takes so much time to travel to office, so work at home is better 	Location of office, skills, technology
Boss	<ul style="list-style-type: none"> The big boss comes to me directly to help resolve the problems, it is a little strange to me but I feel good. 	<ul style="list-style-type: none"> The boss does not know how long the work will take, so they just issue the order and then my life become stressed Their supervisor don't allow chatting in the office 	Hierarchy, Culture

Colleague	<ul style="list-style-type: none"> • I eat lunch with my colleague and chat with them • I can talk with my colleagues 	<ul style="list-style-type: none"> • I have no friends in the office • The system is not designed by me, so sometimes it brings trouble for me. • Sometimes, my colleagues talk with me, so the efficiency is low. 	Culture
Friends	<ul style="list-style-type: none"> • I have time to eat lunch with my friend 	<ul style="list-style-type: none"> • I have no friends in the office 	Routine & Culture

7. Conclusions

In this study, an IC eco-system is virtualized to some extent from the perspective of sociology. Through using IE as the research framework, the empirical data of IC eco-system are collected. The web of life, mapped by combining the “work” and “rules of relations”, presents the critical function of IC in terms of living a good life in the social eco-system stage. The good quality of life is also described to some extent. Among several roles in daily life, it is interesting to see that the role of an “employee” is merely one of many other roles a human being often assumes. Such roles may be parents, children, spouse/girl/boyfriends, roommates etc. It is seen that a good employee in no way guarantees “goodness” of other roles. Thus, good quality of life cannot be guaranteed by any single facet. Therefore, IC management in the organization cannot merely focus on how to cultivate the good employees, or the good quality of employee’s life cannot be guaranteed.

Meanwhile, in the implementation of this strategy, on the one hand, the practitioners can use the autoethnography to understand themselves, and the web of life constructed also can be put into the management practice. Researchers, on the other hand, can get a good opportunity to enter into the field to see the actual experience of investigating targets. Thus, this is also a good strategy to bridge the research and practice.

However, the research methodology first introduced into IC research still needs to be further refined. Furthermore, real time and comprehensive visualization of the eco-system are also needed to appraise IC holistically and continually by consolidating and analyzing the collected empirical evidence.

Structured Abstract

Purpose – This paper presents the first results of an ongoing research project aimed to define a general model to identify and assess performance and impacts of the Technological Districts (TDs). In particular, the idea is to provide a methodological framework, a system of indicators and a set of related tools able to drive the evaluation, the management and the reporting of the performance and the impacts of the TDs. The logic of the work is to define a model that may be objective, rigorous and able to become standard according to scientific, operative and methodological perspectives.

Design/methodology/approach – At strategic level, the adoption of an integrated and multidimensional approach has been used for the elaboration of the general model. In particular, the model of the Strategy Map (Kaplan and Norton, 2000) has been coherently declined for a TD; the dimensions of performance and a set of scorecards have been defined and then integrated systemically in the unique and coordinated framework of the Strategy Map. Specifically, great attention has been paid to avoid confusion on contents and methods as well as avoiding overlapping of economic, financial, managerial performance and impact dimensions that often have characterized the academic and policy literature.

Originality/value - This paper contributes at theoretical and practical level to improve the managerial and policy methods and tools to identify, assess, manage and report the performance and the impact of the TDs. Till now, in fact, it is possible to trace a lot of “cold fusions” about frameworks, aspects, dimensions, metrics, often very different among them and difficult to integrate and to become a general modeling. The originality and the value of the paper resides then in its attempt to improve and to let more shared

and transparent the informative quality on which the TDs are called to operate and report to the stakeholders, in particular regulators and public organizations.

Practical implications – The definition of this general model has also the objective to support the elaboration of a structured set of managerial and policy implications able to drive respectively the management in the strategy formulation and implementation, as well as in the actions for the performance improvement, and the decision-makers in the elaboration of effective policies of development and correct evaluation of the impact of the TDs on the different places.

Keywords – Technological Districts; Performance; Impact; Models.

Paper type – Academic Research Paper

1. Introduction

During the last decade, the Technological Districts (TDs) have gained more and more importance as elements of economic development and innovation strategies of the European Union (EU) and relatives Member States (Lerro and Jacobone, 2013).

However, after years of TDs' promotion and support, the performance, the effects and the impacts of the TDs still require a specific attention. In fact, both policymakers and programme owners on one side and TDs' meta-management structures and TDs' stakeholders are increasingly searching shared models and tools on identifying and assessing how the desired effects and impacts have to be achieved and what kind of policy and managerial actions have to be elaborated and implemented to lead to more effective and efficient outcomes.

Unfortunately, the novelty of the form of TDs and the high attention and pressure they have received has determined a sort of "measurement mania" of their activities but not linked to a strategic approach about the assessment and the evaluation of their performance and impact. Measurement mania is the obsessive creation of measures for everything, usually resulting in such a confusing picture. It is often driven by the mantra "what gets measured gets managed". As a result, everything gets measured and determines the tyranny of measures and targets as obsessive compulsive disorder for decision-makers and consequently for TDs' meta-management structures and TDs' stakeholders. Often, these dynamics creates conflicts and confusion and may create dysfunctional behaviours to reach inappropriate objectives and targets: it is common the case of asking measures and other information that have no relevance to those who need to provide or use them.

Having a strategic approach to the performance measurement and management may help to avoid this kind of problem and drive in a better way the TDs' stakeholders to maximize the effects and the impacts of their actions and resources.

According to Kaplan and Norton (2000), this paper is about strategy mapping elaboration and application to the TDs aimed to represent the logic and operative meta-model for their performance and impact evaluation.

Strategy mapping provides a clear line of sight into how TDs stakeholders' activities and tasks are linked to the overall objectives of the TD, enabling them to work in a coordinated, collaborative fashion toward the TD's desired goals. The map provides a visual and a logical representation of the TD's critical objective and the crucial relationships among them that drive organizational performance.

2. Why strategy maps? General structure and mechanisms

The strategy maps show how organizations and systems of organizations at private, no profit, and political level plan to convert their various assets into desired outcomes and then assess performance and impact deriving from the execution of their strategic planning. (Kaplan and Norton, 2000). In general terms, the template of a strategy map provides a common framework and language that enables an organization to describe and illustrate clearly its objectives, initiatives, and targets; the system of dimensions, indicators and measures used to assess its performance; and the linkages that are the foundations for strategic direction (Kaplan and Norton, 2000).

The best way to build strategy maps is from the top down, starting with the destination and then charting the routes that will lead there. Corporate executives should first review their mission statement and their core-values. With that information, managers can develop a strategic vision, or what the company wants to become. This vision should create a clear picture of the company's overall goal. A strategy must then define the logic of how to arrive at that destination (Figure 1).

Building a strategy map typically starts with a financial strategy for increasing shareholder value (no profit, governments units and systems of organizations often place their customers, stakeholders or constituents – not the financials – at the top of their strategy maps). Usually, companies have two basic levers for their financial strategy: revenue growth and productivity. The former generally is about how to maximize revenue

from new markets, new products, new customers, and increasing value to existing customers. The productivity strategy also usually has two parts: improve the company's cost structure by reducing direct and indirect expenses, and use assets more efficiently by reducing the working and fixed capital needed to support a given level of business.

Accordingly, attention is paid then to the customer perspective. It is widely recognized that the core of any business strategy is the customer value proposition, which describes the unique mix of product and service attributes, customers relationships and corporate image that a company offers. The value proposition is crucial because it helps an organization connect its internal processes to improved outcomes with its customers.

Once an organization has a clear picture of its customer and financial perspectives, it can then determine the means by which it will achieve the differentiated value proposition for customers and the productivity improvements to reach its financial objectives. The internal process perspective captures these critical organizational activities, which may fall into sub-level processes to reach operational excellence, by improving supply chains management, costs, quality and cycle time of internal processes, asset utilization and capacity management.

Finally, the strategy map has the learning and growth perspective, which defines the core competencies and skills, the technologies, the know-how at the basis of an organization's strategy. These objectives enable a company to align its intellectual capital with its strategy.

Summarizing, strategy maps help organizations view their strategies in a cohesive, integrated and systemic way. A strategy implies the movement of an organization from its present position to a desirable but uncertain future position. Because the organization has never been to this future place, the pathway to it consists of a series of linked hypotheses. A strategy map specifies these cause-and-effect relationships, which makes them explicit and testable (Kaplan and Norton, 2000).

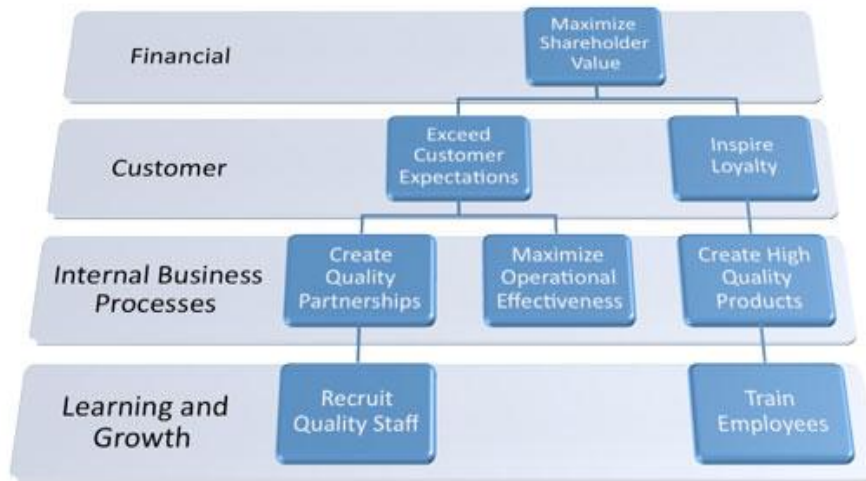

Figure 1. A general scheme of the Strategy Map at company level

3. Defining a Strategy Map and a Performance Measurement and Management System for assessing Technological Districts

Although the emphasis on knowledge and science-based resources has strongly contributed to create a wide acknowledgement of the strategic role of the TDs for the development paths at national and local level, there is still a need for a better understanding about the impact activated by the TDs as well as the assessment of the TDs performance. As Bonaccorsi and Nesci (2006) outline, engineering and orchestrating the creation and the development of TDs is not an easy task to undertake. First of all, there is the open issue of characterizing properly a firm as technology-driven (Grinstein and Goldman, 2006). Moreover, besides a strong attention to the economic and productive aspects, it also requires a new understanding and perspective about the identification, the role and the networks of the stakeholders, the governance structure and the managerial approaches aimed to identify and assess TDs performance as well as their impact on territorial development paths. All this in order to better define, implement and re-frame policies, programs and projects for the TDs aimed to effectively support the development dynamics. Despite this importance, models, frameworks, approaches, tools and indicators aimed to properly identify and assess strategic and operative dimensions of the TDs are still missing. The following subsections aim to fill these gaps.

3.1 TD's performance measurement and management models: the state-of-the-art

The issue about how an organization identifies a set of measures that reflects the performance it is trying to achieve is a common theme in the economic and managerial literature. Numerous frameworks have been proposed according to which organizations should follow in order to design and implement performance measurement systems (Kaplan and Norton, 1996; Neely, 2002; Neely et al., 2002 and many others). The objective of such frameworks is to help organizations to define a set of measures that reflects their objectives and assess their performance appropriately (see Neely, 2002 for a review). However, it is possible to state that the same attention and the same effectiveness in elaborating and applying strategic performance management and measurement systems has not been paid about organizational systems more complex to model and assess, such as clusters, innovative networks, technological districts and *similia*. This is probably linked to the nature and the specific features characterizing these complex organizations – i.e. the role of the stakeholders involved (big companies, Small and Medium Enterprises (SMEs), Universities and research centers, public institutions, governments and policy agents, banks and investors, local communities), the role of the governance model, the political constraints, the issues about the Intellectual Property Rights (IPRs), the ways to access to funding - that let more difficult the applicability of managerial models, techniques and tools create and traditionally and successfully applied on profit companies.

In the last years, in particular in the EU and in the Italian context, there have been different attempts to elaborate and propose models and scorecards to identify assess and report TDs' performance (EU Innovation Scoreboard, the EU Regional Innovation Scoreboard, the European Report on Science & Technology Indicators, ESCA). For example, the German Institute for Innovation and Technology (2011) as part of the VDI/VDE Innovation +Technik GmbH, in the context of the project "*Expertise on developing a common evaluation/benchmarking system for all Hamburg clusters*" has elaborated a Cluster and Network Evaluation Model, Indicators groups and traits of methodologies for the evaluation of clusters and networks. It addresses specifically three different "subjects of evaluation" such as cluster policy, cluster management, and cluster actors, and is based on the consolidated assumption that there is a link between input,

produced activities directly linked to the measure (output) and intended results that occur within the target group (outcome).

The Italian Agency for the Diffusion of the Technologies for Innovation (2012) in its report “Indicatori di risultato intermedi per misurare la performance di Distretti Tecnologici e Poli di Innovazione – valutazione di impatto: metodi ed esperienze” provides an analysis of the methodological stages to develop a system of indicators to assess TDs’ performance as well as a synthetic picture of an economic and managerial model grounding the set of the indicators. Moreover, various regional institutions in Italy – within their industrial policy planning - have tried to elaborate, develop and apply grids and scorecards aimed to assess TDs’ performance; particular attention has been paid on the TDs based at administrative level in their territorial borders: for example, in the last years, the Regional Agency for Technologies and Innovation of the Puglia Region (ARTI Puglia) has been strongly involved in these issues.

Although these appreciable attempts, the issues still presents different weaknesses and challenges to be addressed. Many institutions have built grids, or even scorecards, not strategy maps able to effectively model the TDs nature, properties, and specific objectives to be reached and assessed through the performance system. Moreover, it is possible to trace a sort of confusion on contents and methods as well a recurring overlapping of economic, financial, managerial performance and impact indicators characterizing a TD. Another limitation occurs when institutions have built key performance indicators (KPI) scorecards. For example, they reveal several missing components: no stakeholder requirements-oriented measures, common use of single process metrics often focused on initiatives and not on outcomes and impacts, no defined role for organizational competences and intellectual assets, a strange omission of the identification and the measurement of relevant meta-organizational processes. In actuality, KPI scorecards seem more a confuse collection of measures, a checklist, or perhaps elements in a “scheme” useful for political affairs rather than tools to collect relevant data to support decision-making activities. In other words, they do not describe strategic plan and often do not reflect the working mechanisms of the TDs and therefore in different cases KPI can be a dangerous illusion to assess TDs’ performance. Moreover, the different policy and normative constraints according to which TDs normally work – for example ways to access to funding, constituency, weight of the public actors in the governance models,

problems related to the IPRs – are not considered properly according to the effects they generate in practice.

The main challenge, then, is to elaborate and use a general model able to incorporate strategy and performance measurement and management systems but declined coherently in accordance to the particular characteristics of the TDs. In particular, the idea grounding this paper is to provide a general model, a methodological framework, a scheme to define a system of indicators and a set of tools able to drive the evaluation, the management and the reporting of the performance and the impacts of the TDs. The logic of the work is to define a model that may be objective, rigorous and able to become standard according to scientific, operative and methodological perspectives.

3.2 Aims and properties grounding the elaboration of a new model for the strategic performance measurement and management of the TD: the methodological background

At methodological level, the elaboration of a new model for the strategic performance measurement and management of the TD has been driven by the following considerations:

- *Applicability and validity for the evaluation of any TD:* the modeling has to be applicable to any TD and had to integrate potential heterogeneity regarding criteria such as industry sector, size, age, governance structure, places, etc. The aim is to find a balance between the need of any single TD to have specific and context-related value/performance dimensions and indicators and common overall value/performance and indicators applicable to any TD;
- *Clarity of the contents:* the model has to pay great attention to avoid confusion on contents and methods as well as avoiding overlapping of economic, financial, managerial performance and impact dimensions that often have characterized the academic and policy literature about the performance and impact measurement systems of the TDs;
- *Model design:* the model has to be able to collect, elaborate and report both quantitative and qualitative data and information; in case relevant information cannot be integrated in the general model, to avoid confusion and overlapping of

different issues, these information had to be provided in separate but related frameworks and schemes;

- *Decision-making orientation:* the model has to be a decision-making tool supporting managerial, policy and political choices. It should be also a self-evaluating and learning tool able to drive performance improvement paths;
- *Integration, modularity and scalability:* the model has to lever the strengths and the relevant contents of the previous existing models, scorecards and grids already provided by literature and practice, but it has to integrate them in a more effective, rigorous and TD-oriented meta-model. It has to be thought according to modules letting a scalability of the level, intensity and extension of the analysis;
- *Usability and efforts:* the model has to avoid not useful and redundant questioning and has to consider always the decision-making orientation. The effort both for the actors involved in collecting data and receivers of the data have to be reduced to a minimum. The search of a right balance between the interest in revealing the “full picture” of the phenomena and the related efforts on times, costs and resources has to be strongly considered;
- *Commitment and involvement of the stakeholders:* the model has to forecast open and transparent processes to achieve desired validity of results and acceptance of the stakeholders involved. Thus, stakeholders groups should be included in the process of elaboration and sharing of the model;

3.3 The Strategy Map applied to a TD: the theoretical background

According to the nature and the characteristics of the TDs as well as their specific needs of performance assessment, the model of the Strategy Map (Kaplan and Norton, 2000) has been selected and adopted as the conceptual model driving the strategic performance measurement and management system and related indicators for the evaluation of the TDs.

The fundamental assumptions grounding the adoption of the Strategy Map for a TD can be summarized as in the following (Figure 2). In order to maximize its impact, TD has to achieve and maintain high performance. Improving TD’s internal performance equal an increase in the value generated for the key stakeholders of the TD. The generated

value is the result of TD's ability to manage its key internal and external processes and functions. The effectiveness and the efficiency of performing internal and external processes are based on TD's competencies and particularly on the core competencies of the TD's key-stakeholders. The quality, effectiveness and efficiency of the TD's competencies are based on the knowledge assets of the stakeholders of the TD (the group of the knowledge assets are commonly synthesized in the notion of Intellectual Capital).

It is important to underline that the identification of the stakeholders' requirements and the value generated for them is a critical step in institutionalizing strategy and performance orientation at TD level, since the way to intend performance and value creation and the level of priority to which any single stakeholder is interested to develop and gain benefits can be very different (Lerro and Jacobone, 2013). For this reason, it is necessary to integrate and coordinate the single actions and decisions of the stakeholders through different kinds of policy actions aimed to balance potential disequilibria. Policy-makers' decisions and actions play a fundamental role. They are increasingly called to a pro-active role in order to really contribute to achieve TD's targets and performance improvement through the definition, the support, the implementation and the control of political choices in function of the stakeholders' aims as well as of the whole national and regional industrial and research policies.

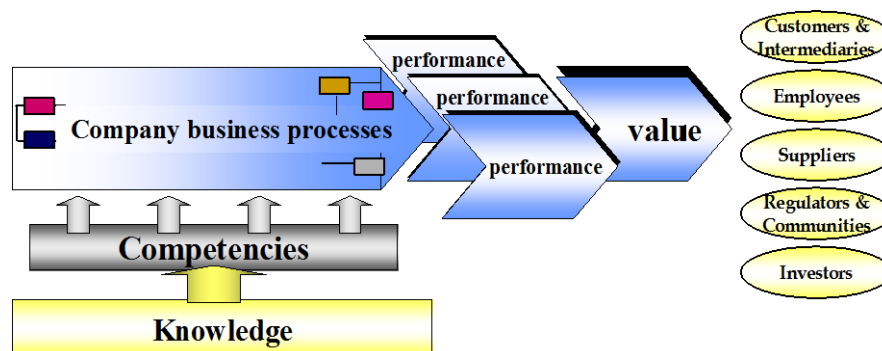

Figure 2. Basic theoretical scheme grounding the adoption of a Strategy Map for a TD

According to the previous basic theoretical scheme, a Strategy Map for the TDs has been elaborated. The model is finalized to analyse how TD's components, independently, complementarily and interactively, may or may not enhance the value creation capacity of

the TD. A better understanding of the cause-effect relationships between the TD's components has to drive the elaboration of the performance measurement and management system of the TD.

As depicted in Figure 3, the Strategy Map applied to a TD is composed by four levels of analysis. Following a top down logic, they are I) Stakeholder Value and Performance, II) Organization Processes, III) Organization Competences, and IV) Organization Intellectual Capital (Figure 3).

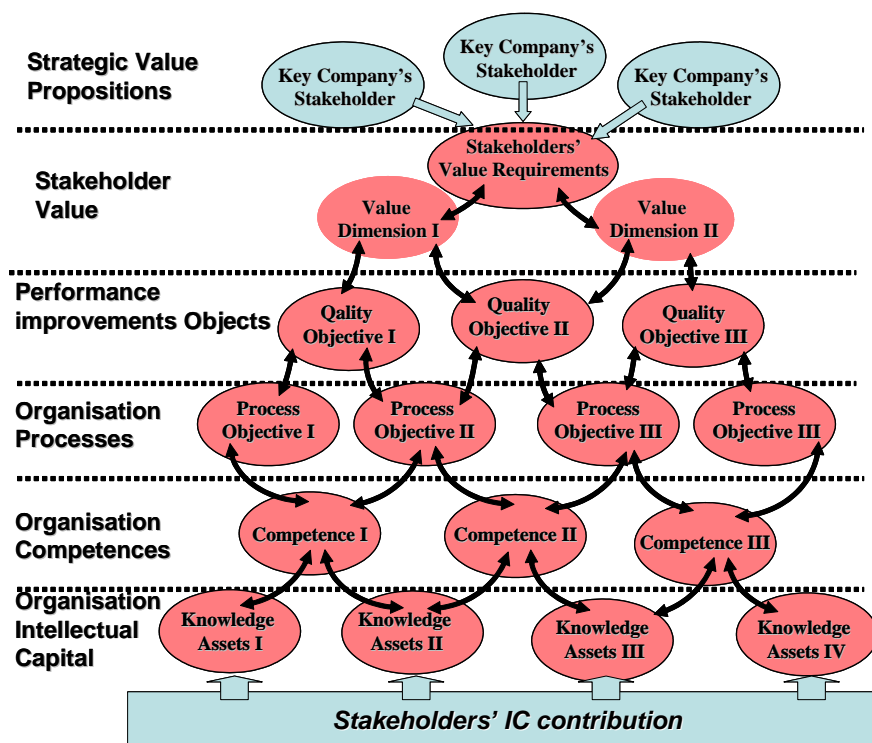

Figure 3. A Strategy Map applied to a TD

The choice to adopt the Strategy Map as conceptual framework for defining specific TDs performance indicators is motivated by different managerial and operative reasons. In general terms, it seems to emerge as the “best” model addressing the needs presented in the previous sections being able to fill the different gaps identified both in literature and practice.

First of all, the Strategy Map permits to link effectively strategic vision and performance measurement. Moreover, it is a flexible model that may be easily used in different context of application thanks to the possibility and the easiness to decline its general perspectives.

Moreover, it considers not only the financial figures of the performance, but it considers a wider approach, adopting a stakeholder centric view of performance measurement and management according to the notion of value. This could be particular relevant for a TD in which, as highlighted before, stakeholders act as constituent and fundamental element. Finally, the structure of the Strategy Map fits optimally to the real operative activities of the TDs as well as it permits to effectively and directly define TDs' performance indicators, enabling all measures to be mapped on to it so that gaps in measurement can be identified. All these reasons determined the opportunity and the convenience to adopt the Strategy Map as model grounding the performance measurement and management system of a TD.

However, in order to make it operative, i.e. to be used as a real performance measurement and management tool, its different level of analysis and related performance dimensions need to be populated with a set of indicators in order to build an informative base to design, communicate, implement and review policies and actions aimed to check, develop and manage TDs activities. This determines that the Strategy Map, in order to be practically applied as assessment tool for the TDs, has to be integrated with a dedicated measurement system, i.e. a systemic body of metrics to perform a qualitative and a quantitative evaluation. Accordingly, a related Balanced Scorecard can be effectively used (Figure 4.). However, despite the different attempts to provide a common informative base for the assessment of the TDs, there is still a lack of consensus about the measures to be adopted for assessing the TDs. This is a particular important issue, since the definition of a list of standard measures can benefit both the assessment of the TDs at national level, and the benchmarking evaluation at international level.

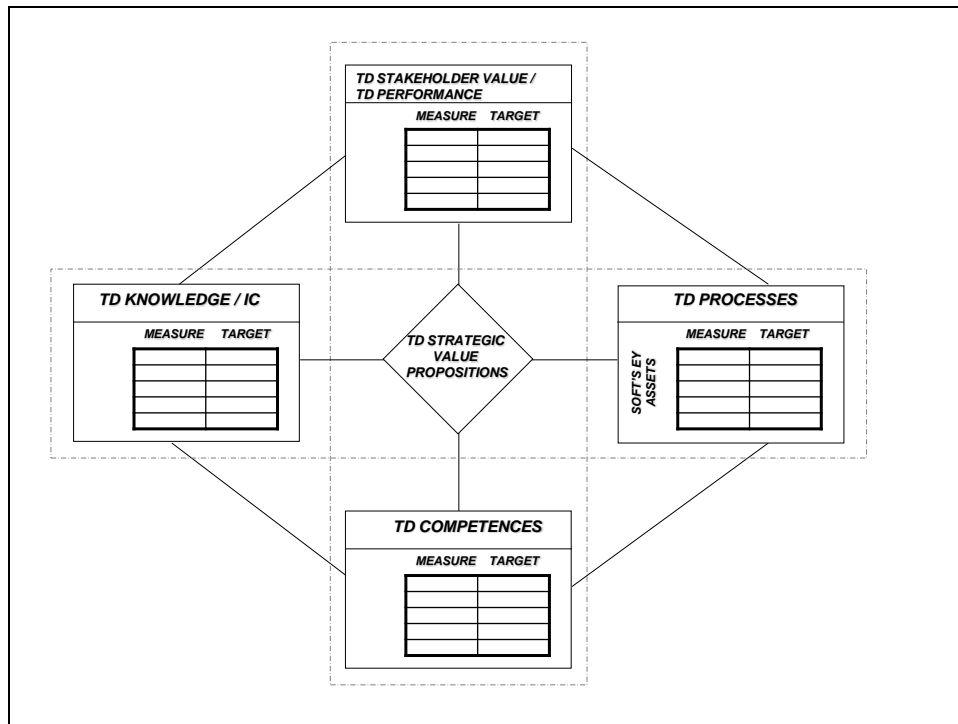

Figure 4. A Balanced Scorecard applied to a TD

3.4 The Strategy Map applied to a TD: a first case example

A main aim of this paper is to contribute to an improved and more transparent understanding about TDs' strategic performance measurement and management. According to the theoretical background as well as to the practical needs, a first case example of a Strategy Map for the TDs is presented. The main issues of each level of analysis of the Strategy Map are introduced as follows:

Level: Impact

- Maximizing the positive impact at industrial, socio-economic and employment level, both on the territorial system and on the sectors referred to the TD;
- Accelerating the structural processes for the growth of the national and regional economic systems;

- Supporting the strategic programs about research, technological development and innovation aligned and coherent with the strategic agendas at European Union (i.e. Horizon 2020) and global level;

Level: Stakeholder value

- Big companies: exploiting technological assets and IPRs within projects of development and collaboration with SMEs and research centers; optimizing patents' portfolio, capitalizing no-core patents; reinforcing their supply chains with excellent SMEs;
- SMEs: addressing markets for their technological assets; achieving critical level of funds to finance R&D activities; overcoming their limited capacity of market and technological intelligence; improving their attitude to buy technologies and patents;
- Research Centers/Universities: delivering quickly their inventions and innovation to the market; improving their capacity of technological transfer; overcoming the lack of processes and systems of asset management; reinforcing applied research; accessing to financial resources;
- Banks/Investors: allocating funds on companies and technologies more promising; sustaining development and performance of their customers; innovating their portfolio of financial services;
- Public institutions: protecting and extending employment; allocating public resources to more promising sectors; developing territorial system;
- Meta-management structure of the TD: supporting economic and not economic performance of the members of the TD; accessing to financial resources to manage operatively the TD;

Level: Performance

- Quality of the industrial research;
- Quality of the technological transfer;
- Accelerating the innovative dynamics in the TD's sector and the transferring of the outputs to the market;
- Promoting and sustaining the creation of new companies technology-driven (start-up; spin-off);

- Optimization of the public financial resources and capacity of attraction of financial capitals and private investors;

Level: Processes

- Elaborating and providing innovative, value-added and high quality services, both for TD's members or not; Effectiveness and timing of the new services development and management;
- Enhancing the relationships among research, companies, banks and investors, and territorial system; Extension, effectiveness and timing of the networking processes management;
- Stimulating participation, coordination and the kick-off of initiatives and projects at national and international level in the specific sectors of the TD; Effectiveness and efficiency of the projects management (from call to close);
- Promoting connections of all the players and actors operating in the supply chains of the specific sector of the TD; Extension and effectiveness of the supply chains management;
- Effectiveness of the TD's governance model;
- Extension, effectiveness and timing of the internationalization processes management;
- Effectiveness and benefits provided by TD's operative support to the national and regional politics and policies about industrial and research issues;
- Extension, effectiveness and timing of the research activities developed by the TD;

Level: Competences

- Capacity of managing the specific network of the TD - at operative, technical, scientific and policy level;
- Capacity of collaborating with other relevant national and international TDs;
- Capacity of managing applied and industrial research at project, prototyping and operative level;
- High competences on project management and technological marketing;

- High competences at technical and organizational level of the meta-management structure of the TD;
- High competences about industry intelligence, market research, technology intelligence, competitive intelligence, valuation, valorization strategy, monetization and financing, performance monitoring about intangible and intellectual property assets;

Level: Knowledge/Intellectual Capital

- High-skilled human resources among the TD's stakeholders/capacity to attract talents;
- Quality of the training activities provided by the TD;
- Endowment and use of knowledge management tools (databases; social networks; ecc.);
- Specific know-how of the TD;
- Endowment and use of R&D tangible and intangible infrastructures;
- Access to relevant industry-oriented and research-oriented dataset;
- Creation, development and exploitation of a TD's "brand";
- Reputation and business ethic; TD's culture;

4. Conclusions

This paper has presented the first results of an ongoing research project aimed to define a general model to identify and assess performance and impacts of the Technological Districts (TDs). In particular, the model of the Strategy Map (Kaplan and Norton, 2000) has been coherently declined for a TD. Specifically, great attention has been paid to avoid confusion on contents and methods as well as avoiding overlapping of economic, financial, managerial performance and impact dimensions that often have characterized the academic and policy literature.

This paper contributes at theoretical and practical level to improve the managerial and policy methods and tools to identify, assess, manage and report the performance and the impact of the TDs. Till now, in fact, it has been possible to trace a lot of "cold fusions" about frameworks, aspects, dimensions, metrics, often very different among them and

difficult to integrate and to become a general modeling. The originality and the value of the paper resides then in its attempt to improve and to let more shared and transparent the informative quality on which the TDs are called to operate and report to the stakeholders, in particular regulators and public organizations. Of course, it is possible that the paper pays a sort of disadvantage of the first moving about multifaceted issues on which a complex and strong debate at academic, political and policy level is still working. So, we recognize some limitations of this study in order to drive further research on the issues, at academic and practical level. Among them, particularly important in the future researches will be the definition and the selection of the detailed indicators to operationalize the different level of analysis identified in the Strategy Map declined for a TD.

Structured Abstract

Purpose - This paper investigates Smart Working (SW), a set of modern and non-conventional organisational models that are characterised by high flexibility in the choice of the working spaces, time and tools, and that provides all employees of a organisation with the best working conditions to accomplish their tasks. Specifically, the paper aims to: (i) identify whether firms adopt different SW models: (ii) explore complementarities between the elements that can lead to choose a SW model, and (iii) figure out whether contingent variables matters in the implementation of a particular SW model.

Design/methodology/approach - This study is based on a continuative research initiative promoted since 2012 by the School of Management of Politecnico di Milano, i.e. the Smart Working Observatory. In order to achieve the paper goal, during 2013 we have run a survey delivered to 100 HR directors of medium and large Italian organizations to collect empirical evidence on SW phenomenon, and accomplished multiple, embedded case studies to better explain the findings achieved in the quantitative analysis.

Originality/value - The paper aims to look inside the black box of SW, by unpacking the elements that can generate complementarities between the adoption of digital tools, workplace and work practice innovation.

Practical implications - Managers who aim to fully benefit of SW practices should not only invest in the enabling digital technologies, but also make the complementary trans-

formations in organisational policies and workspace settings, according the contingent conditions under which they operate.

Keywords - Smart Working, ICT, Physical Workplace, Work behaviour, Performance.

Paper type - Academic Research Paper

1 Introduction

The methods and the tools through which work practices are accomplished have changed dramatically in the last decade (Hamel, 2012). Successful organizations are increasingly characterized by the ability to abandon now inappropriate working configurations (Birkinshaw et al., 2008) to support new organizational principles, such as emerging collaboration (Vlaar et al., 2008), autonomy in the choices of work settings (Leonardi and Balley, 2008), talent enhancement, responsibility and widespread innovation (Hamel, 2007).

According to Birkinshaw (2010), if, on the one hand, organizations tend to manifest inertial behaviours in dealing with this paradigm shift, on the other hand, they are consistently looking for elements to balance new business targets with the evolving needs of their employees (Leonardi, 2011). In fact, the generation of value within the business domain is no longer linked only to insightful business models (Gunther McGrath, 2013), but also to how employees actually create, perceive, realize, defend and evolve these business models in day-by-day activities especially in highly turbulent competitive environments (Brown and Eisenhardt, 1998).

Actually, most of the innovation potential of employees remain unexpressed due to inappropriate organisational models (Oksanen and Stähle, 2013), and an increasing number of firms are rethinking these organizational models, referring to the emerging ones with the term ‘Smart Working’ (SW) (Plantronics, 2014). Specifically, a SW corresponds to non-conventional organizational models that are characterized by higher flexibility and autonomy in the choice of working spaces, time and tools, and that provides all employees of an organization with the best working conditions to accomplish their tasks.

Thanks to the development and diffusion of digital technologies, along with the increasingly pervasive dissemination of powerful and easy-to-use mobile devices, firms can be supported in the progressive implementation of a SW model (Ahuja et al., 2007). However, digital levers could be necessary but not sufficient in realising the innovation potential associated to SW. Based on these considerations, this paper aims to look inside

the black box of SW, by unpacking the elements that can generate complementarities between the adoption of digital tools and innovations of organizational models. Specifically, the purpose of this paper is threefold: (i) identifying the different SW configurations adopted by firms; (ii) exploring complementarities between the elements affecting these configurations; (iii) figuring out whether contingent variables matters in the implementation of a SW model

The paper is structured as follow. In paragraph 2, we discuss the theoretical background. In paragraph 3, we show the research methodology and the data measures used to collect and analyse empirical facts on SW phenomenon. In paragraph 4 we discuss the key findings of the quantitative and qualitative analyses. Finally, we conclude the paper with empirical and theoretical implications of the findings and directions for future research that it could be interesting to pursue.

2 Theoretical Background

The development and diffusion of digital technologies (especially those supporting communication, collaboration and social network creation), along with the increasingly pervasive dissemination of powerful and easy-to-use mobile devices, can support organizations in developing a SW system (Ahuja et al., 2007). While recent literature has analysed how IT has made work more portable and ubiquitous (e.g., Yoo et al., 2010), there is not yet a comprehensive understanding and empirical evidence of the existence, if any, of complementarities between elements on which firms should focus in case want to adopt a SW organizational model.

According to a preliminary analysis of the organizational, IT and managerial literature (Mann, 2012), the three elements that can constitute a SW model are: (i) the usage of ICT-based solutions (*ICT element*); (ii) the innovations in the human resource practices and in the organizational model (*HR element*); and (iii) the reconfiguration of the workplace and of the office layout (*layout element*) (

Figure 1 – *Elements of a SW organizational model*
)

Figure 1 – *Elements of a SW organizational model*

These three elements can allow firms to adopt a SW model for different reasons. First, IT solutions, especially the collaborative ones, allow groups to share more easily files, information and ideas (Chudoba et al., 2005). In such a way, all employees can interact in real time in a flexible and effective way by contributing to a SW environment. Second, changes in the HR practices can be introduced when a new organizational model is chosen, as SW is. Specifically, change management actions for managing the organizational models chosen can be applied by the organizations (Cameron and Green, 2012), such as training programmes for the middle and top management, training for the end users, new communication plans, new management by objectives processes systems, projects of cultural change, or processes' reorganization. Third, recent works emphasize the importance of promotion strategies in spatial reconfiguration of the office layout (e.g. Smith et al., 2013). In this way, employees can increase their productivity and can manage better their work-life balance. Therefore, particular office reconfigurations may lead to innovative ways of collaborating with others and thus simplifying the development of a SW model.

3 Methodology

This study is based on a continuative research initiative promoted since 2012 by the School of Management of Politecnico di Milano, i.e. the Smart Working Observatory, which is focused not only on analysing the SW phenomenon as well as its impacts on organizations' performance, but also on supporting organizations in the progressive implementation of SW models. Refer to Gastaldi and Corso (2014) for an overall description of the Observatory, its results and how it accomplishes its activities.

In order to achieve the goals of this paper, we have triangulated quantitative and qualitative analyses (Jick, 1979). The former is based on a survey run among Italian companies and AIDA Bureau van Dijk database, which contains financial data of Italian firms. The latter has been developed through multiple, embedded case studies oriented in better explaining the findings achieved in the quantitative analysis. In the following paragraph we will describe the methodological choices that have shaped the research process.

3.1 Quantitative Analysis

The quantitative analysis occurred in two steps. First, descriptive statistics and a cluster analysis were computed to examine the diffusion patterns of the three elements taken into exam, and to delineate the main configurations used by firms in terms of SW. In the

second step, ANOVA analysis and Kruskal-Wallis non-parametric tests were used to understand the contingent conditions under which SW configurations are chosen by firms.

The survey has been delivered through an electronic platform to a convenient sample of 100 HR directors of medium and large Italian firms. On data gathered, a cluster analysis was conducted in order to investigate the complementarities between the three elements that can characterize a SW strategy.

We complemented the data gathered through the questionnaires with data contained in the AIDA Bureau van Dijk database, which includes financial data of Italian firms, for evaluating through ANOVA analyses the contingent conditions and the organizational performance that characterize firms that choose a particular SW practice, provides the definition, variable construction, and sources for all of the three elements used in this research. As can be observed, they were operationalized using the survey responses.

Table 1 – Measure of the three elements

Elements	Variable Construction/ Definition	Measure	Reference	Data source
Layout element	Adoption of initiatives of redesigning of the physical workspace for creating environments more flexible and oriented to the workers collaboration	From 0 (none initiatives) to 2 (multiple initiatives)	Elsbach and Bechky (2007)	Survey
	Extent to which employees telework	From 0 (none employee) to 2 (all employees)	Martínez-Sánchez et al. (2007)	Survey
ICT element	Extent to which employees use IT personal devices (pc, tablet, etc.)	From 0 (none employee) to 2 (all employees)	Martínez-Sánchez et al. (2007)	Survey
	Extent to which employees use external IT services (skype, twitter, linkedin,...) at any-time from anyplace	From 0 (none employee) to 2 (all employees)	Martínez-Sánchez et al. (2007)	Survey
HR element	Extent to which employees can manage in a flexible way their working hours	From 0 (none employee) to 2 (all employees)	Coenen and Kok (2014)	Survey
	Percentage of employees for which the company uses a MBO system for evaluating their KPI	From 0 (none employee) to 6 (all employees)	Coenen and Kok (2014)	Survey
	Change management actions for managing the organizational models chosen: 1) Training for the middle and top management, 2) Training for the end users, 3) Communication plans, 4) New MBO systems, 5) Projects of cultural change, 6) Processes' reorganization	From 0 (adoption of any change management action) to 6 (adoption of all the change management actions)	Coenen and Kok (2014)	Survey

We assisted the data collection effort with the AIDA Bureau van Dijk database. We use this database in order to figure out contingent variables that may influence the decision of adopting a particular SW model. Their operationalization is shown in

3.3 Qualitative Analysis

We performed four case studies on the Italian branches of International organisation, which were similar in terms of C-level's willingness to invest in SW, but adopted different implementation strategies.

As suggested by Eisenhardt (1989), we have relied on several data sources: face-to-face interviews, phone conversations, follow-up emails, and archival data such as internal documents, press releases, websites, and news articles. In order to maximise the benefits from these sources of evidence, and better deal with reliability issues, two of the three principles suggested by Yin (2003) have been followed: the triangulation of data sources, and their organisation in an electronic and navigable case study database.

The primary data source was 49 semi-structured interviews conducted over seven months (from April 2013 to October 2013) with the HR director of the firms, at least one of the C-levels, and - through a snowball technique (Patton, 2002) - other knowledgeable informants involved in SW implementation process. Within each firm, authors continued recruiting informants until additional interviews failed to dispute existing, or reveal new, categories or relationships that is, until theoretical saturation (Strauss and Corbin, 1990) was achieved. Table 3 proposes the organisations involved in the case studies as well as the interviews accomplished.

Table 3 – Organisations involved in the qualitative analysis

Org.*	Industry	Employees	Interviews**			Total
			HR manager	C-levels	Others	
A	Public administration	3,407	2	2	5	9
B	Food and beverage	3,764	5	8	2	15
C	Brewing	961	4	2	6	12
D	Food packaging and processing	824	6	2	5	13

* Pseudonyms are used to protect the anonymity of the organisational and their members
 ** Each interview lasted approximately 1.5 hours

Potential informant bias has been addressed in several ways. First, the interviews collected both real-time and retrospective longitudinal data in several waves over seven months. According to Ozcan and Eisenhardt (2009) these kinds of data collection are ideal because retrospective data enable efficient collection of more observations (thus

enabling better grounding), while real-time data mitigate retrospective bias (Leonard-Barton, 1990). Second, anonymity has been promised to companies and informants. According to Eisenhardt (1989) this decision encourages candour. Third, the interviews have been complemented with wide-ranging archival and observational data, as suggested by Bingham and Eisenhardt (2011). Fourth, open-ended questioning has been used to give the informants wide scope to relate the concept as they chose. According to Koriat et al. (2000), this helps in addressing potential informant bias. Fifth, informants not only from multiple levels of hierarchy, but also with different perspectives have been considered during the interviews (Ozcan and Eisenhardt, 2009). Finally, interview techniques like courtroom questioning, event tracking, and nondirective questioning (Martin and Eisenhardt, 2010) have been used to yield accurate information (Huber and Power, 1985).

Following recommendations regarding multiple cases theory-building (Eisenhardt and Graebner, 2007), within and cross-case analyses have been performed with no a priori hypotheses. The authors cycled among the emergent theory, case data, and literature to further refine abstraction levels, construct measures, and theoretical relationships (Eisenhardt, 1989). To converge on a parsimonious set of constructs, authors focused (and will present) only on the most robust findings (Andriopoulos and Lewis, 2009).

Table 2 – *Variables operationalisation*

Variable	Operationalization	Data source
Industry types	Firms are classified into public administration, retail industry, bank sector, engineering industry, food industry, ICT sector, other industries.	Survey
Size	Number of employees	AIDA
Capital intensity	Ratio between the property plants and equipment and the number of employees	AIDA
Human capital	Ratio between the total labour cost and the number of employees	AIDA
Year of foundation	Year of foundation	AIDA
VA/employees	Ratio between the value added and the number of employees	AIDA
EBITDA/employees	Ratio between EBITDA and number of employees	AIDA

3.3 Qualitative Analysis

We performed four case studies on the Italian branches of International organisation, which were similar in terms of C-level's willingness to invest in SW, but adopted different implementation strategies.

As suggested by Eisenhardt (1989), we have relied on several data sources: face-to-face interviews, phone conversations, follow-up emails, and archival data such as internal documents, press releases, websites, and news articles. In order to maximise the benefits from these sources of evidence, and better deal with reliability issues, two of the three principles suggested by Yin (2003) have been followed: the triangulation of data sources, and their organisation in an electronic and navigable case study database.

The primary data source was 49 semi-structured interviews conducted over seven months (from April 2013 to October 2013) with the HR director of the firms, at least one of the C-levels, and - through a snowball technique (Patton, 2002) - other knowledgeable informants involved in SW implementation process. Within each firm, authors continued recruiting informants until additional interviews failed to dispute existing, or reveal new, categories or relationships that is, until theoretical saturation (Strauss and Corbin, 1990) was achieved. Table 3 proposes the organisations involved in the case studies as well as the interviews accomplished.

Table 3 – *Organisational involved in the qualitative analysis*

Org.*	Industry	Employees	Interviews**			Total
			HR manager	C-levels	Others	
A	Public administration	3,407	2	2	5	9
B	Food and beverage	3,764	5	8	2	15
C	Brewing	961	4	2	6	12
D	Food packaging and processing	824	6	2	5	13

* Pseudonyms are used to protect the anonymity of the organisational and their members
 ** Each interview lasted approximately 1.5 hours

Potential informant bias has been addressed in several ways. First, the interviews collected both real-time and retrospective longitudinal data in several waves over seven months. According to Ozcan and Eisenhardt (2009) these kinds of data collection are ideal because retrospective data enable efficient collection of more observations (thus enabling better grounding), while real-time data mitigate retrospective bias (Leonard-Barton, 1990). Second, anonymity has been promised to companies and informants. According to Eisenhardt (1989) this decision encourages candour. Third, the interviews have been complemented with wide-ranging archival and observational data, as suggested by

Bingham and Eisenhardt (2011). Fourth, open-ended questioning has been used to give the informants wide scope to relate the concept as they chose. According to Koriat et al. (2000), this helps in addressing potential informant bias. Fifth, informants not only from multiple levels of hierarchy, but also with different perspectives have been considered during the interviews (Ozcan and Eisenhardt, 2009). Finally, interview techniques like courtroom questioning, event tracking, and nondirective questioning (Martin and Eisenhardt, 2010) have been used to yield accurate information (Huber and Power, 1985).

Following recommendations regarding multiple cases theory-building (Eisenhardt and Graebner, 2007), within and cross-case analyses have been performed with no a priori hypotheses. The authors cycled among the emergent theory, case data, and literature to further refine abstraction levels, construct measures, and theoretical relationships (Eisenhardt, 1989). To converge on a parsimonious set of constructs, authors focused (and will present) only on the most robust findings (Andriopoulos and Lewis, 2009).

4 Findings

4.1 Configurations of SW practices: The cluster analysis

Descriptive statistics (Table 4) highlighted that firms invest more in ICT solutions (59% of companies surveyed) regard to the reconfiguration of the workplace and of the office layout (39% of companies surveyed). However, the majority of the organizations surveyed (the 67%) make innovations in the human resource practices and in the organizational model followed.

Table 4 – Descriptive statistics

Variable		Mean	Median	Dev. std.	Min.	Max.
Element	Layout	0.39	0	0.49	0	1
	ICT	0.59	1	0.49	0	1
	HR	0.67	1	0.47	0	1
Industry	PA	0.14	0	0.35	0	1
	Bank	0.13	0	0.34	0	1
	Engineering	0.08	0	0.27	0	1
	Food	0.06	0	0.24	0	1
	Retail	0.06	0	0.24	0	1
	ICT	0.06	0	0.24	0	1
	Other	0.47	0	0.50	0	1
Co nti	Human capital (k€)	54.76	57.00	16.84	10.00	88.00
	Capital intensity (k€)	762	128	2,980	1.00	21,319

Size	4,197	566	18,387	57	140,435
Year of foundation	1984	1996	29	1865	2010
VA/employees (k€)	80.15	77.00	34.28	15.00	165.00
EBITDA/employees (k€)	25.60	20.50	26.94	-62.00	104.00

The three binary variables¹ operationalizing the three elements that may determine a company to adopt SW practices were subject to a Hierarchical Cluster Analysis using Ward's method (Forst and Vogel, 1977), which produced a dendrogram². The dendrogram showed that within the sample there were four distinct approaches to SW, which are shown in Table 5. The existence of distinct approaches provided empirical evidence on the existence of complementarities between the elements investigated.

Table 5 – ANOVA results

Smart Worker		1. Inconsistent	2. Analogical	3. Digital	4. Complete	Total
Element	Layout	Low ³	High	Low	High	39%

	Size	566	1,579	274	606	566
	Year of foundation	1978	1974	1993	1981	1984
	VA/employees (k€)	66.76	70.80	89.40	85.11	80.15
	EBITDA/employees (k€)	22.00	17.20	31.60	24.67	25.60
Percentage of firms		28%	13%	33%	26%	100%

A first approach (*cluster 1*) consists of 28% of companies surveyed. We called these firms “inconsistent smart workers” as they do not invest significantly in any of the three elements investigated. This cluster is composed mainly by organizations that operate in the public administration and in the retail industry. These organizations have not high-

¹ Values in the scale higher to the median value were converted into a 1 and the others to 0.

² For further details please contact the authors.

³ “Low” means that the value of the element is under the mean of the sample, “high” otherwise.

level human capital and are capital intensive. Furthermore, the majority of them are older than the others are, and are characterized by low levels of productivity.

The second group (*cluster 2*) in terms of frequency in the sample consists of 13% of surveyed companies whose features are based on attributing importance to investments in innovations in the human resource practices and in the organizational model followed, and in the reconfiguration of the workplace and of the office layout. Since ICT element is not significantly used by this cluster, we labelled it as “analogical smart workers”. This cluster is mainly composed by organizations operating in banking and with medium qualified employees. These organizations are older than others, have more employees, are labour intensive, and have relatively low productivity levels,.

The bigger group (*cluster 3*) consists of 33% of organizations whose distinguishing trait is the limited importance for the reconfiguration of the workplace and of the office layout. For this reason, we labelled this group as “digital smart workers”. This cluster is composed mainly by organizations of the engineering and in the food industry. These organizations have medium-qualified human capital and are labour intensive. The majority of them is younger than others firms, have a medium size and are characterized by high levels of productivity.

Finally, a fourth approach to SW (*cluster 4*) consists of 26% of organizations that have invested in all the three elements investigated. Given the typology of investments made by these organizations, we labelled this group as “complete smart workers”. This cluster is composed mainly by organizations of the ICT industry that have hired qualified employees (high human capital levels). These companies are labour intensive, are characterized by medium dimensions, and have medium productivity levels.

4.2 Results of Qualitative Analysis

We have structured the results of the case studies according to the main reasons that led the different organisations to invest in SW (Table 6), and the specific configurations of the three elements characterising each SW model (Table 7). The rest of the paragraph will briefly describe the cases deepening the statements reported into the tables. A final sub-paragraph will report the considerations rose during the cross-case analysis.

Table 6 – Main reasons for investing in SW

Organisation*	A (Inconsistent SW)	B (Analogical SW)	C (Digital SW)	D (Complete SW)
Organisational efficiency	<u>Cost reduction</u>	<u>Rationalisation</u>	<u>Productivity</u>	Flexibility
Organisational effectiveness	Response rate	Quality improvement	<u>Collaboration</u>	Innovation
Employees engagement	Empowerment	<u>Creativity</u>	Sense of community	<u>Work-life balance</u>

* For each organisation we have underlined the main reasons explaining the investments in SW

4.2.1 Organisation A: Inconsistent Smart Worker

Organisation A is a public administration managing a big Italian Region. With 3,407 employees and different facilities spread throughout a large geographical territory, the C-levels of organisation A started thinking to SW principles with the main aims of reducing the commuting costs of their employees while increasing their functional integration and, thus, their effectiveness in answering citizen requests. The underlying objectives were not only to switch from silos-based to cohesive service delivery, but also to progressively empower all employees toward the usage of ICT as a lever through which disrupting the service processes.

Table 7 – Usage of the three elements in the cases

Organisation	A (Inconsistent SW)	B (Analogical SW)	C (Digital SW)	D (Complete SW)
Layout element	<ul style="list-style-type: none"> • No significant intervention made • Building constraints to be faced (old facilities not easily reconfigurable) 	<ul style="list-style-type: none"> • Development of a new building focused on fully exploiting a SW model • Concentration rooms, collaboration rooms and relax rooms 	<ul style="list-style-type: none"> • No significant intervention made • Building constraints to be faced (necessity of changing building in order to fully benefit from SW models) 	<ul style="list-style-type: none"> • Intelligent, modular building, which adapt to organisational needs • Building automation (light and temperature) • Acoustic isolation
ICT element	<ul style="list-style-type: none"> • No significant intervention made • Unified collaboration and communication as enabling investment 	<ul style="list-style-type: none"> • No significant intervention made • Unified collaboration and communication as enabling investment 	<ul style="list-style-type: none"> • Mobile workspace for all employees • Unified collaboration and communication • Cloud solutions • Social network within the firm 	<ul style="list-style-type: none"> • Full digitalization of archives and documents • Unified collaboration and communication • Mobile workspace and app for employees
HR element	<ul style="list-style-type: none"> • No significant intervention made • Assessment of the effectiveness of current model in balancing employees' needs with firms performance goals 	<ul style="list-style-type: none"> • Extension to all senior managers • Training • SW leadership program (engagement) • Clear definition of the SW priorities on which focusing 	<ul style="list-style-type: none"> • Preliminary pilots in ICT and marketing divisions • Quantification of the SW benefits • Extension to all other employees • Training 	<ul style="list-style-type: none"> • Extension to all employees (blue collars) • Full autonomy in choosing working times, places and tools • Self-certification of working hours

Organisation A started to invest in a unified communication and collaboration suite (instant messaging, presence and collaboration) as an enabling ICT-based investment to

achieve these potential benefits. However, the lack of a solid budget associated to strong financial constraints not only forced to focus on a (suboptimal) general-purpose suite, but also to ignore other complementary SW elements. In particular, the lack of training programmes explaining how to take advantage of the digital solution limited its extension from the convenient pilot units in which it has been tested to the whole organisation. Recognising this initial mistake, organisation A is now focused on assessing the effectiveness that the current organisational model has in balancing employees' needs with firms performance goals, and compare it to models used in other public administrations and firms. The results of this exercise will be used to define the next priorities to move organisation A along the continuum toward SW models.

4.2.2 Organisation B: Analogical Smart Worker

Organisation B is the Italian branch of a multinational food and beverage company that, in the last months of 2013, has moved all its employees into a new building structured into functional areas (concentration rooms, collaboration rooms, relax rooms, etc.). This change provided an opportunity to rethink the whole working model, with the aims of rationalising the cost of facilities (as well as their management), improving the quality of the internal decision-making processes and stimulate creativity in individuals.

During the construction of the new building, the organisation has extensively invested in training all senior managers regarding the levers and benefits related to SW. Once a clear idea of SW levers and benefits was disseminated, organisation B developed a leadership program to engage senior managers in the development of SW model and mature the capabilities necessary to efficiently and effectively accomplishing this task. A clear definition of specific SW priorities completed the programme of HR development, and allowed to fully exploit the new building once ready. One of the results of the prioritization of all SW efforts has been the choice of not making particular interventions in ICT domain. Two are the main reasons explaining this choice: (i) the organisation already had a supportive and mature digital infrastructure; (ii) managing also this element could compromise the effectiveness of the whole process of SW development (to many variables to be taken into account). Only unified collaboration and communication solutions has been considered an indispensable and enabling investment that cannot be neglected.

4.2.3 Organisation C: Digital Smart Worker

Organisation C is the Italian branch of a multinational brewing company that in July 2013 started developing a SW model with the objectives of increasing the productivity and the level of collaboration of its employees instilling a sense of community in them. Starting from the consideration that it was impossible to work on layout element, since current building structure impedes the rearrange of office layout allowing to fully benefits from SW principles, the C-levels of organisation C decided to start a SW initiative involving its HR and the ICT divisions. This initiative has been structured according to three phases: (i) evaluation of current organisational and individual needs; (ii) piloting of a SW model into controlled, supportive settings; (iii) quantification of SW benefits and extension of SW model to the whole organisation through a set of training sessions.

During this process, organisation C invested in the development of a digital environment complementing the HR strategy of letting people work whenever and wherever they wanted. Thus, in addition to some investments in unified communication and collaboration tools, a mobile workspace (constituted by a laptop, a smartphone and an internet connection) has been made available to all employees. Moreover, a set of cloud-based solutions has been developed to improve the performance, the reliability and the scalability of the applications used in day-by-day tasks. Finally, a corporate social network significantly increased the inter-organisational knowledge exchange.

The combination of HR and ICT elements allowed achieving significant results in compressed timeframes. For instance, organisation C registered a productivity growth from 20% to 30% regarding its marketing unit in just 3 months of experimentation. With these numbers, the promoters of SW initiative convinced the C-levels of organisation C to significantly invest into the development of a SW model.

4.2.4 Organisation D: Complete Smart Worker

Organisation D is the Italian branch of a multinational food packaging and processing company. Organisation D started thinking to SW in 2006 in order to increase the innovativeness of its employees and the flexibility in managing them. Underlying these objectives there was the necessity of retaining key human resources in a geographical territory full of other strong employer brands. Within these settings, and recognising the centrality of human resources in producing the competitive advantage of the firm, organisation D focused on increasing work-life balance.

One peculiarity of organisation D is that its HR director is also the ICT leader as well as the facility manager of the firm. This organisational configuration ensured high levels of interrelations and complementarities among the three SW elements. An intelligent and modular building has been developed to adapt to organisational need. Thus, if employees necessitate of a big conference room, open spaces are autonomously created by moving transparent walls and dynamically rearranging office layout. The light and the temperature within the building are centrally controlled in order to provide employees with the most conformable conditions to accomplish their tasks.

All archives and documents have been digitalised or moved to a separated warehouse. An internal logistic service brings the documents that employees need where and when they needs it. In this way the working place is highly simplified, and human resource can focus on one task at a time and boost both their efficiency and effectiveness. The organisation has developed a set of apps allowing to book a meeting room on the run, release it, check the queue at the canteen, etc. More generally, organisation D has created a mobile workspace allowing employees to work whenever and wherever they want.

These and many other benefits (corporate kindergarten, wellness areas, centralised commuting services, etc.) have been made to all employees - blue collars included. These last ones have not only a full autonomy in choosing their working times, places and devices, but also self-certificate their working hours and spontaneously coordinate in the different R&D projects within the firm. The end result is a reduction of the HR, IT and layout yearly costs by an order of 10%,

5 Discussion

This study allows highlighting some consideration regarding the objectives and the elements characterising SW models. The main reasons for which an organisation invests in SW tend to shape and being shaped by both the investments accomplished in SW elements. Inconsistent smart workers tend to see SW only a paradigm to reduce cost. Analogical smart workers tend to combine resources rationalisation with employees creativity. Digital smart workers focus on establishing collaboration and a sense of community among its employees. Complete smart workers tend to focus on work-life balance, and see the innovativeness and the flexibility of its assets as a by-product of a satisfied employee to be retained as a key resource.

Overall we demonstrate that there are complementarities between the elements that can characterize a SW model. At least two elements are developed in each SW configuration found. Quantitative and qualitative analyses show the centrality of HR element in the development of SW models. In particular, the cross-analysis of the four different implementation strategies of SW suggests that the development of pilots in controlled organisational niches, the quantification of the benefits associated to SW, the engagement of senior managers and employees trainings are central in the development of SW. Indeed, SW requires the concurrent presence of at least two elements, where HR element is always developed.

Regarding the layout element, it is important to note that most of current organisational facilities have different constraints that impedes to fully benefit from the potential of SW. Recognising that the organisational layout tend to shape working practices in a significant way, many organisation are deciding to start from green field, and “use” the development of new facilities as an opportunity to rethink organizational models in order to combine efficiency (e.g. less space used due to the usage of shared desks) with effectiveness (e.g. exploitation of room favouring collaboration among employees). In the quantitative analysis we found that younger firms do not make any particular investments in the layout element. This maybe is due to the fact that such companies adopt already flexible solutions that allow them to be “smart” and do not need do reconfigure their organizational facilities.

With a reference to the ICT element, the cases suggest that the unified communication and collaboration solutions seem to be a necessary but insufficient investment to develop a SW model. In order to concretise the SW potential, most advanced cases complements these investments with (at least) the development of a mobile workplace allowing: (i) employees to work also outside the firm facilities, and (i) firms to progressively develop flexible models of ICT governance opening up further SW opportunities. What is clear is that there are different stages of ICT maturity towards a SW model, and practitioners ask for models to help them prioritise their investments coherently to other SW elements. Further, looking survey results, they suggest that banks invest to a lower extent in ICT solutions probably given security problems that can arise in an extensive usage of them.

Future research needs to further investigate the development dynamics of SW configurations in order to understand the adoption timing of the three elements. Moreover, future studies will focus on studying SW adoption at a functional level in order to measure the relative performance.

6 Conclusion

In conclusion, the proposed study contributes to clarify that there is not a unique path for developing a SW, but there is a set of potential paths that have to be designed taking into account the characteristics of the firm investing in SW. In this study we show that there is a risk of not being able to implement SW if firms focus on all elements on all three domains. It is better to focus on a specific area and/or proceed through a gradual developmental process. While there is certainly more research on this topic, we believe that this study provides an important approach to how we conceptualize and operationalize SW concept.

Structured Abstract

Purpose – The main aim of this work is to place the value creation process within the *Sustainable Growth Strategies* framework.

The economic sustainability of a strategy at first requires value creation for all stakeholders, according to the *Stakeholder Value Theory*.

The economic sustainability of a strategy also requires it to be legitimized in terms of *Corporate Social Responsibility (CSR)*. In this context, *Intangible Assets* and *Knowledge Management* assume a special relevance.

The authors retain that the notion of *Value Added (VA)* and the accounting based on the *Value Added Income Statement*, adapted to a context of *Intellectual Capital*, is the best way to measure the value creation of a strategy that considers the *Corporate Social Responsibility*.

Design/methodology/approach – The paper uses the notion of Value Added (VA) (Pulic, 2000; 2004; 2008) to propose a methodology that is able to distinguish between industries that carry out sustainable strategies and industries that are unable to do it. The proposed methodology is based on the analysis of the Value Added and its components, starting from a reinterpretation of the concept of VAIC (Value Added Intellectual Coefficient) made up by the same authors of this paper. An empirical analysis based on the composition of the VA in ten Italian industries, by using an overall sample of 1,000 firms, has been carried out.

Findings – From results it emerges that:

1. in industries with not so sustainable strategies (traditional sectors) the weight of the Cost of Employees on the VA (human capital investments) is less than the other sectors (low human capital intensity). In these sectors the value creation strategy is mainly based on *dead knowledge*, embedded in machines (physical capital);

2. in industries with more sustainable strategies (non-traditional sectors: consulting, advertising, research, etc.) the economic value creation is mainly based on *live knowledge*, embedded in human resources (high human capital intensity). In these sectors we have lower productivity of work (VA/Human Capital) and higher employment.

Originality/value – The originality and the value of our methodological proposal can be appreciated by taking into account that in the literature there is no accounting-based methodology that is able to identify the firms with sustainable strategies within the set of all firms.

Practical implications – Our approach, based on the extension of Pulic's contribution, makes it possible to reduce the risk of myopic valuation of economic performance. Through our methodology it is possible to highlight the effects of sustainable strategies based on knowledge investments oriented towards the *Stakeholder Value Theory* and *Corporate Social Responsibility (CSR)*.

Keywords – Sustainable Value Creation, VAIC, Intellectual Capital, Corporate Social Responsibility, Performance measurement

Paper type – Academic Research Paper

1 Introduction

It is a quite shared opinion that knowledge-based strategies have a satisfactory degree of sustainability (Grant, 2010).

In this paper, for Sustainable Growth Strategies we mean those long-term behaviours aimed at legitimizing the social, environmental and economic expectations of the various stakeholders, both internal and external (Donaldson and Preston, 1995).

The main reason that distinguishes knowledge-based strategies as sustainable strategies derives from the fact that the modern firm is seen as an assembly of accumulated knowledge whose value derives from its utilization (*knowledge-based view of the firm*). Knowledge management is, therefore, one of the main resources to support sustainable competitive advantage (Edvinsson and Malone, 1997; Kaplan and Norton, 1992; Nonaka, 1994; Nonaka and Takeuchi, 1995; Sveiby, 1997; 2001).

Attention to the research of sustainable knowledge-based strategies also derives from growing interest in themes of *Corporate Social Responsibility (CSR)*. The behaviour of large firms has a profound effect on the economic and social context. For this reason they are called to operational accountability by different social and political subjects, *stakeholders*. The interaction between the themes of *Knowledge Management* and those

of *Corporate Social Responsibility* is pointed out in many studies of company strategies (Collins and Montgomery, 2005).

Now, the economic sustainability of a strategy needs above all the creation of economic value for all the stakeholders (*stakeholder value theory*). In fact, a strategy that fails to create value or that creates value only for few agents cannot be defined as sustainable from a social point of view.

Therefore, the problem of measuring value creation arises (Andriessen, 2004), for all the stakeholders, associated with the utilization of knowledge and *Intellectual Capital*. This problem is the specific subject of this paper.

The paper is organized as follows: in section 2, following the approach suggested by Pulic (2000; 2005; 2008), the reasons will be stated leading to the belief that Value Added (VA) is the best method to measure value creation for stakeholders associated with a strategy that takes into account *Corporate Social Responsibility*; in section 3 the concept of Value Added is used to describe the two main strategies of value creation, that of a “*Win-Win*” type, which is based on value creation for all the stakeholders, and the “*Win-Loss*” type, which is based on value creation only for the shareholder; in section 4 the two previously-mentioned strategies (*Win-Win*, *Win-Loss*) will be compared with working strategies that exploit “*dead knowledge*”, incorporated in machinery, and with strategies that employ “*live knowledge*”, incorporated in human resources; section 5 illustrates empirical analysis: the various value creation models will be applied to 10 industrial sectors each made up of 100 firms. The way that the categories elaborated by Pulic will be shown to be of use in interpreting the characteristics of the value creation strategies of the different sectors; finally, paragraph 6 contains the conclusions and a discussion of some aspects considered in the paper.

2 Stakeholder point of view and Value Added

In the traditional way of measuring the company performance of an organization the focus is mainly on value creation for the shareholder (*shareholder point of view*). But, as already seen, a strategy that is socially sustainable has to create value not only for the shareholder, but also for the other stakeholders and, in particular, for the employees.

A strategy that only considers the shareholder’s interests is a strategy that can only be satisfactory for a part of society. The idea underlying performance measurement in terms of satisfaction only from the point of view of the shareholder is based on the idea that by

maximising profit (NOPAT, EVA, Dividends, etc.) also social wellbeing is maximised. But it is immediately evident that the economic facts of the last twenty years, dominated by *shareholder value analysis*, have not brought social benefits for everyone, as promised. Mass unemployment a characteristic of the current world economy does not allow the affirmation that the application of the “philosophy” of *shareholder value analysis* has brought socially sustainable benefits.

The reason, as Pulic states (2000; 2004; 2008), is that value creation has not been correctly measured. Value from the social sustainability point of view cannot be measured only by EBITDA or by other measures such as EVA which are based, on final analysis, on NOPAT which is a variant of EBITDA (Iazzolino *et al.*, 2014).

If the measurement of value creation is based only on EBITDA then we should not be surprised that the strategies which emerge cannot be socially sustainable. The reason is obvious. Creating value for the shareholder does not mean creating value for all the stakeholders.

In fact, the EBITDA measures the value created for all capital investors (within which category there is also the shareholder) whereas value created for all the stakeholders is measured by Value Added. This is the fundamental criticism that Pulic (2000; 2004; 2008) levels at traditional value measurement. This concept will be better explained in the next section.

According to Pulic, in addition to value created for capital investors and for the shareholder, it is necessary also to consider value created for employees, which is measured by wages and salaries, that is by the capital invested in acquiring human resources. Value Added is, therefore, the adequate measure of value creation from a stakeholder point of view

3 Value Added and value creation for stakeholders

The short-sightedness of the traditional measures of value creation can be illustrated following the approach proposed by Pulic (2000; 2004, 2008).

From the point of view of society as a whole, value created is equal to :

$$VA = HC + SC \quad [1]$$

where:

VA = Value Added

HC= Human Capital (= Cost of Employees = wages and salaries)

SC = Structural Capital

Considering Pulic's definition, Structural Capital in fact coincides with EBITDA (Earnings Before Interest, Taxes, Depreciation and Amortization) (Iazzolino and Laise, 2013). Expressing EBITDA in terms of its components, it holds that:

SC = Structural Capital = EBITDA = Depreciation/Amortization + Interest expenses + Taxes + Net Income.

The latter definition stresses the fact that in EBITDA, less taxes, there are the remunerations of various capital investors, understood in the physical sense and in the financial sense (and therefore also shareholders).

Some elucidation is needed to link the equations [1] with the themes of Knowledge Management. Knowledge that creates value is incorporated in Human Capital (people). Pulic states that: "People are the main carriers of knowledge" (Pulic, 2008). If this observation is correct then expenditure on human resources has to be seen as an investment and not as a cost: "it is only reasonable to give this resource the status it deserves of investment and not cost anymore" (Pulic, 2008). But: "employees, who are treated as investment, are the beginning and the end of the new, knowledge-based, economy" (Pulic, 2008). The reason for investing in human resources is that they are "the main value creators of the contemporary economy" (Pulic, 2008).

Now, considering human resources as an investment and not just a cost, needs a change in managerial mentality. In fact, costs owing to their nature have to be cut and the traditional performance measurements are based on a logic of "cost cutting". To increase the Ebitda the cost of human resources is also cut. But, if human resources are the source of value creation then cutting them can be a "short-sighted" strategy in the long term. Maybe the saying: "the lower the cost, the higher the profit" can be fine for the cost of raw materials and energy costs, but not when it refers to human resources. The reason is obvious: human resources create value.

Using formula [1] the significance of fundamental strategies for value creation can be explained.

Equation [1] in terms of variations can be rewritten in the following way:

$$\Delta VA = \Delta HC + \Delta SC \quad [2]$$

Now, it is worth increasing investments in human resources ($\Delta HC > 0$) when an even greater increase on VA ($\Delta VA > \Delta HC$) can result from that investment. In that case in fact there is an increase in work productivity (VA/HC) and, therefore, there is also an increase in working profits ($\Delta SC > 0$). In Pulic's terminology this means that an investment in human resources makes HCE = VA/HC (Human Capital Efficiency) grow and therefore makes the efficiency of the structural capital grow that is the working profits with respect to the Value Added (SCE = SC/VA). In fact, the following relation holds (Iazzolino and Laise, 2013):

$$SCE = 1 - (1/HCE) \quad [3]$$

It is clear that if $\Delta HCE > 0$, then $\Delta SCE > 0$.

This is an example of socially sustainable strategy because it creates new value for the employees ($\Delta HC > 0$) and for capital investors ($\Delta SC > 0$). It could be said that such strategy is an example of "Win-Win" strategy that does not dissatisfy anyone, since it creates new value for everyone.

It is for this reason that it can be understood as a socially sustainable strategy. Using the metaphor of a "cake" (Pulic, 2004), it can be said that a *Win-Win* strategy does not dissatisfy anyone because there is an increase in the size of the cake (Value Added) and, therefore, an increase in the size of the "slice" apportioned to human resources (HC) and an increase in the size of the "slice" apportioned to capital investors (SC).

Therefore one should ask oneself: why is this *Win-Win* strategy not adopted by all firms?

The reason can be explained using, again, equation [2].

If one invests in human resources ($\Delta HC > 0$) which however have a low knowledge content and low professional qualifications, the growth of Value Added, as a result of investment, is insufficient, and in particular is lower than the investment effected ($\Delta VA < \Delta HC$). In this case there is a reduction in profits for capital investors ($\Delta SC < 0$). This is what happens in the majority of traditional sectors exposed to competition, where there are not the conditions to make the Value Added grow adequately.

The only strategy possible in these cases, to make profits grow, is that of reducing the workforce (destruction of the value quota of employees) through a growth in work productivity obtained by investing in *labour saving* plants. In these cases value growth for

capital investors ($\Delta SC > 0$) is obtained by the destruction of investment in human resources ($\Delta HC < 0$) by means of reducing employment. This is an example of occupational strategy of the “*Win-Loss*” type, since there is the creation of value only for capital investors.

But this *Win-Loss* strategy is not socially sustainable in the long term since it destroys jobs and income for employees.

4 Sustainable value creation and knowledge-based strategies

The two occupational strategies outlined in the preceding paragraphs (*Win-Win*; *Win-Loss*) can be better described by distinguishing two types of knowledge.

When investing in human resources trust is placed in “*live knowledge*”, which is incorporated in the employees, that is, in men. It is believed that only human beings are able to create new knowledge and, therefore, produce Value Added in such a way as to justify investment. Only qualified and educated human resources are, in fact, able to create patents, copyrights, know-how, etc. Moreover, only highly-trained human resources are able to increase the quality and quantity of intangible assets (organisational relations and relations with customers).

Value creation for all stakeholders therefore necessitates heavy investments in highly trained and skilled human resources. It is from this type of resource that comes value added suitable to make investment in HC convenient. It is necessary to increase the size of the cake ($\Delta VA > 0$) so that everyone can have a bigger slice ($\Delta HC > 0$, $\Delta SC > 0$). This is the way to create greater motivation, greater satisfaction and greater employee collaboration. This is the way for a *Win-Win* strategy.

The other more traditional strategy places its trust in “*dead knowledge*” incorporated in ever more perfected machinery whose use is “labour saving”. With this strategy operating profits can be increased (SC) also at parity of Value Added, that is profits can be increased destroying value for employees (HC).

This strategy presupposes a given cake ($\Delta VA \cong 0$) and is based on the reduction of the slice of the cake that goes to the employees ($\Delta HC < 0$) to increase the size of the slice that goes to capital investors ($\Delta SC > 0$). If the Value Added is given, then its distribution among employees and capital investors becomes “*a game with a zero sum*”. It is as already stated *Win-Loss* strategy. The problem with this strategy is that it is less socially sustainable. In fact, growing structural unemployment can transform itself into non-

negligible social conflict. For this reason a strategy based on live knowledge (human resources) is the only feasible way in social terms. But, as Pulic states, a change of mentality at the managerial level is needed to be able to carry it out.

It is necessary to understand what is the fundamental driver of value creation. That is, it is necessary to place human resources at the centre of management and understand that the following factors are of crucial importance.

1) first and foremost, it is necessary to aim at innovation, which is able to continuously increase the knowledge content of products and services. Continuous innovation is nothing other than new knowledge for the growth of value added.

2) secondly, it is necessary to develop and increase employee skills with the aim to develop value added of products and services.

It is necessary, definitively, to abandon the idea that profits are low because the costs are high and think instead that profits are low because the Value Added is low. But growth strategies of Value Added come through the development of knowledge incorporated in human resources.

It is necessary to start from the presupposition that profits can also be made in non-traditional (*labour intensive*) sectors in which the division of Value Added is more balanced due to a greater weight of capital invested in human resources (HC/VA). These are sectors where the profits for capital investors (SC/VA) are lower, since they are obtained through the creation of value also for employees.

The research we carried out, detailed in the next section, confirms the feasibility of the strategies of value creation of the Win-Win type that are based on consistent investments in highly qualified human resources.

5 The empirical analysis: value creation models in different Italian industries

An empirical analysis on a sample of firms belonging to different Italian industrial sectors was carried out, with the aim of finding an empirical validation of Pulic's thesis. The data used in the empirical research were taken from the AIDA Bureau Van Dijk Database.

In particular, 10 industrial sectors were analysed:

1. Legal and accounting activities (ATECO M69);
2. Manufacture of wearing apparel (ATECO C14);

3. Manufacture of computer, electronic and optical products (ATECO C26);
4. Manufacture of chemicals and chemical products (ATECO C20);
5. Electricity, gas, steam and air conditioning supply (ATECO D35);
6. Manufacture of food products (ATECO C10);
7. Manufacture of wood and of products of wood and cork, except furniture; manufacture of articles of straw and plaiting materials (ATECO C16);
8. Computer programming, consultancy and related activities (ATECO J62);
9. Advertising and market research (ATECO M73);
10. Employment activities (ATECO N78).

The first 100 firms in each section were chosen, in decreasing order of turnover, which could provide available balance sheet data for the last 8 years. Overall, the sample is made up of a total of 1000 firms.

No.	Industry	Numbers
1	Legal and accounting activities	100
2	Manufacture of wearing apparel	100
3	Manufacture of computer, electronic and optical products	100
4	Manufacture of chemicals and chemical products	100
5	Electricity, gas, steam and air conditioning supply	100
6	Manufacture of food products	100
7	Manufacture of wood	100
8	Computer programming, consultancy and related activities	100
9	Advertising and market research	100
10	Employment activities	100
	TOTAL	1000

Tab. 1 Sectors and number of firms

The average values of the components of Value Added were calculated for each sector, considering the time interval relative to the last three years available (2010, 2011 and 2012).

The sectors considered were then subdivided into two wide classes.

Class I Traditional Industries (T)

- 1) Manufacture of wearing apparel
- 2) Manufacture of food products

- 3) Manufacture of chemicals and chemical products
- 4) Electricity, gas, steam and air conditioning supply
- 5) Manufacture of wood

Class II) Non-Traditional Industries (NT)

- 6) Computer programming, consultancy and related activities
- 7) Advertising and market research
- 8) Employment activities
- 9) Legal and accounting activities
- 10) Manufacture of computer, electronic and optical products

The results of the survey, in Pulic's codification, are reported in Tab.2.

Sectors	HC/VA (a)	SC/VA (b)	VA/HC (c)
Traditional			
1. Manufacture of wearing apparel	0.50	0.50	2
2. Manufacture of food products	0.52	0.48	1.92
3. Manufacture of chemicals and chemical products	0.46	0.54	2.17
4. Electricity, gas, steam and air conditioning supply	0.20	0.80	5
5. Manufacture of wood	0.60	0.40	2.5
Non-traditional			
6. Computer programming, consultancy and related activities	0.64	0.36	1.56
7. Advertising and market research	0.55	0.45	1.81
8. Employment activities	0.63	0.37	1.58
9. Legal and accounting activities	0.72	0.28	1.38
10. Manufacture of computer, electronic and optical products	0.58	0.42	1.72

Tab.2. Performance per sector

As can be clearly seen from Tab. 2 two very different situations emerge. In the traditional sectors the entity of investments in human resources (HC) with respect to VA is on average lower compared with the non-traditional sectors. This datum is unsurprising since in traditional sectors the weight of Capital is greater compared with the weight of human resources (human capital). In the course of time, in fact, in traditional sectors technological progress has triggered *labour saving* processes that have made the use of

human resources obsolete. This also explains the diversity among the sectors in terms of operating profits on VA (SC/VA). In traditional sectors the greater work productivity (VA/HC) and the lower cost of work on the VA (HC/VA) is translated into in greater operating profits on the VA (SC/VA).

With the aim of better highlighting the main sectorial differences the data of Tab.2 have been recalculated in terms of average quantities and are reported in Table 3.

Sectors	Average Cost of Employees % (HC/VA) _{av}	Average EBITDA % (SC/VA) _{av}	Average work productivity (VA/HC) _{av}
TRADITIONAL (T) (1-5)	45.6%	54.4%	2.7
NON-TRADITIONAL (NT) (6-10)	62.4%	37.6%	1.6

Tab.3 Average performance per sector

The data reported in Tab. 3 highlight that in traditional sectors a kind of value creation strategy of the “*Win-Loss*” type has been carried out. In fact, in these sectors the weight of investments in human capital (HC/VA) is low and, moreover, is much less than that of non-traditional sectors.

In fact:

$$(HC/VA)_T = 45.6\% < 62.4\% = (HC/VA)_{NT}$$

Most probably, in traditional sectors a logic prevails that has favoured, in the first place, value creation for capital investors. That is, a logic has asserted itself that places the interests of the employees the background, who have become superfluous. In all probability value creation in traditional sectors has come about investing in “*dead knowledge*” incorporated in ever more sophisticated machinery of the “*labour saving*” type. Human resources are seen as *a cost to cut* by introducing automation and robotics that have increased the work productivity and have reduced the requirements for human resources.

This strategy of a “*Win-Loss*” type also emerges from the data relative to work productivity (VA/HC). As can be seen from the data in Tab.3, the work productivity in traditional sectors is higher than that achieved in non-traditional sectors. In fact:

$$(VA/HC)_T = 2.7 > 1.6 = (VA/HC)_{NT}$$

this, as already seen, explains the “*labour saving*” effects of the strategy carried out by the traditional sectors.

The traditional sectors achieve better performances also from the point of view of operating profits on the VA. In fact it results:

$$(SC/VA)_T = 54.4\% < 37.6\% = (SC/VA)_{NT}$$

But greater profits are paid for by employees in terms of higher unemployment, which is the downside of greater operating profits.

In non-traditional sectors the opposite of what happens in traditional sectors is found. In fact, in non-traditional sectors value creation comes through investing more in “*live knowledge*” incorporated in human resources. This is a more *labour intensive* strategy, that is, it is of the “*Win-Win*” type. This greater attention to human resources is also reflected at the level of operating profits (% on VA) of the non-traditional sectors, which are inferior to those of the traditional sectors.

Overall, from the data of the empirical analysis two very different strategic profiles emerge. In the traditional sectors there is a distribution of Value Added that favours operating profits (and therefore capital investors) and penalises human capital creating structural unemployment. Vice versa, the strategy of the non-traditional sectors is characterised by a distribution of Value Added that is favourable to human capital. This is a socially more equitable strategy, since it is compatible with greater employment of human resources. In this sense it can be said that it is also socially more sustainable.

6 Conclusions

This paper has examined the conditions necessary to set up a sustainable value creation strategy in social terms, utilising the conceptual categories introduced in the literature by Pulic (2000; 2004; 2008).

Some concluding remarks could be useful to point out better some aspects of the theme examined.

Knowledge is certainly a notably competitive weapon since it is the most important driver for value creation for all stakeholders, measured by Value Added. Pulic's idea is, therefore, sharable.

In Pulic, however, there is no specification of the cultural context of industrial relations able to sustain a *Win-Win* strategy . In many industrial systems the idea still prevails that profits can be gained on through *Win-Loss* type strategies. In these philosophies, the "machine" (dead knowledge) is seen as the best ally of the shareholders in the conflict between capital investors and employees. While this "managerial philosophy" remains dominant it will be difficult to set up a *Win-Win* employment strategy in the field, which provides for heavy investments in human resources with a wealth of knowledge. This is perhaps the main contradiction of modern industrial systems.

The strategies of the last few decades, based only on the point of view of the shareholder, have created value, but only for a part of society. For the other part of society and for young people in particular, these strategies have created unemployment. In other words, the increased operating profit has been paid, by other stakeholders, by increased unemployment.

Structured Abstract

Purpose – Companies are trying to respond to the increasing uncertainty and complexity in various ways. Development of open innovation and networking have already been well documented; they are based on the notion that tackling challenges in contemporary business environments demands a recognition of a shift in competitive factors from the company and industry level towards co-operation of companies and other stakeholders linked together through knowledge flows and shared value creation processes. This study aims to find how knowledge sharing for the collaborative organizations in the co-operation between health care professionals and sport counsellors can be supported by complexity leadership theory.

Design/methodology/approach – The empirical context in this study is from the ongoing MOTION! project which aims to develop the exercise and well-being industry, and create new collaboration models for co-operation between the private, public and third sectors. Case study is a preferred strategy when the investigator has little control over events, and when the focus is on a contemporary phenomenon within some real-life context. In this study two development sessions from 2012 and a survey conducted in the beginning of 2013 are mainly used to answer the research problem.

Originality/value – Current leadership theories do not sufficiently address the needs of complex business environments. First of all, before successful leadership models can be applied in practice, leadership needs to shift from the industrial age to the knowledge era. Many leadership models still view leadership solely through the perspective of linear process thinking. In addition, there is not enough knowledge or experience in applying these newer models in practice, particularly, in the co-operation between health care professionals and sport counsellors from sport departments or third sector organisations.

Practical implications – This study suggests that the complexity leadership theory represent applicable model to advancing sustainable knowledge sharing for the collaborative organisations. An implementable method for organizations may be assembled by assimilating different roles of complexity leadership into development practices featuring diverse activities and interaction channels. As MOTION! project wise, Physical activity pharmacy online platform was co-created. This is a good example of co-operation enhancing knowledge flows and co-creating value creation processes in

offering private sector companies an opportunity to offer their services at all levels of the health and exercise service chain and to find new service and product concepts.

Keywords – complexity leadership theory, knowledge sharing, co-operation, health care, sports

Paper type – Academic Research Paper

1 Introduction

The paradigm of complexity and uncertainty challenges existing theories of leadership and organizational management. (Lichtenstein et al., 2006; Uhl-Bien and Marion, 2008; Snowden and Boone, 2007) More holistic views are emerging in the field of leadership: more affirmative forms of leadership are being proposed in the literature, and increasingly leadership is being disseminated and shared throughout organizations. Furthermore, leadership is being viewed as a complex, emergent dynamic within organizations. Generally speaking, the field of complexity leadership demands more substantive research. (Avolio, Walumbwa and Weber, 2009; Dooley and Lichtenstein, 2008)

According to Nonaka, Toyama and Konno (2000), existing economics and organizational theories lack a general understanding of knowledge and how knowledge-creating processes are created and managed in contemporary organizations and business environments. (Aasen and Johannessen, 2009) Hence, Nonaka et al. (2000) claim that the knowledge management that academics and businesspeople refer to is often actually information management. Bessant and Tidd (2007) emphasize, however, that complex interaction is all about knowledge; the ways it flows and is linked as well as exploited to make innovation and emergence happen (Hyypiä, 2013).

Knowledge flow and transfer has been an active research area over the years (e.g. Nonaka, 1994; Nonaka and Konno, 1998; Spencer, 2000; Borgatti and Cross, 2003; Szulanski and Jensen, 2006) According to Mu, Peng and Love (2008): “knowledge flow comprises the set of processes, events, and activities through which data, information, and knowledge are transferred from one entity to another. The end results are knowledge capture, creation, retention, and application”. Moreover, suggested by Chesbrough (2003) companies can and should use external as well as internal ideas to advance their technology, and integrate external sources into a company’s innovation process to increase possible sources of innovation (Mu, Peng & Love, 2008).

Making sense of changing environments produces more insight when it takes place through sharing extremely divergent knowledge and competencies. In today's world, the knowledge creation as a function distinct from knowledge use is no longer sufficient. Furthermore, knowledge is context specific (Kurtz and Snowden, 2003), dependent on a particular time and space. In this instance, space refers not only to physical place; it also means virtual space (technology) and mental space (shared ideas). Without being put into context, data is just information, not knowledge. Information becomes knowledge when it is interpreted by individuals and given a context and anchored in the beliefs and commitments of individuals (Nonaka et al., 2000).

Thus, the primary goal of this study is to find how knowledge sharing for the collaborative organizations in the co-operation between health care professionals and sport counsellors can be supported by complexity leadership theory. In addition, the characteristics of CLT and its leadership roles (adaptive, enabling and administrative) and its applicable to practice are studied.

2 Complexity leadership theory

Despite the fact that complexity leadership theories are fairly young, the field of complexity science is not new (Panzar, 2009; Avolio et al., 2009). It has been argued that the possibilities of complexity science are not sufficiently acknowledged in the management or organisational sciences – that complexity thinking has been adopted only at the theoretical level. (Demers, 2007; Brown 2011)

The complexity perspective is a relatively new arrival to the field of leadership studies. (Panzar, 2009; Avolio et al., 2009). Yet over the past decade, a group of researchers have focused on reframing and advancing this field through the application of complexity science and approached it from a variety of directions (Panzar, 2009): dissipative processes management (McIntosh and McLean, 1999), generative leadership (Goldstein, Hazy, and Lichtenstein, 2010; Hazy, Goldstein, and Lichtenstein, 2007; Surie and Hazy, 2006), leadership as meta-capability (Hazy, 2005; 2007), adaptive leadership (Lichtenstein et al., 2006), complex responsive processes (Stacey, Griffin and Shaw, 2000; Stacey, 2003) and complexity leadership theory (Marion & Uhl-Bien, 2001; Uhl-Bien et al., 2007; Hyypiä, 2013).

“Complexity Leadership Theory is about setting up organizations to enable adaptive responses to challenges through network-based problem solving. It offers a tool for

knowledge-producing organizations and subsystems dealing with rapidly changing, complex problems. It also is useful for systems dealing with less complex problems but for whom creativity is desired? (Uhl-Bien et al., 2007, 304).

In the current knowledge era, leadership should be framed as a complex interactive dynamic from which adaptive outputs, for instance innovation and learning, emerge. This conceptual framework includes three key leadership functions: adaptive, administrative, and enabling, the last of which reflects a dynamic relationship between the bureaucratic, administrative functions of the organisation and the emergent, informal dynamics of complex adaptive systems. (Marion & Uhl-Bien, 2001; Uhl-bien and Marion, 2008; Uhl-Bien et al. 2007; Rotmans and Loorbach, 2009; Hyypiä, 2013)

The theory of complex adaptive systems (CAS) is a cornerstone of complexity leadership science. CAS is a key element of analysis in both complexity science and complexity leadership theory (Brown, 2011). It aims to explain the functioning of systems characterised by open, evolutionary aggregates (Kauffman, 1993), neural-like networks (Bak, 1996), interactions, and interdependent agents who are cooperatively tied together and share a common goal, purpose or outlook. (Cilliers, 1998; Marion, 1999; Uhl-Bien et al., 2007). Arising naturally in social systems, a CAS is able to learn and adapt rapidly as well as solve problems in a creative manner. In components of CAS, events and ideas collide with each other in an unpredictable way, with change emerging from this reasonably organic, dynamic interactive process (Uhl-Bien et al., 2007; Carley and Hill, 2001; Goodwin, 1994; Levy, 1992). Complexity theorists, such as Stacey (1995), Levinthal (1997), Uhl-Bien et al. (2007) and Kurtz and Snowden (2003), essentially frame organisations as complex adaptive systems that are composed of heterogeneous agents interacting and affecting each other, thereby generating novel behaviour for the whole system (Marion & Uhl-Bien, 2001).

As proposed by Uhl-Bien et al. (2007) and Kurtz and Snowden (2003), among others, it is more beneficial for the development of organisational development processes or change in general that an organisation increase its complexity to match that of its environment (Holland, 1995), rather than trying to simplify its initial structures. Yet CAS is not a valid theory for explaining human behaviour and organisations, as it assumes agents (humans) are similar and systems are deterministic. Humans may always think differently about things or change their minds (Stacey, 2003; Hyypiä, 2013).

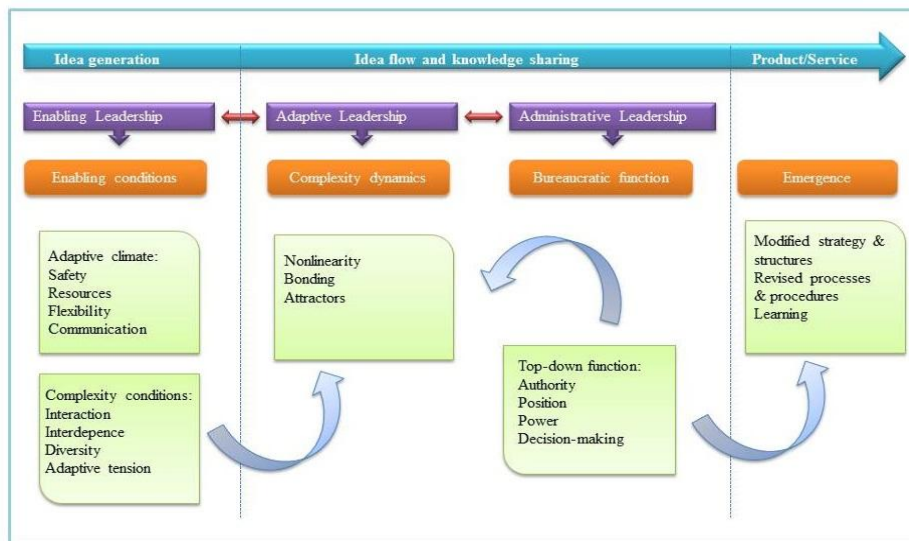

Figure 1. Complexity leadership theory and the key elements of the development process (Marion, 2010)

In the CLT framework, enabling leadership enhances effective complex dynamics by fostering and manoeuvring the mechanisms and contexts that catalyse adaptive leadership, as well as allow for the appearance of adaptive behaviour. In reality, however, enabling leadership can be found anywhere, because it manages the intertwining of administrative leadership (formal managerial systems) and adaptive leadership (organisational conditions). In addition, enabling leadership is able to foster complex networks through interaction, interdependency and adding adaptive tension (Prigogine, 1997), aimed at motivating and coordinating interactive, complex dynamics. (Uhl-Bien et al., 2007; Plowman et al., 2007).

Adaptive leadership is clarified within the framework of CLT as an emergent, interactive dynamic producing an adaptive outcome in a social system (Uhl-Bien et al., 2007). Adaptation is a dynamic process of shared influence (Goldstein, 2008). All creatures act on their environments, and their environments, in turn, act on them. Adaptive leadership describes an active form of leadership, not a passive effort taken purely to adjust to circumstances as found. Biology teaches us that relationships between living entities are circular and interactive (Kauffman, 1993). Organisations are also living systems, being composed not just of capital goods and technology, but of people. Organisations are capable of intelligent, purposeful collective action, actions taken to

influence their environments in desired directions. Like all living organisms, organisations are able to learn, adapt and grow. (Uhl-Bien et al., 2007; Rotmans & Loorbach, 2009; Hyypiä, 2013)

3 Research design

3.1 The methodology

In order to explore how knowledge sharing in the co-operation between health care professionals and sport counsellors can be supported by complexity leadership theory, case study approach was applied. This study uses case study as research strategy. As a research strategy, case study is used in many situations to contribute to our knowledge of individual, group, organizational, social and related phenomena (Stake, 2005; Yin, 2009; Erikson and Koistinen, 2005). However, case study is only one strategy among several others of doing research. Others include, for example, experiments, surveys and historical research. In this study the type of research question, the fact that the investigators have only little control over actual events and the focus of the study as a contemporary phenomenon favoured the decision to use case study as a research strategy. According to Yin (2009), a case study is an empirical inquiry that investigates a contemporary phenomenon in depth and within its real-life context, especially when the boundaries between the phenomenon and the context are not clearly evident. A case study strategy is also preferred when the researcher seeks answers to how and why questions.

Case study is also known as a triangulated research strategy, which means using different types of material, theories, methods and investigators in the same study. The present study utilises the triangulation of data and investigators in order to understand the complex phenomenon and to increase the quality of the study. The case study is also suitable for this study as complexity leadership theory as a concept have been studied only little and the purpose is to add understanding of the selected case.

Particularly the two development sessions, were planned in close co-operation with university, health care professionals and experts of sports. The results are analysed in co-operation with other researchers and the results are reviewed by the case organisation and experts.

3.2 The empirical context

The need for health enhancing sports activities has increased dramatically in the past decade. A resident who does not get enough exercise for his/her health, who is overweight and who is in poor physical condition is at a higher risk of falling ill and thereby creating social welfare and health care expenditure for the local authority. Physical activity is fundamental in improving people's physical and mental health. It reduces risks of many diseases. Thus, different kinds of developments both in public and private sector are needed to encourage physical activity (Parjanen & Hyypiä, 2014).

The case builds on the on-going MOTION! project which aims to develop the exercise and well-being industry, and create new collaboration models for co-operation between the private, public and third sectors. The project's key measures are creating the exercise clinic service platform and piloting it together with the public, private and third sectors, ensuring the quality of services provided by the exercise industry in the health and exercise service chain, developing well-being entrepreneurship by using cluster operational models, developing new business models for the well-being industry through innovation and strengthening collaboration between sectors through networks.

Physical activity referral schemes aim to identify inactive adults in the primary care setting. The primary care professional refers the patient to a third party service, with this service taking responsibility for prescribing and monitoring an exercise program tailored to the needs of the client. To enhance physical activity counselling and referral process the MOTION!-project is establishing an online physical activity pharmacy. Physical activity pharmacy platform will provide a toolbox to support physical activity counselling and referral. It will also offer private sector companies an opportunity to offer their services at all levels of the health and exercise service chain and to find new service and product concepts (Parjanen & Hyypiä, 2014).

3.3 The data

The empirical data of this study consists of two development sessions for nurses and physiotherapists and a survey.

The purpose of the survey was to increase understanding of the current situation as well as the required development areas in the public sector physical activity promotion. The survey was conducted in the beginning of 2013 via Webropol; online survey and analysis software. The surveys included questions like what kind of abilities there are

related to sports counselling at your health centre, what kind of experiences you have about sport counselling processes, what kind of experiences you have about sport counselling with customers, is there need for further training or education about the issue and what issues should be taken into consideration in developing sport counselling processes.

The open and multiple choice questions for the survey were formulated in co-operation with a researcher, a representative from the case organisation and with the external sport counsellor. The online questionnaire consisted of multiple choice questions using a rating scale from 1 to 5 (strongly agree, agree, neutral, disagree and strongly disagree), adapted from the Likert scale. The survey questionnaire was sent to 127 representatives of employees in primary health care organisations in different municipality by email and its response rate was 30,7. The respondents of the survey were doctors, nurses, public health nurses, physiotherapists, practical nurses and memory nurses.

The analysis of the data was focused on complexity, co-operation, knowledge sharing and areas for beneficial improvements in physical activity counselling. The inquiry of the data was based on the content analysis, for example, evaluating appearance of mutual themes, adversarial feedback, experiences and suggestions for improvements. Additionally, differences and similarities between open and multiple choice questions were evaluated.

In 2012, two similar sessions for nurses and physiotherapists were organised and the amount of participants was altogether 16. The sessions consisted of tasks related to, for example, the role of health promotion counselling and physical activity referral, how to motivate inactive people, what kind of tools as well as practises are needed to facilitate sport counselling processes. Session methods were pair and group working as well as general discussions.

During the sessions the role of the researcher was to observe. The data analysis from the sessions is focused on listing opportunities and threats in physical activity counselling based on the written material and notes from the sessions. In addition, data from the survey and sessions was compared in order to find differences and similarities between the gathered data. It should be noticed that data were not only gathered for the purpose of this study. Instead, the data were collected for both development and research purposes.

4 Findings

4.1 Knowledge sharing

In general, the results of this study indicate that co-operation between different organisations and professionals are considered significant, and health promotion counselling and physical activity referral are beneficial tools in order to enhance people's physical and mental health. On the other hand, respondents pointed out that many opportunities for the public sector physical activity promotion are yet to be recognised. Based on the results of the study, it should be noticed that different organisations and professionals were in different phases of the development processes.

In order to enhance explicit knowledge sharing about developing sport counselling processes among health care professionals and sport counsellors, tacit knowledge and experience based information is required. The results of this study highlighted the fact that interaction and communication channels are crucial in co-operation between different sectors. Aiming towards collective interaction from diverse viewpoints, proper arenas for encounters are essential. These co-created arenas are able to support knowledge creation and sharing but also these would be useful on diminishing social distance between professionals in public, private and third sectors.

4.2 Co-operation

In the public sector physical activity promotion was considered as a collaboration of many experts from different fields of operation. The co-operation is done between health care professionals and sport counsellors from sport departments or third sector organisations. However, according to the questionnaire every fourth health care professional did not take a stand whether s/he cooperates with sport counsellor. Also in the workshops there was a clear wish that co-operation between sport counselling and physiotherapy should be tighten. One respondent said that "co-operation between sports counsellors and health care professionals is one of the most important issues" in successful physical activity counselling.

On the contrary, it could be pondered about the opportunities and tools that employees are available to in practical co-operating between different sectors. Additionally, it should be recognised how these accessible tools and practices meet the needs of public sector physical activity promotion.

Table 1. Perceptions of the practical co-operation among different sectors

In this sense, development processes should be focused on enhancing users' experiences and communication possibilities between developer and customers, i.e. inactive people, via participatory methods. Surprisingly, however, the data of this study revealed no significant importance for taking customer along in co-creating health promotion counselling and physical activity referral.

One respondent stated that "We need more co-operation! No more meetings or bureaucracy in improving health promotion counselling and physical activity referral.. instead, developing practices in the way that we are able to share information and knowledge via phone and web-based tools."

4.3 Complexity and development challenges

In this study several challenges are identified that may hinder the development potential. Some of these challenges were found inside the organisation related to, for example, how employees interact with each others. There were also challenges between different organisations related to differences in expertise, misunderstandings and lacking knowledge sharing practices. In practice, drawing the lines between the different challenges may be very difficult, but identifying and discussing them is useful both in theoretical and practical sense.

68 % of respondents perceived that customers are now aware enough of the public sector physical activity promotion. For example, have of the respondents felt that health promotion counselling and physical activity referral requires novel tools, particularly

virtual ones. In addition, results of the study reflected that customers may perceive the public sector physical activity promotion rather uneasy as they are unfamiliar with the concept. Though, according to the survey in general, talking about health and exercise with customers was considered easy. But based on the results of the open question from the survey as well as data from different sessions, talking about the physical activity promotion was perceived rather challenging.

In daily practices, the public sector physical activity promotion competes with the counselling of diets and rehabs as one of the respondent stated “.. sometimes I feel that time is running out before I would have an opportunity to suggest health promotion counselling and physical activity referral”.

4.4 Complexity Leadership theory

The development of health enhancing sports is situated, context-specific and takes place in very practical environments like in primary care organisations, private companies or third sector organisations.

Administrative leadership i.e. condition that plans and coordinates bureaucratic functions in an organisation was reflected in the research data. For example, there were also lacks of knowledge how to bring up physical activity with the client or how to discuss about the need of physical activity promotion inside the organisation. For example, many health care professionals considered that they would like to have more conversation about the role of physical activity counselling and referral in health promotion. This was considered as a responsibility of the management. One respondent explained that organisation “should give a clear presentation about why physical activity counselling is important in the organisation and how it should be given”. It was also considered important to increase the knowledge of local councillors about the effects of health enhancing sport as a preventive method. In real-life context, however, complex processes are multi-layered and several actions and behaviours are happening simultaneously.

In order to enhance interaction and communication between health care professionals and sport counsellors from sport departments or third sector organisations, encounters via development sessions was required. The idea was to bring together a group of diverse people i.e. the participants of the different sector and facilitate them to develop the practices in which they interact in their daily work life. By enabling forums to tackle

different perspectives and experiences together, directors and managers were able to use their leadership as a process and let participants solve problems creatively together without top-down emphasis on it. Furthermore, encouraging employees to share ideas and suggestions to improve existing organisational systems indicates *enabling leadership* behaviour.

In this study, development sessions, as an arena, can be reflected as a main condition for *adaptive leadership*, since the basic idea was to improve knowledge sharing through co-operation between different sectors with dynamic interaction. In other words, participants do not represent formal organisational and professional roles during idea generation. In addition, meetings with the case organisation were handled successfully by the case organisation and experts analysing results and development processes in co-creative manner and planning action steps on how to proceed in the future jointly.

Conversely, many respondents found that there are many things that should be developed further between social and health care sector and sport department. For example, many considered that responsibilities and duties are unclear. Also the sport counsellors felt that the health care professionals do not know enough about their expertise.

Table 2. Perceptions of the defined roles and responsibilities in co-operative organisations

All development processes involves resistance to some extent. It could be very interesting focus on future development conditions based on the attitudes of employees and co-operation partners that especially seem to view development in the physical activity promotion most negatively. The focus of development processes or change

evolves to match of its environment and therefore, critical viewpoints are able to provide valuable information what kind of resistance might be come across.

5 Discussion and implications

Aim of this study is to explore how knowledge sharing for the collaborative organizations in the co-operation between health care professionals and sport counsellors can be supported by complexity leadership theory (CLT) and how the CLT and its leadership roles (adaptive, enabling and administrative) can be recognized as well as applied to practice.

Complexity leadership theory (CLT) is the study of the generation and emergence of complex dynamics within an organisation. It explores the nature of interaction and adaptation in complex interacting systems and the influence of such things as emergence, innovation and suitability. Due to this, this study is focused more on complex dynamics – i.e. multiple interactions, nonlinearities and non-deterministic behaviour – than on exploring complex adaptive systems as such in development processes.

The results of this study indicate that social characters of interaction, for example, reliability and expertise of colleagues, collectivity and mutual goals, have significance influence. In this sense, formal and informal gatherings are crucial such as coffee breaks or teambuilding days. Modifying the shared and common goals and ability to identify roles and responsibilities together, communication between diverse viewpoints and sectors are essential. Through knowledge sharing an increased understanding of the complexity and hindered challenges in organisation and its environment can be better achieved.

According to Snowden (2005), in the complex context, diverse methods have the opportunity to reduce costs and foster rapid responses in organisations. To achieve emergence or innovations in the activities of organisations and various forms of co-operation, enabling and supporting continuous interaction and integrated knowledge flows is of crucial importance. Furthermore, according to Bessant & Tidd (2007), complex interaction is all about knowledge and the ways it flows and is linked and exploited to make emergence and development happen. On the other hand, interaction and knowledge co-creation among diverse individuals requires patience and time for reflection (Snowden & Boone, 2007).

Recognition of diverse environments, their various contexts and roles in the activities of and collaboration between organisations and their interest groups is ever-more important to achieving better interaction in which strategic or formal statuses or structures may be bypassed. In the development process, it is not necessarily the leader who is in possession of essential knowledge; thus, it is the role of leadership to offer methods and arenas where different actors may generate advances.

External knowledge and ideas can only be recognised; accessed and assimilated when organisations develop new practices and change their organisational structure to facilitate development processes. According to the evaluation workshop in prime care organisation “the cross-sectoral work has increased in the organisation”. This has been possible, because the focus of development has been defined, the own role in co-operation has been clarified and understanding of the need for co-operation throughout the case organisation. It was also seen that the cross-sectoral collaboration has “changed the organisational culture”

6 Conclusions

Reframing and advancing leadership is always a topical theme. The complexity leadership theory is a relatively new view in the field of leadership theory but it has generated an important perspective that facilitates the understanding of complex organizational behaviour. In addition, bringing a complexity perspective to the study of leadership reveals dynamics and forces present within and across organizations that no other approach to leadership offers (Brown, 2011). Global challenges, complexity and continuous uncertainty demand development of leadership approaches, employees and multi-organization co-operation. Current leadership theories do not sufficiently address the needs of complex business environments, particularly in the co-operation between health care professionals and sport counsellors. First of all, before successful leadership models can be applied in practice, leadership needs to shift from the industrial age to the knowledge era. Many leadership models still view leadership solely through the perspective of linear process thinking. In addition, there is not enough knowledge or experience in applying this conceptual framework in practice, particularly in the co-operation between health care professionals and sport counsellors.

The results of this study suggest that the complexity leadership theory represent applicable model to advancing sustainable knowledge sharing for the collaborative

organizations. An implementable method for organizations may be assembled by assimilating different roles of complexity leadership into development practices featuring diverse activities and interaction channels. As MOTION! project wise, Physical activity pharmacy online platform was co-created. This is a good example of co-operation public, private and third sectors enhancing knowledge flows and co-creating value creation processes in offering private sector companies an opportunity to offer their services at all levels of the health and exercise service chain and to find new service and product concepts.

The CLT was chosen for this study because it approaches leadership as being embedded in a complex interplay of numerous interacting forces. It is not just about the influential acts of an individual, the leader. (Uhl-bien et al., 2007; Avolio et al., 2009) However, it is important to acknowledge that not all leadership activities entail a complexity leadership approach. (Snowden & Boone, 2007; Brown, 2011) As a matter fact, in some contexts, such an approach is unnecessarily multi-faceted and not useful when traditional managerial and leadership practices are sufficient. (Snowden & Boone, 2007; Uhl-Bien et al., 2007; Brown, 2011; Bass & Bass, 2008; Bass & Riggio, 2006)

The results of this study are subject to some limitations. The research was conducted in Finland. It might prove fruitful to investigate a wider range of industries and include case studies from abroad in future research. In addition, comparisons between different industries and nationalities could provide additional perspectives for leadership, development processes and complexity studies.

The main contribution of this study relates to applying the rather conceptual model in practice. Empirical evidence on the relevance of different leadership roles in development processes in public, private and third sector is another valuable contribution. Finally, the study sheds light on the significance of combining complexity science with leadership and emergence theories in research.

Structured Abstract

Purpose - The paper presents a thematic conceptualization of a Regional Entrepreneurial Learning Center, conceived as a catalyst of the knowledge-intensive entrepreneurship in the regions and a strategic asset for their growth in the scenario of the entrepreneurial economy (Thurik, 2008; Audresch and Thurik, 2001). Incardinated on the Knowledge Triangle and aimed to enhance, primarily, the social and economic valorization of the Key Enabling Technologies, the Center will promote the synergic integration between the universities, primary actors in the process of the knowledge creation, the companies, that allow the socio-economic valorization of the knowledge available through the innovation and entrepreneurial processes, and the governmental institutions, supporting their knowledge exchanges and knowledge valorization processes. Coherently with the emerging nature of the knowledge-intensive entrepreneurship as entrepreneurial learning process and inspired by the current debate on the innovation ecosystems, the Center will promote the development of continuous and dynamic entrepreneurial learning processes to create a young knowledge intensive entrepreneurs, the evolution of the Universities towards an entrepreneurial configuration, and to accelerate the diffusion of entrepreneurial behaviors and culture in all the regional organizations and institutions.

Design/methodology/approach - The study is based on a constructive and qualitative review of the academic and policy-based existent literature on the issues related to the meaning and dynamics characterizing the knowledge economy as entrepreneurial economy, the knowledge-intensive entrepreneurship as technology-driven entrepreneurship, the entrepreneurial learning processes as main dimension of the entrepreneurship in the knowledge scenario. The theoretical background previously recalled addresses the conceptualization of the Regional Entrepreneurial Learning Center proposed by providing useful insights for determining its mission, processes, and strategies as well as to comprehend its meaning as booster of knowledge-intensive entrepreneurship and source comparative advantage in the regions.

Originality/value - The paper presents elements of originality under different perspectives. In particular, a first valuable element springs from its contribution to the current debate on the knowledge intensive entrepreneurship as core process for the social and economic growth of the regions starting from the valorization of the knowledge and the Key Enabling Technologies. The focus on the dynamic perspective of the entrepreneurial learning process is a further valuable contribution at the scientific debate on the comprehension of the meaning and instances of the behavioral implications on the entrepreneurship and its implications on the effectiveness of the process of knowledge creation, absorption and diffusion in innovation ecosystems.

Practical implications - The practical implications provided by the paper are identifiable into the main areas in which the Center will focus on. In operating as catalyst for the diffusion of knowledge intensive entrepreneurship in the regions, the Center will impact on the growth of the knowledge intensive entrepreneurship in the young people, and the diffusion of entrepreneurial culture and behaviors within the organizations, institutions and Universities. Such practical implications result coherent with the objectives of the European Agenda for the Smart Specialization and the several initiatives launched for overcoming the European Paradox of low innovation capability.

Keywords – Knowledge-intensive Entrepreneurship, Entrepreneurial Learning Process, Innovation Ecosystem, Intelligent Growth

Paper type – Academic Research Paper

Introduction

The paper aims to present the conceptual model of a Regional Entrepreneurial Learning Center as strategic mean for the diffusion of knowledge intensive entrepreneurship and driver for the social and economic valorization of the Key Enabling Technologies (KETs).

Starting from the interpretation of the knowledge economy as entrepreneurial economy, through the “structuralist-evolutionary model”, based on the Schumpeterian research streams (Arthur, 2009, 1999; Lypsey, et al., 1998; Schumpeter, 1934), and the comprehension of the main shifts characterizing the transition from the managed to the entrepreneurial economy (Audretsch and Thurik, 2001), the paper focuses on the knowledge-intensive entrepreneurship as driver for the growth of individuals, organizations and regions.

The knowledge-intensive entrepreneurship arises in the study as a not linear process and a radical foundation of the entrepreneurial process as entrepreneurial learning process (Minniti and Bygrave, 2001) is so implied by its knowledge-intensive and technology driven nature.

Framed in the above premises, the Regional Entrepreneurial Learning Center is presented as source of comparative advantage in the regions and expression of a knowledge-intensive regional partnership composed by the knowledge producers (universities), knowledge users (companies) and institutions, and giving priority to both the anticipatory and action learning strategies.

The conceptual model of the Center, discussed in the paper in terms of mission, processes, expected results, is described as booster for the activation of entrepreneurial learning processes aimed to create a mass of young knowledge intensive entrepreneurs, to accelerate the evolution of Universities towards an entrepreneurial configuration, to diffuse entrepreneurial behaviors in the regional organizations and institutions.

In coherence with the objectives of the European Agenda for Smart Specialization and the several initiatives launched for reinforcing the innovation capacities of the European Regions, the meaning of the Center as source of comparative advantage is, so, debated in the paper with its several practical implications.

The paper is structured as follows: the first paragraph is devoted to the analysis of the current social and economic scenario of the knowledge economy interpreted as entrepreneurial economy, and to the identification of the knowledge intensive entrepreneurship as one of the most relevant structural changes implied by the large diffusion of the KETs. In the second paragraph, the comprehension of the meaning of knowledge-intensive entrepreneurship is afforded through the comparison between the traditional entrepreneurship and the knowledge-intensive one, in terms of market-driven and technology-driven entrepreneurship, linear and not linear entrepreneurial ideation processes, till to derive the importance of an entrepreneurial learning theory. In the third paragraph, the conceptual model of the Regional Entrepreneurial Learning Center is detailed in terms of mission, goals, processes and strategies, with the aim to deepen its main distinguishable features and the areas of actions. In the last paragraph, the meaning of Center as source of regional comparative advantage is debated, in order to derive implications for the agenda of scientists and policy makers.

1. The knowledge intensive economy as entrepreneurial economy

In the XXI century, the social and economic systems are interested by several structural changes due at the impact of technological knowledge.

According to the “structuralist-evolutionary model”, based on the Schumpeterian research streams (Arthur, 2009, 1999; Lypsey, et al., 1998; Schumpeter, 1934), the economy can be conceived as an expression of the General Purpose Technologies or Key Enabling Technologies (KETs). This means that economy changes constantly over time as far as the technologies evolve, and arises ultimately out of the phenomena that create technology. The process of technology evolution impacts and transforms “the economic structure from within, incessantly destroying the old one, incessantly creating a new one” (Arthur, 2009; Schumpeter, 1934).

Actually KETs, identified into Micro-nano electronics, Nanotechnology, Advanced Materials, Photonics, Industrial Biotechnologies and Advanced Manufacturing Technologies, are the main forces behind the structural changes. These technologies are knowledge intensive, and are determining rapid innovation cycles and highly skilled employment demand. They enable innovation in goods, services and processes. KETs feed into many different industrial value chains and sectors, in heterogeneous ways. They are multidisciplinary, with a trend towards convergence and integration. Due to their transversal nature, KETs catalyze the strengthening and modernizing of the industrial base, as well as drive the development of entirely new knowledge intensive industries.

KETs are determining structural changes in all the components of the economic system: physical capital, human capital, organization of production facilities, labor practices, managerial and financial organization of firms, geographical allocation of industries, industrial concentration, infrastructures, private-sectors financial institutions and financial instruments (Lipsey, et al. 1998). The level and the scale of these changes, which differ greatly from one technology to another, can produce some evolutionary effects. The main can be identified into the renewing of traditional sectors, through higher value added activities and new market niches; differentiating technologically from existing specialization into related fields; starting new economic activities, through radical technological changes and breakthrough innovations; and taking advantage of new forms of innovation, such as open and user-centric innovation, social innovation and service innovation.

The knowledge intensive nature of the aforementioned enabling technologies, as causes of the structural changes, are characterizing the economy as a knowledge intensive economy.

A large variety of recent studies and researches has contributed at the comprehension of the main features characterizing the knowledge intensive economy. In particular, two different types of economy's models have been proposed: the model based on the intensive use of the material resources, natural and not renewable, and so characterized by the law of decreasing returns, and the model of the knowledge intensive economy, where knowledge represents the strategic asset for the production and competitiveness, as a renewable and an appropriable resource based on the law of the increasing returns.

The first model, predominant in the XX century, has been codified as managed economy, while the second, more representative of the current scenario, as entrepreneurial economy (Audretsch and Thurik, 2001).

The analysis of Audretsch and Thurik (2001) has identified a set of tradeoffs between managerial and entrepreneurial economies.

In the managerial economy, the dominant factors of production are labor and capital; in the entrepreneurial economy, the determining factor of production is knowledge, not only in terms of technical and scientific software, but also as an input that includes aspects such as creativity, skills to communicate, emotional intelligence. Indeed, in the entrepreneurial economy, the competitive advantage is driven by innovative activity, and knowledge spillovers are an important source of this activity.

The managerial economy is mainly focused on continuity, i.e. on incremental innovation, compatible with existing core competencies and technological trajectories of the firm or the industry. The entrepreneurial economy of the twenty-first century is, instead, focused on radical innovation, standing beyond the boundaries of the core competence and the technological trajectory of the firm or the industry.

In the managerial economy, unemployment can be reduced only at the cost of lower salaries. In the entrepreneurial economy, high employment can be combined with high wages, while a low wage does not necessarily imply high employment. Small firms in general, and new ventures in particular, are the engine not only of employment but also of productivity.

In the managerial economy, the external environment is characterized by stability, homogeneity and specialization. Turbulence, diversity and heterogeneity, instead, typify the external environment of the entrepreneurial economy.

In the managerial economy, firms are based on controls and transactions, competition is alternative to cooperation, economies of scale have a strategic role. In the

entrepreneurial economy firms are based on motivation, market exchanges, flexibility. Competition and cooperation are complementary.

In the managerial economy, public policy has an essentially constraining nature (antitrust policy, regulation and public ownership, concerns about excess profits and abuses in terms of market dominance). In the entrepreneurial economy, governmental policy aims at creating an environment suitable for supporting the success and sustainability of firms. The appropriate policy has to be the facilitator of international competitiveness, growth and employment, by creating links and networks, proposing incentives to firms and knowledge institutes, stimulating special and functional flexibility of labor, creating forms of social innovation.

The model of the managed economy revolves around the links between stability, specialization, homogeneity, scale, certainty and predictability on the one hand, and economic growth on the other. By contrast, the model of entrepreneurial economy focuses on the links between flexibility, turbulence, diversity, novelty, innovation, linkages and clustering on the hand and economic growth on the other (Thurik, 2008).

In synthesis, the entrepreneurial economy as knowledge intensive economy results to be driven by the innovation; the human capital represents, so, the strategic asset for its competitive growth in reason of the contribution of significant importance that it can provided to the processes of knowledge creation, diffusion and absorption.

A wide large spectrum of the working force competencies is involved into the valorization of the innovation. Such competencies are not limited to scientific and technological activities but interest also laboratories for producing, commercializing, marketing and managing human, financial and organizational resources.

The linkages between innovation and competencies of the human capital arises so as a necessary condition for the success in the entrepreneurial economy, this because the human capital with its competencies fosters innovation, by generating, through the research, new knowledge that is finalized towards radical innovation; adopting or adapting existing ideas and technologies and by this facilitating the processes of incremental innovation; reinforcing the social capital and the innovation networks; and diffusing the knowledge within the organizations and enhancing a process of knowledge absorption within the components of the human resources into the organizations (Romano, 2013).

A radical innovative profile of human capital is represented by the knowledge-intensive entrepreneur, or innovation driven entrepreneur, or technology driven entrepreneur. Because this entrepreneur is considered the driver, in the scenario of the knowledge economy, the study aims to comprehend how is it possible to create this strategic asset and which are the main processes to execute in order to achieve such goal. To answer at this question, it results, preliminarily, important to characterize the nature of the knowledge-intensive entrepreneurship and mainly of the processes that concurrent to create it. The paragraph that follows is devoted to exploit this question.

2. Characterizing and Creating Knowledge-intensive Entrepreneurship

It is important for the goal of this study to comprehend which are the elements characterizing the knowledge-intensive entrepreneur, considered as the driver of the competitive growth in the knowledge-intensive economy and mainly which are the processes concurrent to creating knowledge intensive entrepreneurship.

Recent studies and empirical researches highlighted and identified two different types of entrepreneurs: the entrepreneur who identifies a market need and explore a technology with which to exploit it (market-driven entrepreneur); and the entrepreneur who first identifies a technology and then explore a market need toward which it can be exploited (technology-driven entrepreneur). As Newbert et al. (2007) argued, the first operates to match a known demand with new technologies, the second, instead, an unknown demand with unknown technologies.

Market-driven entrepreneurs begin their entrepreneurial processes with the discovery of a market's necessity and then search for a mean to satisfy it. Technology-based entrepreneurs, instead, typically consider the identification of a market necessity as a secondary element in front of the technology development, and think about the commercialization only after the new science has been developed (Newbert et al., 2007).

In market-driven entrepreneurship, the entrepreneur identifies a market need and then explores a technology by which to satisfy it; in technology-driven entrepreneurship entrepreneur first identifies a technology and then explores a market need to be satisfied.

Technology driven entrepreneurs utilize complex and sophisticated social networks as sources of ideas, as well as to test, refine and validate trial ideas, exhibiting an

extraordinary domain specificity that allows him to filter ideas outside specific markets and technologies (Gemmell, et al., 2011).

The emergence of a new type of entrepreneurship, in the scenario of the knowledge-intensive economy, is confirmed by a recent study of Aulet and Murray (2013), published by the Kauffman Foundation. The study provides a comparison between the features characterizing the traditional SMEs with that one of the Innovation driven entrepreneurship.

The innovation-driven entrepreneurship is addressed towards global markets, even if at the beginning it can be limited to regional or niche segments of demand. It is the focus on innovation, intended as technology, product, process, or business model, to guarantee the strategy of expansion at global level and the success of the entry strategy in a new market.

Focusing on the profiles of the human capital enabling an innovation-driven entrepreneurial process, the study argues as they have generally higher level of education, and as usually innovation-driven start-ups are conceived and leaded by PhDs in technological and scientific fields.

The study provides, also, a deepen comparison between the two different typologies of entrepreneurship, as it is synthetized in the following table:

Table 1. Adapted from the Aulet. B., and Murray, F., (2013) “A Tale of Two Entrepreneurs: understanding differences in the types of Entrepreneurship in the Economy” – Kauffman Foundation.

	<i>Traditional SME Entrepreneurship</i>	<i>Innovation-driven Entrepreneurship</i>
Market	Local or regional	Global
Innovation	Not necessary	Fundamental
Type of Job	Non-tradable jobs	Tradable Jobs
Ownership	Familiar and little external capital	Distributed ownership and large external capital
Rate of growth	Linear	Exponential

In providing a clear identikit of the innovation-driven entrepreneur, the study highlights some implications for the governments to support the growth of such type of entrepreneurship, and that are called firstly to assume with entrepreneurial behaviors. The focus of the governments, in promoting and accompanying the arising of innovation driven entrepreneurship is suggested in the study also for the fundamental contribution it

can provide in the creation of new employment opportunities as well as for the socio-economic value it can create in the regions.

In this paper, the figure of entrepreneur emerging in the current social and economic scenario is, so, interpreted as knowledge-intensive entrepreneur, because the focus on the KETs, that are transforming the economic systems, have a knowledge-intensive nature.

Interpreting such entrepreneurship as driver for the growth in the knowledge intensive economy, the following research question arises: which are the processes enabling the generation of such knowledge intensive entrepreneurs?

The entrepreneurship disciplines don't currently possess sufficient conceptual frameworks to explain how an entrepreneur learns (Cope and Watts, 2000). For this reason, entrepreneurial learning has emerged as an important area of inquiry in relation to both the academic studies of entrepreneurship and the practical development of new entrepreneurs.

The literature of the entrepreneurial learning includes a variety of theoretical approaches focused on diverse aspects of the phenomenon; overall these approaches are divided into two main fields depending on their unit of analysis: those focusing on the figure of the entrepreneur and those focusing on the organizational context (Erdélyi, 2010). The first approaches are concerned with the personal learning experience and the cognitive capabilities of the "entrepreneurial individuals"; the latter on how entrepreneurship takes place as a collective activity and at various scales, from the single firm and its immediate network towards the national system of innovation. In brief, entrepreneurial learning is hidden considered as an individual activity or as a collective activity (Erdélyi, 2010).

The nature of our research question implies the identification of the entrepreneurial learning process as unit of analysis of our study, because learning is of increasing importance in knowledge intensive entrepreneurship, given the growing significance of science, technology, and innovation in new venture creation.

Indeed, knowledge-intensive entrepreneurship involves a learning process, an ability to cope with the problems and to learn from those problems; as a consequence the entrepreneurship is a process of learning and a theory of entrepreneurship requires a learning theory (Minniti and Bygrave, 2001).

Rae (2006) develops a conceptual framework for analyzing entrepreneurial learning for the emergent knowledge-intensive entrepreneurs. He highlights that there has been an

extensive writing on entrepreneurial education from which it can be concluded that while such education can provide cultural and personal support, knowledge and skills development about and for entrepreneurship, the “art of entrepreneurial practice” is learned better in the experiential based environments rather than in the educational environments. “This must lead to the exploration of learning as a situated and active experience rather than as a plurality of educational and theoretical processes”. In his triadic model about the entrepreneurial learning assumes relevance the contextual learning theme, which includes related experience and social relationship people learn intuitively and may develop the ability to recognize opportunities. “Contextual learning includes the development of skills, expert knowledge and social contacts from employment, experiences and know-how in industry. Much of the learning is functional, technical and problem solving funding up by discovering and experiential learning how things are done and established routines and practices that work in given situations. The influence of the contextual career experience on the entrepreneurial formation is often profound” (Rae, 2006).

Contextual learning has important implications for knowledge-intensive entrepreneurship because innovation, opportunities and entrepreneurial skills are developed through contextual learning and this cannot occur without participation.

And it is in this perspective, that the current debate on the innovation ecosystems, as differentiated, collaborative and knowledge-intensive set of actors, relationships, and institutions affecting the process of sustainable innovation of a region (Romano, et al., 2013; Asheim and Gertler, 2005) provides useful insights for comprehending the meaning of a collaborative process of learning, addressed in the paper.

According to the purposes of this paper, it is fundamental to identify which are the entrepreneurial ideation processes characterizing the contextual learning proposed by Rae (2006).

Recent empirical researches (Gemmell et al., 2011) highlight as the knowledge intensive entrepreneur presents the following characteristics: the usage of complex and sophisticated social networks to identify, test, refine and validate new ideas, the possess of an deepen knowledge of domain specify through the filter of ideas outside technologies and market, the experimentation and iteration of ideas rather than engagement in protracted conceptual analysis. Indeed, the authors identify the entrepreneurial ideation process as a not linear process articulated into 5 recursive phases, as in the figure 1:

Fig.1 A Not Linear Entrepreneurial Ideation Process
(adapted from Gemzell et al. 2011)

This process Entrepreneurial ideation process describes how a potential entrepreneurial team incubates ideas in response to problems before generating a trial idea and hypothesis. This entrepreneurial ideation process contrasts with the linear process characterizing the traditional incubators, as in Figure 2 .

Fig.2 A Linear Entrepreneurial Ideation Process
(adapted from Gemzell et al. 2011)

From the virtuous combination of the nature of the contextual learning and the features of the entrepreneurial ideation processes, previously described, arises the proposal of the Regional Entrepreneurial Learning Center as comparative advantage of the regions in the scenario of the knowledge-intensive economy.

3. The Regional Entrepreneurial Learning Center

In the previous paragraphs, we highlighted the meaning of the accelerated evolutionary process of the economic systems towards the scenario of the knowledge-intensive economy, interpreted as entrepreneurial economy. The driver for accelerating such evolutionary process has been identified in the knowledge-intensive entrepreneurship, or technology-driven entrepreneurship, or innovation-driven entrepreneurship.

More in general, such acceleration calls for a more diffused entrepreneurial mindset in the organizations, public and private, as well as in the institutions. This with the aim to

facilitate the processes of structural change in all the components of the socio-economic systems, coherently with the “structuralist-evolutionary” model, and in consideration of the nature of the KETs.

Within the structural changes, the genetic mutation of the entrepreneurship, driver of the economic growth, arises as one of the most significant one, together with the overcoming of the linear processes characterizing the traditional business incubators. Such mutation results in the archetype of the knowledge-intensive entrepreneurship.

The nature and the specifics of the knowledge-intensive entrepreneurship imply, as seen, the *radical foundation of the entrepreneurial process* represented by the transition *towards the entrepreneurial learning process*.

And it is in this perspective that the unit of analysis, in our study, is identified into the processes and conditions enabling the activation of knowledge-intensive entrepreneurship in the regions.

Due at the knowledge-intensive and technology-driven nature of the entrepreneurship, this is the reason why, in the economy of the XXI century, some authors argue that the theory of entrepreneurship is identifiable into a learning theory (Cope, 2005; Minniti and Bygrave, 2001).

In order to sustain the acceleration of the structural changes implied by the KETs, the paper proposes the strategic role of the Regional Entrepreneurial Learning Centers (RELC) focused on the activation of entrepreneurial learning processes to:

- create young knowledge intensive entrepreneurs, involved in the socio-economic exploitation of the KETs,
- accelerate the evolutionary path of the Universities towards a entrepreneurial university model, taking into account their strategic role in the competitive scenario of the knowledge intensive economy,
- diffuse entrepreneurial behaviors in all the regional organizations and institutions.

RELC, as expression of a regional innovation ecosystems emerging from the organic cooperation between knowledge producers (universities and research institutions), knowledge users (companies operating in the market), and other institutions (financial and public), is incardinated on the knowledge triangle: “technological knowledge, innovation, learning” (EIT, 2012).

RELC, conceived as contextual learning theme (Rae, 2006) or as learning organization, gives priority to both the *anticipatory learning strategy* and the *action learning strategy*.

As well known, the anticipatory learning is a generative or creative process, aimed to learn by various anticipated futures.

This means that, in coherence with the focus on the entrepreneurial learning processes related to the socio-economic exploitation of KETs, people in the RELC will be involved in an *interactive and collective learning*, aimed to:

- explore the evolution of enabling technologies combined to determine the specifics of goods and services (product technology), the processes to create them (process technology), the forms in which the processes can be organized (organizational technologies), the concurrent processes to explore market opportunities (marketing technologies);
- include, through the active involvement in interactive processes, the impact of enabling technologies on production systems, trading, consumption, labor market, on the profiles of the human capital, socio-institutional and environmental issues;
- infer, starting from the nature of the changes, the new paradigms that characterize the knowledge intensive economy and rules that differ with respect to the economy and society of the twentieth century but, more importantly, understand what are the dynamics that characterize the trajectories of specialization strategy of the EU.

The action learning strategy connotes the entrepreneurial processes, activated by RELC, as *experiential entrepreneurial learning processes*. This means that people involved in RELC will be engaged into the solution of concrete problems, projects, challenges, questions, with a growing social relevance.

In this way, the action learning strategy is built on the whole cycle of learning: learning and creating knowledge through concrete experience, by observing and reflecting on this experience, by creating formalization from this experience, by testing the implications of these generalizations, through new experience and starting the process from the beginning (Kolb, 1984).

Therefore, through the *action learning*, people involved will entry in contact with industries, universities and research institutions and other formal and informal networks through which individual experiences are related, compared and shared.

Through related experience and social relationship, people learn intuitively and may develop the ability to recognize opportunities and to understand how to transform such opportunities in socio-economic value.

The practice of the *action learning* strategy, by RELC, will offer to people involved to:

- acquire knowledge and competencies to connect knowledge with practical experience on issues relating to the dynamics of growth of regions to innovate and the rules that govern the knowledge economy;
- initiate, design and execute dynamic projects for the development of Entrepreneurship and Innovative smart specialization of territories;
- act as agents of change in the territorial systems imagining creative solutions to afford complex challenges of social and environmental considerations;
- combine the technological opportunities with the complex social and environmental challenges, perceiving the meaning of radical innovations.

In giving priority to both the anticipatory learning strategy and action learning strategy, the conceptual model of the Center as learning organization presents element of coherence with a plurality of initiatives have been recently launched, not only in US but also in other European Countries. Such initiatives arise, mainly, in the schools of engineering rather than in the business schools, considering the nature of the technology-driven entrepreneurship in the scenario of the knowledge-intensive economy.

4. RELC as source of regional comparative advantage: implications for the agenda of scientists and policy makers

The coherence of the RELC's conceptual model with a growing number of initiatives of entrepreneurial education at international level as well as its areas of interventions identified into the young knowledge intensive entrepreneurs, the entrepreneurial universities and the large diffused entrepreneurial culture allow to understand as RELC is characterized as strategic asset and source of comparative advantage of the regions, for their successful positioning in the knowledge-intensive economy.

This because, RELC aims to operate as facilitator of the overcoming of the European Paradox of the excellence in the scientific and technological research but low capabilities of innovation.

As well known, the regional economic performances are not just determinate by new knowledge creation, but also by the abilities and willingness of innovative entrepreneurs to develop new products, processes based on a technological knowledge (Audretsch, et al., 2008).

The knowledge-intensive entrepreneurs are so identified as central actors for transforming the new knowledge into socio-economic value for the regions.

Policies focusing only on the promotion of processes of knowledge generation are not sufficient to produce higher regional economic performances; policy makers have to work on processes aimed to create entrepreneurial capital for sustaining the exploitation of the knowledge created into new products and translating innovation from the laboratories into economic performances (Audretsch, et al., 2008).

As known, this mismatch between knowledge creation and knowledge exploitation, has been named European Paradox. In order to overcome this paradox, the UE has recently launched (EU COM 955688) the “Entrepreneurship 2020 Action Plan - Reigniting the Entrepreneurial Spirit in Europe”.

The Action Plan starts from the following stylized facts:

- Europe needs more entrepreneurs, in order to bring back sustainable growth and higher level of employment;
- Knowledge intensive entrepreneurship is identified as core process for the economic growth and job creation, in reason of its contribution to the creation of new companies and jobs, to the openness at new markets, the nurturing of new skills and capabilities.
- The new companies are fundamental for guaranteeing the level of employment that without the jobs from them will be negative.
- It is important to recognize or aware on the entrepreneurial endeavor. The culture of celebrating successful entrepreneurs as models to create jobs and incomes is still absent.
- Europe needs a cultural change to understand the strategic role of entrepreneurship as engine for the growth.

The Action Plan proposes interventions into the three main areas:

- Entrepreneurial education and training to support growth and business creation;
- Strengthening framework conditions for entrepreneurs by removing existing structural barriers and supporting them in crucial phases of the business lifecycle.
- Dynamiting the culture of entrepreneurship in Europe, nurturing the new generation of entrepreneurs.

A particular focus is reserved to the entrepreneurship as key competence to embed into all the curricula, at primary, secondary, vocational, higher and adult levels of education, before the end of 2015.

This complex emerging demand of change highlights the strategic role of RELC, conceived as booster of the intelligent growth and so as source of comparative advantage for the regional systems involved in the actuation of the Smart Specialization European Strategy. This because the main impacts of RELC on the regional systems are identified in terms of creation of a mass of young knowledge-intensive entrepreneurs, encouragement at the genetic mutation of the universities, as well as the genetic mutation of the incumbent enterprises towards assets and processes charactering the learning organizations.

The crucial role of the Universities in the knowledge-intensive economy and their involvement in the dynamic operations of the Center will provide positive feedbacks for accelerating the evolutionary path of the Universities towards an entrepreneurial configuration (Gibb. 2005).

At this purpose, Universities are, so, called to become more entrepreneurial, coherently with the framework developed by the UE with OECD. The framework helps interested universities to assess themselves and to improve their capabilities with tailor made learning modules.

The entrepreneurial behaviors of the Universities can be identified into their capability to:

- promote their connectivity with regional growth, fielding actions consistent with the processes and dynamics that characterize the sustainable knowledge society on a global scale;
- contribute to the development of human capital in the regions, attracting young talents and enhancing the mobility of researchers and students to industries and research centers, national and international;

- promote innovative entrepreneurship and the development of economic activity and growth, through the creation of enterprises by students and researchers and the development of learning networks with existing businesses, even on a global scale;
- promote the integration of principles of innovative Entrepreneurship in the curricula under-graduate, graduate and post-graduate;
- operate as agents of entrepreneurship by creating spin-outs with which to transform the results of research into innovation in the products and / or services;
- support regional innovation through research in collaboration with industry to facilitate the development of knowledge;
- reduce the various forms of social exclusion, through the provision of a program of “life-long learning” for cultural development and retraining.

The progressive growth of the number of knowledge-intensive entrepreneurs and the rapid evolution of the university system towards entrepreneurial model induced by RELC will contribute to diffuse the entrepreneurial culture in the regional societies and to increase the competitiveness of the regional economic systems.

Structured Abstract

Purpose – Effective knowledge management (KM) entails knowledge assessment capability to enable identification of knowledge assets and proper governance of value creation dynamics. Although some studies have attempted to use different methods to measure knowledge at the organisational level, few have addressed the individual knowledge holder. The purpose of this paper is to present a state-of-the-art framework, referred to as *MinK*, that enables organisations to measure individual knowledge in the business context using a novel diversity of indicators.

Design/methodology/approach – The model was developed based on a comprehensive conceptual framework. A pilot study composed of 20 semi-structured interviews elicited valuable feedback from practitioners and was followed by a validation phase in which an electronic questionnaire is used to survey a large sample of senior managers.

Originality/value – This paper contributes to the literature by presenting an innovative integrated individual knowledge measurement framework, and proposing a theoretical framework for the pivotal role of individuals in the organisational knowledge environment.

Practical implications – The model provides managers with a valuable tool capable of identifying knowledge holders and supporting effective KM decision making to achieve optimal organisational performance. Results showed that the *MinK* framework was also well received by industry and accepted as a valid framework.

Keywords – Knowledge Management, Knowledge Measurement, Intellectual Capital, Stocks and Flows

1 Introduction

In a business environment characterised by dynamic market needs and fierce global competition, knowledge emerges as a vital strategic resource and an antecedent of sustainable competitive advantage in today's knowledge economy (Spender, 1996, Drucker, 1999). An exponential growth of the Knowledge Management (KM) domain was triggered by the realisation that value creation is no longer dependant on financial assets only, but rather on intangible ones whereby organisations need to strive to leverage and exploit their knowledge resources (Carmeli and Tishler, 2004, Serenko and Bontis, 2013). The capacity to manage any organisational dimension becomes quite a challenging endeavour without the ability to assess what is being managed (Marr et al., 2004). Effective KM entails knowledge measurement capability to enable proper governance of an organisation's value creation dynamics (Carlucci and Schiuma, 2006). Knowledge measurement supports managers in identifying 'hidden' knowledge assets (Edvinsson and Malone, 1997), evaluating the impact of KM initiatives (Liebowitz and Wright, 1999), and aligning strategic plans with available intellectual capital (Wiig, 1997, Zack, 1999).

Based on extensive literature review of existing knowledge measurement methodologies, three main approaches: financial, intellectual capital components, and performance were identified by Ragab and Arisha (2013a). The financial approach uses data from a company's financial records to provide a holistic assessment of intellectual capital (IC) in financial terms based on the notion of market over-valuation (Grossman, 2006). IC is usually computed as a result of the difference between a company's book value and its market value (Tobin, 1969, Stern et al., 1995). The IC components approach divides IC into a human component and an organisational component and attempts to assess each component using metrics (Edvinsson and Malone, 1997, Bontis et al., 1999b). On the other hand, the performance approach tends not to measure knowledge/IC, but rather its impact or effect on organisational performance (Ruggles, 1999, Shin, 2004).

The literature review in knowledge measurement shows that the majority of knowledge measurement frameworks are developed at an organisational level, with very little efforts directed into the assessment of individual knowledge holders within organisations (Kannan and Aulbur, 2004, Ragab and Arisha, 2013b). This critical gap is vital in attempting to effectively manage knowledge in isolation of 'the knowers who own it' as it overlooks the essential role of individuals in the organisational knowledge

environment (Fahey and Prusak, 1998). The proposed research is aiming to address this issue by focusing on individual employees and knowledge holders. It also proposes a novel framework referred to as ‘*MinK*’, an acronym for *Measuring Individual Knowledge*. *MinK* provides managers with the visibility required for effective decision-making in the allocation, exploitation and development of knowledge-holding individuals within their organisations.

2 Conceptual Framework

The objective of the initial phase in the development of an individual knowledge measurement model is to develop an overarching theoretical framework that depicts the pivotal role of individuals in a company’s knowledge environment. A number of KM theories were combined veritably in the conceptual framework to represent the theoretical foundation of *MinK*. An organisation is envisaged as the sum of its financial capital (monetary and physical assets) and its IC, both of which are exploited to improve organisational performance (Stewart, 1998) (Figure 1). IC could be divided into Structural Capital (SC) (i.e. knowledge held within the organisation’s supportive infrastructure, business processes, IT systems and customer relations), and Human Capital (HC) (i.e. knowledge held by employees). In the ‘stocks and flows’ theory, IC is seen as the stock of knowledge a company holds at a certain time, while KM is concerned with managing knowledge flows between individuals and the organisation (Bontis et al., 1999a, Al-Laham et al., 2011).

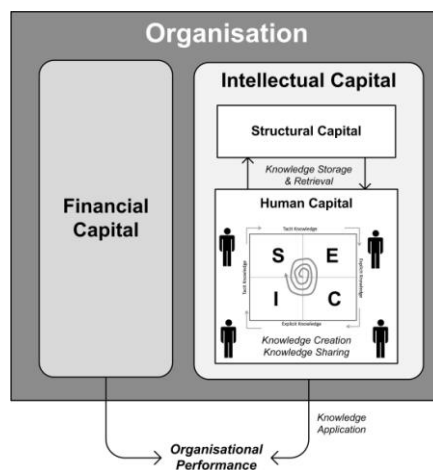

Figure 1: *MinK* Conceptual Framework

The dynamics of knowledge flows are governed by a number of knowledge processes starting by *knowledge creation*, followed by *knowledge sharing* and *knowledge storage & retrieval*, and ending by *knowledge application* (Alavi and Leidner, 2001, Mertins et al., 2003, Goldoni and Oliveira, 2010). The processes of knowledge creation and knowledge sharing within organisations are best represented by the renowned SECI model developed by Nonaka and Takeuchi (1995), which views the individual employee as the core of knowledge creation. They distinguish between explicit and tacit knowledge (Polanyi, 1967), then clearly state, “*At a fundamental level, knowledge is created by individuals ... an organisation cannot create knowledge without individuals.*” They define organisational knowledge creation as a process of elaborating and sharing tacit knowledge created by individuals by converting it into explicit knowledge through four simultaneous conversion modes. They are:

- *Socialisation (S)* – conversion of tacit knowledge into other forms of tacit knowledge through social interaction and dialogue with other individuals.
- *Externalisation (E)* – conversion of tacit knowledge into explicit knowledge through narratives and analogies to convey an individual’s conceptualisation to others.
- *Combination (C)* – conversion of explicit knowledge into other forms of explicit knowledge through codification and documentation.
- *Internalisation (I)* – conversion of explicit knowledge into tacit knowledge within an individual through learning and experience.

The SECI model therefore portrays the knowledge production process that creates knowledge stocks and the consequent knowledge flows resulting from the knowledge sharing process between individuals. Similarly, the process of storage and retrieval underpins the flow of knowledge between an individual and the organisation. Explicit knowledge is codified by individuals into organisational ‘knowledge items’ such as knowledge repositories, business processes and intellectual properties (Bolisani and Oltramari, 2012). On the other hand, new employees acquire knowledge through knowledge retrieval from such items creating reciprocal knowledge flows between human capital embedded in employees and structural capital that is owned by the company (Roos et al., 1998, Bontis, 2001).

The knowledge application process is the ultimate objective of knowledge management and measurement whereby knowledge is utilised in business decision making to enhance organisational performance and achieve competitive advantage. It could be described as the aggregation of individuals' knowledge to create value through conversion of inputs to outputs in the form of products and services (Grant, 1996).

3 The *MinK* Framework: Development and Structure

The journey of developing an individual knowledge measurement model began by questioning what makes certain individuals "knowledgeable"? It is found that an individual's knowledge manifests itself in her/his *attributes* and *actions*. Knowledgeable people have certain knowledge-related characteristics (attributes), and engage in certain knowledge activities (actions) such as creation, acquisition, learning, sharing and application. Accordingly, instead of measuring knowledge *itself*, characteristics that indicate that knowledge is present within an individual could be identified and assessed. The *MinK* framework is therefore built on the premise that assessing certain of an individual's attributes and actions would provide a good indication of their knowledge. This is achieved by adopting a component-based structure similar to IC models in which individual knowledge is broken down into components that reflect an individual's knowledge-related facets and each component is then measured individually using a set of metrics.

Recognising that it is onerous -if not impossible- to measure the totality of an individual's knowledge, the scope of assessment is directed towards one's knowledge in their business domain, the knowledge that is of value to their organisations. It is acknowledged that an individual may hold knowledge in other areas that are unrelated to their work but such knowledge is viewed as irrelevant and out of the scope of the proposed framework. The focus of this study is individual knowledge in a business context and identifies relevant knowledge as one that contributes to improving organisational performance (Baron, 2011).

3.1 Indicators and Metrics

The *MinK* Framework defines a list of *Individual Knowledge Indicators (IKI)* each of which implies that an individual holds certain knowledge that is valuable to their

organisation, or is active in acquiring, creating, sharing and applying such knowledge (Figure 2) (Ragab and Arisha, 2013c).

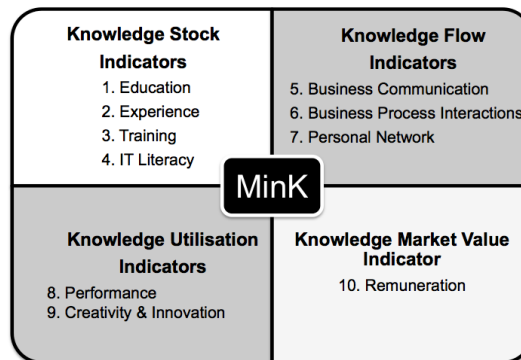

Figure 2: Individual Knowledge Indicators (IKIs)

The key four IKI groups are: Knowledge Stock, Knowledge Flow, Knowledge Utilisation, and Knowledge Market Value. Knowledge stock indicators are background measures which reflect the knowledge an individual has internalised through learning and experience. The assumption is that such indicators will measure *enabling attributes* that thrive an individual’s creation and exploitation of knowledge (Bolisani and Oltramari, 2012). Knowledge flow indicators are process measures that reflect an individual’s exposure to knowledge flows and their likely roles in accumulating knowledge stocks (Malhotra, 2003). The assumption here is that knowledgeable individuals would be highly engaged in knowledge acquisition and sharing activities through communication with their social networks, would contribute to the codification of knowledge into business processes, and would learn from existing ones. Knowledge utilisation indicators are indirect measures that evaluate the *effect* an individual’s knowledge has had on their work output. The assumption is that there is direct correlation between knowledge and its effects on performance and innovation (Bolisani and Oltramari, 2012). Knowledge market value indicators assess an individual’s knowledge using its market value by using remuneration as a measure. The assumption is that the market value of an individual (i.e. salary scale) could be used as a proxy indicator of their knowledge in the same manner the market value of an organisation is used to calculate its IC.

The next stage in the *MinK* framework was to develop metrics to measure each IKI. Metrics are measurement units, which may be direct counts, monetary values or percentages, when used to measure quantitative attributes, or numerical scale-based

ratings when used to quantify qualitative attributes. Accordingly, sets of metrics were proposed to evaluate each indicator (see Ragab and Arisha, 2013c).

3.2 Data Sources

To ensure the practicality of the solution, it is important to determine the sources of data the model requires about an individual to perform the assessment. It is noted that such data is of two types: *quantitative data* and *qualitative data*. The first type is used by such quantifiable metrics as the count of years of experience, hours spent in training, and the financial value of remuneration. This data is, to a great extent, objective and could be obtained from the individual's records in the company's Human Resources department then would be validated by the individual under assessment to ensure the information is up-to-date.

The second type of data includes ratings of parameters such as performance, innovation, and networking capacity and these have to be obtained mainly through qualitative assessments. Since such assessments involve one individual - usually the direct manager - evaluating another (the employee) they are challenged by subjectivity and bias diminishing their credibility. Managers may not be fully aware of employees' knowledge-related capabilities and may be influenced by other factors, such as personal relationships, when rating subordinates (Toegel and Conger, 2003). To overcome this challenge, a *360-degree* approach is proposed whereby individuals would be assessed by themselves, their peers, subordinates, managers and possibly external stakeholders. This approach has gained great interest from both managers and researchers due to its contribution in increasing objectivity of qualitative assessments and reducing bias, and has recently been introduced in the human capital domain (Peter et al., 2011).

3.3 Aggregation

Given the multiplicity of IKIs and metrics in the *MinK* framework, there is an urge to combine the different measures into a concise format that represents an individual's knowledge for reporting and benchmarking purposes. Consolidation would be achieved by aggregating the results of IKIs to produce an *Individual Knowledge Index*. This would require an *aggregation methodology* that incorporates a technique for the combination of indicator and metric results and assignment of weights that would reflect the relative importance of different parameters (Figure 3).

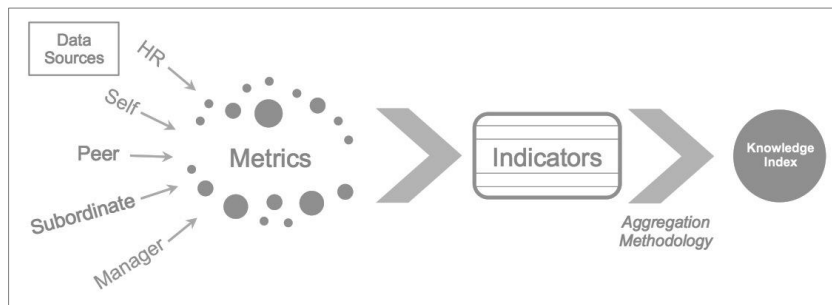

Figure 3: MinK Framework – Data Sources

4 Pilot Study

Before proceeding to the next phase of this research, it was necessary to examine the validity of the proposed framework and elicit the opinions of businesses. A pilot study was done through interviews of practitioners from a variety of organisations (e.g. leading multinationals, indigenous companies and Small/Medium Enterprises). Interviews were conducted with management level and deemed to be an effective method of revealing information about views and experiences (Dunn, 2000). Interviews were semi-structured to provide interviewees with the flexibility to elaborate on their understanding of individual knowledge and to allow the interviewer to alter the phrasing and sequence of questions to maintain conversational flow while ensuring that all scheduled issues were addressed. A total 20 interviews were completed and this sample size was considered appropriate for a pilot study. Managers represented corporations that operated in a number of industries namely consulting, IT, healthcare, education, pharmaceuticals, and food manufacturing. Interviews were conducted in person and by phone and typically lasted 30 - 45 minutes.

Interview responses were systematically analysed using an inductive and interpretive approach and coded for qualitative analysis. Codes were not pre-assigned and the coding scheme was developed as key themes emerged from the data (Glaser and Strauss, 1967, Iaquinto et al., 2011). At the beginning of interviews, participants were provided with brief background information about this research then were asked the first set of questions which aimed to examine the status of KM in their companies. Participants were then introduced to *MinK* and were asked to express their views about the model's methodology and components.

During initial discussions, it was apparent that all interviewees were aware of the concept of the ‘knowledge economy’ and KM as a business field. Most of their organisations implemented some sort of KM activity that ranged from ‘hard’ technology-based initiatives to ‘softer’ people-based ones. Most participants, however, expressed doubts about the effectiveness of their companies’ KM initiatives and felt that they still suffered from knowledge attrition. When asked whether their organisations attempted to measure knowledge, several interviewees discussed their performance appraisal systems, which revealed a mix-up between knowledge measurement and performance measurement. This was, however, not unexpected because it stemmed from the implied notion of ‘measuring knowledge through its effects’ and the assumption that the most knowledgeable employees are the best performers. When the distinction between knowledge assessment and performance appraisal was clarified and *MinK* was introduced, participants stated that their companies did not have a clear knowledge measurement system. Nevertheless, they expressed keen interest in the study and in the *MinK* framework. They believed it would enhance their KM capabilities and reduce the loss of valuable knowledge.

When asked to express their views on the model, managers found knowledge stock IKIs to be very relevant indicators of individual knowledge and noted that the same four parameters are used by most managers to evaluate individuals from their CVs during recruitment. When reviewing metrics, a number of participants disagreed to the use of number of hours and expenses as measures of training. They believed that the duration and cost of training are not necessarily valid indicators of the knowledge gained and that training should be evaluated based on outcomes and impact on business performance. This view was found to be confirmed by the training evaluation literature (Alliger and Janak, 1989, Alvarez et al., 2004, Pineda, 2010). Similarly, few managers commented that based on their experience, grades should not be used as measures of knowledge gained during education as in many cases an individual’s performance at work is not related to their academic performance. Although there is debate in the literature about the link between college and work, a number of researchers have agreed with practitioners that this correlation does not exist (Cohen, 1984, Waldman and Korbar, 2004).

While most of interviewees agreed with the three knowledge flow indicators, most of them were not convinced with the proposed metrics. They found that the recurring use of

counts as quantitative metrics provided misleading results and criticised such metrics for measuring the *quantity* and not the *quality* of their respective indicators. As one manager stated, “an employee receive hundreds of emails per day only for bureaucratic tasks that have nothing to do with his or her individual knowledge.” The general recommendation in this regard was to replace quantitative metrics by qualitative assessment. For example, instead of counting how many people an individual has in their personal network, the quality of their network and its relevance to the business would be assessed instead.

The approach of measuring individual knowledge via its market value was problematic to a number of managers who were critical of salary structures in their companies or in the job market at large. They questioned the link between knowledge and remuneration, because they believed there is a multiplicity of factors that determine a person’s salary, leading to the fact that knowledgeable employees are sometimes underpaid while less-knowledgeable ones are overpaid. Given their emphasis on the effect of knowledge on performance, all interviewees heavily endorsed knowledge utilisation IKIs as indicators of individual knowledge. Overall, most managers agreed that *MinK* would provide a good indication of individual knowledge if their suggestions for improvement were considered.

A number of participants concluded their interviews with few interesting and constructive comments. One manager questioned the generalisability of *MinK* and suggested that the model should incorporate the flexibility to adapt its indicators and metrics to different organisational profiles. This is similar to the approach adopted by Roos et al. (1998) in their work related to the *IC Index* framework where they recommended that IC indicators would be determined by the company’s top management based on its industry, size, age and strategy. The authors found this to be a valid point that should be studied. Moreover, few managers heavily emphasised their view that the value an organisation would derive from an individual’s knowledge is highly dependant on the individual’s attitude towards knowledge sharing. This factor - referred to by managers as *willingness, tendency, or motivation to share* - emerged as a key determinant of the value managers place on an employee’s knowledge. Researchers widely agree with this view as the vital importance of knowledge sharing motivation is undisputed in the KM literature (Vilma and Jussi, 2012, Witherspoon et al., 2013).

On a final note, another manager discussed the optimal frequency of individual knowledge measurement within organisations. He suggested that knowledge assessment should not be a one-time practice, but rather should be conducted in regular time intervals to enable organisations to monitor the development of their knowledge stocks. Recent research has also adopted this perspective. Lerro et al. (2012) state that knowledge asset evaluation should not be a “*snapshot*” because by time knowledge assets either evolve or lose their value. They recommend that measurement would be conducted systematically to enable tracking of “*evolution trajectories*” of knowledge assets.

The pilot study provided valuable practitioner insights and recommendations that were, in many cases, confirmed by the findings of recent academic research publications. In light of the interviews and discussions with KM experts, the *MinK* framework was subsequently modified and some of the recommendations were incorporated. The modified version of *MinK* is used in the ensuing validation stage.

5 Validation

5.1 Design and Data Collection

In order to validate the framework, a survey approach is adopted. It was found to be the most suitable method to collect data from a large geographically dispersed sample of respondents in a cost effective manner and to be analysed quantitatively (Saunders et al., 2009, Easterby-Smith et al., 2012). A structured questionnaire composed of 58 questions divided into four sections was designed as the data collection instrument. Before populating the questionnaire, a preliminary survey was carried out with a group of senior managers and KM experts. Positive feedback was obtained from this exercise, which helped in fine-tuning the questionnaire and adjusting some terminology to ensure clarity. Redundant and/or irrelevant questions were excluded to shorten the number of questions in the final version.

The first section of the questionnaire comprised multiple-choice questions about the demographics of the participant and the organisation including the company’s industry, size, age and location. In the second section, respondents were asked to indicate their level of agreement with a number of statements about KM in their organisations. Questions adopted a seven-point Likert scale ranging from 1=“Strongly disagree” to 7 = “Strongly agree” (Likert, 1932). The third section introduced *MinK*’s ten IKIs and

respondents were asked to rate the relevance of each indicator to individual knowledge using the same scale. A statement explaining each IKI was provided in the footer for further clarification. In the fourth section, respondents rated metrics that are proposed to measure each IKI then evaluated the effectiveness of the *MinK* framework holistically.

The sample of respondents consisted of managers in junior, middle and top positions from small and medium enterprises in addition to large corporations across a diversity of industries and excluded employees in non-managerial positions. To obtain reliable data, it was decided to choose organisations with 10 or more employees that have existed for more than five years and preference was given to leading multinationals. Smaller and younger companies were viewed as less likely to have a fully developed KM strategy and practice. Other criteria for selected managers included English language proficiency and researcher's access to their email addresses.

The questionnaire was conducted using the internet-based software *SurveyMonkey*. Formal emails were sent to more than 1000 managers inviting them to participate in the questionnaire. The invitation email provided a brief introduction to the research and its purpose and directed recipients to the web link of the survey. Respondents were offered to receive a summary of the research findings, if interested, as an incentive to complete the questionnaire. Follow-up e-mails were also sent at weekly intervals to increase the response rate. To eliminate concerns regarding confidentiality, respondents were informed that the questionnaire is completely anonymous since no personal information was required at any stage of the questionnaire. This meant that researchers had no means of linking a certain response to a specific email address to ensure anonymity.

The administration of the questionnaire took place in stages and responses were monitored to ensure the data collected had a minimum of errors and missing data. Incomplete responses are eliminated from results. After verification, data is organised in tabular form to be analysed using the Statistical Package for the Social Sciences (SPSS). Since data collection was still on-going during the writing of this paper, only sample results composed of 179 completed responses received to-date are presented in this article. The full set of results, the final response rate and an extensive statistical analysis of the data will be reported once the data collection phase has been completed.

5.2 Results

The characteristics of the organisations that contributed in the survey are demonstrated in the data sample (Table 1, Figures 4-5). Respondents are clearly from a diverse background of industries and mostly senior and middle managers where the proportion of top management so far is 39.1%. Almost half of the companies surveyed are large organizations having more than 1,000 employees and around 30% are medium size having between 100 and 1000 employees. The proportion of multinational enterprises amounted to 86%, while the rest (14%) were indigenous companies.

Figure 4: Profile of respondents – Company size

Figure 5: Profile of respondents – Job level

Table 1: Profile of respondent organisations

Industry	Frequency	Proportion (%)
Advertising & Marketing	8	4.5%
Agriculture	2	1.1%

Banking, Financial Services	11	6.1%
Consulting	6	3.4%
Education & Training	28	15.6%
Food & Beverage	13	7.3%
Government & Non-profit	8	4.6%
Healthcare	13	7.3%
Logistic & Warehousing	10	5.6%
Manufacturing	8	4.5%
Petroleum & Energy	10	5.6%
Pharmaceuticals	15	8.4%
Real Estate	3	1.7%
Retailing	10	5.6%
IT & Telecom	21	11.7%
Tourism & Travel	7	4.0%
Trading & Distribution	6	3.3%
Total	179	100%
Company Age		
5-10 years	20	11.2%
11-20 years	35	19.6%
21-35 years	40	22.3%
36-50 years	20	11.2%
50 - 100 years	23	12.9%
More than 100 years	41	22.9%
Total	179	100%

In the first section of the questionnaire, the value of individual knowledge was emphasised by the managers as results confirmed organisations believed most of their knowledge was held by individual employees and that such knowledge was directly correlated to their company's performance (Figure 6).

Figure 6: Questionnaire results - Importance of individual knowledge

(SD: Standard Deviation)

When the relevance of IKIs was assessed (Figure 7), most indicators were highly rated with nine out of ten indicators gaining average ratings of over 5 and the experience IKI rating 6.05. The lowest average rating of 4.49 was given to remuneration, which confirms the findings of the pilot study in which it was seen as the least relevant IKI. Metrics corresponding to each IKI are listed in Table 2 along with their mean ratings.

Figure 7: Questionnaire results - IKI Ratings

Table 2: Rating of Metrics

Indicator	Metrics	Mean	SD
Experience	Number of years in the company	4.8	1.5
	Number of years in function	5.5	1.3
	Number of years in the Industry	5.7	1.2
Education	Level of education	5.6	1.1
	Relevance of education to job	5.7	1.3
	International Exposure	5.6	1.3
	Proficiency in different languages	5.0	1.5
IT Literacy	Proficiency in general software & hardware	5.4	1.3
	Proficiency in function specific software & hardware	5.2	1.4
Training	Level of professional qualifications	5.5	1.1
	Number of training programs attended	4.8	1.4
	Impact of training attended on performance	6.1	1.1

Business Communications	Number of meetings attended per week	3.8	1.7
	Type of meetings attended (internal/external)	4.9	1.4
	Level of meetings (with managers/peers/subordinates)	5.2	1.3
	Rate of communications received per week	4.5	1.5
	Rate of communications sent per week	4.6	1.5
Business Process Interactions	Number of processes utilised	4.8	1.3
	Level of specialisation in utilised processes	5.3	1.1
	Number of processes supervised/reviewed	5.3	1.1
	Number of process improvement suggestions	5.7	1.1
	Level of involvement in business process improvement systems	5.7	1.2
Personal Network	Extent of contacts within the company	5.3	1.2
	Extent of external contacts	5.7	1.2
	Extent of international contacts	5.6	1.1
	Relevance of contacts to business	5.9	1.2
	Contact acquisition rate	5.0	1.5
Creativity & Innovation	Number of new ideas suggested	5.3	1.3
	Number of new ideas implemented	6.0	1.2
Remuneration	Salary	4.8	1.6
	Market cost of equivalent services	5.4	1.3

The last question in the questionnaire enquired whether managers believed that, overall, *MinK* would provide a *good* measure of individual knowledge. Results indicated it received a mean rating of 5.5. The response to this question in addition to the average ratings of indicators and metrics indicate that the *MinK* framework was *well received* by managers and accepted as a valid individual knowledge measurement tool.

6 Conclusion

This study presented the development of *MinK*, a framework designed to measure individual knowledge in a business context to support managers in KM decision making, enhance the effectiveness of KM systems, and to address an existing research gap. Ten indicators denoting knowledge stocks, flows, performance and market value were selected and metrics were developed to assess individuals' knowledge characteristics for each indicator. As a preliminary validation practice, a study was conducted through semi-structured interviews with managers from different industries to obtain feedback on the

model from a practitioner perspective. This provided valuable comments and constructive feedback that were used to refine the model.

A number of managers suggested that training should be evaluated by outcome rather than by duration or cost, and believed that remuneration and academic grades were irrelevant measures of knowledge. There was a general preference to use qualitative assessments rather than quantitative metrics while measuring knowledge flow parameters in order to reflect *quality* rather than *quantity*. The generalisability of *MinK* was also questioned and researchers were encouraged to investigate whether it would be a generic framework or should be adapted to different company profiles. Another proposition discussed the frequency of knowledge assessment and suggested it should be conducted periodically to monitor the evolution and/or loss of knowledge assets. Finally, the motivation to share knowledge emerged as a crucial factor for the success of KM in organisations. It was noted that most of the aforementioned practitioner views were found to be confirmed by researchers in the KM literature.

In the subsequent phase, a wide scale web-based questionnaire targeting managers was launched as part of the validation stage. Since data collection is still in process, only sample results were presented in this paper. Results showed that the *MinK* framework was highly rated by managers and well received as an individual knowledge assessment model. Once data collection has been completed, planned work includes an extensive statistical analysis of the questionnaire results to reveal data trends and correlations that may provide other new research insights.

Acknowledgements

The authors would like to thank Pharos University in Alexandria, Egypt, for its support of this research. Special thanks to Dr. Mona Salah for her valuable contributions in data analysis.

Structured Abstract

Purpose – The purpose of this paper is to show preliminary results from an international research project on intellectual capital and value creation led by Lappeenranta University of Technology (Finland) In the case of this paper, results from Italy will be reported and specifically . The Italian analysis focuses on the Entrepreneurial Capital (EC) and it analyses how large Italian companies develop and enhance this intangible element. The main research question is: What is the current level of Entrepreneurial Capital (EC) in Italian organizations and how does it affect value creation? To this end, the research addressed the different definitions of entrepreneurial capital that literature offers. As a secondary step we analysed the variables suggested by previous literature and we proposed an original definition for our research project. Our definition is that Entrepreneurial Capital is a stock of competences and the personnels' attributes related to proactive, risky and aggressive decision-making and behaviour.

Design/methodology/approach –In most studies IC has been seen to consist of three elements: human capital, structural capital and relational capital. However, we suggest that also three other elements could be included: “renewal capital”, in terms of innovative solutions, products and services available for the firms, “trust capital” i.e. the trust embedded in its internal and external relationship and “entrepreneurial capital” i.e. the competence and commitment related to entrepreneurial activities in the organisation. These variables were operationalized through meetings of the international working group. An empirical survey follows which analyses the Italian state of art . In particular the target population is made up of Italian companies with 100 or more employees. The companies involved were selected among 2,000 companies chosen from the database AIDA according to a stratified sample (according to geographical area, sector of activity and size). A questionnaire has been applied in order to gather information. This questionnaire is the same for all the countries participating in the project and has been administered mainly by means of e-mail and phone interviews. 100 companies have answered the questionnaire so far and this number is expected to increase during the next month. Additional economic and financial ratios have been obtained from AIDA

database, which contains economic and financial information for Italian firms. Descriptive analysis techniques will then be applied and differences according to industry and size will be explored.

Originality/value – This research provides researchers and managers with unique insights into the evolutionary nature of the relationships between distinct IC variables and draws a picture on the state of art of corporate entrepreneurial capital in the selected sample.

Practical implications – This research highlights and improves companies' abilities to manage their entrepreneurial capital. Furthermore this research will set the agenda for improving the entrepreneurial capital practices of Italian companies and will allow future comparison with firms from other countries that are participating in the same project identifying different pathways to success.

Keywords - Entrepreneurial Capital, Risk-taking, Proactiveness and autonomy, Aggressiveness.

Paper type – Academic Research Paper

1. Introduction

The purpose of this paper is to show preliminary results from the Italian research unit of an international project on intellectual capital and value creation led by Lappeenranta University of Technology –LUT (Finland).

The two key academic discussions addressing knowledge in organizations are Intellectual Capital (IC) and Knowledge Management (KM) streams of research. In particular, IC literature focuses on intangible resources that contribute to value creation (e.g. Edvinsson & Malone 1997; Sullivan 1998) that is “knowledge-based resources that contribute to the sustained competitive advantage of the firm” and “knowledge that can be converted into profits”. However, very few earlier studies systematically combine IC and KM practices to examine the key knowledge-related factors impacting value creation in firms

Yet the main question of the overall project is: << how do IC assets and their management practices interact to create value?>> and the common goal of the international research team is to examine the current state of IC stocks and KM practices, and how these interact in firms' value creation.

Academic Partners involved in the project are the following:

- Lappeenranta University of Technology, Finland (The Core Team)
- University of Rome 3, Italy
- Hong Kong Polytechnic University, China
- Deusto Business School, University of Deusto, Spain
- St.Petersburg University Graduate School of Management, Russia
- Educons University, Serbia
- Universidade Lusitana, Portugal
- Academy of Economic Studies, Bucharest, Romania

In most studies IC has been seen to consist of three elements: human capital, structural capital and relational capital(e.g. Bontis 2001; Guthrie 2001). The IC literature helps in identifying the kind of intangible resource stocks within the firms and in assessing them. However are the above-mentioned three elements sufficient?

In our research design we suggest that also three other elements could be included in IC visualizing and mapping: “renewal capital”, in terms of innovative solutions, products and services available for the firms, “trust capital” (i.e. the trust embedded in its internal and external relationship) and “entrepreneurial capital” (*i.e. the competence and commitment related to entrepreneurial activities in the organization*) (Kianto 2007; Kianto 2008; Kianto et. al. 2013).

Within the overall project, the Italian research unit will focus on Entrepreneurial Capital (EC). In particular it will be analysed how medium-sized and large Italian companies develop and enhance this intangible element. Consequently the research questions of our investigation are the following: what is the current level of Entrepreneurial Capital (EC) in Italian organizations and how does it affect value creation?

To this end, our investigation aims to highlight the importance of Entrepreneurial Capital as a stand alone component of the Intellectual Capital. As a secondary step we’ll analyse the variables suggested by previous literature trying to understand this phenomenon and we’ll propose a definition that fits our research design. The emerging definition is that *Entrepreneurial Capital is a stock of competences and the personnels’ attributes related to proactive, risky, innovativeness and aggressive decision-making and behaviour.*

Our research agenda will provide academics and managers with unique insights into the state of art of corporate entrepreneurial capital in the selected sample.

Furthermore this research will set the agenda for improving the entrepreneurial capital practices of Italian companies and will allow future comparison with firms from other countries that are participating in the same project identifying different pathways to success

2. Literature Review

Intellectual capital has been defined as “the total stock of capital or knowledge-based equity that the company possesses” (Dzinkowski, 2000). Intellectual capital is either the end product of a knowledge transformation process or the stock of organizational knowledge itself. Intellectual capital incorporates three main components that together form value: human capital, organizational (structural) capital, and customer (or relational) capital (Bontis 2001; Guthrie 2001).

Human capital refers to and includes know-how, education, work-related competencies, and psychometric assessments. McGregor et al. (2004) define human capital as the size and quality of broader labor markets, but also as the sum of individual competencies in organizations. Teece (2000) recognizes that knowledge assets or products result from the experience and expertise of individuals. However, the “physical, social, and resource allocation structure” of organizations are important if such experience and expertise is to be translated into competencies that help generate knowledge products (Teece, 2000; McGregor et al., 2004).

The term structural capital reflects these allocation structures and includes assets such as corporate culture, management processes, databases, organizational structure, patents, trademarks, and financial relations. Engstrom et al.(2003, p. 288) suggest that structural capital “includes all non-human storehouses of knowledge in organizations.”

Finally, relational, or customer capital refers to, in part, an organization’s customers, brands, customer loyalty, and distribution channels. Customer capital also refers to consumers as repositories of information and knowledge that is valuable to organizations (Bontis, 1998).

For the purpose of our research we deem that EC (roughly intuitively defined as *the competence and commitment related to entrepreneurial activities in the organization*) should be taken into consideration as a stand -alone element of IC in the light of the following rationale:

- in a unsteady and unpredictable business environment like today, Entrepreneurial Capital might be found as one of the most influent intangible to enhance corporate value;
- the construct of Entrepreneurial Capital is characterized by several attributes which, in the traditional definition of IC refer both to Human Capital (i.e. entrepreneurial competence and behavior) and Structural Capital (i.e. entrepreneurial corporate culture and processes).

2.1 Previous studies in the field of Entrepreneurship

It must be highlighted that no previous research within the IC domain refers to Entrepreneurial Capital , while many efforts have been done in the field of entrepreneurship studies especially to investigate the relationship between corporate Entrepreneurial Orientation (EO) (also called Corporate entrepreneurship- CE) and firm's performance.

Lumpkin and Dess, 1996 define *EO* as the *propensity of firms to be innovative, proactive to the market place opportunities and be willing to take risk*. While the EO is identified as a process, the entrepreneurship is define as the content.

To Schumpeter (1934), an entrepreneur is a person who carries out new combinations, which may take the form of new products, processes, markets, organizational forms, or sources of supply. Entrepreneurship is, then, the process of carrying out new combinations. In contrast, Gartner states that "Entrepreneurship is the creation of organizations" (1988, p. 26). Gartner was careful to specify that this was not offered as a definition but rather as "an attempt to change a long held and tenacious viewpoint in the entrepreneurship field" toward "what the entrepreneur does, not who the entrepreneur is" (p. 26). Nevertheless, it is clear from the literature that a large number of researchers in entrepreneurship have employed this definition, including Gartner (Gartner, Bird, & Starr, 1991; Learned, 1992).

The analysis of entrepreneurial capital can effect two level. The individual or organizational levels and from this levels depends the influence how contributes to

performance. EO by some scholar is associated only to SMEs because they are responsible for the majority of economic growth and new job creation (Birch 1979). **But recently (Guth & Ginsberg 1990) there has also been particular attention on corporate entrepreneurship as a means of growth and strategic renewal for existing larger firms.**

The organizational dimension may be viewed as encompassing the entire range of organizational activities that involve planning, decision making, strategic management and many aspects of the organization's culture, i.e. share value system and corporate vision. So many researchers have focused on delineating the dimension of EO in different ways.

Miller (1983) says that an entrepreneurial firm is one that "engages in product market innovation, undertakes, somewhat risky ventures and is first to come up with 'proactive' innovations, beating competitors to the punch".

So, to understand EO construct we must say that it had different definitions and that the scholar has been using several variables to identify it. At the **organisational level**, Vesper (1984) defined "corporate entrepreneurship" as any one of or any possible combination of new strategic direction; initiative from below; and autonomous business creation.

In other circumstances, reference is made to it as a "process of transformation of organisations through strategic renewal" (Antonicic and Hisrich, 2001; Guth and Ginsberg, 1990), corporate venturing (creating business in existing or new fields, markets or industries using a core competency within a firm: Ellis and Taylor, 1987; Narayanan et al., 2009), organisational innovation (Sharma and Chrisman, 1999; Yiu and Lau, 2008), as well as intrapreneuring (creating

an entrepreneurial mindset or culture within a firm, Pinchot, 1985; Thornberry, 2001).

At the **individual level**, Entrepreneurial Orientation has been associated to an individual who creates innovation of any kind within an established firm (Pinchot, 1985). A corporate entrepreneur is someone who engages in identifying and developing new opportunities relative to operations, methods, products or markets, sets the strategic vision for the organisation or persuades the top management to adopt these opportunities, and motivates others to implement them (Ireland et al., 2009). In more general terms,

corporate entrepreneurs are managers or employees who demonstrate key entrepreneurial attributes or behaviors within an established firm.

Each definition in the different levels (organizational or individual) has been associated with a number of characterizing variables that we'll discuss in the following.

All the researchers provided for each definition several variables to explain the meaning of EO/CE and its synonyms.

Each of the variables used was explained by attributing a shared definition. In the following we'll report on the meanings some of the variables used by the scholars.

Innovativeness : Developing new or improved products or services; may involve radical and discontinuous change, improvement and redevelopment of existing products or processes, or the introduction of novel products or production methods based on new technology.

Risk taking : Measuring and taking risks for the sake of profits; to take bold actions such as venturing units unknown new market or committing a large portion of resources to ventures with uncertain outcomes; preference is for moderately high risks rather than extremely high risks.

Networking : Developing personal relationships in which others willingly defer to one's wishes; networks include all internal and external, as well as formal and informal relationships that share information, experiences and resources and/or provide socialemotional support; networks represent a source of power that facilitates the acquisition of physical and monetary resources and advice, information and reassurance.

Integration: Being involved in all aspects of the organisation; requires seeing things in a broader perspective, analysing things in the abstract, and putting seemingly unrelated elements together in a meaningful way; may involve creating of a new order by selecting and fitting unrelated potential parts into a new pattern

Opportunism : Recognising and exploiting opportunities to develop new products and processes, improve existing operations, and/or develop new marketing approaches; may discover mundane opportunities that enhance efficiency or quality; evaluation of

opportunities involves balancing inadequate commitment of resources and the potential for return.

Non system bound orientation: Being unconstrained by rules, regulations and structures of existing organisational systems to be able to take advantage of opportunities; may require manipulating or bypassing the system; such freedom must be justified from the perspective of organisational benefit

Change Orientation: Responding to environmental changes in a proactive or reactive manner; proactive approach involves taking the initiative to shape the environment to one's own advantage; reactive approach involves responding to changes rather than exploiting and initiating change

Flexibility in Control: Having the ability to adopt flexible planning systems and take varying degrees of control as appropriate to take advantage of emerging opportunities; facilitates changing strategic plans in response to highly complex and ever-changing environmental threats and opportunities.

Informality: Preferring simple systems and informal structures; characterized in terms of being autonomous, resistant towards conformity and having a low need for support; allows for free crossing of organizational boundaries to promote a more open, cooperative atmosphere that is conducive to flexible decision-making processes, open communication and simplified work processes.

Result Orientation: Focusing on results; making decisions and solving problems intuitively to foster commitment to action; may become so immersed in work details that they are involved everywhere, ignoring corporate politics and individual egos, and violating bureaucratic procedures; similar to Type A behavior in terms of intense competitiveness, time urgency, polyphasic behavior and preference of immediate action over planning

As can be seen in the previous table, key words to define Entrepreneurial Orientation/Corporate Entrepreneurship are the following: Risk taking, Proactiveness, Innovation.

Despite the many names and the many variables studied it is yet unclear how these dimensions and business performance are linked. It is evident that all or at least a combination of some exhibit some relationship with business performance, generally positive link.

Lumpkin and Dess (1996) reasoned that the different variables of EC might lead to favorable outcomes on one performance dimension but unfavorable outcomes on another and this may also depend on different firm conditions (size, age, firm context).

3. Research Design: from Entrepreneurial Orientation to Entrepreneurial Capital

For the purpose of our current research, drawing from the above-mentioned literature, EC is comprehensively defined as “a stock of competences and the personnels’ attributes related to **proactive, risky, innovative and aggressive decision-making and behavior**”.

Proactiveness means taking initiative by anticipating and pursuit new opportunities and participating in emerging markets also has become associated with entrepreneurship.

Risky reflect an acceptance of uncertainty and risk inherent in original activity and is typically characterized by resource commitment to uncertain outcomes and activities.

Aggressive decision-making is the intensity with which a firm chooses to compete and efforts to surpass competitors reflecting a bias toward out doing rivals. Also includes the authority and independence given to an individual or team within the firm to develop business concepts and vision and carry them through to completion (Hughes, M., Morgan, R.E., 2006).

Innovativeness reflect the propensity of the firm to engage in a new idea and new processes and also new creative solution and opportunities (Wiklund, 1999).

To further address how the different dimensions are related to performance and value creations, we here overview several hypothesis. In fact to draw our research design it is necessary to examine how each individual variable of EC might influence business performance and value creation.

We will explore each dimensions above-mentioned and investigate why a specific variable might have a positive influence on business performance and value creation.

HP 1: Proactiveness is positive linking with performance and value creation

Proactiveness represents a forward-looking perspective where firms actively seek to anticipate opportunities to develop and introduce new or improved products, instigate changes to current strategies and tactics, and detect future trends in the market (Lumpkin & Dess, 1996; Slater & Narver, 1995).

Proactive firms, through proprietary learning and experience effects gained over time, tend to be more attuned to changes and trends in the marketplace, which yields opportunities to the firm to meet expressed and latent needs ahead of competitors (Hamel & Prahalad, 1991).

Proactiveness in firms is characterized by intentional change. That is, by force acting on information to make change not merely anticipating it (Bateman & Crant, 1993). This alleviates the risk of complacency by ensuring firms are better placed to serve markets in the short term and shape them in the longer term. The emphasis on anticipating and acting on future needs orients the firm to seize initiative and act opportunistically in the marketplace thereby shaping demand (Miller & Friesen, 1978)

HP 2: Risk-taking is positive related with performance and value creation

Risk-taking represents a willingness to commit resources to implement projects, activities, and solutions that contain inherently a high level of uncertainty regarding the likely outcomes (Lumpkin&Dess, 1996).When deciding to take risks, firms must tolerate one of two possible scenarios—the first being the risk of failing and second the risk of missing out on an opportunity

(Dickson & Giglierano, 1986). The former is caused by fear whereas the latter is caused by inaction. A tolerance of risk-taking orients the firm toward action and induces it to embrace uncertainty.

Timely risk-taking has been associated with strategic decision speed and both have subsequently been linked to improved business performance (Eisenhardt, 1989).

Risk-oriented firms combine opportunity-seeking behavior with constructive risk-taking to generate a bias for exploration and exploitation (Baird & Thomas, 1990; Lumpkin & Dess, 1996).

Risk-taking managements usually seize opportunities and make commitments of resources before fully understanding what action needs to be taken (Covin & Slevin, 1991). Such an approach seeks to take advantage of evolving situations by capitalizing on the fact that markets rarely stabilize for any length of time. Risk aversion renders firms passive to developing newmarket opportunities which is likely to deteriorate performance in an age of rapid change (Miller & Friesen, 1982).

HP 3: Aggressive decision-making is positive related with performance and value creation

Firms that are highly aggressive see competitors as enemies that must be conquered.

Aggressiveness can be implemented through the mobilization of resources to launch direct attacks on competitors with the aim of overwhelming their market efforts, steadily erode their competitive strengths, or establish advantage through continuous offensive tactics (Davidson, 1987).

Aggressiveness can improve performance because the emphasis on out-doing and out-maneuvering competitors strengthens the firm's competitiveness at the expense of rivals (Lumpkin & Dess, 1996). Examples of the manifestation of such an aggressive competitive strategy include aggressive price competition, market entry with a new or superior offering, fast-following a rival into a market, continuously exploiting information, and using unconventional surprise tactics.

Such an emphasis on acquiring market share and customers by aggressively targeting rivals' weaknesses should improve performance because it undermines competitors' ability to compete and

restricts the ability of competitors to anticipate and respond to what the aggressive firm will do next. Since the aggressive firm does not sit still and constantly implements incremental and adaptive change to undermine competitors, it is hypothesized Autonomy conveys the freedom to employees to encourage them to be self-directed, to exercise creativity, pursue opportunities,

and champion new ideas which are essential for effective entrepreneurial activity to occur Lumpkin & Dess, 1996).

Autonomy is, therefore, an important driver of flexibility, which is an essential attribute if a firm is to be able to respond promptly to environmental change and market signals by quickly reconfiguring its actions and activities (e.g., Grewal & Tansuhaj,

2001). Flexibility is created when people within the firm are given freedom to apply their human capital in ways that help the firm

change adaptively and be responsive to the needs of its markets and actions of its rivals. A lack of autonomy would likely result in passivity when change is needed to initiate effective response to

opportunities and threats to performance. The presence of autonomy, in contrast, should encourage a greater flexibility in the firm to facilitate active and reactive response to change. Although some framework of coordination is likely to be needed, on balance we expect that autonomy will be beneficial to improving business performance.

HP 4: Innovativeness is positive related with performance and value creation

Innovativeness represents a bias toward embracing and supporting creativity, experimentation, technological leadership, and R&D in the development of products, services, and processes to

generate novel solutions to customer needs and problems (Hughes and Morgan 2007). It is said to be present when firms pursue active implementation of new ideas, products or processes not merely their generation (e.g., Hurley & Hult, 1998).

Calantone, Çavuşgil, and Zhao (2002) establish that firm innovativeness has a positive impact on performance and contributes to competitive advantage by facilitating creative thinking within a firm's learning activities. Innovativeness also improves the application of market intelligence acquired through market orientation activities, which can benefit performance (Han, Kim, & Srivastava, 1998; Hurley & Hult, 1998). Also, a study by Hult, Hurley, and Knight (2004) uncovered that innovativeness benefits business performance regardless of market turbulence. Innovativeness changes how a firm applies market information (e.g., Slater & Narver, 1995) and together informs the generation of intelligent solutions.

3.1. Research Methodology

While the Italian research unit focuses on the Entrepreneurial Capital (EC), the overall research design aiming to understand links between IC managing and value creation.

In the next paragraphs, the following steps will be addressed:

- 1) Operationalising variables;
- 2) Survey Data Collection;

- 3) Target Respondent;
- 4) Public Data Collection.

1) Operationalising variables

Operationalising variables in social science involves defining a concept so that it can be measured. All variables defining Entrepreneurial Capital were addressed and discussed in meetings of the international working group.

As far as Entrepreneurial Capital is concern, the following are the operationalised variables and the related statement included into the questionnaire:

ENTCAP	Concept: Entrepreneurial capital <i>Variables:</i> <i>Risk-taking</i> <i>Proactiveness</i> <i>Aggressive decision-making</i> <i>Innovativeness</i>
--------	---

To what extent do the following statements on the entrepreneurial orientation apply to your company?					
(1 = completely disagree, 5 = completely agree)					
	2	3	4	5	1
ENTCAP1				Risk-taking is regarded as a positive personal quality in our company.	
ENTCAP2				Our employees take deliberate risks related to new ideas.	
ENTCAP3				Our employees are excellent at identifying new business opportunities.	
ENTCAP4				Our employees show initiative.	
ENTCAP5				The operations of our company are defined by independence and freedom in performing duties.	
ENTCAP6				Our employees have the courage to make bold and difficult decisions.	
ENTCAP7				The operations of our company can be described as creative and inventive.	

It must be noted that in the social sciences, much of what we study is measured on what would be classified as an ordinal level. In our questionnaire we then assign a value of “1” if interviewed Completely Disagree with the statement, up to a “5” if they Completely agree with the statement.

The finalized research instrument (survey questionnaire) was distributed in the beginning of September 2013 by the LUT research team.

The questionnaire was in English. Each partner should take care in translating the questionnaire to their own language. Utilization of professional language expert the first step. Additionally, the substance and flow of the questions was finally checked by the Italian research team to ensure that respondents could answer the research questions. The

core message of each item should remain the same to ensure standardization and applicability of the measures across countries.

The survey was conducted in exactly the same format in all cases. This means using all of the items in the survey, and in the same order, and with the same scales. The data were collected using survey questionnaire by the end of the year 2013.

Publicly available data were collected right after the primary data collection has ended.

2) Survey data collection and targeted population of firms:

In particular the target population is made up of Italian limited liabilities companies with 100 or more employees. The companies involved were selected among 2,000 companies chosen by a random sampling procedure from the database AIDA but according to the mix of a stratified sample representative of all population of the database (that is companies were randomly chosen within fixed percentage according to geographical area, sector of activity and size).

The main goal was to get a multi-industry sample with a representative variety of firms within Italy.

Up to April 2014, 100 companies have answered the questionnaire so far and this number is expected to increase during the next month. Additional economic and financial ratios have been obtained from AIDA database, which contains economic and financial information for Italian firms. Descriptive analysis techniques will then be applied and differences according to industry and size will be explored.

Aida data base covers 1 million companies in Italy and it contains comprehensive information on Italian companies, including: Detailed Accounts following the scheme of the 4th Directive CEE, indicators and trade description of Italian companies, Ownership and management, Consolidated accounts and accounts in IFRS.

3) Targeted respondent/informant:

The survey should be answered by one key informant from each firm

Preferably CEO, because the CEO will have best knowledge about the themes covered in the survey

If CEO cannot be realistically reached, the other high-level directors/managers in following fields are feasible respondents (in the order of preference)

- Chief operating officer
- HR / KM Director
- Development director

The data have been collected from October 2013 and March 2014. An hybrid approach to gather data has been followed. First by Internet-survey: the research team used internet-administered survey questionnaire (Google questionnaire), and sent each respondent a link to the questionnaire. This also allowed for follow-ups and reminders. Then to increase the number of filled in questionnaires the respondents were called via phone and each question was asked and filled by the research team. Finally, via face to face interviews.

In order to make respondents comfortable and willing to filling the questionnaire information about Why the survey is conducted, How the data will be utilized, Instructions for the answering was given. Furthermore we emphasize the confidentiality in analyzing the data **and we promise** them to receive a managerial report concerning the country's results .

4) Public data collection

Then the following Corporate Performance measures were collected trough AIDA database:

- Return on Assets (ROA) last three years
- Return on Equity (ROE) last three years
- Growth in Revenue last three years
- Growth in Turnover/Sales last three years

While Control variables are the following:

- Sales/Turnover (2010,2011,2012)
- The number of personnel (2010,2011,2012)
- Year of Foundation/Establishment
- Market to book value **OR** Price to book value (P/B), if available
- Industry information (NACE coding highly preferable, or other official industry coding)

4. First Results

Frequency of answers (%), Tot. = 100 questionnaires

VAR	KEY WORD	1	2	3	4	5
ENTCAP1	risk taking	2	20	19	40	19
ENTCAP2	new ideas	7	26	30	30	7
ENTCAP3	new business	8	30	32	25	5
ENTCAP4	initiative	4	20	31	35	10
ENTCAP5	independence	5	19	32	35	9
ENTCAP6	difficult decision	10	22	38	24	6

More than fifty % of all respondents (value = > 3) agree that in their companies there is a satisfactory level of Entrepreneurial Capital as defined by the above-mentioned variables.

5. Conclusions and a Research Agenda

As stated in Introduction this is a first conceptual paper on <<IC and Value creation>> aiming to:

- enlighten the overall framework of the international project and the specific role of the Italian unit;
- explain why EC should be considered – for the purpose of our investigation- as a stand-alone element of IC;
- illustrate the research methodology of the Italian research unit;
- define and operationalise the concept of Entrepreneurial Capital.

In the first step the Italian research team will address a deep analysis of data gathered in order to describe what is the current level of EC in Italian medium-sized and large companies. Clusters of firms by dimension, activity sector and geographical location will be investigated.

Future research agenda considers comparison with results emerging in other Countries in order to address environmental variables effects on EC, IC and corporate performance.

Finally, next year causality relation between EC and value performance will be tested.

Structured Abstract

Purpose – An intertemporal comparison of the value created by Intellectual capital cannot disregard the current prices realized on the market by individual companies, because, at the corporate level, a decrease in sales prices results in a decrease of the value created (Zappa, 1919; 1920–1929). On the contrary, in comparisons in constant prices, this decrease is not measured at macroeconomic level (Weil, 2007; OECD, 2001). The goal of this paper is to examine the different measures of the Value Added created by Intellectual capital at micro and macroeconomic level and the relationship between these measures and the Neoclassical Theory of Subjective Value (Menger, 1976; Robbins, 1945; Wieser, 1889–2006; Wicksell, 1898–2006; Fisher, 1892; 1911–2006).

Design/methodology/approach – We present the theoretical and practical limits of the use of index numbers to express the value created in constant prices even in international comparisons (Fisher, 1911–2006). As stated by the Theory of the Subjective Value any quantity of the same good has a different value as a function of *marginal utility* (Marshall, 1890–2006); so the deflating by means of a price index, distorts the value attributed by the market at micro economic level to different goods. In this way, comparison to constant prices also modifies *relative prices*.

Originality/value – The valuation at current prices implies a different theory of the value of goods and we have identified a Third Generation of Marginalism in Friedrich von Wieser, Knut Wicksell and Irving Fisher since they indicate the difference between *subjective* and *objective* value. Intertemporal comparison at macroeconomic level is conducted deflating value so to consider the variation of the purchasing power of money (ISTAT, 2011). But the separation of changes in quantity from changes in price implies several problems (Fisher, 1911–2006) and we use *modified input-output analysis* to quantify in current prices the Value Added and the production realized in the economic system.

Practical implications – The international and intertemporal comparisons made by governments and by the statistical institutes via National Accountings, should be at current prices and at purchasing power parity, i.e. excluding the use of index numbers to deflate changes in production. The comparison at current prices would result in assessments of the contributions provided by the intellectual capital (VAIC) differ from those measured in constant prices and without indicating the *net asset* of the economic systems (GDP). It is therefore necessary that the comparison measures not only indicate the statistical model, but also the economic theory of reference.

Keywords – Intellectual capital measure, Economic Growth, Quality adjusted indexes, Value Theory.

Paper type – Academic Research Paper

1 Introduction

In this paper we survey the problem of quantification of the Value Added created by Intellectual capital at a macroeconomic level, related to the use of a deflating procedure by means of a Price Index.

First of all we'll identify a Third Generation of Marginalists which founded, in our opinion, the theory of the *objective value* that requires to quantify the subjective value of exchanged goods in terms of *current prices*.

We then intend to create a specific statistical and economic instrument – Modified Supply and Use Tables (M-SUT) – in order to represent the Value Added created by Intellectual capital in an economic system of production and exchange. This is because the *traditional* Supply and Use Tables, utilized in the National Accounting systems to describe the interrelations between the different economic sectors and the economic system as a whole (European Union, 2013), do not consider the remuneration of production factors as *intermediate consumption* and do not indicate the *origin* and the *allocation* of the economic wealth participating in the production process.

In addition, deflating modifies nominal and real value produced by Intellectual capital. So we propose an integration of System of National Accounts to include capital-value as sum of *corporate book value* and calculate the Value Added Intellectual Coefficient – VAIC (Pulic, 2000; 2004) at macroeconomic level.

2 Intellectual capital and price or quantity variations

We don't focus on Intellectual capital quantification, but on the relations between Economic Theory and the quantification of Value Added created by Intellectual capital.

The Intellectual capital value creation is related to the *effects on productivity*, either through a reduction of the input needed to produce the same output, or the increase of the output without prejudice to the same input. The effects, however, may also relate to market price that can then be higher in terms of a more efficient use of Intellectual capital.

The consequences, *ceteris paribus*, are then related to:

- Smaller quantity of inputs;
- Higher amount of output;
- Increased market price.

At macroeconomic level, these effects must be aggregated and compared with those obtained by all the companies and in an intertemporal perspective.

The aggregation and intertemporal comparison of Value Added, however, set the problem of the separation of changes in *quantities* of input and output from the *price* changes.

Here we see a radical difference. If, at corporate level, a change of price is recognized as a change of its Value Added, on the contrary at the aggregate level this intertemporal variation is usually deflated because the *deflating procedure* aims not to consider a “change in the price” as a “change of wealth”.

This procedure is based on the Theory of Subjective Value, which states that any individual economic agent attributes a subjective value to any good, according to its marginal utility. So, market prices for the same goods should be different according to the different subjective values of the commodities. However, a further part of the theory indicates that the process of price formation on the market is actually reversed.

The market price is not different depending on the subjective value attributed to each individual commodity. Instead, the marginal utility of the individual economic agent, through the procedure of exchange, adapts itself to the market price.

To make this clear there were *marginalism theorists* who have dealt with the macroeconomic aspects of the theory of subjective value and the relationship between money and market prices.

Economists which we refer to, in particular, are Friedrich von Wieser (1889–2006), Knut Wicksell (1898–2006) and Irving Fisher (1911–2006).

3 The Third Generation of Marginalism

As is well known (Schumpeter, 1990; Roncaglia, 2003–2011) the *First generation* of Marginalism (Jevons, 1871; Menger, 1871; Walras, 1874–1877–2006) believed that the marginal utility was measurable and therefore they reasoned about *Cardinal utility*. The

Second generation (Marshall, 1890–2006; Edgeworth, 1881; Pareto, 1919), focused instead on the problem of *Ordinal utility*, working on *Indifference curves*.

Almost simultaneously with this second generation, Wieser, Wicksell and Fisher produced fundamental works which allowed, in our opinion, to move from a vision of the economic system focused mainly on the exchange, to a vision based on the relationship between production and consumption in the long run, and on the analysis of the role of money in setting prices.

In his book about *the natural value*, Wieser (1889–2006, p. 118), the first to use the term *marginal utility*, said: “Subjective value represents a distinct feeling; that of being dependent upon the possession of a good for the satisfaction of a want,— a distinct degree of personal interest in goods. Objective value, on the other hand, merely represents a definite price; a definite amount of payment which is expected or required in buying and selling. The former has its measure in the different gradations of desire, the latter in the quantities of coin,— in the figures of the price.” Two years later, he wrote: “value in use is not only particular but also subjective; value in Exchange is not only general but also objective” (Wieser, 1891, p. 118).

Knut Wicksell, instead, studied the relationship between the isolated exchange (between two or a few people) and the exchange on the market, and wrote that “as a result of the prevalence of competition on both sides, among the sellers and among the buyers, an approximately uniform price for each commodity soon pervades the market...” and “if longer periods of time are being considered, this equilibrium between supply and demand gives way to an equilibrium between production and consumption.” (Wicksell, 1898, Cap. III, p. 131).

Irving Fisher, in his work about the *purchasing power of money*, as in many other parts of his vast scientific production (see: Serafini, 2013), studied in depth the aggregation of goods and the best way to express the purchasing power of money, reversing the logic of the previous studies on the *general level of prices*. Through the reformulation of the Quantity Theory of Money, in fact, to aggregate the goods he replaces the sum of the value of the goods, for an amount given by multiplying the volume of trade for a Price Index (Fisher, 1930–2006). In this way he expresses change in prices according to the quantity of money in circulation, trying to mediate between all of the different changes in the prices of individual commodities. In doing so, he argues that “a price is an objective datum, susceptible of measurement, and the same for all men.

Marginal utilities, on the other hand, not only are impossible to measure, but are unequal and vary unequally among individuals. The purchasing power of money in the objective sense is, therefore, an ascertainable magnitude with a meaning common to all men.” (Fisher, 1911–2006, p. 468).

According to these works, therefore, the price of commodities becomes something “objective” (Wieser), “approximately uniform” (Wicksell) and “ascertainable” (Fisher).

The relative size of prices is then determined by the balance between supply and demand in the short-term, and between production and consumption in the long run. Price level would depend, instead, on the amount of money in circulation.

In our opinion, the above mentioned statements indicate a *Third Generation of Marginalists* who make a leap from microeconomics to macroeconomics (in this paper we do not examine in depth the differences between this and the Keynesian macroeconomics or later), because they switch from the *subjective* value to the *objective* value. From the value determined in the exchange to the value determined in an exchange economy and dependent on the different *ownership structures, production factors productivity and needs*.

This is because, and this is the key point in our view, changes in prices set by coin are only the (roughly) parallel changes in the general level of prices. The changes in relative prices, however, are determined by changes in the relative productivity of individual producers and/or alteration of the wants and willingness to pay of the economic agents.

As stated by Gino Zappa (Zappa, 1919) price changes resulting from commercial causes exist only with respect to one, some, or many goods. On the contrary, variations that stem from monetary conditions manifest themselves in all the elements of wealth and income of all members of society or even in a given country and would result in changes in the general level of prices.

We note, therefore, that, if a change in price is not offset by a change in the opposite direction in other prices, such as to leave unchanged the overall value, there would be a change in the economic wealth produced and exchanged.

4 Price or Value variations

At the aggregate level and in the intercompany comparisons, therefore, through the calculation of price index numbers, a deflating of these changes takes place to separate

the change in price, which does not correspond to a change in wealth in real terms, but only in nominal terms. In case of increase of a single price, everything else being equal, by deflating through a price index, the amount of production accounted at a corporate level is reduced and the relative value of the production among the different companies is modified.

On the basis of these considerations, we believe that the process of deflating currently used to quantify the changes in real production is not consistent with the economic Theory of Value, as expressed by the *Marginalists* of the *Third Generation*. Even if the prices were only relative, and their absolute size – their level – was dependent on the amount of coin (Quantity Theory of Money; see Schumpeter, 1990), in an economic system is almost impossible to detect parallel shifts in prices. Only in the case of parallel variation of prices, in fact, we could identify the price changes in a change in the coin value.

In addition, in the current practice of business accounting, the Value Added created also by Intellectual capital is accounted in cash, at nominal value, and the production process is considered by the *Marginalist Authors* themselves as a production process of additional value.

So we come to the conclusion that the value of commodities, also in its level, has as its determining cause the production process and does not depend automatically on the amount of money in circulation.

We don't explore here the problem of *absolute prices* (Roncaglia, 2003–2011) and refer to our work on this topic (Serafini, 2012). However, according to this perspective, the Value Added variation, compared to the previous period, will be quantified in nominal terms because the deflating changes the *relative size* and the *objective value* of the company production.

In the next section we introduce an accounting and comparison system of the wealth produced by Intellectual capital which also complies with the guidance of the *Third Generation of Marginalism* and quantify changes without deflating. In particular, we represent an economic system of production and exchange, based on the model of Input–Output Analysis, whose foundation dates back to the theoretical and practical works by François Quesnay, Karl Marx and Wassily Leontief, and whose further evolution is now in use in the modern Systems of National Accounting (see: European Union, 2013).

5 Supply and Use Table with *objective value*

To represent an overall economic system, both in production and exchange, economic theory has developed the Input–Output Analysis (Leontief, 1986) and through the development of Systems of National Accounts (Vanoli, 2005 and Siesto, 1973), has created the Supply and Use Tables – SUT (European Union, 2013).

According to the previous version, the Input–Output Analysis consists of a square matrix that indicates per line the branches (industries) from which production is *originated* and in the corresponding column the branch that *use* the same production.

In the current Systems of National Accounts, however, the SUT are not square matrices but tables consisting of three parts.

A square matrix that indicates the wealth produced and reused as intermediate consumption; a part (graphically placed on the right of the first) that indicates the Final Uses (Government consumption, Investments, Exports, and minor items); and a part (located below the first) that indicates the Primary Resources, given from the revenues of the factors of production (wages, capital gains, taxes, profit, amortization and minor items), and Imports, which are a resource for a domestic economy. Read per row, the table indicates the sum of Intermediate and Final Uses, and read per column it shows the Intermediate consumption and Primary Resources. By means of this table, we can analyze the *entries* and the *payments* (Pasinetti, 1975–1981) that occur in an overall economic system, characterized by production and exchange.

From the theoretical point of view, according to the Theory of Subjective Value, in the long run profit tends to disappear as a result of competition. SUT, therefore, represent a short– term economic system, because there is profit. But even if Böhm–Bawerk (1998) and Fisher (1930–2006), for example, believe that there is *value creation* in the production process, SUT depict an economic system without indicating the source of additional value created, which, even according to the *Classical economists*, could be the labour–force and/or capital. Among the Classics we also include Karl Marx, which clearly states that the source of value is not just the *job* (see: Marx K., 1875–1990, p. 7). For further details on the thought of this *author*, who has expressed the economic problem of private ownership of the means of production, see Serafini (2012).

Since Vilfredo Pareto (1919) and Paul Samuelson (1993) (see: Schumpeter, 1990), for example, have highlighted the importance of the ownership structures of production factors in order to determine the level of production, as will become clear later, in the

tables that we developed you can also identify the *origin* and the *allocation* of the resources that enable productive investment.

In our case, the accounting system should highlight the added value produced by Intellectual capital, so we have created and implemented a *Modified Supply and Use Table*, M-SUT, which shows per column the production factors and per row the branches of production in which those factors are used. At first we indicate the variables in “value” – price per quantity – and then present the problems of measuring the Value Added, associated with a separate evaluation between price and quantity. The *net profit* will vary, like other variables, depending on Intellectual capital capability for Value Added creation.

In the following paragraphs we indicate the theoretical implications of this representation, modified with respect to that of traditional SUT. Now, to explain the limits of deflating, we assume a system with five economic sectors – branches – and two factors of production, such as that of *Table 1*, in which we express the different inputs and outputs in value. If the nature of Intellectual capital is both labour and capital, it can be present on both factors.

Assume a rate of profit equal to 10% of the capital invested in each industry, equal to 4000 for each branch and then 20000 for the whole production system.

Table 1: SUT in Value

Branch	Capital Consumption	Wages	Profit	Prices/Supply
I	40	8	400	448
II	40	6	400	446
III	30	36	400	466
IV	12	8	400	420
V	7	30	400	437
Intermediate Consumption	129	88	2000	<i>Total Supply</i> 2217
<i>Profit invested</i>	0	0		
<i>Profit not invested</i>	600	1400		
<i>Additional investment</i>	0	0		
<i>Total Use</i>	729	1488	2217	
<i>Total Use in produce</i>	129	88	217	

The amounts per line indicate the *capital consumed* in the production process, *wages* paid and the *profit* realized. In the section below the “Intermediate Consumption”, the first two lines indicate the share of the profit realized that was *reinvested* or *not invested* again (hoarded), in the production process. The third line instead indicates the additional

amount, as external source of the production process, which was necessary to proceed to the exchange of the finished production, indicated per line as *Total Supply*.

We start from these quantities and we assume an increase of efficiency in Intellectual capital, in the different sectors, according to the percentages shown in *Scheme 1*. Let us assume an increase in efficiency just for the factor remunerated in Wages.

Scheme 1: Efficiency variation

Branch	Capital	Wages
I	0%	5%
II	0%	7%
III	0%	10%
IV	0%	12%
V	0%	5%
<i>Average</i>	<i>0,0%</i>	<i>7,8%</i>

The effects of these increases in productivity consist of a reduction in the consumption of invested capital, as shown in *Table 2*.

Table 2: SUT in Value after efficiency variation

Branch	Capital Consumption	Wages	Profit	Prices/Supply
I	40	7,6	378	426
II	40	5,6	378	424
III	30	32,4	378	441
IV	12	7,0	378	397
V	7	28,5	378	414
Intermediate Consumption	129	81,1	1892	<i>Total Supply</i>
<i>Profit invested</i>	<i>0</i>	<i>0,0</i>		<i>2102</i>
<i>Profit not invested</i>	<i>945,8</i>	<i>945,8</i>		
<i>Additional investment</i>	<i>0</i>	<i>0,0</i>		
<i>Total Use</i>	<i>1075</i>	<i>1026,9</i>	<i>2102</i>	
<i>Total Use in produce</i>	<i>129</i>	<i>81,1</i>	<i>210</i>	

The amount of wages is reduced because we assume that the increased efficiency produces greater value, for the same use. In a competitive economy the profit remains the

same, as a percentage of invested capital, and thus decrease in the amount. This situation would lead to a reduction in available system resources (in the tables: *Total Supply*) where prices are intended as the sum of the compensation of the production factors, even though they contain profit.

According to the *Theory of subjective value*, an increase in efficiency in the use of resources, in fact, leads to a reduction in the price of goods as production increases in quantity. We did not, therefore, indicate an increase of profit in place of lower amount of money spent on wages. We will do this in the next example. We could also represent a SUT with the same production, indicating additional investments in other sectors. But, since reinvestment is an autonomous decision of entrepreneurs, we have just shown the *direct* consequences of a more efficient use of resources, without indicating possible additional production processes.

In addition, we have assumed a total hoarding of profit so as to indicate only the *endogenous variables* of the production system, which is strictly related variations inside the process. This representation of the production process is expressed in terms of value but to analyze the effects of a change in the Intellectual capital efficiency (as well as in any other productive asset) we have to separate the effects on quantity from those on prices. In this way, we will see the effect of the deflating of Value Added created, carrying out the three hypothesis of *reduction in the amount of input* (see: *Table 4*), *increase in the amount of output* (*Table 5*), or *increase in the price realized* (*Table 6*).

To analyze a reduction of the quantities, as a first step we divide the values in *Table 1* between *prices* and *quantities*, and generate *Table 3*.

Table 3: Prices and Quantities

Branch	Capital Consumption			Wages			Profit			Prices/Supply		
	p	q	v	p	q	v	p	q	v	p	q	v
I	4	10	40	2	4	8	40	10	400	20	22	448
II	5	8	40	3	2	6	133	3	400	20	22	446
III	5	6	30	4	9	36	100	4	400	23	20	466
IV	4	3	12	2	5	8	80	5	400	33	13	420
V	1	7	7	5	6	30	57	7	400	2	219	437
Intermediate Consumption	129			88			2000			<i>Total Supply</i>		
<i>Profit invested</i>	0			0						2217		
<i>Profit not invested</i>	600			1400								
<i>Additional investment</i>	0			0								
<i>Total Use</i>	729			1488			2217					
<i>Total Use in produce</i>	129			88			217					

Assuming an improvement in the use of Intellectual capital according to the percentages previously indicated in *Scheme 1*, and assuming that the change in efficiency does not change the final price (*Total Supply*), we see an increase in profit (now amounting to 2007 from the precedent 2000) and an increase in the rate of profit (from 10,0% up to 10,7%).

Table 4: Prices and Quantities after Efficiency variation (Stable Prices/Total Supply)

Branch	Capital Consumption			Wages			Profit			Prices/Supply		
	p	q	v	p	q	v	p	q	v	p	q	v
I	4	10	40	2	3,8	7,6	40	10	400	20	22	448
II	5	8	40	3	1,9	5,6	133	3	400	20	22	446
III	5	6	30	4	8,1	32,4	100	4	404	23	20	466
IV	4	3	12	2	4,4	6,6	80	5	401	33	13	420
V	1	7	7	5	5,7	28,5	57	7	402	2	219	437
Intermediate Consumption	129			80,7			2007			Total Supply		
<i>Profit invested</i>	0			0,0						2217		
<i>Profit not invested</i>	602,05			1404,8								
<i>Additional investment</i>	0			0,0								
<i>Total Use</i>	731			1485,5			2217					
<i>Total Use in produce</i>	129			80,7			210					

Total Supply being equal, the increase of efficiency in Intellectual capital is measured by a reduction in spending on *Wages* and a redistribution of resources in favour of the profit.

In the case, instead, of equality in spending in inputs, a higher efficiency in Intellectual capital would be expressed in a higher amount of output. In this latter situation we obtain *Table 5*, in which we consider the profit directly expressed in value, as a residual.

Table 5: Prices and Quantities after Efficiency variation (Increase in Total Supply)

Branch	Capital Consumption			Wages			Profit			Prices/Supply		
	p	q	v	p	q	v	p	q	v	p	q	v
I	4	10	40	2	4	8			534	20	29	582
II	5	8	40	3	2	6			512	20	28	558
III	5	6	30	4	9	36			493	23	24	559
IV	4	3	12	2	5	8			442	33	14	461
V	1	7	7	5	6	30			444	2	240	481
Intermediate Consumption	129			88					2425	Total Supply		
Profit invested	0			0,0						2641		
Profit not invested	727,43			1697,3								
Additional investment	0			0,0								
Total Use	856			1784,8					2641			
Total Use in produce	129			88					217			

We see that the rate of profit has risen from 10% up to $(2425/3.784 =)$ 12,3%. Total Supply is grown from 2217 up to 2641.

6 Deflating and price index numbers

The effect of deflating the variables of the overall economic system, however, is seen only in the third case, i.e. in a table that assume that a variation of efficiency in Intellectual capital consists of the chance to achieve a higher price for the same quantity placed on the market. As a matter of fact, the competitive advantage may also consist in the possibility to spend less in wages, as shown in Table 4; but to study the effects of deflating, we create the example shown in Table 6.

Table 6: Supply after variation of Price in branch I

Branch	Capital Consumption			Wages			Profit			Prices/Supply		
	p	q	v	p	q	v	p	q	v	p	q	v
I	4	10	40	2	4	8			512	25	22	560
II	5	8	40	3	2	6			400	20	22	446
III	5	6	30	4	9	36			400	23	20	466
IV	4	3	12	2	5	8			400	33	13	420
V	1	7	7	5	6	30			400	2	219	437
Intermediate Consumption	129			88					2112	Total Supply		
Profit invested	0			0						2329		
Profit not invested	600			1400								
Additional investment	33,6			78,4								
Total Use	763			1566					2329			
Total Use in produce	129			88					217			

In this example, the variation with respect to the initial situation (see *Table 3*) consists of a change in price on the market in the *branch I*. It has gone from 20 to 25. Other variables, however, changed due to this increase. In particular, the profit of the same sector rose from 400 to 512, and so the *Total Supply* from 2217 to 2329, even though the capital consumed remained at 217. The wealth produced is therefore increased and accounted for the individual sector and the productive system as a whole, as a mere effect of an increase in the market price. At the aggregate level, it becomes important to understand the effects of deflating, as the expression of the variables has so far taken place in current prices.

In case of deflating by the *Laspeyres Price Index* – see: Fisher (1921), for the construction and identification of index numbers suitable for every purpose, and Leti (1983), Bracalente *et alii* (2009) and Guarini *et alii* (2000), for the construction and the modern use of Price Index Numbers –, the increase in the general level of prices in *Table 6* was about 5,05%, as shown in *Scheme 2*.

Scheme 2: Price Index Number

Branch	Before		After	
	p	q	p	q
I	20	22	25	22
II	20	22	20	22
III	23	20	23	20
IV	33	13	33	13
V	2	219	2	219

Price Index Number: 105,053

Since quantities before and after the change in price did not change, even the *Paasche* or *Fisher Price Index* would have the same value.

In all these cases, the increase in profit recorded in the first branch amounting on $(112/400=)$ 28% and overall industries amounting on $(112/2000=)$ 5,6%, would be decreased due to the difference in value attributed to price changes and recorded by the index number. Profit in real terms would remain roughly the same as before, both in the first branch and in the economic system.

7 The meaning of the *Modified-SUT*

In the transition from *Table 3* to *6*, there wasn't a parallel shift of all prices. Instead, what changed was the purchasing power of money, because production changed between the different branches. According to Zappa, variations in relative prices have commercial or productive origins; so deflating may hide changes in the structure of production system. Moreover, in every production system, commodities change over time, even in quality and we have discussed elsewhere the problems of *Quality adjusted indexes*, and *Hedonic indexes* (see: Serafini, 2013). Now, since the same variation indicates the amount of money that has changed hands from buyers to sellers in *branch I*, deflating hides changes in production. Let us explain this passage.

If we recognize that production results in a net product (Böhm-Bawerk, 1998; Fisher, 1930–2006; Keynes, 1936–1978; Marx, 1867–1989), the change in output is usually measured in quantity. Since the additional quantity has an objective price on the market, to evaluate it we have to use a homogeneous size among all – and also with respect to the input –. Usually you multiply any quantity produced for its price, so to obtain a measure in coin.

The combination of these two premises, which assumes that the *production creates value* and that this is directly *expressed in money*, otherwise it would not be comparable, implies that changes in the economic wealth are not changes only in quantity or only in price, but are directly *changes in the value of exchange*; objective wealth, not only relative.

A confirmation of the effectiveness of this hypothesis arises from the fact that resources, risen to 112 to pay that extra price in *Table 6*, come from outside of the production process (see the row: *Additional investment*. Specifically: *Capital consumption* +33,6 and *Wages* +78,4). The increase of a price, therefore, is actually a greater economic value of the mass of resources inserted in the production circuit.

In this way we can say that *exchange process* depends on *production process* as they are strictly connected. Investment and Consumption depend on autonomous choices of the *economic agents*, but if the production process generates added value, as we can see in the M-SUT, profit can be *hoarded* or *invested* during the same period.

If the profit is hoarded then *Total Supply* will be reduced because of capital consumption and in the subsequent period there will be less wealth to spend; if the profit is invested, there will be a higher level of production and more value to purchase/sell.

This stems from the fact that by means of the M–SUT we analyze the production system and we see that the influence of money on the price level is opposite to the provisions of the *Quantity Theory of Money* (Fisher, 1930–2006). In the case of M–SUT, in fact, wealth is objectively assessed and directly in value, so coin does not determine price level, but the value of money is determined by the price level. The algebraic relationship is the same but the variable that controls is the opposite.

Connected with this, there is also the question of what resources are capable of economic assessment and therefore the assessment of economic capital and wealth not involved in the production process; but the allocation of the additional price (distribution), i.e. of the volume of the production process, depends on the destination of the resources themselves, and they depend on the ownership of final goods like that of the means of production.

From the M–SUT it is understood that *saving* cannot be considered as a virtue if it is a hoarding of productive resources. If, in fact, additional investment had not intervened from the outside (see the row *Additional investment*), the total profit achieved would be hoarded to a greater extent, and this would have resulted in a lower total value of the following production process, due to capital consumption. Therefore, we could not consider adequate the use of the SUT at current prices already developed by the National Accounts, because they do not show the variations in wealth put into the productive cycle.

Moreover, traditional SUT do not indicate where produced wealth is directed and the amount of the possible lack of hoarding that, although it seems to allow the production of capital, actually inhibits it.

8 M–SUT and Intellectual capital

8.1 Capital, Wages and Intellectual capital

As well as Intellectual capital is a productive factor, *Wages* and *Capital consumption* are not part of the net product, as they are inputs of production.

The traditional SUT, instead, do not indicate the wages as a factor of production since *Wage* is part of the Value Added (see: Vanoli, 2005; European Union, 2013) and the second is defined as the difference between the value of production and the value of goods consumed in the production process (Pasinetti, 1975–1981).

Although a part of economic theory (see: Sraffa, 1960–1991), believes that the *net product*, intended as *additional product* compared to the value of the factors of production, would be divided between labour and capital and that there would be a distributive conflict between *labour-force* and *capital*, there is a theoretical reason for our different representation.

If, on one hand, output is entrepreneur's property, on the other hand, in corporate accounting, Value Added is the remuneration of production factors and, after deductions, we get the profit as income amending heritage (see: Zappa, 1920–1929).

8.2 Economic agents decisions

By means of M–SUT is possible to understand the decisions taken by economic agents and quantified in supply/use changes, i.e. the mass of capital in production, as well as all its variables (productivity, distribution, production quality, etc.).

Such decisions can be traced in:

- 1) decisions of the entrepreneurs to hoard the productive capital;
- 2) decisions of money capital owners, not yet entrepreneurs, to enter more wealth into the production circuit;
- 3) decisions of those who are not owners of enough money but are willing to borrow in order to purchase – whether for investment or consumption – in the *capital* or *wage* field (the two columns in which we have grouped the factors of production).

In the latter case, we see a correlation between the *economic growth* and that of *loans*. In particular, an increase in debt, private or public, indicates that the production system has necessitated a purchasing power on the market that is built up by borrowing funds, from those who possess them in excess (or directly from banks) to those who do not have enough of them. To that effect, a more efficient use of Intellectual capital, produces an additional value which, to determine an increase in the production process, requires an increased mass of monetary resources; and this increased mass is *profit reinvested* or *previous savings* or *loans*.

To conclude this study, in the next section we indicate some reflections about the relationship between the most widely used measure of Intellectual capital efficiency (VAIC) and the Gross Domestic Product (GDP). In this way we clarify that more efficient use of Intellectual capital depends on both the characteristics of the production process and the autonomous decisions of economic agents.

8.3 VAIC and GDP

Regarding the relationship between the capital employed in the production process and the generated *income*, the Value Added Intellectual Coefficient is a measure that considers both *income* and *book value*.

According to Ante Pulic (2004), VAIC formula is:

$$\text{VAIC} = \text{ICE} + \text{CEE}, \text{ where: } \text{CEE} = \text{VA}/\text{CE}; \text{ ICE} = \text{HCE} + \text{SCE}$$

To understand the formula:

- HCE = VA/HC;
- SCE = SC/VA;
- SC = VA – HC;
- VA = Value Added
- CE = Book value of the net asset of company
- HC = Total salaries and wages for the company

The VAIC is inversely correlated to changes in the *book value*, which in turn directly depends on the Value Added created.

The example in *Table 7* and *Grafic 1* shows the relationship between VAIC, the VA and the *book value*, to understand how the added value, if not entirely distributed, increases the book value and thus makes the VAIC divergent with respect to GDP, because the latter is not related to the net assets of the economic system.

Table 7: VAIC, VA and GDP

	Year 1	Year 2	Year 3	Year 4
OP (EBIT)	20.000	20.000	20.000	20.000
HC	30.000	30.000	30.000	30.000
Depreciation	12.000	12.500	13.000	14.000
Amortization	5.000	6.000	6.500	7.000
VA	67.000	68.500	69.500	71.000
CE	10.000	12.000	14.000	16.000
ICE	2,79	2,85	2,89	2,94
CEE	6,70	5,71	4,96	4,44
VAIC	9,49	8,55	7,85	7,38
GDP (= VA)	67.000	68.500	69.500	71.000

In M–SUT, economic capital is only present as capital consumption as well as in the System of National Accounts (see: European Union, 2013). Since GDP measures only *income*, to measure the VAIC of an economic system we should dispose of the amount of the *net assets* of all the companies. For this reason, until the economic capital will not be present in the National Accounting systems, VAIC cannot be calculated at a macroeconomic level. A qualitative notation, however, can be deduced from the main Schools of Economic Thought because, according to the main theories of value, *Capital* tends to create *Income* as a decreasing percentage with the increase of capital.

According to Irving Fisher (see: Fisher, 1930–2006; Serafini, 2013), the rate of interest is determined by the *rate of time preference* between current and future consumption, while capital–value is the expected income, discounted at the interest rate. Since the consumption impatience tends to decrease with the increase of wealth, *Income*, in relation to capital–value, tends to decrease.

According to John Maynard Keynes (1936), the *marginal propensity to consume* is decreasing as income increases, because the needs arising after the most urgent have been fulfilled, find it hard to be in the form of *Aggregate Demand*. Therefore, the increase of capital tends to decrease the return on capital.

Finally, according to Karl Marx (1894–1989), the *falling rate of profit as a trend* stems from the fact that profit is generated only by labour–force employed in capitalistic production and the expense for this input tends to be compressed by the capitalists such as they reinvest in capital in order to increase the labour–force productivity. Against this

trend, on the other hand, there are *opposing forces*, and therefore this approach leaves open a possibility of variation of VAIC in all directions, not only in a necessary reduction for each growing economic system.

9 Conclusions

Changes in prices set by coin are only the *parallel* changes in the *general level of prices* and in an economic system is almost impossible to detect parallel shifts in prices. According to this perspective, Value Added produced by the Intellectual capital has to be measured in *current prices* because the deflating changes the *relative size* and the *objective value* of the company production. To validate this hypothesis we state that the process of deflating currently used to quantify the real changes in production is not consistent with the economic Theory of Value, as expressed by the *Marginalists* of the *Third Generation*. Wieser, Wicksell and Fisher produced fundamental works that make a leap from microeconomics to macroeconomics and switch from the *subjective* value to the *objective* value.

To represent an overall economic system without deflating procedure, we have used the Input–Output Analysis and created Modified–Supply and Use Tables to compare the theoretical and practical results. In this way we have disclosed that deflating is not consistent with the economic theory and with a correct quantification of the Value Added produced by the Intellectual capital. However, we refer to a future work the construction of the macroeconomic M–SUT for a real economic system.

In the last section of this paper, we have made a comparison between VAIC and GDP starting from the same data set and we get a *negative correlation* between the two methods because Value Added increases the book value and *tends* to reduce VAIC. In this way, being equal all other variables, a positive variation of GDP may result in a decrease of VAIC.

Finally, we hope for the accounting of the economic capital in the Systems of National Accounting in order to calculate the VAIC at macroeconomic level too.

Structured Abstract

Purpose: The aim of this paper is to measure the sustainability of a tourist destination. The tourist destination competitiveness is the result of combining the governance of tourist firms that are part of it and the sustainability of environmental resources of a 'geographical area. In this paper we will refer to the "albergo diffuso" experience. The "albergo diffuso" will be useful for the purposes of our analysis to see if this new and original model of hospitality meets the characteristics of innovation for sustainability, providing a good example of enhancement of an area in the perspective of sustainable tourism development.

Design/Methodology/Approach: The methodology is the case study research (Yin, 2003). The results will be validated through the application of the model of Weaver (2000, 2011). The model proves to be more explanatory for the evaluation of the level of sustainability of investigated tourist destinations.

Originality/Value: The sustainability implies that tourist destinations are governed and managed to satisfy the new expectations of the tourist's experience in accordance with the socio-economic and natural environment in which they operate. In this context, the strategic role rises in support of the development of an entire area within the perspective of sustainable tourist development.

Practical Implications: To be competitive, the tourist destination has a duty to propose an innovative bidding system that improves the quality of the tourist preserving natural resources and the cultural specificity on which the tourism is based. In this way, the tourist destination is identified as a node in a complex network of relationships that transcends national borders and involves different business actors who share goals and strategic decisions influence each other.

Keywords – Destination management and governance, knowledge management, sustainability, innovation, competitive advantage

Paper type – Practical Paper

1 Introduction

The hypothesis of this paper is based on the observation that the changes in the economy and society promote new business opportunities. In recent years, the recent downsizing of tourism in the World, was accompanied by a significant change in the quantitative composition of the tourism supply and demand.

From the point of view of tourism demand, companies are to relate more and more tourists with "elite", both Italian and foreign, who wish to spend quality leisure time tourist experience. In this context, the tourist shows a heightened sensitivity to the experiential aspects of their free time to discover the authenticity of the territory and to enable closer relations with the local native.

From the tourist point of view, the need to satisfy the most diverse needs of tourists has led to the success and development of specific formulas of entrepreneurial nature of accommodation, consistent with the changing needs of the tourists in a sustainable way. In particular, we refer to the agritourist firms and the "alberghi diffusi". The agritourist firms have experienced strong growth compared to the other components of the sector hotels and other facilities over the past five years. They are the result of the rediscovery of rural life and the rural world. The "alberghi diffusi" however, represent innovative models of hospitality and tourism Made in Italy, the result of renovation / redevelopment of historic towns, ancient hamlets, and ancient palaces, located in the center of the city of art and not. It is a reality differentiated within itself as to the degree of innovativeness of the business, still limited in number but strong in development and particularly appreciated internationally for its innovativeness (Paniccia, Silvestrelli and Valeri, 2010).

Undoubtedly, to intercept and manage the dynamics emerging in the tourism sector, it is necessary to analyze the problems of governance and management of the destination and the tourist industry. According to the setting of the coevolutionary perspective, tourism firms co-evolve with tourist destinations in the search for competitive advantage, being conceived, businesses, as critical resources for the development of the territory (Weick, 1969; Lewin and Volberda, 1999; Paniccia, 2006; Paniccia, Silvestrelli and Valeri, 2010). It becomes more and more essential to know how to manage the co-evolution, favoring a synergy of intent and behavior among all actors of the territorial system based on a sharing of goals (Selznick, 1976). In this sense, it appears increasingly central to the systemic capacity of tourism firms to perceive and evaluate the external

environment, which requires answers professional and responsible (Golinelli and Simoni, 2005). This can be a possible source of creativity for development more sustainable).

Therefore tourism businesses must be able to devote attention to the needs expressed by tourists visiting the tourist destinations competitors in order to implement strategic paths consistent (Nahapiet and Ghoshal, 1998).

2 The theoretical framework

In a globalized competitive environment, tourist destinations must act according to a decidedly more entrepreneurial than ever before. It is no longer sufficient to manage the relationships between the tourism system and the tourists, but it becomes indispensable upstream govern the relationships between all stakeholders in the tourism sector which, in various ways, contribute to the tourism. In this context, the competitiveness of a tourist destination is dependent on the capacity of each undertaking / tourist organization that works to compete in it compared to competing tourist destinations, national and international. This necessarily implies that each tourist destination not only the individuals operating in the territory of its borders, but especially to define an authority of governance, whether public or private or mixed (Pencarelli, 2001), able to develop a strategic plan that enhances not only the business but also the attractions of the area (Pechlaner and Weiermair, 2000; Franch, 2002; Golinelli, 2002; Ritchie and Crouch, 2003; Sainaghi, 2006; Martini, 2008; Valeri and Baiocco, 2012).

In the management literature, the concept of tourist destination plays a central role. We are witness to numerous studies, national and international that have long investigated this issue thoroughly, especially if linked to interventions to support the competitiveness of the tourism sector. In this regard, one can not but mention the contribution of Cooper (1993), commenting on the concept of destination region at the base of the model Leiper (1979) writes " [...] *the destination region is perhaps one of the most important elements. The destination represents the reason of travelling and the attractions at the destination generate the visit*".

By analyzing the extensive bibliography on the concept of a tourist destination (Pechlaner, Paniccia, Valeri and Raich, 2012), it is difficult to arrive at a single definition

that, both in terms of interpretation both in terms of managerial interventions, is satisfactory. This variety is justified considering that the topic is of interest both from scholars in different disciplines (Tamma, 2000). Some scholars see this as the cause of so much confusion and so many difficulties still exist for its own theoretical framework fully convincing. Over the years, leading experts in tourism management were compared on trying to shed light on issues that for years have been the focus of scientific debate (Pechlaner, Paniccchia, Valeri and Raich, 2012). In particular, one often tends to coincide with the tourist destination tourist product dispensed (eg destinations mono- product), forgetting that the latter is one of the possible outputs of the tourist destination.

Aware of the difficulty of proposing a work of systematization of the literature, the doctrinal debate on the concept of a tourist destination can be traced back to two different analytical approaches:

- 1) *touristic demand - side approach*
- 2) *touristic supply – side approach*

Compared to the same tourist destination, the tourism expert can analyze it in a different way; in the first case (touristic demand - side approach) it is privileged destination as a tourist product, or rather as a set of points of attraction, natural and artificial, capable of attracting tourists (Bieger, 2000), in the second case (touristic supply - side approach) priority is given to the importance of the supply system and tourism companies operating in the tourist destination (Tamma, 2000; Brunetti, 2002; Martini, 2002). From this there are inevitably different modes of design, management and organization of the tourist destination (Paniccchia, Pechlaner and Valeri, 2010; Minguzzi and Presenza, 2010) due to the historical, economic, cultural, social and geographical allocation of the available resources.

The prospects of analysis - touristic demand - side approach and touristic supply - side approach - have generated a multiplicity of positions by authoritative experts. They are not opposed, but on the contrary should definitely intersect when there is a need to adapt to the environment of the tourism through the preservation and change (Cafferata, 2009). The request to consider an integrated approach to emerging tourist destination, although this is not always given explicit mention, in some more recent contributions on the specific issue (Leiper, 1979; Della Corte, 2000; Pencarelli, 2001; Buhalis, 2000; Franch,

2002). Nevertheless, this integrated perspective is, to date, not too exhaustively developed as it deserves, even in view of a unitary systematization of the different approaches to the management of a tourist destination.

The management literature has dealt not only to define the concept of a tourist destination but also took care to address the problems and methods of government of a tourist destination. The identification of an authority of governance is of fundamental importance for the competitiveness of a tourist destination. The governance of the destination can be conceived as a system of decisions and actions aimed at consolidating and enhancing the competitiveness of the destination, setting clear goals and shared development between the actors of the tourism system. The identification of the authority of government to a destination is not easy; it depends on the characteristics of each destination.

The authority of government must seize and exploit the tangible and intangible components that characterize the cultural identity of a destination compared to competing destinations, local, national and international level. This assumes that there is a strong sharing of decisions, directly or indirectly, to each level of government tourism business both in the government of the destination and that all decisions are aimed at increasing the territory attractiveness and the tourist destination competitiveness.

Governance involves not only the shareholders, but also those who have an interest in the destination (eg. Individual managers, coalitions of labor providers) and an interest in the tourist destination: we refer to organizations "relevant" environment which operates as a tourist destination (the so-called stakeholders). Some of these issues directly affect the purposes of the destination (eg. Brokerage firms or companies providing tourist services), others are bearers of a public or social interest to the tourist destination, for example, the state organizations or associations of citizens.

The governing difficulties of a tourist destination are inherent in the structuring of strategic decision-making and in the allocation of the power to control resources within the tourist destination. This can be seen both in the tourist destinations strongly hierarchical, with a center of gravity well identified strategic and managerial (Franch, 2002) and in the *corporate* and *community* tourist destinations (Bieger, 1998; Flagesta and Hope, 2001). Both differ in relation to the design of the tourist offer and consequently have very different governance issues.

In the *corporate* destinations (eg, amusement parks, tourist villages, resorts, etc.), The tourist offer is designed by a firm which directly or indirectly controls, the attractiveness of the destination resources through contractual agreements. In this case, the destination assumes the configuration of a real firm, where problems of government are similar to those found in any other tourist organization (Bieger, 2000).

In the community destinations the local area offers a system of natural and manmade attractions in the tourist market. As a consequence the government is far more complex, considering that the resources of attraction are not owned by a single firm, but from independent business units, each of which pursues specific policies in terms of investment and income generation. In this regard, it is crucial the role of local institutions to the competitiveness of the tourism sector. In fact, they exert their control over resources (natural and artificial) and may support the tourism offer through forms of financing. Therefore, what distinguishes the corporate and community destination is a strong need to coordinate in the medium - long term the services offered by the different actors (public and private) which, through the direct control of the resources of attraction, help the generation of the tourist (Sautter and Leisen, 1999; Bramwell and Sharman, 1999; Della Corte, 2000; Presenza, 2007).

3 The Methodology of the research

The research methodology is the case study research (Yin, 2003). This methodology was useful to see if the “alberghi diffusi”, meets the common characteristics of innovation, providing a good example of enhancement of an area within the perspective of sustainable tourism development of a tourist destination. In this regard were analyzed some “alberghi diffusi”, representative of the universe of “alberghi diffusi” in Italy. For each case study we have identified the distinctive features and their consistency in terms of innovation, and verified the contribution of the company to achieve sustainable development of the territory of the local settlement, jointly from the viewpoint of economic, social and environmental.

The survey has made use of the following main sources: interviews we conducted with entrepreneurs and experts from local and national authorities operating in the tourism sector (CCIAA, Municipalities, Tourism Promotion Firms); disclosure documents of trade associations (National Association of “Alberghi diffusi”, Association Authentic Italian Villages); Web sites and corporate balance sheets; regional regulations in force;

articles published in daily newspapers, including international economic and political as well as academic publications related to the topics of this paper.

The results were further explored and validated by an attempt to apply the Weaver model (2000, 2011) to the reality of “alberghi diffusi”. This model is taken as a key to the sustainability of a tourist destination. It is applied by us with the particular aim of identifying the best conditions whose verification is essential to an effective diffusion model of the multi on our territory. The application of the model more appropriate adaptations required and it turned out to be explanatory for the evaluation of the level of sustainability of tourism in the investigated reality, and for the identification of the basic conditions that can promote more sustainable development.

4 Discussion of the results

The idea of *widespread hospitality* binds to the 1976 earthquake in Friuli Venezia Giulia, where it poses the need to appreciate whole villages of Carnia, converting them into tourist facilities.

The " diffuso " adjective denotes an integration enterprise with the socio-cultural reality and nature of the place. It is manifested from the horizontal configuration of the building structure, the authenticity of the buildings and furnishings that characterize the hotel (do not build anything new, but it restructures the existing carefully). The “albergo diffuso” is divided horizontally spread of existing housing units and of particular historical, cultural and artistic, which integrates with a land area according to different modes. Some hotels are divided in a historic village in a small mountain village or hill ; sometimes the structure of the hotel extends to cover a large part of the village, becoming an example of authentic experiential context in which the village and the inhabitants, farmers and artisans who live there, they become part of the experience of hospitality together with guests. Other hotels, however, are articulated in a rural or mountain area which, while not constituting a historic village, is, however, a local rich typicality ; still other hotels also are located in the center of a small or large cities.

From the point of view of technical and organizational, a second common feature is that the bedrooms are all located within the pre-existing units. They are of different sizes, independent and distant generally not more than 200/300 meters from the main building in which the activity takes place of reception and information. Unlike traditional hotels, the restaurant business is considered an ancillary service and therefore can not be carried

out; However, in most of the cases analyzed, we found that this activity is given special attention and care in key cultural. Species in some "alberghi diffusi" where we found annexed farms also of considerable size, the restaurant business takes an obvious role in the socio-cultural as well as economic. Similarly, it is considered the information activity to tourists, which is often supported by small libraries, mini-museums, training on local cuisine, etc

These interdependencies highlight in a very different way compared to traditional hotels, even the most traditional management activities of these companies (reception, information, accommodation, catering). During periods of increased tourist influx, some companies involved in its own process, as well as the homes owned by the hotel, other typical houses of the place owned by residents that are sold rented to guests.

The varied historical, cultural and architectural identity of the rooms that make up the hotels investigated (old houses of a village, a place of typical homes, old houses, agro-industrial wastelands, farms) and their equally varied possible dislocations in the area are distinctive elements very important, not only compared to other traditional formulas but also within the hotel segment of the "alberghi diffusi" among business and firms.

In the paper were examined 4 business cases properly selected within the universe of the "alberghi diffusi". It is small firms small within territories between their different. These hotels are suitable to be regarded in itself as a micro-business contexts territorial tourist destination, within the regions concerned.

4.1 *The "Al Vecchio Convento" albergo diffuso*

The "Al Vecchio Convento" albergo diffuso is an initiative by private entrepreneurs Italian with thirty years experience in the restaurant industry, which in 2007 decided to convert the hotel issued a prestigious building dating back to 1940, until then used as a restaurant. The renovation work lasted seven years and involved mainly the resident on-site and local cultural institutions attentive to the respect of the recovery of the real estate.

The hotel structure extends horizontally within the village for an area of 10 hectares or 10% of the total area of the village. The hotel consists of 7 units for a total of 25 rooms, which represent 61% of the total capacity of the village (41 rooms) and 0.2% of the carrying capacity of the destination Forlì-Cesena (18,674 rooms) (Istat 2011).

As regards the type of rooms, two consist of the main building and the annex that are owned by the entrepreneur, the other five rooms are rented by the inhabitants residing in

the borough. This is a good example of cooperation between the entrepreneur and the residents of the village attentive to the development of the area . The process of disbursement of the hotel service is configured as a "context of experience " authentic, in which the inhabitants and local artisans interact with hotel guests on the occasion of a series of events organized on site, such as painting classes and ceramics, typical local fairs and festivals . The hotel's clientele is predominantly international (30 % Italian and 70 % international) and comes not only from European countries (Netherlands, England, Belgium and Germany), but also from the United States, Russia, New Zealand and Brazil. In 2013, the number of arrivals registered in the hotel is 650 units. During the same period, the average stay of tourists was 3 nights . The data show that the " Al "Vecchio Convento" hotel still fails to express a strong tourist attraction because it is newly established and because located near tourist destinations known and characterized by high tourist flows.

4.2 The «Sextantio» albergo diffuso

The "Sextantio" albergo diffuso is located inside the fascinating medieval village of Santo Stefano di Sassano in Abruzzo (AQ). "Sextantio" is an initiative of Daniele Elow Kihlgren, Swedish-Italian entrepreneur, who in 1999 decided to buy part of the housing units in the village, now abandoned for years (Paniccia, Silvestrelli and Valeri, 2010). The hotel is made up of units and from a farm where the crops were reactivated typical products of Abruzzo cuisine, for years now abandoned. The "albergo diffuso" extends horizontally within the village for an area of 5,500 square meters, which represents approximately 40% of the total area of the village. The hotel consists of 9 units, 32 rooms and 72 beds, which represent 40% of the capacity of the village (70 rooms) and 0.5% of the carrying capacity of the L'Aquila destination (6,437 rooms) (Istat, 2011). Renovation works of the multi lasted 5 years and has involved mainly the resident on-site and local cultural institutions attentive to the recovery of the local real estate.

The process of service delivery involves fifteen hotel workers, all residents in the borough. The customers ' Sextantio consists for 25% of Italians and 75% of foreigners who come from Northern Europe (mainly Germany and England), the United States and Russia. In 2013, the number of arrivals registered at the hotel was 6,000 units. During the same period, the average stay of tourists was 2 nights . These data show that "Sextantio" is an important tourist attraction not only for the village of Santo Stefano di Sessano but

for the entire region . The hotel has in fact helped to revitalize a part in the history and local culture (from architectural structures to the typical food and wine) and, secondly, to generate economic value for the country, thereby strengthening the regional identity of the inhabitants of the village ; This is also reflected in the drastic reduction in the migration of the population residing in the village that until a few years ago was likely to jeopardize the survival of the local community .

4.3 *The «Sotto le Cummerse» albergo diffuso*

The "Sotto le Cummerse" albergo diffuso was founded in 2002 by two local entrepreneurs who have fully supported the huge initial investment for the restoration of the apartments in the town center . The units available to the hotel there are eleven (25 beds), of which ten apartments and a building used as a reception and lounge, from which are no more than 200 meters. There are three different types of accommodations (standard, superior and suites). The hotel offers accommodation only service to its customers and the food service is provided in collaboration with local catering companies . The process of disbursement of hotel service involves 4 people. The room occupancy rate during 2013 was 56 %, with an average stay of 2 nights during the winter and in the summer of 7 nights. During the same period, the number of arrivals amounted to 1,966 units . The hotel's clientele spread is composed of 70 % by Italian tourists (especially from Campania, Lazio, Lombardy, Piedmont and Puglia) and the remaining 30% are foreign tourists from Northern Europe (England, Sweden and the Netherlands) and Canada, Australia and Russia.

4.4. *The «Val di Kam» albergo diffuso*

The "Val di Kam" albergo diffuso was founded in 2002 by an Italian entrepreneur with experience in banking and insurance. The "albergo diffuso" was formed to retrieve the village of Sant'Angelo Muxaro in Sicily (AG), abandoned for years. The historic village is located in the town of Sant'Angelo Muxaro, which extends over an area of 64.55 square kilometers, and is located on a hill at an altitude equal to 335 meters above sea level The village of Sant'Angelo Muxaro assumes, in Europe, a position of particular importance in view of the archaeological world relative to the pre-proto (XII-th century BC.). Compared to the village of Sant'Angelo Muxaro, the "Val di Kam" albergo diffuso is in a kind of symbiosis with the territory integrating strongly with the local socio-

cultural reality. The hotel structure extends horizontally within the village over an area of 3,700 square meters, or 30% of the total area of the village. The “albergo diffuso” consists of 4 housing units, 20 rooms and 60 beds, which represent 40% of the capacity of the village (80 rooms) and 0.6% of the carrying capacity of the destination Agrigento (3,185 rooms) (Istat, 2011). The process of service delivery involves seven hotel workers all residents in the borough. The clients of "Val di Kam" “albergo diffuso” are Italians (30%) and foreign (70%) coming from the Netherlands, Spain, France and Germany. In 2013, the number of arrivals registered at the hotel was 660 units. During the same period, the average stay of tourists was 2 nights. Compared to the village of Sant'Angelo Muxaro, "Val di Kam" has strong capacity to attract tourist flows to the history and cultural traditions valued by local institutions, always attentive to the protection of the territory.

5 Conclusions and limitations

The case studies analyzed are placed within the Weaver matrix (2000; 2011) and are reinterpreted in the light of its two constitutive dimensions: "tourism intensity" and "regulation" . For each case we will verify the first position within the matrix and the possible evolutionary trajectories. Given the specificity of the investigated reality, the positioning of the hotels analyzed in different villages - specific points within the same quadrant of the matrix is not indifferent . In a dynamic view, it is evident that for all the analyzed cases it is desirable to develop towards a state of tourism " approved alternative " based primarily on the definition of a clear regulation of these activities. However, there are cases such as particularly "Val di Kam", "Le Cummerse" and " Sextantio " for which the challenges require higher capacity adjustment . It 'also clear that the development of enterprises surveyed towards greater sustainability requires all parties involved more attention to the cultural and social dimension of the territory of the settlement, which should be further enhanced to attract tourist flows in similar locations. In this sense, no less important is the issue of economic sustainability of these ventures, which indeed makes it even more critical the role of regulation. One example is "Al Vecchio Convento" who have benefited from a gradual increase in attendance at the property due to regulatory actions and policies of territorial marketing, provincial and regional.

The Weaver model is therefore more explanatory in relation to cognitive purposes of our investigation. In this regard, the following considerations apply. Our investigation

was concerned with a business model that tourist like a small tourist destination. In these cases, the identification of the company with the village allows to consider them as a whole with respect to the broader regional context in which they are located. It was thus possible to analyze the placement of such enterprises by assessing their ability to contribute to the development of local tourism. In this regard, the case is emblematic of "Sextantio" which has contributed significantly to the promotion of the territory at the provincial, regional and international levels.

A further consideration is that the reality under investigation for the "adjustment" variable takes on an important role in terms of sustainability. However, given the positioning of the cases analyzed in the CAT quadrant of the matrix, it is obvious that no less important is the "tourism intensity" variable and, in this context, particularly the amount of tourist flows, although these are niche destinations. We should not neglect the issue of economic sustainability of the analyzed firms. The "albergo diffuso" model can be considered a sustainable hotel service that presents original structures and places of production-service delivery, experiential contents and participants involved. In fact, it is not just a hotel spread of particular historical-cultural and artistic but it is a project to promote the history and culture of an area that can have a major impact on competitiveness, also because of its economic development social-local, as demonstrated by some excellence examples.

Within the historic villages, the tourism cannot become a mass phenomenon; However, it can play an important role in disseminating local and regional contexts in a new culture that relies on the small tourist business on the role of driving force for a healthier and more sustainable development of more territories, more and more local community.

From the legal point of view, still lacks a clear and consistent rules in the field of "alberghi diffusi". In regions with a higher concentration of these situations there is no proper regulation. Conversely, there is a more comprehensive legislation in the regions in which they operate a limited number of "alberghi diffusi".

Structured Abstract

Purpose The purpose of this paper is to better comprehend the interplay between MAS and innovation in research-intense networks. These networks are characterised by multifaceted knowledge sharing/integration/transfer processes that will be taken into account in order to understand how an effective MAS can positively affect innovation, and in turn how innovation shapes MAS.

Design/methodology/approach The research employs the single case study of a research-intense network located in Campania, namely *Campania Bioscience*, and investigate these issues through the lens of the *Middle Range Thinking* (MRT) approach developed by Broadbent and Laughlin (1993, 1997, 2003, 2005, 2013) advancing the Habermas Theory about Society, since this is particularly suitable to examine the issues relating to an on-going strategic change in management accounting practices fostered by changing environmental conditions.

Originality/value The novelty of this paper relies on the possibility to explore the peculiarities of an effective MAS supporting the innovation processes within a complex setting such as the researched network, that involves multifaceted knowledge sharing/integration/transfer. Moreover, it offers a newer perspective of analysis to

interpret the role of MAS in innovative networks, thus contributing to the growing debate on the antecedents and facilitators of knowledge sharing and knowledge integration.

Practical implications Our findings will be will to all the organizations involved complex processes of co-production of knowledge and innovation. Indeed the study broadens current knowledge on the factors that may contribute to bringing about an effective and positive interaction between MAS and innovation, relevant for both professionals and practitioners, opening the well-known “black box” of the creation/sharing/transfer/integration of tacit knowledge.

Keywords Management Accounting System, Innovation, Knowledge sharing and integration, Research Intense Network.

Paper type – Academic Research Paper

1 Introduction

This research focuses on the issues relating to the management tools and practices that support innovation processes in networks, and how these work in practice. Indeed, it is well acknowledged that given the importance of networks, it is fundamental to better comprehend how the progressive evolution towards these more complex and articulated organizational structures impacts on management practices and decision-making processes.

Over the last 20 years organizations, particularly those characterized by strong innovative approaches, have been prompted to redefine their boundaries, undertaking collaborative relationships with external subjects, to reinforce their strategies (Powell et al., 2005). What should be noted is that the involvement of several different actors for the development of the same project is regarded as an essential element to support innovation, because of the increasing complexity of external economic environments and the variety of tangible and intangible resources needed to develop new knowledge (Kale and Singh, 2007). From this perspective, the importance of networks lies in their role as mechanisms enabling participants to access more easily and less costly external and heterogeneous knowledge resources that can be combined with the existing ones, or used to create new expertise. Accordingly, networks constitute a conduit that channels the flow of information and know-how among the firms within the network, with each member acting as both a recipient and transmitter of knowledge (Ahuja 2000, Owen-Smith and Powell 2004). Not surprisingly, relatively copious literature investigated the key role played by networks for innovation processes, highlighting that diverse features can

variously influence the dynamics of information diffusion within networks. Some authors have explored how different network structures influence the generation of innovation and their performance (Podolny and Stuart, 1995; Powell et al., 1996). These studies provide a number of positive evidence in relation to networks' effectiveness. Moreover, other researches enlighten how the direct alliance relationships facilitate knowledge flows between partners (Gomes-Casseres et al. 2006, Mowery et al. 1996), thus enhancing the innovative performance of firms (e.g., Owen-Smith and Powell 2004, Soh 2003).

Despite the above-mentioned advantages relating to network relationships, it is undeniable that these latter profoundly influence the aspects of strategic planning and control that consequently need a broader attention. In this regard, it is important to highlight that when innovation is pursued going beyond the organizational boundaries it is essential to correctly understand how inter-organizational relationships should be managed, in order to promote collaboration and knowledge sharing within the network. In this context it is worth remembering that the provision of adequate management accounting systems¹ (MAS) - able to ease the information flows and to enhance the fiduciary dimension among the actors involved - assumes a vital importance.

With specific regard to management accounting systems, in the last decade a growing debate has focused on their strategic role, highlighting some key and still partially unclear aspects. In particular, some authors have highlighted small businesses in the initial growth stage's needs for adequate MAS, understood as strategic elements crucial to promote their development (Davila and Foster, 2005; Davila, 2005). Other scholars focused on the need to identify appropriate information systems and management accounting tools for the strategic management of network relationships (Tomkins, 2001). A further line of researches found that in research-intensive sectors, such as pharmaceuticals (Ma and Tayles, 2009) and aerospace, MAS have gradually assumed a strategic importance (Bromwich and Bhimani, 1994), by virtue of their ability to support decision-making and value creation (Simons, 1990; Nilsson et al., 2012), and therefore should not be regarded as mere instruments of conventional control. This literature agrees that MAS can stimulate the involved innovation processes (Bisbe and Otley, 2004; Widener, 2007) by assuming a crucial role as means of knowledge transfer and integration (Rhodes et al., 2008; Ditillo, 2004; Canonico et al., 2012). We claim here that the above-mentioned

¹ For the purposes of this research the expressions management accounting systems and management control systems are regarded as synonymous, on the ground of Broadbent and Laughlin's claim (2013, p.13) that the latter is an attempt to rename the domain of the former.

studies rather than providing clear and definitive answers, have emphasised the need for further investigation of these issues from the theoretical and the practical point of view. In fact, there is also some scepticisms in relation to the role of MAS as innovation facilitators, since some authors still argue that controls are likely to constrain and diminish innovative approaches. On this basis, existing literature emphasizes the need for a deeper understanding of the interplay between MAS and innovation, that as previously highlighted, assumes specific characteristics within networks, which deserve further research.

Hence, the purpose of this paper is to better comprehend the interplay between MAS and innovation in research-intense networks. These networks are characterised by multifaceted knowledge sharing/integration/transfer processes that will be taken into account in order to understand how an effective MAS can positively affect innovation, and in turn how innovation shapes MAS. To this aim, the paper employs the single case study, focusing on a research-intense network located in Campania, namely *Campania Bioscience*. This network has been recently created and is now facing a relevant process of change in its management accounting practices. Thus, the issues under investigation are examined through the lens of the *Middle Range Thinking* (MRT) approach developed by Broadbent and Laughlin (1993, 1997, 2003, 2005, 2013), advancing the Habermas Theory about Society, since this is particularly suitable to examine the issues relating to an on-going strategic change in management accounting practices.

The remainder of the paper is structured as follows. The second section provides an assessment of prior studies investigating the interplay between MAS and innovation. The third section describes the MRT approach advanced by Broadbent and Laughlin, which will be used as a theoretical lens to guide the interpretation of results. The fourth section discusses the research design. In the fifth section the context of reference for the case study is described. In the sixth section the main findings of the analysis are summarised. In the end, we discuss the results and provide some concluding remarks.

2 Assessment of prior studies

Over the last years a number of studies focused on the relationship between innovation and management accounting systems, providing heterogeneous evidence. As stated above the MAS are alternatively seen as innovation facilitators, or as tools constraining or (at best) irrelevant for innovative settings. Given the strong debate still

taking place, the following pages attempt to explain (not pretending to be exhaustive) the main issues raised concerning MAS and innovation, in order to better clarify the boundaries of this discussion.

Some studies claim that MAS hinder innovation. In particular, several articles argue that management accounting and management control systems cannot exert a constructive influence over product innovation (Damanpour, 1991; Dougherty and Hardy, 1996; Gerwin and Kolodny, 1992; Leonard-Barton, 1995; Tidd et al., 1997; Verona, 1999). Sometimes, formal control systems are seen as tools constraining, or at best irrelevant in innovation and R&D settings (Abernethy and Brownell, 1997; Birnberg, 1988; Brownell, 1985; Hayes, 1977; Rockness and Shields, 1984; Rockness and Shields, 1988). Also, these are regarded as obstacles to creativity and incapable of supporting innovation (Abernethy and Stoelwinder, 1991; Amabile et al., 1996; Miles and Snow, 1978; Ouchi, 1977; Ouchi, 1979; Tushman and O'Reilly, 1997).

However, a second stream of research agrees on the importance of MAS as strategic processes or tools, crucial to promote innovation both for small and medium businesses in the start-up phase (Davila and Foster, 2005; Davila, 2005), and also for the strategic management of network relationships (Tomkins, 2001). Still the positive role played by MAS is acknowledged for research-intensive sectors, such as pharmaceuticals (Ma and Tayles, 2009) and aerospace. Here, MAS have gradually assumed a strategic importance (Bromwich and Bhimani, 1994), by virtue of their ability to support decision-making and value creation (Simons, 1990; Nilsson et al., 2012), and therefore should not be regarded as mere instruments of conventional control. Also, this literature agrees that MAS can stimulate the involved innovation processes (Bisbe and Otley, 2004; Widener, 2007) by assuming a crucial role as means of knowledge transfer and integration (Rhodes et al., 2008; Ditillo, 2004; Canonico et al., 2012).

Also other studies in the management accounting field highlight that MAS are crucial for innovation (Clark and Fujimoto, 1991; Cooper and Kleinschmidt, 1987; Cooper and Slagmulder, 2004; Davila, 2000; Davila and Wouters, 2004; Hansen and Jönsson, 2005; Ittner and Kogut, 1995; Ziger and Maidique, 1990). From this perspective, management control systems can be enabling for corporate activities (Ahrens and Chapman, 2004, 2007), and their interactive use can stimulate innovation (Bisbe and Otley, 2004; Widener, 2007).

One of the main reasons that justifies the central role of MAS for innovative settings

is that, according to Simon (1990), in turbulent markets (where innovation plays a crucial role and is one of the main factors stimulating turbulence and rapid variations) the existence of formal management accounting and management control systems can help firms to promptly recognise changing markets or product conditions and to positively face the new circumstances. From this perspective it is well-argued that when the environments of reference are complex and dynamic, either for technological and scientific evolution or for changing regulation, the interactive use of MAS, such as planning, budgeting, cost accounting and performance measurement systems, can be helpful to set objectives and action plans, and to monitor their achievements, also supporting a timely adaptation to changing conditions where needed (Bisbe & Otley, 2004). Clearly, and as Davila (2000) states, from this perspective there is the need to regard MAS and MCS in their broader definition, going beyond financial measures and objective quantification, to include non-financial measures and qualitative dimensions. This suggests that researching management control systems in innovative settings, such as research-intense networks, cannot be restricted to traditional accounting measures, but needs to encompass a broader set of elements. In this regard, what should be noted is that the use of different combinations of financial and non-financial information depends on the characteristics of the context under investigation, also in terms of types of uncertainties that managers have to face.

It is worth remembering that both financial and non-financial information are essential elements of an effective MAS which assume the existence of *accounting calculations* that, as Robson (1992) argues, mobilise distant places of the organisation and make them parts of managers' world. Literature agrees that management accounting calculations provide a good deal of the knowledge that is available for management (Cooper, 1992, 1997; Law, 1996; Briers & Chua, 2001; Chua, 1995; Miller & Rose, 1990; Hines, 1988; Quattrone & Hopper, 2005; Miller, 2001). This knowledge develops visibility by stating what belongs to the past, and of what the future consists of and, by defining what comes before and what comes after, and making things visible, it allows the definition of what the elements to be accounted for are, thus influencing "how different spaces and different times may be produced inside the networks built to mobilise, cumulate and recombine the world" (Latour, 1987), towards (we say) innovation.

In this view, given that the nuances of the existing debate are various and that agreement has not yet been reached, a number of authors claim that there is still room for

further research on the interplay between innovation and MAS. Indeed, what should be noted is that in complex and dynamic settings, such as research-intensive networks, a fundamental question to take into account when addressing the issues relating to the interplay between management accounting systems and innovation is the so-called knowledge management.

Indeed, since the seminal work of Nonaka (1991), literature has assumed that innovation processes necessary involve the generation of new knowledge (Nonaka, 1991; Nonaka and Takeuchi, 1995; Subramaniam and Youndt, 2005; Du Plessis, 2007, Lundvall and Nielsen, 2007). For instance, according to Subramaniam and Youndt (2005) the innovation consists of an ongoing attempt to achieving new and unique knowledge. Similarly, Du Plessis (2007) states that innovation implies the generation of new knowledge and ideas to support new business processes and outcomes. Finally, Lundvall and Nielsen (2007) assert that the essence of innovation is to look for something new to add to existing knowledge. In this sense, what should be noted is that innovation involves different processes of knowledge management. Developing new knowledge should in fact require its transfer, interpretation, and integration within the previous existing knowledge contexts of other parts of the organization (Kusunoki et al., 1998; Rhodes et al., 2008). In this regard, several studies have focused on different mechanisms and initiatives which could act as facilitators of *knowledge sharing* (Rhodes et al., 2008; Stewart, 1998; Turner and Makhija, 2006). For instance, Stewart (1998) highlights that the information technologies play a crucial role for knowledge sharing. More generally, Turner and Makhija (2006) theoretically demonstrate that the organizational ‘control mechanisms’ influence the firm's knowledge management process by affecting how knowledge is acquired, disseminated, interpreted, and used to accomplish organizational goals. Other studies have instead enlightened the relevance of management control systems as crucial tools for knowledge *integration* (Koga and Davila, 1998; Nixon, 1998; Davila, 2000; Ditillo, 2004; Canonico et al., 2012). According to Koga and Davila (1998) and Nixon (1998) management control systems within product development projects provide information directed to coordination and learning by positively affecting the performance outcomes. Ditillo (2004) adds that the relationship between knowledge integration and control mechanisms in knowledge-intensive firms depends on the level of knowledge complexity. Finally, Canonico et al. (2012) report that within product innovation teams the formal control mechanisms may play the role of administering information exchange

in order to achieve projects outcome and the desired level of knowledge integration.

Notwithstanding the increasing relevance of the topic, literature is still lacking with reference to the understanding of the interplay between MAS and innovation in complex and research-intense contexts, such as networks, characterised by even more multifaceted knowledge sharing/integration/transfer processes. Thus, the aim of the paper is to better comprehend the interplay between MAS and innovation in research-intense networks, by referring to their multifaceted knowledge sharing/integration/transfer processes, in order to understand how an effective MAS can positively affect innovation (thanks to its contribution to knowledge sharing/integration/transfer processes), and in turn how innovation shapes MAS (thanks to enhanced knowledge sharing/integration/transfer processes).

On this basis, the paper, differently from prior studies, aims at gaining rich and detailed picture, through the observation of an on-going process of change, of the factors that possibly influence in a positive manner the effectiveness of a change in MAS in a research-intense network, with especial regard to the possible strategies to render a change in MAS seductive, effective (by avoiding resistances) and able to support innovation processes. What should be noted is that the above-described elements of complexity that characterise innovative settings and particularly networks, are an essential and unavoidable element for the correct understanding of the dynamics and the problems relating to implementing accounting and management accounting systems in innovative networks. Indeed, such complexity is able to exert a certain influence on the process of change and on the results of the process itself (Broadbent and Laughlin, 2005). Thus, in this view, the MRT approach developed by Broadbent and Laughlin (1993, 1997, 2003, 2005, 2013) is well suited to the study, as it allows the investigation of the dynamics of change in the MAS by also considering the effects exerted by complexity and any resistance to the introduction of the new management tools.

3 Theoretical framework

In short, it is possible to state that Habermas regards society as the combination of three elements: lifeworld (i.e. a symbolic dynamic space, a normative context within which culture, tradition and identity can be reproduced), systems (i.e. a functionally definable arrangement of operations, such as organizations, which represent the tangible expressions of the lifeworld), and steering media (i.e. mechanisms such as power, money,

law that steer the interface and interaction between lifeworld and systems, and play a role in ensuring that the latter reflect the former). He clarifies that increasing complexity of the systems can generate decoupling between them and the lifeworld, creating a situation in which the steering media follow the systems instead of the lifeworld, so that systems colonize the lifeworld.

Building on his view Broadbent and Laughlin's Middle Range Thinking elaborated a more practical oriented model based on the following refinements: (i) steering media are considered as "societal institutions" (e.g. government); (ii) systems of actions are considered as "societal organizations" (e.g., corporations, local health authorities, schools and universities); (iii) every societal organization has its own lifeworld, systems and steering media, which they regard as an interpretative scheme, subsystems and design archetypes respectively, where the design archetypes (such as MAS) attempt to balance and make coherent the interpretative scheme and subsystems.

The authors claim that internal colonization of the life-world/interpretative scheme arises not only at societal but also at organizational level and that the MAS as design archetypes, absorbing the external influences and transferring these to the interpretative scheme represents a crucial issue. In this regard, it is important to highlight that the equilibrium of the whole organization resulting from the coherence between the internal elements and the external environment (Mintzberg, 1989) needs to be considered. Indeed, when equilibrium is achieved, the organization tends to inertia, (Laughlin, 1991, Miller and Friesen, 1984) that can be interrupted only by an environmental disturbance (Laughlin, 1991). Clearly, the effectiveness of any change depends on a wide range of factors. In this regard, Brunsson (1985) argued that organizations with strong ideologies might be resistant to fundamental changes, Greenwood and Hinings (1988) found that contingencies creating contradictions between circumstances/context and organization lead to greater change, which can be mitigated by commitment to previous schemes, favoured or hindered by the dominant coalition's interpretative scheme, and is easier the higher the level of the skills and the capabilities of the top management. Smith (1982), Dunphy and Doug (1988) emphasize that morphogenetic changes are favoured by collaborative approaches between individuals and shared values.

On this basis, it is possible to investigate how societal institutions influence societal organizations, considering that according to Smith (1982) and Laughlin (1991), the following two types of changes may occur.

- ✓ Morphostasis (first order change) occurs when the change neither really affects the heart of the organization, which is reluctant and tends towards the pre-existing conditions, nor the interpretative scheme. It can arise as a Rebuttal, i.e. an environmental disturbance is tackled through changes in the design archetype, but afterwards this comes back to the original situation, or as a Reorientation, that consists in environmental disturbances that are internalized into the organization because they cannot be rebutted and therefore affect subsystems but not the interpretative scheme.
- ✓ Morphogenesis (second order change) is a change that influences the interpretative scheme because it profoundly permeates the organization. This may occur as Colonization, when the change is limited to the mandatory aspects, or as Evolution, when the change is free and not compulsory.

In this paper we draw on the aforementioned framework, by considering networks as Societal Organizations and the (Regional) Government as a Societal Institution. Accordingly, the subject of our analysis is the examination of the MAS as design archetypes of the network, capable of assimilating influences from the external environment, and effectively translating these influences into the interpretative scheme of the organizations.

4 Research Design

As already stated, the aim of the paper is to better comprehend the interplay between MAS and innovation in research-intense networks, characterised by multifaceted knowledge sharing/integration/transfer processes, in order to understand how an effective MAS can positively affect innovation thanks to its contribution to knowledge sharing/integration/transfer processes, and in turn how innovation shapes MAS thanks to enhanced knowledge sharing/integration/transfer processes.

The approach chosen for this research is qualitative, thus the paper employs the single case study methodology (Yin, 2003; Ahrens and Chapman, 2006). Indeed, consistent with Siggelkow (2007) view a single case study can contribute to existing knowledge through the deepening or widening of the current understandings. The real potential of the case study for the purposes of this research is also due to the fact that it helps the researchers to deeply understand the social systems of reference by providing an holistic view of the social practices in a specific set of circumstances (Scapens, 1990).

Moreover, the single case-study approach facilitates the use of in-depth longitudinal data, which is less feasible in multiple case-study designs.

The network chosen for the case study was *Campania Bioscience*. Indeed, this network has been recently created in the wake of external regulative pressures and is now facing a relevant process of change in its management accounting practices. Moreover, the complexity of this network, in which a wide range of entities (private companies, public entities, research organisms) and stakeholders (with different interests and backgrounds) are now interacting, renders *Campania Bioscience* an interesting setting to examine the issues under investigation.

The analysis of the case study has been carried out as follows. The data were collected over an eighth-month period in 2013-2014. This has enabled a closer examination of the developments and changes in MAS, as well as barriers, episodes of resistance, and accomplishments. At first, a relationship was established with the Chairman. He was briefed about the research project and the authors asked to be introduced to the managerial group.

Subsequently, the authors personally interviewed some of the managers. The informal interviews, which were later transcribed, followed an agenda of topics to be covered rather than a structured set of questions. This approach allowed a full coverage of the issues and resulted in a detailed picture of the practices and issues involved in the management of the network, with specific regard to the on-going changes in MAS. The aim of the dialogues with the people involved in the project was to investigate the areas of interest to the researchers, by identifying emerging issues of significance. In particular, these interviews aimed to build up a deeper picture of how the interviewees felt about their roles, what they thought about the network's role in the context of reference, the practices and management tools available within the network, and how they perceived the newly introduced MAS, and the impact of changes on their activities.

The interview strategy was mostly informed by a balanced consideration of the approach suggested by Scapens (1990), Yin (2003) and Ahrens and Chapman (2006). Each of the interviews lasted around one hour and most of them took place with two of the researchers present (always the same two members of the team carried out the interviews). An important aspect to underline about the interview phase is that the two researchers adopted tactics (Marginson, 2004) to improve the clarity of the data collected and limit misunderstandings when interpreting the responses. A first tactic was to make it

clear that the researchers did not have a specific theory to prove or disprove, and thus interviewees were not meant to provide the ‘right answers’. Also the researchers in several cases required respondents to illustrate the behaviour or issue s/he was describing (‘that’s interesting, could you provide an example or elaborate a little more?’), or in other cases asked permission to re-phrase within their own words, in order to find out the importance and comprehension of emerging issues. Over the study period interviews with 10 individuals, some of which repeated, were held at the study site (see table 1 below), amounting to a total number of 17 interviews. These were digitally recorded and then transcribed for analysis soon after the event. Moreover, a telephone follow-up with the respondents was conducted when a few data were missing. Before the analysis of the data, the interviewees were asked to review the transcripts and to make any corrections. Where necessary, we made a second visit to confirm some of the information or to follow-up on something which had arisen in another interview.

Table 1 – The interviews

Categories of individuals interviewed	Number of individuals interviewed	Total number of interviews per category
<i>President</i>	1	2
<i>CEO</i>	1	2
<i>Researchers</i>	3	5
<i>Entrepreneurs/Top Managers</i>	5	7

Once all the interviews were completed, the members of the research team discussed the main issues raised during the dialogues, and were thus able to develop the starting point for the analysis. These data were supplemented by an examination of other documentation, policies and digital videos for strategies and practices, publicly available for both the Region and the network considered, as well as some internal documents (see table 2). This information was collected and triangulated with data drawn from the direct interviews in order to enhance research reliability. This approach resulted in the production of a comprehensive analysis of the processes of change in the MAS of the network.

In summary, to guide the interpretation of the data gathered, several categories of relevant themes were identified to ease the analysis. Especially, the story of the change is addressed chronologically, by focusing in particular on the progressive role of MAS in supporting knowledge sharing and innovation and also on the role of the innovative

environment to support the effective implementation of MAS. The researchers carried out discussions about the interviews trying to refer all the responses to such categories where possible. In agreement with Ahrens and Chapman (2004), the interview transcripts were organized chronologically and the areas of agreement between the interviewers regarding the categories of analysis were identified. Subsequently, any area of disagreement was reviewed and discussed also in the light of the documentary sources available. The developing issues or emerging problems were then the subject of separate discussion and used to better understand/explain the phenomena or to identify any unsolved/open question for further investigation.

5 Setting the context

As previously stated, the case study examined in this paper is *Campania Bioscience*, a network located in Campania and created in 2013. Hence, for a purpose of clarity this section will briefly describe the characteristics of the sector, the Regional environment and, the peculiarities of the network under investigation.

5.1 The sector

Biotechnology can be understood in its most basic conception as the application of biological systems and organisms to industrial processes. It has developed rapidly over the 20th century, to encompass a broad and diverse range of industrial sectors and products. What characterises the sector, in addition to the enormous growth opportunities, is the high level of technological discontinuity that also leads to considerable uncertainty, with biotechnology firms producing without assurance in terms of whether a market exists for their products, or whether the production process is technically feasible and economically sustainable.

The peculiarity of biotechnology is that it is a science-based activity, and its development primarily derives from academic research. This clearly leads to the increasing demand for a stronger linkage between industry and academic institutions. In fact, as Porter (1983) argues, biotechnology is characterised by number of entry barriers, including proprietary technology, which raises the effective opportunity cost of capital. The cost of entering the biotechnology industry is largely related to the R&D expenses. Thus, academic-industrial relationship (AIR) is regarded as an organizational means to reduce entry barrier by lowering R&D costs for commercialization. These AIR may have many forms, sizes, and designations through cooperative agreements, direct funding, or other contacts (Etzkowitz, Webster, & Healey, 1998) and can be advantageous for both the academic institution (in terms of replacement of lost government funds, avoidance of complex government regulations, potential for long-term financial and industrial support, and trainee support for students and scientists) and for the industrial partners (in terms of new ideas, approaches, and products, improved capabilities with an easiest access).

An essential element to take into account is that in this sector a crucial role is played by the knowledge that forms the basis of the development of such products. Clearly, knowledge is strongly related to people that over the years have contributed to its development, and this in complex settings such as the academic ones may complicate the sharing and transfer of biotechnology innovations, as well as the protection of its innovative outcome (Vona, 2008). The big firms deal with these problems by introducing internal units to coordinate and develop such knowledge through relevant financial investments. Nevertheless, it is worth noting that these kinds of formal structures, despite ensuring the protection of innovative outcomes, especially when the patentability is expensive or hard to achieve, may prevent the creativity of innovative process due to

strict and bureaucratic procedures (Sorrentino, 1995). From this perspective, the existence of informal organizations such as networks is well suited to achieve the needs of knowledge sharing that form the basis of the innovative process in this sector (Vona, 2008; Laycock 2005), preventing the risk of constraining the activities and the creativity, which is a typical limitation of formal bureaucracies.

5.2 The Regional environment

Campania is an ideal setting to examine the issues relating to innovation, as it represents a highly challenging region for innovation with its 7 Universities, 40 advanced Research Institutes, 10 Competence Centres, 1 Technology District, 5 Business Incubators and 2 Science and Technology Parks. Moreover, the Region is the main research hub in the *Mezzogiorno*, and since 2007 is the Italian region devoting the greatest amount of public resources to Research & Development activities.

To deeply understand the actions undertaken by the regional government over the last ten years to support innovation, it is important to consider that it constantly faces the highly competitive environment in persistent evolution that has characterised Europe over the last decades. The complexity of the environment and the competitiveness of the systems at the international level as well as the need to achieve industrial leadership and standards of excellence in research, prompted a number of regions all over Europe to develop pathways based on distinctive competencies and resources specific to the territory and complementary with those of other EU areas, that can be summarised as follows (Campania Region Position Paper):

- ✓ Knowledge-based strategic objectives based on fundamental priorities, challenges and development needs (priority setting)
- ✓ Policies to enhance the strengths, competitive advantages and potential for excellence (competence based)
- ✓ Actions to support technological innovation, combining the development of regional research systems (knowledge based research) and innovative capacity of firms (technology-based research)
- ✓ Mechanisms to ensure full participation of the actors involved in the different phases of the innovation process (open innovation system)
- ✓ Tools to ensure continuous monitoring of the public intervention through ex-ante, ongoing, and ex-post performance evaluation systems.

In this context, since 2001 the Campania Region has progressively attempted to elaborate specific legislation and new measures to promote research activities, innovation and scientific progress. The first decree was enacted in 2002 and further modified in 2010. The purpose of this legislation was to contribute to the promotion of the advancement and dissemination of basic research in science, technology, humanities, economy and law, encouraging the creation of funding opportunities for research designed and led by young people. Particular attention was devoted to the actions needed to avoid the risk of depletion of the innovative human resources in the system of the regional research, and to favour a proper management of the multiple skills within the region, with the aim of creating a real connection between the world of research and the world of production in the overall development process. What certainly deserves attention is that between 2000 and 2006 the Campania Region has strongly focused on a process to define the priorities of the various areas with high potential and territorial impact. Thus, in the following years (2007-2013) the strategic areas identified were categorized in 8 clusters, namely (i) aerospace/aviation, (ii) environment and safety, (iii) cultural heritage, (iv) energy and energy saving, (v) ICT, (vi) advanced materials, (vi) biotechnology and human health, (vii) transportation and advanced logistics, for which specific lines of action were elaborated and several funding programs were activated (Campania Region Position Paper).

In addition to the regulatory attempts the Region issues annual Plans which central concern is that scientific research and technological innovation are essential to strengthen competitive capacities, entrepreneurial creativity, knowledge and opportunities for growth. To achieve these objectives, in addition to the above-cited Plans, based on which are defined the priorities for action and investment in the territory of the Campania Region for the reinforcement of the system of research and the Promotion of Innovation, it has also a variety of tools, such as the funds made available with the POR 2007/2013 (POR FESR e POR FSE). A further tangible proof of the commitment of the Region to pursue the innovation is also the creation of the Regional Agencies *Campania Innovazione S.p.A.* (2011) and *Campania In Hub* (2012) to support research and innovation, by ensuring connection, communication and collaboration among the regional actors. The Agencies were created to strengthen Research and Innovation within the region by creating a network of multiple connections between research and enterprise system, and to exert the role of coordinators among all the actors involved into the

creation of innovative startups, finance for innovation, technology transfer, participation in European Programmes and International Networking.

5.3 The structure of the network

The process to create the network *Campania Bioscience* started in 2011 to benefit from the national and regional initiatives for funding (Europe 2020 and PON “Research Competitiveness”) and also in the light of the opportunities and constraints imposed by Regional Plan for research, innovation and ICT (Regional Council Decree April 29, 2011). The network *Campania Bioscience* actively operates within the Campania Region since the beginning of 2013. It has been created in the wake of an increasing attention within the Region for the issues relating to innovation and the need to find appropriate ways, such as the creation of networks, to support innovation on the territory and to enhance the previous-existing abilities and skills. In the South of Italy *Campania Bioscience* represents the first example for the biotechnology sector of a structured and organised model of cooperation capable in terms of size and skills available to compete on the international scene. The funds made available to constitute the network and to fund the operations for the first three years of activities amount to 50 millions euros provided by both private and public funders. The investments within the network are primarily directed to the development of innovative projects with especial priority for the testing of new therapies. Furthermore, over the first three years, the focus is not only limited to the development and testing of new therapies, but attention is also devoted to the production of nutraceuticals and cosmeceuticals, diagnostics, biosensors and innovative technologies for the biomedical industry.

The legal form of *Campania Bioscience* is a limited liability consortium (SCARL: Società Consortile a Responsabilità Limitata). The consortium has a capital of 1,7 million and is distributed among 47 companies (44%), 7 research institutes (44%) and 3 firms for knowledge and technological transfer (12%). The governance of the network is the classic one with the Assembly, Board of Directors (with an equal participation of representatives of public entities and private companies), Chairmain, CEO, and two committees (executive committee, internal audit committee) and an external assessment organism. However, what should be noted is that given the multifaceted nature of the innovative projects that the network is developing, in addition to the above-described structure five thematic tables were created to closely monitor each of the projects and also the transfer of

knowledge within the network. In particular, these tables define the programs to achieve the strategic objectives and are involved in the realisation of several projects. They are composed by three thematic round tables responsible of the industrial research and experimental development in the three thematic areas of interest of the network. The first group deals with the development and production of nutraceuticals and cosmeceuticals; the second is involved with diagnostic systems, biosensors and innovative technologies for the biomedical industry; the latter focuses on the development and testing of new therapies. In addition to these thematic tables, there are two transverse tables related with the advanced training, and the promotion/internationalisation/diffusion/transfer of technology.

6 Findings

Since the beginning of 2011, in the wake of the increasing attention paid at the Regional level to elaborate action and strategies to support innovation within the territory, as well as on the basis of the European, National and Regional regulation, the actors operating within the biotechnology domain started a process to create a formal network structure, with a view of benefiting from a relational model to foster innovation and to get access to public and private funds to support both basic and applied research, as well as the development and commercialisation of existing prototypes. The first action was the realisation of a feasibility study by the proponents of Campania Bioscience that was sent to the MIUR for approval. In 2012 after the positive response by the MIUR a Framework Program was signed and after a long negotiation process among parties the network was formally created in the form of a SCARL, which is now actively operating.

The process involved a number of different steps because, despite the general willingness on the territory to adhere to the proposed initiatives, some unclear aspects and misunderstanding needed to be carefully addressed. In particular, some of the interviewees clarified that a first set of problems was related to the perception of the actors involved about the real role of the network. As the following quote clarifies, some people were keen to participate as they could see the possible advantages relating to entering the network in terms of both knowledge sharing and access to new skills.

“We have the financial resources but do not have enough specific skills and abilities required at each stage of the process to support innovation. On the other hand, small businesses or universities have specific skills related to the individual stages but do not

have adequate resources to purchase the necessary technologies. For example, there are small firms with revenues of few million euros that produce very innovative components requiring to buy a number of technologies that they cannot afford...but we can offer them! In this sense, the participation in the network allows us to carry out an exchange of information, expertise and knowledge!” (Top manager of a big firm).

Other, as the Chairman claimed, perceived the upcoming network *only as a formal structure, with no effective potential and no real impacts, to get access more easily to the funding programs available to support innovative networks.*

The scarce clarity on the purposes and the potential of the network was acknowledged by a number of different actors. One of the major problems at the very beginning was that there were only a few and very *fuzzy* documents available to the various stakeholders and persisting communication barriers between them. The following quotations can effectively summarize the feelings about the network that characterized its emerging phase.

“When the network was going to be introduced in 2011, I was the general manager of Regional Centre for Industrial Biotechnology ... I read a hundred pages of statements of wonderful objectives and the long list of actors involved in the creation of the emerging network. I said to myself: ‘this is great but how we can achieve these goals is a different question!’ I had some doubts about the chance to achieve a real agreement among such heterogeneous actors because it was not clear at all how people at any level of the network should behave to support the initial phase”. (CEO)

“When we received the proposal to join the network, I had chats with some other entrepreneurs and no one had any idea about the way we could take advantage of the introduction of the newly created network. This is mainly because we were quite scared about the risk of losing the property rights of our knowledge and our innovative ideas”.

(Small Entrepreneur)

“When our university shared the news to join the network, my colleagues and I had some doubts about it. Hence, we did not immediately realize the motivations and the goals that lead to the introduction of this network (...). We dislike that someone else far from the world of research establishes the scope and the objectives of our activities (...) The innovation process is only matter of research! However, we also thought that probably

our participation will have given us the chance to get more funds and therefore we entered the process to see it was going to work". (Researcher)

In order to face with these misunderstandings and difficulties, which represented barriers and resistances possibly threatening the real potential of the emerging network, the proponents adopted a participative approach based on the involvement of the actors at all the levels in order to substantially share the purposes of the network and to elaborate in a participative manner any future actions. The following quotation from the CEO elucidates this approach.

"We suddenly realised that to avoid resistance by people, leading to the ineffectiveness of the new structure we had to make them aware of the fact that this was an opportunity that they could not miss. Hence, we stimulated the participation of the actors to the meetings, always fostering an open dialogue. Also, we clarified that the activities of the network would have never taken away individuals from their specific activities and the possibilities to benefit from the existing opportunities". In particular, we developed a shared strategic planning activity in order to stimulate cohesion and a real interaction between the actors, which however should be the primary aim of every networking initiative". (CEO)

With reference to the activities carried out to build the network in question, a central question pertained the strategic planning phase. This, as already highlighted, was characterized by a strong participative approach and was developed mainly relying upon what was defined at the Regional level when the Plan for research, innovation and ICT (Regional Council Decree April 29, 2011) was issued. In particular the two following documents laid the ground for the introduction of strategic planning and monitoring at regional level and acted as the starting base for the strategic planning of Campania Bioscience.

- ✓ *The final draft of the Campania Region Position Paper* which defined the regional technological priorities for the health, biotechnology and agro-industrial sectors for the 2014-2020 period.
- ✓ *The Campania Region Innovation Scoreboard Report* edited by *Campania Innovazione S.p.A.* Agency to identify the areas, dimensions and indicators to measure the degree of innovation within the Region.

On the basis of the tools and practices that were analytically established for the planning, monitoring and performance evaluation of the overall regional innovation system, *Campania Bioscience* could specifically define its strategic priorities both at a general level and focusing on specific projects. The starting point of the strategic planning was the analysis of the biotechnology regional context and its potential for the innovation. To this aim the existing industrial (number of big firms, revenues, employees) and scientific (number of academic departments, involved researchers) conditions were mapped and analysed to get a clear idea of the available resources, assets and capabilities. Moreover a negotiation and participative process was undertaken to define several technological pathways for the network.

Initially the problems with this process mirrored the limited comprehension of the purposes of the network addressed above, as the pressures for the definition of the strategic plan created the premise for a number of contrasts between actors with a varying degree of knowledge about the questions under discussion. Indeed several conflicts arose between the managers, the representatives of companies and the researchers due to the different interests that they wanted to pursue.

A particularly threatening problem was the unwillingness of researchers to accept strategic planning, as they wanted to keep doing research preserving their autonomy and had no clear view of the economic sustainability concerns that were discussed. To clarify we quote from a researcher.

“At the beginning we found it difficult to really rationalize why directors and top managers of the network wanted to intervene in decisions for which they did not have the skills. Moreover the economic focus of the companies was a bit far from our view that basic research is crucial and needs to be preserved. In this situation the negotiation of the objectives and projects was really difficult and I must confess that in the first meetings we tried to fight to defend our positions”. (Researcher)

However, thanks to the participative approach that has characterized the network since its very beginning the top managers tried to involve all actors at all levels in the strategic planning by using various tools. To elucidate this point we quote from the CEO.

“We were sure that changes could not be welcomed if the motivations and the goals that lead to the definition of the strategic planning were not enough understood. Hence, we wanted to build consensus before proceeding, in such a way that people did not feel

threatened but on the contrary were pervaded by a participatory and proactive spirit. So it was essential to clarify immediately that any type of instrument would be aimed at sharing opportunities and improving the results at both the individual-level and network-level (...) We organized a number of formal and informal meetings with the representatives of the researchers and top management, using several innovative communication tools such as Skype". (CEO)

During such meetings top management asked for an active participation at any level, towards the definition of the priorities, technological trajectories and projects that resulted in the position paper. Thus, the representatives of each group were involved in a survey to provide a more complete picture of know-how, specific skills, financial resources, roles and responsibilities that were necessary for developing the projects. This initiative was welcomed by participants that started to show greater interest and acceptance, as highlighted in the following quote from one researcher.

"I appreciate this kind of involvement as I am convinced that no one can identify the resources and the necessary steps to fulfil the goals of the projects better than someone who is involved in this process every day. Of course I recognize that I cannot replace an expert of strategic planning, but I think that our contribution was crucial to make sure that everything will work, and this is certainly an opportunity for improvement that we cannot miss." (Researcher).

The negotiation process of the strategic planning has been favoured by the existence of simple kind of electronic information system to share knowledge among the coordinators of different projects and, when necessary, among all members, further favouring the creation of a collaborative environment, ready to accept the strategic planning. What should be noted is that the involvement of different actors thanks to a user-friendly information system completely changed their perspectives, as the initially resisting people switched from being those who passively suffered the choices of top management to being active agents of the change. The following quotes from a CEO and a researcher can clarify this argument.

"The negotiation was more productive and useful thanks to a communication system that helped us to share the objectives of the strategic plans. From this point of view the technology has helped and allowed us to easily discuss each step of the planning process and develop a shared and agreed course of action" (CEO)

“Being involved in the definition of the strategic plan, also thanks to an easy and quick information system, made me feeling part of the challenge and prompted me to question my previous conceptual schemes. I realized that the subsequent defined lines of actions would have been in our favour and not against us or our intellectual freedom”

(Researcher)

At the end of the negotiation process, the following eight projects were defined.

- ✓ Recovery strategies of bioactive compounds from waste biomass from the oil industry and canning
- ✓ Design, development and production of functional foods and/or eriche
- ✓ Development and testing of molecules with nutraceuticals and cosmeceuticals
- ✓ New strategies for medical diagnostics and molecular and traceability and monitoring of food
- ✓ Diagnostic methods with high efficiency to the patient osteoarticular
- ✓ Smart materials and new devices for applications in the biomedical field;
- ✓ Preclinical development of new therapies and innovative strategies for the production of molecules of pharmacological action
- ✓ Development and preclinical and clinical evaluation of phase 0 and phase 1 of molecules with nutraceuticals, cosmeceuticals, pharmaceutical and new indications for already approved molecules.

These projects were attributed to one of the three thematic tables that were held responsible for the achievement of the objectives and the monitoring of the performance. Hence, the coordinators of each table together with the other member of the team gave way to smaller consultations with participants in the specific projects to establish more specific lines of action, as well as to identify operational roles and responsibilities. This approach was essential to ensure that what stated at the upper level in the Strategic Plan was implemented at any level within the network and put into action. It is also worth noting that to ensure the achievement of the stated strategic goals the network introduced a formal governance structure characterized by multilevel-monitoring mechanisms. At the bottom there are the five round tables appointed by the board of directors that ensure a first assessment of each project. In the middle, there is an executive committee composed by the coordinators of the projects monitoring the execution of the on-going programs, while at the top there is the Board of Directors. To clarify how this structure was established, we quote from one Director and the CEO.

“We strongly thought that the typical governance model could not fit the multifaceted nature of our network. Hence we tried to create something that goes beyond the traditional governance model composed by the board of directors, general manager and so on. Since the beginning, we created a series of tables and working groups with specific functions. Also, we allowed representatives of the private companies and of the public entities to participate in these tables on the basis of voluntary application mechanisms that avoid the risk of scarce legitimacy of the governance structure and are helpful in managing the risk of resistance by the actors involved”. (Director)

“Our aim was to create a place where both industry and public research could meet and really develop a common path through strong relationships and dialogues. To this aim a crucial role was played by the trust that the formal monitoring mechanisms of the projects created. Indeed, in addition to the round tables we also created a coordinating body whose members were chosen among public and private researchers, top managers and technical representatives coordinating the projects, that created a real and additional space of interaction and dialogue with both the participants to projects and the Board of Directors, also contributing to ease the information flows”. (CEO)

All the categories of individuals interviewed highlighted the positive aspects relating to the participative governance and their involvement that allowed avoiding misunderstandings and achieving cohesion at each level. The following quotations elucidate this situation with more detail.

“In my opinion the choice of involving us either at the bottom or at the top level of the governance structure has been really worthwhile for our leading role. In particular, the involvement in the coordination of the round tables and in the executive committee has been useful because this has allowed us to interface and dialogue with the board of directors by negotiating those action programs that better fit with our business needs”.

(Top manager of big firm)

“Our category is often not considered in the executive committee and the board of directors, but this was not the case. Even though my colleagues and I were not formal members of such bodies, we could attend those meetings mostly related to our research activities. This motivates us to act for and not against the new governance system as we were aware of what the Top Management were talking about”(Researcher).

“Being involved in the board of directors made me feeling active part of the decision making process. Thus, the strategic decisions were not merely imposed but for the first time could fully reflect the different needs expressed by our small business” (Small Entrepreneurs).

Moreover, regarding the monitoring bodies, it is worth noting that the network has also recently established an external assessment organism that will provide an independent evaluation on the research activities as well as on the impact of the projects in terms of technological transfer. This is made of three independent members, a professor, a top manager and an expert in entrepreneurship, that have to perform a general assessment of the activities of the whole network. The choice to create this independent organism was really appreciated by the majority of members. Indeed, as one of the researchers clarified *“The network has a great potential for research, there is no doubt that we have the skills to do research, but the point is how to transform our abilities in outcomes that impact the territory becoming innovation but also social and territorial development. I think that the objective and constant monitoring and evaluation of our performance from an external party will lead us to effectively achieve these aims.”* (Researcher)

This organism has not yet started to carry out its activities but it is surely important to highlight that the willingness of the actors to create such an organism represents a positive signal of the fact that the changes in action are working well and that there is an on-going transformation also in the cultural and ideological boundaries of these subjects.

What needs to be highlighted at this stage is that a common opinion shared by interviewees is that the existence of the network and the use of the new tools had for them three main advantages. First, they were able to create relationships that go beyond the network and often decided to cooperate also autonomously to carry out their projects, with enormous advantages in terms of access to skills, knowledge sharing and fostering new innovation processes. Second, the use of the information systems allowed them to share an unbelievable amount of information and previous knowledge, thus facilitating also the activity that they carry out outside the network. Third, the participation in the network and the necessity to collaborate with people from different backgrounds gave them the chance to acquire new knowledge and to develop other capabilities that they could then transfer to their own organizations. In turn, it is also interesting to note that all the interviewees agreed on the fact that they were more and more willing to accept the

changes in action, and to contribute to shape the new tools introduced as soon as they recognized the above cited advantages. However, despite the positive results achieved in this first phase what should be noted is that some difficult issues are still around and need to be resolved to ensure the embeddedness of the MAS introduced. Indeed, some of the interviews highlighted two major problems. First, some researchers are still reluctant to accept a formal governance structure. Second, not all the actors constituting the governance bodies had the right skills to actively participate to the decision making process.

7 Discussion and conclusion

The subject of this paper is the investigation of the matters concerning the implementation and effectiveness of management accounting systems in complex organizations, and especially networks, to support innovation processes. The study was developed on the ground of the lacking understanding of the interplay between MAS and innovation, that in research-intense networks assumes specific characteristics given their multifaceted knowledge sharing/integration/transfer processes that need to be taken into account. Hence, the specific purpose of the research was to understand how an effective MAS can positively affect innovation, and in turn how innovation shapes MAS. To this aim, the paper employed the single case study, focusing on a research-intense network located in Campania, namely *Campania Bioscience*, which has been recently created and is now facing a relevant process of change in its management accounting practices. Thus, the issues under investigation were examined through the lens of the *Middle Range Thinking* (MRT) approach developed by Broadbent and Laughlin (1993, 1997, 2003, 2005, 2013), advancing the Habermas Theory about Society, since this is particularly suitable to examine the issues relating to an on-going strategic change in management accounting practices. Hence, this section discusses the results of the analysis in the light of the theoretical model, to understand which are the factors that possibly justify an effective change in MAS and what are the implications for practitioners and professionals involved in the process of change.

For purposes of clarity, it is important to briefly recall here the implications of the theoretical model addressed in the second section. In particular, we have previously highlighted that changes may occur as Morphostasis (first order change) when the change neither really affects the heart of the organization nor the interpretative scheme, or as

Morphogenesis (second order change) when the change influences the interpretative scheme because it profoundly permeates the essence of the organization. Especially, the former can arise as Rebuttal, when an environmental disturbance is tackled through changes in the design archetype, but afterwards this latter returns to the original situation, or as Reorientation, when environmental disturbances are internalized because they also affect subsystems, but do not affect the interpretative scheme. On the other hand, Morphogenesis may alternatively occur as Colonization, such as a compulsory change, or as Evolution, when there is a free and non-compulsory change.

With specific regard to the findings of our research, it is possible to maintain that the examined network has experienced a successful process of change, i.e., an Evolution (Morphogenesis of the second order), because the MAS introduced in the wake of changing regulation and environmental competitive disturbances at the European, National and Regional level, have been effectively implemented within the organization. Indeed, the MAS introduced were able to translate the pressures coming from the outside in terms of new legal requirements, to the interpretive schemes of the network, towards the creation of a shared and accepted business culture aiming to maximize the effective and efficient use of the resources, and to create a common locus for interaction and the development of new knowledge. This is possible because the abilities, skills and knowledge of the territorial jurisdiction of the network are now organized in a system, thus fostering a more effective collaboration to realise innovative products and to trigger new development processes, through projects with a relapse of the market of short-medium term. The network is a great achievement that fully enhances the skills in the field of biotechnology that characterise its territory of reference, and the partnership built with about 50 industrial companies, as well as the choice of a joint Executive Board between public and private partners, are important elements to ensure the success of the initiative.

What should be noted is that a crucial element to ensure such effectiveness has been the constant involvement of the various actors over the different phases of the changing process. Actually, one would expect that a complex organization such as *Campania Bioscience*, characterized by multiple strong (and sometimes conflicting) ideologies, might be resistant to fundamental changes in the interpretative scheme. On the contrary, the effort of the management to continuously involve the various subjects, the constant attention to their needs, the negotiation of measures to be taken with the representatives

of the various groups, rather than simply the coercive adoption of pre-packaged systems, have made the difference, by helping to create, if not entirely at least in large part, a corporate culture that did not exist before. This fully reflects the view of Dunphy and Doug (1988) who highlight that Morphogenetic changes benefit from shared values collaborative approaches between individuals.

Furthermore, it is worth remarking that at the very beginning, the introduction of the MAS shed light on the existence of problems in terms of lack of dialogue between the different categories of people involved. However, the need to sit at a negotiating table in a compact way to deal with the management led the various groups of professionals to put more effort into developing the dialogue among them. This not only resulted in a more rational mode of approaching the innovation process, but can be also identified as an additional element in the ultimate success of the process of change. In fact, the improvement in the innovative performance of the single subjects was possible thanks to the integration between the different actors that made them aware of the potential of the network and of the new measures. They were able to verify that the new tools were useful in achieving not only economic objectives but also a better performance, through the reduction of waste and the release of resources of knowledge not accessible before, thus pushing them to proactively support the changes taking place.

That having been said, it is also worth highlighting that, even if the changes in the MAS have been effective and have helped to create a corporate culture oriented to fulfilling the objectives of efficiency and innovation in the broadest sense, a number of issues, as the results of the analysis show, are still open and will need further work. The reference here is to the concerns relating to the persisting resistance of several categories, which has been reduced but not completely set aside. Then, the tools currently available need to be refined, and more importantly effort need to be made to eradicate the factors or conditions that may favour resistances.

Therefore, it is possible to maintain that a proper understanding of the changes taking place requires a move beyond the oversimplified reference to the moment in which the tools implemented begin to be correctly used. From this perspective, the effort that the various subjects involved have made in terms of commitment towards the improvement of the MAS also for the future, agreeing on the introduction of external evaluation is a further positive signal. In particular, this bears witness not only to the authentic evolution that is on-going within the network, but also emphasizes that the MAS has exceeded the

objectives of strategic and operational planning, as well as of the control system for which it was initially conceived. Accordingly, the MAS of *Campania Bioscience* can be regarded as a means of change and mediation between different and contrasting institutional subjects. From this perspective, their real potential has not yet been entirely revealed. The usefulness of the MAS lies here in its future ability to create a common language that will facilitate a productive exchange, and dialogue and discussion between the different subjects, helpful in superseding their previous inability to interact, due to a lack of comprehension that led to strong opposition or open conflicts among them. Indeed, a common language allows more relaxed relationships within the organization, based on understanding, and leads increased participation favouring improvement of organizational performance in terms of efficiency, effectiveness, and innovation.

On this basis we can conclude that the novelty of this paper relies on the possibility to explore the peculiarities of an effective MAS supporting the innovation processes within a complex setting such as the researched network that involves multifaceted knowledge sharing/integration/transfer. It is worth noting that this study can have a twofold contribution. First, from a theoretical point of view it adds a newer perspective of analysis to interpret the role of MAS in innovative networks, thus contributing to the growing debate on the antecedents and facilitators of knowledge sharing and knowledge integration. Also, from a more practical point of view it broadens current knowledge on the factors that may contribute to bringing about an effective and positive interaction between MAS and innovation, relevant for both professionals and practitioners, opening the well-known “black box” of the creation/sharing/transfer/integration of tacit knowledge. In fact, this case study will have an important impact, by providing useful practical suggestions for all the organizations involved complex processes of co-production of knowledge and innovation.

Structured Abstract :

Purpose - The purpose of this research, beside the general comprehension of the phenomenon, its dissemination and penetration in the medical community, is mainly to gain a better understanding of determinants and factors that may impede or enhance its use in the medical context considering the potentials provided by the new technologies. On these assumptions, this study offers an insight on two of the most popular operating systems on the market (Android and Apple) analyzing the specific aspects of the Apps present on the main store of the operating systems as referred above (Play Store and iTunes).

Design/methodology/approach - The methodology will use a blended approach articulated in two phases. The first phase of inquiry explores the phenomenon object of study, outlining the potentials to it connected, with a particular reference to the Italian context. The second phase is oriented to build up a data base with the different medical Apps of the two main operating systems, trying to map the offer of medical Apps which are available at present and finally identify possible reading keys of the phenomenon and its developments from a socio-medical viewpoint.

Originality/value - This methodology puts in evidence that the adoption of “mobile health” is regarded as the creation of a new market full of opportunities and potential growth. This paper provides a reflection on how the use of Apps may improve the relationship with the different stakeholders (wholesalers- patients- customers) by giving qualitative answers in real time on the base of provided data, creating a trust community through the sharing of information and offering a support and/or coaching to the different users as well.

Practical implications - The knowledge of the use and the spreading of new technological systems, such as Apps for specific and particular demands related to the new emerging informative needs in the medical field, give rise to doubts concerning safety, privacy and reliability of information itself. Therefore, we would like to know the real motivations which drive patients to use the device. The users themselves should not be disregarded in the overall process play an important role by applying the information they have at hand to the product they are interested in and evaluating whether it meets their needs.

Keyword: Knowledge Society, Health Mobile App, Health Knowledge Management.

Paper type – Practical Paper

1 Introduction

It is quite evident as they become present in our daily lives, Apps, the particular utility, available on most mobile devices – like Smartphone and / or tablet - are able to offer a wide range of information and or solutions to the most varied demands of our curiosity. On the other hand it's clear how such a situation is highly dependent on the impact that new technologies have on our lives, so deeply changing and not always consciously, our rhythms, skills, effects, and not least social relations. While these considerations are easily shared, others are less, therefore ignoring the emotional effect. This reflection wants to bring attention and focus on the Apps as information tools available to the complex system of health, with the capacity of transferring knowledge, learning, and then, perhaps, attention to the complex world of prevention in medicine. On the other hand, the use of the network as the context in which the apps take shape and force , suddenly brings our attention on an international and global level, so as to urge the same to the Food and Drug Administration (FDA). In fact, with specific reference to the health sector, the U.S. Supervisory Authority has started an intense phase of analysis and study of appropriate proposals to control the medical applications downloaded directly to mobile devices, having regard in a specific way for those Apps capable of "Influencing the performance or functionality of currently regulated medical devices" and therefore may represent "a major risk for patients" (Sole24Ore, September 2013). The principle object of the research is to understand the general dynamics of the new phenomenon, by getting an updated picture of the different existing Apps (Medicine Category) in the Italian context. In order to obtain this goal we focused on the two main available operating systems (Android and MacIOS) ¹, through the use of dedicated stores, such as play store and itunes. The working progress research permits to identify, however, a whole range of possibilities and limitations in the use of Health Apps, regarding the actors involved, the process to ideate the instrument, the trust/reputation respect the user/patient. The different aspects of analysis stimulate a serie of considerations on the opportunities to use the Apps in the Italian Health Context, both regarding the organizational performance and the impact on society and community.

1 The survey on different browser share shows worldwide the following situation (Mobile-Tablet, march 2014): Internet Explorer 2,31% - Chrome 12,94% - Safari 53,61%- Opera mini 3,51% - Android 23,44%; Other 3,88%; Operating System Share (march 2014): Ios 53,29%;Android 36,58%; Symbian 3,92%; Java me 3,36%; Blackberry 1,13%; Kindle 0,85%; Windows phone 0,69%; Samsung 0,10%; Bada 0,04%; Windows mobile 0,02%; lg 0,02%; Huawei 0,01%; Brew 0,00%; Source www.netmarkshare.com;

2 Conceptual Framework

As a starting point, the assumption is the impact of new Information and Communication Technologies in everyday life (ICT). With "Knowledge Society" is indicated a kind of collective structure in which the ability of humans to innovate the system of things and relationships has become a key instrument for the promotion of social and individual welfare, through the interconnection of people for learning and intelligence (Volonté, 2010). These interconnections promote the creation of a global knowledge society that it is found on the exchange of information and data by highlighting the focus on individual and social learning. The technological infrastructure of the network makes this exchange effective and real, like a unique virtual and global space, able to create conversation, communication and the exchange of ideas (Moreno-Jiménez et al., 2012). The widening of knowledge and information and the strengthening of technological infrastructure based on internet and web allow to remove the physical distances and to change the same concept of time, in order to implement new learning process. So, in this way the "Knowledge Society" is able to organize the acquisition, maintenance, utilization, and distribution of knowledge (Meier, 2012), and it (Moreno-Jiménez et. al., 2009) can be understood as a space oriented to the talent, intelligence, and creativity of the human being, true protagonist of this new society. The main objective of the "Knowledge Society" focuses on building partnerships and platforms that allow the integration of the skills of all actors involved in the process of resolution, the promotion of interrelations and the improvement of society (in terms of quality of life and cohesion). The four key aspects of this " Knowledge Society" are: 1. the increasing value of intangible aspects; 2. the de-territorialisation of knowledge and power; 3. the interconnection between the actors involved in the decision making processes and 4. the importance of the human factor, particularly regarding continuous learning and education (Moreno-Jiménez and Polasek, 2005). In the "Knowledge Society" the principle role is related to Information and Communication Technologies (ICT), that gives to people the opportunity to produce a lot of information and to facilitate its collection, processing, handling, storage, retrieval and exchange. In recent last years, the knowledge and information (that is an implicit assumption of knowledge), used in addition to traditional paper-based the most innovative new technologies and their interrelationships through the web. So, this situation changed the way in which people can communicate and access to a

lot of data and information, but often unfortunately they are redundant, irrelevant or of poor quality (Albano, 2011). Furthermore in this new changing context, a particular role plays the Apps (on mobile devices), like a new technological systems of transmission, creation and sharing of knowledge. In fact, the use of the internet through computers and the use of WIFI networks allowed a further evolutionary step. The use of new generation phones and the development of tablet and / or laptop computers led to a freely "available" and "user friendly" knowledge in order to modify or stimulate new ways of using it for learning and exploration. If this is true in general terms, the implementation of specific Apps in the health sector - available for download on mobile devices (like smartphones and tablets) - spurred particular interest to investigate this phenomenon.

3 Methodology

The used methodology adopt a mixed approach based on two step: the on the desk step explores the phenomenon and underline its characteristics and peculiarities, through the study of the main literature; the on the job step, is focused to obtain a survey of the different Medical Applications existing in the national context through principle operating systems; the resulting mapping give us identifying keys in order to understand the phenomenon and suggestions for improvement. Specifically, in the second phase, focus is on the figure of user / patient and so it has been articulated in order to understand the ways of its fruition, following the process of using the App: a) identification of keywords with which it's possible to access the services offered by Apps, belonging to Medicine Category (source: Sole24ore – Special Report on Health, December 2013); b) research and taxonomy of available Apps in the Italian context by Mac and Android, with smartphones and tablets; c) focus and selection the resulting Apps, respect the costs related to them in order to classify the various information; d) furthermore, another selection covered those apps with comments; e) definition of specific database.

4 New Technology for Health Knowledge Management

The evolution of the application of Information and Communication Technology (ICT) has inevitably led to a new clinical management of information flows (Buccoliero and Nasi, 2004). The relevance of information systems, depends on the availability of integrated information and it is confirmed by the constant research for synergies between

the organizational system, management processes and information systems. More generally, in the world of health care, trends caused by the introduction of ICT and Web, can be summarize in: 1. more transparency and accountability in the public sector with new governance models (new partnerships, intermediaries involvement, recognition of new roles of stakeholders); 2. greater choice and accessibility of public services and focus on efficiency and quality; 3. a strengthening of policies based on data and evidence that allow us to make correct decisions; 4. an improvement of digital skills in health professionals. In addition, however, several complementary trends exist of "digital inclusivity" that tend to shift the paradigm from organizational aspects to customized health, such as E-Health Applications that are able to securely process large amounts of data integrated, more and more essential for medicine and health management. The same Sole24Ore –Special Health Report on last December – was dedicated to Medical Apps, like a particular tool activated by searching of a series of keywords through which, in different ways, it's possible to access to specific health information. So the starting point is the recognition of different keyword presented by special report of journal (Sole24Ore, Italy), as reported in the following scheme.

Tab. 1- Keyword

1. Psychology	2. Heart	3. Sport
4. Diabetes	5. Kids	6. Flu
7. Heart attack	8. Obesity	9. Tumor
10. Antioxidant	11. Women	12. Skin
13. Diet	14. DNA	15. Cancer
16. Genetics	17. Psyche	18. Drugs
19. Ictus		

Source: Sole24ore Health Report, 2013.

In fact, the use of keywords allows to access to a world of information related and consistent with the topics selected and required. For example, keywords related to the medical context, can be represented (among others) by "heart", "diabetes", "obesity", "diet", "drugs", etc...;the Apps in these cases give the opportunity to access to a range of information suitable to describe, measure, represent and support the user in his quest for knowledge and satisfaction. In this way, the Computer Applications for Health - created to interact directly with users with or without the presence of a healthcare professional - help to better manage their own health (Parsons, 2011). The Apps - Medicine category - are therefore tools that can support health care by increasing user participation in the awareness of one's state of health and, therefore, its ability to self-health-management.

Thus, among the basic objectives of Medical Apps, include those related to the increase of the involvement of the patient in relation to their care process, by improving their ability to monitor and support them in finding alternatives to the focused pathology. In the case of Medical Apps, they can therefore be used as an aid in the diagnosis and treatment of the disease, often portraying similar agendas, where the user can record their clinical values (eg level of insulin in the blood , etc ...), or glossary that it can help to understand the disease or in other cases, guidance on what to do in case of a positive response to some specific diagnoses, etc. ...; other Apps can vice versa, through a virtual tutor, explain the human body. In doing so, the total number of active applications for category Medicine - according to the mechanism of the keywords said in advance - turns out to be several thousand can be reached either through the selected platform Mac-IOS and ANDROID. In fact, the two operating systems allow to access very different applications from each other, both in quantity - the number of tools in the Android world is considerably greater than those on the Mac - for quality and cost - in most cases are open free App on the Tablet, while most of those on Ipad cost directly. From what we saw, the phenomenon appears of great importance; in fact the Apps appear to be widely used with the new mobile devices opening new horizons of knowledge and usability, never achieved before. In recent decades new technologies based on web have profoundly changed the way with which people communicate and access to knowledge and more and more people have access to data and information in ways never seen before; it allows us to find specific and particular needs related to new information emerging needs, to change relational modes, although unfortunately often redundant, irrelevant or low quality (Albano, 2011). Specifically, the mobile App can be installed on device in seconds by clicking a button, without to install complex software, allowing to perform tasks such as creating documents, editing photos and listening music, only with an updated because they break down the time between production and use of knowledge by downloading the App relating to when you need it. The only indication is to use the latest generation of mobile devices, such as smart phones and laptops and tablets. This ease of use and the same portability determine the fortune of those Apps and the exponential growth of their offer. The National Agency U.S. FDA - Food and Drug Administration - (2013) has estimated that over 17 000 Medical Apps are just available on the world market and 500 million smartphone users, potential users of Medical Apps by 2015. However, the relevance and delicacy of the argument treated through Health App, the FDA has begun to

control the available Apps on the U.S. area, and so only one hundred of them was actually authorized. If the focus moves to the Italian national figure, the source of information is represented by the ratio Audiweb Trends of 2013 (special study conducted by the DOXA Research Institute), which indicates the presence of at least one computer owned in over two-thirds of households Italian (70.5 % of households = 15.357 million) and, among these , about 96% have the ability to access the internet. Then the analysis on how to access the world wide web (same source), shows that in the age group between 11 and 74 years is :

- high availability access from home via computer (in 74.9% of cases),
- access to the workplace for 47% of the workforce (10.4 million individuals approx.)
- access to phone / smartphone for 46.8% of individuals (22 million approx.)
- access to tablet for 14.6 % of individuals (6.9 million approx.) .

These data - shown in the Report Audiweb - allow to learn the effective diffusion of these technologies on our community, and therefore, the potential of development that the same Apps have demonstrated with reference to the local context; in the following figure, it is adequately represented and visualized. The analysis of the socio-demographic profile of individuals with access to the internet from mobile phone \ smartphone, shows that the most vulnerable segments of the population are young people (about 70% of individuals aged between 11 and 34 years), residing in the North and in densely populated areas (with more than 250,000 inhabitants); and specifically for the identified segment, the rates of concentration levels are found between the profiles most qualified in terms of education and professional status. In addition, those who declare internet access from a tablet have a socio-demographic profile definitely qualified in terms of education and professional status. In fact, compared to a mean of 12.7% of the entire population aged 11 to 74 years, there has been a concentration rate of 31.3 % for executives, managers and academics, 29.4% for entrepreneurs and professionals and 24.7 % for graduates; higher penetration rates are found among those who live in densely populated areas (with more than 100,000 inhabitants) and in the younger segments of the population, especially among students, academics and otherwise. The same data indicate that 43.1% of those who use the network, it does so primarily because it is able to acquire information on any subject quickly, for the possibility of finding things otherwise unavailable (25.2%), the quick access to public and private services at a distance (26.3%), to be informed in real time on current news (23.4%). On the contrary, those who use the internet or mobile device from

time to time, he would do more often if access to the network would cost less (20.7%), although more than a third said that , however, would connect to the internet no more than they already face (31.7 %).

So the diffusion of these devices show the possibility that the applications are like an effective source of health information and a tool for self-management of the users/patient. The *mHealth Summer Institute* states that "mobile technology allows providers to help patients improve their health in real time, allowing them to personalize health care, and monitoring the progress" (National Institute of Health, 2011).

5 Results

So, mobile applications for health are designed to interact directly with consumers, with or without the presence of a health worker, helping them better manage their own health (Parsons, 2011). In this way, the Apps - Medicine Category - are tools that support health care by improving the participation and the capacity for self-management of the patient. The objectives that are proposed APPs in medicine are to increase patient involvement in their own treatment, improving the monitoring process on their care and supporting them in finding alternatives to the pathology observed. The Apps cover a variety of areas that support people to have a pro-active approach to health with self-monitoring programs associated with the care of your body, definitions and comments about the diseases concerned. The following results show the first analysis of the Android operating system, analyzing the specific aspects of the Apps in the play store, considering both mobile Smartphone and Tablet.

Source: Our adaptation of Tablet, March 2014;

The total number of mobile application is n°4525 for the Android operating system and n°6009 for MacIOS; so through this first representation we analyzed n°23 Apps related to the category "Medicine" in Android and n°148 for MacIOS. In addition we focused only on Apps with comments from users/patients, in this way we reach n°19

applications for Android (n°1518 comments) and n°19 regarding MacIOS with n°373 comments. Regarding the total number of the mobile Application on Smartphone was n°4525 on Android operating system and n°7221 in MacIOS; in this way we map n°23 Apps related to the category "Medicine" Android and n°259 for MCOs. In addition the focus on Apps with comments show n°19 applications for Android, with n°1518 comments and n°38 Apps for MacIOS with n° 334 comments.

In recent years the Health Sector there is a tendency to an increasing use of Information and Communication Technology (ICT) to support the operations, particularly in support of medical research, clinical practices and assistance to citizens. It is expected, in five years, 500 million people worldwide will use mobile applications that help them update-schedule and manage their health by improving their quality of life.

In Italy, even diffusing ICT is extended in different regions unevenly. The main application areas are concerned, however, the electronic medical record (Reina, 2013), electronic health records, telemedicine and so on., Operational tools to manage information, and provide users with remote assistance; view of self-management is part of the mobile application that aims to simplify the relationship between the patient and physician self-management of health status, the reorganization of health care and social progress. The analysis made us understand how the different typing key words "heart attack" - "obesity" - "antioxidants" - "diet" and so on., The apps available for download, not only belong to the category "medicine" but - in most cases-those categories fall within the "other" that collects items as "lifestyle" - "entertainment" - "fitness" - to the category "games". In the event that the apps that appear on the home page belong to the class "medicine", these are used as a mere support to the diagnosis and treatment of the disease, often portraying similar agendas, where the user can record their clinical values (eg level of insulin in the blood, ect); Glossary or that can help you understand the disease or in other cases, guidance on what to do in case of a positive response to some specific diagnosis, ect . In addition it has been shown that there are Apps that through a virtual tour will explain the human organism. In this first phase, the data collected confirms that there are limited data to infer on the 'usefulness of Apps in the process of accompaniment to medical care or what motivates you to discharge the Apps for self-management. Through the comments and reviews issued on a voluntary basis, by users on Apps, more information can be found:

- 83% of cases there is the presence of comments and \ or reviews;

- In the remaining 17% of cases there are no comments and \ or reviews.

In 57% of cases are positive and the remaining 43% are negative comments.

The table n°2 and n°2.1. percentage divided into the following two categories of comments, with the inclusion of some description.

In MacIOS system it's possible to found:

- 85% of cases there is the presence of comments and \ or reviews;
- In the remaining 15% of cases there are no comments and \ or reviews.

In 70% of cases are positive and the remaining 30 % are negative comments.

6 Considerations & Critical

From what we saw, dissemination and use of smart phones and tablets around the world , led to the creation of applications widely available and suitable for multiple uses, in increasing numbers over time. All this is also confirmed by the analysis carried out by the Research Centre of DOXA , with reference to the Italian system. These structural features and the same qualities attributed to the App, easily, availability, quantity and depth of information that can be acquired, allow to predict a future of safe growth and development, being able to have the same Apps all the potential to play a significant role in the education of patient 's own health and in disease management . Obviously if the anticipated stresses the ability to implement even in the medical context , one can not deny the limitations and / or critical to their specific use . In fact, the points that need further study, strongly linked to the excessive novelty of the instrument, being limited literature available information, are on the one hand on the safety of sensitive data and information untreated, the other the same reliability of instrument called. In relation to the first aspect, the information asymmetry that normally exists between the patient and medical information, often means that the user is not in a position to assess the subjective quality of the application, while conversely the sensitivity of the data being transferred requires to know and evaluate the best use. On the other hand , if it exceeds the problem of the sensitivity of the data processed, judging the reliability of the instrument - App - does not appear to be a simple thing; in fact, often the only review process is put to a simple score (by the user) with commentary (Rodrigues and Brody, 2011). Therefore, the only form of protection for the wearer is given by reading the reviews and comments made by those who have downloaded and used the app itself, or alternatively - for those who are more versed in the subject - the verification of credentials who has produced the

specific application. In addition, however, the same research process of most suitable App for their use, is not as direct and immediate, given the use of keywords, which can sometimes be misleading respect the objectives pursued. Sensitivity of the content Treaty reliability of the instrument used, the process of research pursued, are therefore each and all items on which the attention of the research will have to converge in order to provide new answers to new emerging information needs in health care, helping to improve the approach to the health of the citizen / patient , including by means of specific dedicated Apps.

Table n°3 : Detail Card Android- McIOs

	Android Detail Card	McIOs Detail Card

² By the GlobalWebIndex, updated to 2013.

On these initial considerations in the future will be, on the one hand, to deepen the understanding of the use and dissemination of new technological systems such as App, - for specific and particular needs related to new information needs emerging in health care - other , we will focus on typical issues such as those related to the reputation of as a process of interaction and communication in which circulating subjective assessment compared with a target of interest, which may contain truthful statements or deceptive(Conte and Paolucci, 2002). The opportunity that each user has their own opinion about purchasing a load of experience allow comments that made an impact on reputation, positive or negative, that a particular app can take, so you will have to quantify this impact in terms of social innovation related the use of new technologies.

Collaboration for Solving Problem of Poverty, Social Development and Community Happiness Condition

Chalard Chantarasombat *

Department of Educational Administration, Faculty of Education,
Maharakam University, Thailand

Structured Abstract

This study aimed to: 1) create a collaboration between the state (local government) and local communities to solve the problem of poverty and develop appropriate sanitation for local communities, 2) developing a community database to help formulate policies for developing solutions to poverty, social development and community happiness 3) developing learning procedures and knowledge management. Samples were based on 202 families from 12 villages, 6 sub-district, and 6 districts in Maha Sarakham province. Research methods included 1) a household account diary; living development plan, operational handbook, community plan handbook, and sanitation data, and 2) An instrument for evaluation purposes. The results revealed that: 1) Factors of success included the integration of a plan for collaboration matched to a local community plan. 2) Factors of failure consisted of a lack of joined up thinking, consensus amongst stakeholders and volunteer attitudes to community development. 3) The issue of debts accrued by farmers should be highlighted.

Purpose – 1) to construct mechanisms of collaborative parties for development in solving problem of poverty, social and community happiness condition 2) to develop the data base system from community base to policy determination to development at different level, 3) to construct the learning process of community knowledge management leading to solving problem of economic and social and community happiness condition 4) to enhance and support parties of solving problem as needed by community, and 5. To construct a model of collaboration for solving problem of poverty, social development and community happiness condition in Maha Sarakham province.

Design/methodology/approach – The research area covered 6 sub-district, 6 districts and 12 villagers in Maha Sarakham. The focus group consisted of 202 model households research using the operational process of research and development by applying participatory action research (PAR) stage of action : 1) the survey of information concerning current problem conditions, 2) data analysis, 3) participatory making plans, 4) action by following the plans and improvement, 5) follow-ups and evaluation, 6) development of potential and up grading the body of knowledge, and 7) lesson conclusion and learning sharing. Two types of the instruments used were 1) the instruments for development to generate participatory learning innovation including a household account book a life quality development plan work action manual a community plan manual and a manual for making community happiness condition, and 2) the instrument used for collecting data was an evaluation form on achievement indicator and the Satisfaction Questionnaire. The

statistic using for data analysis consisted of the Percentage, Mean, Standard Deviation and t-test.

Practical implications – The level affecting competency obtaining from the project: 1) The project work – staff was appointed according to Maha Sarakham provincial Order Number 918/2011 on An Appointment of research report working – staff on the Project for Collaboration for Solving Problem of Poverty and happiness condition in Maha Sarakham province. The operational mechanisms were generated at the following 3 level: (1) At the community level, there were working staff numbers from local leaders, local area leaders and village public health volunteers, (2) Party agenise at the local area, sub district and district level such as local administrative organization (L.A.O.) were important mechanisms for work driving in work plan integration to support personnel and budgets, and (3) 3The party agencies at the provincial level enchained and supported workplan personnel and budgets and dried work operation at the policy level, 2) For developing the data base system from community base to policy determination for development at different levels, there were data base systems in real action, 3) For building the learning process for organizing the body of knowledge of the community leading to solving economics, social and happiness condition problems, For the PAR was used. The following were significance stages, operational process and operational results: (1) Surveying current problem condition concerning household account and data about community happiness condition, (2) Data analysis leading to planning for solving problem at the household level through the life quality plan and at the community level through the community master plan for solving problem poverty, social development and happiness condition, (3) Participatory making plans through the public opinion forum on the community master plan for solving problem of poverty, social development and happiness conditions leading to perception of common operational goals for seeking cooperation in working both inside and outside the agencies to generate a pilot activity for solving problem with model household volunteer, (4) Following the plans and developing the plans. The working staff encouraged the personnel in their area through various learning activities were the operational results could be summarize as below : In Loeng faek sub district, Kudrung district, In Nong Pho sub district, In Phra that sub district, In Nakha sub district, In Khwao yai sub district, and In lao Dokmai sub district, (5) For follow up and evaluation the working staff organized the learning process through activity for meeting to follow up the process in the operational process as a hole at the area level in continuity, (6) For developing potentials in raising the level of body of knowledge for the focus group, there were resource person training, the process of training, and field trip in accordance with contexts and needs of the community, and (7) For summarizing lessons and exchanging forum for summarizing lesson and presenting operational result from solving problem of poverty, social development and happiness condition , the stage and method of operation emphasized presentation of operational result concerning success, 4) For parties to exchange and supports, for solving problems of poverty as needed by the community, there occurred par lies to enhance and supports the development for solving problem poverty, social development and happiness condition as needed by the community result: (1) For participatory planning in the past operation the working staff emphasized, (2) Real action is a very important factor which could cause the parties to enhance, (3) Reflecting was a factor of stage 3 of learning by doing, (4) For learning sharing, there was organization of activities for summering lessons and learning sharing at

the levels of community sub district, district, and across in continuity, and 5) For the model of collaboration for Solving Problem of Poverty and community happiness condition as constructed and developed through 5 experts, the following were found : 1) the model was appreciate at the highest level, 2) Congruence between participatory action research and the plan for operating learning activity management was all so at the highest level, (3) Forcibility of the model was all so at the highest level. However, some detail of the plan for operating learning activity management sound be slightly as jitted for more clarity. Finally, after trying out with the focus group, it was founded the developed model was highly appropriate to the environment and work operation .

Keywords – Collaboration, solving problem of poverty, social development, community happiness condition

Paper type – Academic Research Paper / Practical Paper: Then, using them as conceptual framework of Participatory Action Research (PAR) stage of action : 1) the survey of information concerning current problem conditions 2) data analysis 3) participatory making plans 4) action by following the plans and improvement 5) follow-ups and evaluation 6) development of potential and up grading the body of knowledge, and 7) lesson conclusion and learning.

1 Introduction

The factors of failure included : lack of good coordination in working ; lack of awareness, sacrifice, and public mind for community development.

The guidelines for further operation included : the model household should implement the life plan to action in a concrete from. The Activity plans should have a forum to follow-ups progress in continuity. The number of households should be enlarged to participate in the operational project. There should be connection with the issues an solving farmers' debt problem. The community financial institutes should be developed. For further operation, the participatory action research could be used.

His majesty the King Bhumibol Adulyadej' s working principle which has been try out which for implemented as an important principle of working development this principle is sufficiency economy philosophy. It is a guide philosophy which aims for Thai society to be a strong and reliable society with 3 aspect society of quality, society of wisdom and learning, and society of reconciliation and assistance. Therefore, implementations of the principle, theory and philosophy in actual and concrete actions should be determined to be the policy and goal of improvement and development of each organization, agencies, community, or stakeholder. This is incongruence with. His Majesty the Kings

address at the graduation ceremony at Kasetsart University on 18 April 1960. He began from he was first interested in community development he transferred his royal through initiation from his own studies his loyal address to the graduates at the graduation ceremonies he kindly pointed out the importance of farmers to the national economy "Economy of Thailand depends mainly upon farmers. Therefore, you must always remember the very great importance of this essence and must help one and another habitable agriculture of the country to be rapidly prosperous. Also, address Majesty the King who kindly to given Khon Kaen University graduates at graduation ceremony on 20 December 1973 his initiation goes To develop the country it is necessary To use the first importance which basic necessities : sufficiency in food, property and expenses of most people using save and right techniques and tools who reasonably stable fundamentals are obtain, then prosperity and economic fundamentals are gradually created (Chalard Chantarasombat. 2009) According to the study from Mr. Chanthi Pathumpha, Chumphuang district, Nakhon Ratchasima province, who focused on using 23 Rai of land ($2\frac{1}{2}$ Rai = 1 aou) for minimum advantages at his economy sufficiency learning center and local wisdom, it was found that there occurred innovations for solving problem of poverty because it was the creation of the body of knowledge through practice knowledge and their occur knowledge management is a concrete form His is accordance with the idea of PhraMahaSupab, the Abbot of Wat Pa Na Khum Monastery. The administrator of farmer learning center for self-reliance who develop the concept of one Rau without poverty to be a more concrete form with an emphasis on real body of knowledge from practice. There was development of successes indicator of the people in the focus group. There were the interested farmer who wanted clear their debts, beginning from surveying income-expenses accounts and enhancing farmers to solve problem by themselves at family through learning by doing. There was knowledge management of the farmer to be a concrete form which could be transferred to interested farmers with high expectation (A summary on the field trip on one Rai without property in Kalasin province on August 2010).

Getting together of formal and informal leaders at the village and sub-district levels to solve problem of community happiness by application of sufficiency economy philosophy of the model village which was important was still limited,

Perhaps, it was because there were no mechanisms for knowledge management to organize group for solving problem by community people to lead to knowing themselves and resources, and to be able to manage basic resource, Especially for Necessity which resulted in sufficiency and happiness. When health operation as well as building awareness mechanism at the sub-district was considered, it was found that working for operation was limited. Therefore agencies in both the state and private sectors have to work cooperatively for development in parties. The results were as follow : In Maha Sarakham province, the farmer's problem were solve and there production abilities were developed and its community happiness conditions network were built. The principle of sufficiency economy was applied at the sub-district and villages. The parties that worked together were Bank for agriculture and agricultural cooperative, MahaSarakhamBanch ; Mahasarakham University, communities school, a local wisdom. Sub-district administrative organization used participatory action research and action plans for organization of learning to construct the collaboration form for solving problem of poverty, developing ability to production system of agriculture and for setting up a appropriate MahaSarakham network. At this stage the farmers relied on themselves, learned in groups in communities and for their own communities. If appropriate participatory work at the village and sub-district levels was found the results could be extended and planed in other communities with similar content

A project for collaboration for solving problem of poverty, social development and happiness condition in Mahasarakham Phrase 1 (2011) was collaboration between Bank for agriculture and Agricultural cooperative (BAAC) and the section of research and development research units and development of community strength and knowledge management, Faculty of Education, Mahasarakham University, began from – March 2011 to February 2012. The operation was divided into 4. The operation area covered 6 district, 6 sub-district and 12 villages. There were Kudrung district, Lerngfak sub-district, cluster 3 and 14 of Buakaew village, Nachuak district, Nong Pho sub district, cluster 3 and 8 of Nongbueng village, Nadun district , Phra that sub district, cluster 4 and 5 of Dongnoi village, cluster 8 of Ton village, Wapipathum district, Nukha sub – district, cluster 4 of Wang chan village, cluster 13 of Wungmai village, cluster 16 of Wang nua village, Katharawichai, Khwaoyai sub district,

cluster 13 of Hin pun village , ChueanChom district, Lao dokmai sub district, cluster 6 of Nongkhu village. For operation in Phrase 1 (March 201 – February 2012) aim to suamine data about potentialities and problem of communities to lead to planning for developing and solving problem of poverty society and happiness condition at next stage.

2 Research Question :

- 1.What should an appropriate form for the community to solve the problems of poverty be?
- 2.How will the community data base lead to determination of policy for local development?
- 3.Can integrated operation for solving problem of poverty generate to action or not?

3 Objectives

- 1.To create mechanism of parties for operation cooperation in development of solving problem of poverty and development of society and happiness condition to be appropriate to the local area,
- 2.to develop data base systems from community base to policy determination for development at different levels,
- 3.To create the learning process for organization of the body of knowledge of community leading to solving economic, social and happiness condition problems,
- 4.To have the parties enhance and support in solving problem of poverty as needed by the communities
5. To construct a model of collaboration for solving problem of poverty, social development and community happiness condition in Maha Sarakham province.

4 Significances

- 1.The research results will provide an appropriate participatory working model at the provincial level for solving problem of poverty and for developing ability to manage the production systems of farmers.

2.The research results will generate learning network and knowledge management for solving problem of poverty for developing ability to manage production systems of farmers across communities sub districts, districts, provinces and network at the regional levels.

5 Research Framework

This research used project administration which generated solving problems of poverty together. This the thinking principle (inside out) in order to stimulate the community sector administration to could be able to manage itself and determine its own needs to persuade supply and administrator supply to be more efficient of empowerment. At the same time, condition were made for Maha Sarakham province and network parties to learn about way to respond to production (demand) at the right point and efficiently (Enrichment) by the uses of participatory action research (PAR) The seven stage were : team preparation examination of problem, conditions and needs ; participatory planning, doing and improvement, summary of operation learning sharing (Chalard Chantaasombat. 2008) were encouraged to be confident in learning from doing in these 5 stage : goal setting, planning together, doing and improvement, reflecting sharing the learning in the groups, community, sub–district and province (Chalard Chantarasombat. 2009) Then, using them as conceptual framework of Participatory Action Research including 6 steps as: (1) Identity Task and Learning Oppornity, (2) Studying Context, Problems, and Needs , (3) participatory planning together, (4) Doing through action, (5) conclusions of implementation findings and (6) sharing according . From the method of learning the action learning in the 5 stage as mentioned a figure can be drawn as below :
Figure 1:

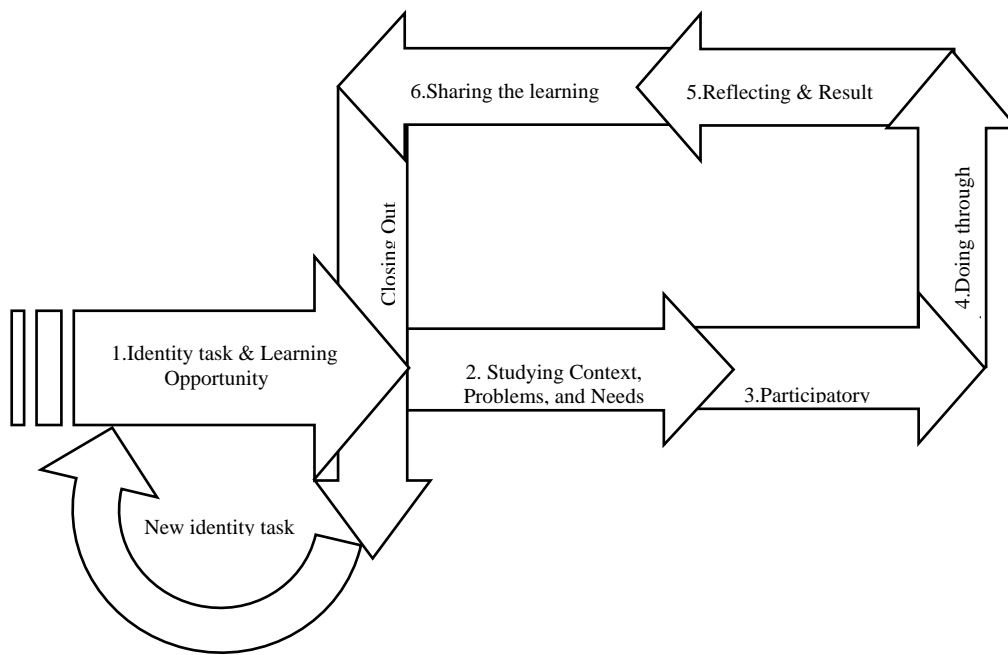

Figure 1 Action Learning (Chantarasombat Chalard. 2011)

6 Methodology

1. research area, the research was conducted in the area of 6 district, 6 sub-districts, 12 village in Maha Sarakham province, purposively selected. Data base of focus village according to the Bank for Agriculture and Agricultural. Cooperative Maha Sarakham province. Six out of 13 districts readiness data base of the focus awareness, simply selected. WapiPathum district, Nadun district, Nachueak district, Kantharawichai district, Kudrang district and Chuenchom district. There were meeting for selecting interested research subdistrict district in activity participation ; six obtained sub district were 1) Nakha sub district , WapiPhathum district 2) Phrathat sub district 3) Naphosubdistrict, Nachuak district 4) KhwaoYai sub district, Kantharawichai district 5) Loengfaek sub-district, Kudrung district, Maha Saralham province, 6) Lao Dok Mai sub district, Chuenchom district and these six sub district consider the sample of 202 model households.

2. The research operational process mainly used the research development method by applying action learning and PAR there were 1) survey of data about current problem conditions 2) data analysis 3) planning together 4) action and improvement 5) follow ups and evaluation 6) developing potentiality to upgrade the body of knowledge and summarizing lesson and learning sharing

Two types of the instrument were 1) the instruments used for the developing work to generate participatory learning innovations included household account books, life quality development plan, work operation manual, community plan manual and manual for organization of data about community happiness condition 2) the instrument for collecting data was an evaluation used forms on success indicators. The statistics used for analyzing the collect data (Boonchai Srisa-ard. 2002) frequency percentage man and standard deviation.

7 Result

1. For creations of mechanisms for collaboration for solving problem of poverty, social development and happiness condition as appropriate to the local area, there was coordination in cooperation of the project research staff as by Maha Sarakham governor and those involved at provincial, district and sub district level. The project work – staff was appointed according to Maha Sarakham provincial Order Number 918/2011 on An Appointment of research report working – staff on the Project for Collaboration for Solving Problem of Poverty and happiness condition in Maha Sarakham province Phrase 1 (2011) Issued on 27 May 2011 and Maha Sarakham Provincial Order Number 2229/2011 on An Appointment of the working staff for driving policy for Solving Problem of Poverty in Maha Sarakham province. The operational mechanisms were generated at the following 3 level:

1.1 At the community level, there were working staff numbers from local leaders, local area leaders and village public health volunteers, no less than 15 persons each. There were totally 17 model volunteers households. In each household, the members had learning activities together through using a household account book, a life quality development plan and data about community happiness condition as instruments for solving problem of poverty at a both households and community levels.

1.2 Party agencies at the local area, sub district and district level such as local administrative organization (L.A.O.) were important mechanisms for work driving in work plan integration to support personnel and budgets. Each school supported personnel to be resource persons and advisors in recording household

account data analysis and places for activity organization district health promotion hospital supported the personnel to participate in activities to integrate community happiness condition plans. The office of District Agriculture The Office of District Community Development Bank of Agriculture and Agricultural Cooperative and the bank branches in each of these area enhanced and supported the operational process, the personnel who gave academic knowledge budgets and integrated the plan to action.

1.3 The party agencies at the provincial level enhanced and supported work plan personnel and budgets and derived work operation at the policy level. For example, the provincial office, the office of provincial community development The office of provincial social and human security development support the personnel to be the working staff at the provincial level the office of provincial cooperative audition supported the printing of account book, the office of provincial commerce supported with budget to buy a cherry – shell grinder for making for feed in the plan for solving poverty in Khwao sub district An institute at the higher education at Maha Sarakham university worked as a coordination unit, and the secretary division of the project working – staff. Bank for agriculture and agricultural cooperative in Maha Sarakham province integrated the plans into practice and helped with places for organization of learning activities and the project operational process.

In addition, in order for the operation to drive according to the established plan, and for the mechanism parties to understand the process, and the operational goal together, then agreement and commitment on working together with the parties t every levels were made and signed. The outcome of working for 1 year as mention caused the working – staff to receive lesson leading to mechanisms for driving work in a more concrete form of collaborative parties. In these parties had earnest collaborative activities for at least 3 years , the working-staff would be greatly confident that the mechanisms parties would lead to working for solving problem of poverty and happiness condition in strength and stability.

2.For developing the data base system from community base to policy determination for development at different levels, there were data base systems in real action. The community participated in every working area. Data were collected in several forms including documents, Hard copy, Field electronic program and

programmed household account and then developing to be project website <http://health.drchalard.com>. Detail included data about income and expenses, maps of community happiness condition and evaluation results before development. When the mentioned data were analyzed and synthesized, participatory policy and work plan for solving problem of poverty, social development and happiness condition in the form of plan for life quality development, community master plans for solving problem of poverty, social problem and happiness condition, pilot were project for solving problem of poverty, model household account, lists of debts, and the result of development.

The data base system condition as mentioned were connected into the information data base system of the agencies for mechanism parties of work at every level of community, sub district, district and province. The plan in solving problem of poverty in every area were pushed to be filled in the plans for local development however, The 3 years development plan of the local administrative organization and the operational results in the first year plans for solving problems of poverty social problem and happiness condition were filled in Expense Budgets Act 2012 with a total of 450,000 baht 5,000,000 baht for Loengfaek sub district, 50,000 baht for Nong Pho subdistrict 50,000 baht for Phra That Noi sub-district 100,000 baht for Nakha sub-district and 100,000 baht for Lao Dokmai sub-district.

3. For building the learning process for organizing the body of knowledge of the community leading to solving economics, social and happiness condition problems in Maha Sarakham province, there was learning process leading to action of the parties cooperation for solving problems of poverty, social development and happiness condition, was appropriate for local conditions. The PAR was used. The followings were significance stages, operational process and operational results.

3.1 Surveying current problem condition concerning household account and data about community happiness condition

3.2 Data analysis leading to planning for solving problem at the household level through the life quality plan and at the community level through the community master plan for solving problem poverty, social development and happiness condition.

3.3 Participatory making plans through the public opinion forum on the community master plan for solving problem of poverty, social development and

happiness conditions leading to perception of common operational goals for seeking cooperation in working both inside and outside the agencies to generate a pilot activity for solving problem with model household volunteer.

3.4 Following the plans and developing the plans. The working staff encouraged the personnel in their area through various learning activities. The operational results could be summarize as below :

3.4.1 In Loengfaek sub district, Kudrung district, households had plans and acted in reducing their own unnecessary expenses, for example, they had vegetable plots, grew all edivle thing, ate all things they grew. Seven household had agricultural plots to grow sugr cane plants. There was one labour bank activity at the village level. There was one truth saving activity in the community. Every model household became a member of the truth saving group. Also the Bio Fertilizer making group to reduce the production cost for community people.

3.4.2 In Nong Pho sub district, it was found that each model household had a plan and could reduce their own unnecessary expense for example. They had plots grow all endive thing. Ate all thing they grew. Four for household had sufficiency economy plant plots. A learning activity outside the community occurred once. There was one truth saving activity, every model household became a member of the truth saving group. There were activity for monastery forest rehabilitation for environmental revitalization and to create unity and reconcilitations of people in the community.

3.4.3 In Phra that sub district it was found that each model household had a plan and could reduce their own unnecessary expenses. There was sufficiency economy learning centers at 62 household. There were 3 learning center at the village level. There were 9 career network group to create jobs and incomes to extend to neighboring sub district. There occurred activities for rehabilitee and campaign for plugging and covering rice straws to reduce production cost and to create unity and recon citation a people in the community. There occurred activity for buying and selling collection to the community. There occurred activity for training to provide knowledge of communicative diseases and incommunicative diseases through coordination in cooperation with promotion sub district hospital and Nadun district hospital, public health volunteer group got

together to serene diabetes according to the maps of happiness condition every three months.

3.4.4 In Nakha sub district, model households had plans and acted in reducing expenses and increasing income. There occurred 12 sufficiency economy learning centers at these households, and one learning center at the village level. There was one Para Rubber planting network to create jobs and incomes to extended to neighboring sub district Twelve households performed modern of 2 Rai of land without poverty (Mr. Na Sudphan, interviewee) There were activities of relitalization for neighbours to help reap rice for reducing production cost and to create unity and reconciliation of community people.

3.4.5 In Khwaoyai sub district Kantharawichai district, it was found that model housesolds hand plans and acted in reducing expense and increasing incomes. They occurred 1 learning center at the village level. They had a group for analyzing household account leading to reduction of expense and interment of incomes for members in the community. Some example were reductions of cost of raising fish in floating raising – nets by producing fish feeds from cherry shells, getting – together to make group for solving community problems, raising funds for rice seeds to help flood victims ; value addition and income creation community potential were such as mushroom culture for expense reduction

3.4.6 In Lao Dokmai sub district, Chuenchom district, the following were found : Main expense were in career operational and daily expense such s expense for child's / children ' s reduction, and food The village viewed that the important should be given to reduction of expenses on living making such as reduction of costs of rice farming, pig raising and bag sewing (bag sewing made from fertilizer sacks) However, the expenses on education and food were difficult to reduce. The villages views that, for reducing expenses, chemical free agriculture to be used. (Comprehensive agriculture, therefore, could motivated these farmer for fields trips concerning comprehensive agriculture and sufficiency economy.

3.5 For follow up and evaluation the working staff organized the learning process through activity for meeting to follow up the process in the operational process as a hole at the area level in continuity. As results there were exchanges in learning, experience, lessons and seeking problem solutions together. In addition

there was education according to the indicators post- before and after development. This cause the working staff and focus group to understand situation and movement of working leading to developing transferring and extending.

The results of the collaborative project for solving problem of Poverty, Social Development and Community Happiness Condition in Maha Sarakham Province in Phase 1 (12 Villages in Maha Sarakham Province)

3.6 For developing potentials in raising the level of body of knowledge for the focus group, there were resource person training, the process of training, and field trip in accordance with contexts and needs of the community. In Laengfaek sub district, Nongpho sub district, Phra that sub district and Nakha sub district, the villager were trained and had field trips on solving problem of owing debt and property in based of the sufficiency way at the sufficiency economy at learning center of Mr. SawaengManolai, Dong KhangNoi sub district Kasetwisai district, Roi Et province. In Khwaoyai sub district, they trained in making fish feed and had field trip at Federation of shrimp Raisero, Yangtalad district, Kalasin province and DonMan village learning center Kham Riang sub district, Kantharawichai district, MahaSarakham province, In Lao dokmai sub district, Chuenchom district, they trained in making pig feeds and had field trips to learn comprehensive agriculture in Don Daeng sub district, Borabue district and Talad Mueng sub-district, Nachueak district, MahaSarakham province.

For the results of training and field trips in each area, the trainees could understand the training contents and showed their satisfaction at a very good level. They had skill and awareness of recording household account, and sought way to reduce expenses and increase incomes for their families. Also they make group for doing activities leading to solving communities problems.

3.7 For summarizing lessons and exchanging forum for summarizing lesson and presenting operational result from solving problem of poverty, social development and happiness condition in phrase 1 (2011), the stage and method of operation emphasized presentation of operational result concerning success. Emphases were also on important lesson problem, obstacles, continues operational plan, including experience sharing, and ideas and recommendation given by academic.

As results, the participation could know the operational result concerning success, important lessons obstacles and continuous operational plan.

4. For parties to exchange and supports, for solving problems of poverty as needed by the community, there occurred parties to enhance and supports the development for solving problem poverty, social development and happiness condition as needed by the community through local Administrative organization by doing process from the stage process and result of operational were as follow.

The stages process results

4.1 For participatory planning in the past operation the working staff emphasized the participating process of parties of network in solving problem of poverty, social development and happiness condition by beginning from examining data about current problem condition and analyzing data as a main mechanism to generate participation of network parties Different type

4.2 For participatory planning, the past operation, the working staff emphasized participatory process of parties of network in solving problem of poverty social development and happiness condition. It began from examining data about current problem conditions and analyzing data as the principal mechanism to generate participation of network parties. Several type of the instruments used consisted of households account for analyzing data to solve problem at the household level for planning to develop the quality of life for solving problems at the community level, happiness conditions and the community master plan were

used. The outcome of using the method as mentioned could lead to the integrated work among network parties in terms of budget and resources and could lead to driving the work of the development plan for solving problems of poverty of the target community.

4.3 Real action is a very important factor which could cause the parties to enhance the plan for solving problems of poverty, social development and happiness conditions. The methods of plan action and important were used as instruments and mechanisms for leading to real action by encouraging the working staff at different level and the target communities to have participatory action plan, to follow the plan and to improve the plan in order to be in accordance with the situations for examples, Khwao-Yai sub-district followed the plan for solving problem of poverty by mushroom culturing to reduce expense without waiting for the budget from the state sector or the project. From an analysis of data about incomes and expenses, it was found that the quantities of mushrooms bought for consumption everyday by the villages and fields trips caused the village to know how to cultivate mushrooms from the materials available in the community. Nong Pho subdistrict raise funds from villages to drive the plan for solving problems of poverty in the same issue. It could be seen from these 2 sub-districts that after following the plan for some each community would improve the plan in order to be practical/

4.4 Reflecting was a factor of stage 3 of learning by doing. This was used as the research conceptual framework for solving problem of poverty, social development and happiness conditions. The action were done through learning activities by development potentials in upgrading the body of knowledge level training, field to enhancement of the operational were encouraged and enhanced to generate awareness of in keeping household accounts and to realize the important of farming according to principle of sufficiency economy, leading to group making for reduction of expenses and increment of income in community. Some examples, group making for rice seeds in Na Kha sub district, group making for comprehensive farming in Lao Dokmai, sub district and rehabilitee and campaign for flushing to cover rice straws to reduce production costs and to create unity and reconciliation of people in the communities, and activities for buying and selling collection in Phra That sub district. These could lead to

connection to coordination in budget, cooperation and sources. There occurred parties to enhance and support for solving problems of poverty as needed by the community. The parties were sub districts, districts, and province.

4.5 For learning sharing, there was organization of activities for summarizing lessons and learning sharing at the levels of community sub district, district, and across in continuity. Learning sharing was regarded as an important factor, which could lead to integrated solution of problems of poverty. Because the community would have opportunity to summarize their own lessons and to share learning together with other communities and government agencies, academics private development organizations there occurred competitions and self-development. This would lead to plan improvement help in the working process to achieve the goal. Also, the exclusive offices would perceive success, problems, obstacles, guideline for solving problems and development plan in continuity. Then these offices could use the result in process of decision making and supporting them into the level of community and local policies. It could be said that the operational results in Phrase 1 in 2011 the organization of parties could enhance and support plans for solving problems of poverty, social development and happiness condition of the target community. Particularly, Sub – district administrative organization (SAO) and Bank of Agriculture and Agricultural Cooperative which could play the roles in support enhancing and connecting the operational process according to the missions of the organization.

5. For the model of collaborative for solving problem of poverty, social development and community happiness as constructed and the Developed through 5 experts, the following Were found : (1) The model was appropriate at the highest level. (2) Congruence between participatory action research and the plan for operating learning/activity management was also at the highest level. (3) Forcibility of the model was also at the highest lever. However some details of the plan for operating learning activity management should be slightly as just led For more clarity. Finally after trying out with the focus group, it was founded the developed Model was highly appropriate.

There were 9 stage of the participatory action research, plans for operating learning activity management with 16 sub-activities and outcome of the model with 16 pieces of work as illustrated in Figure 2.

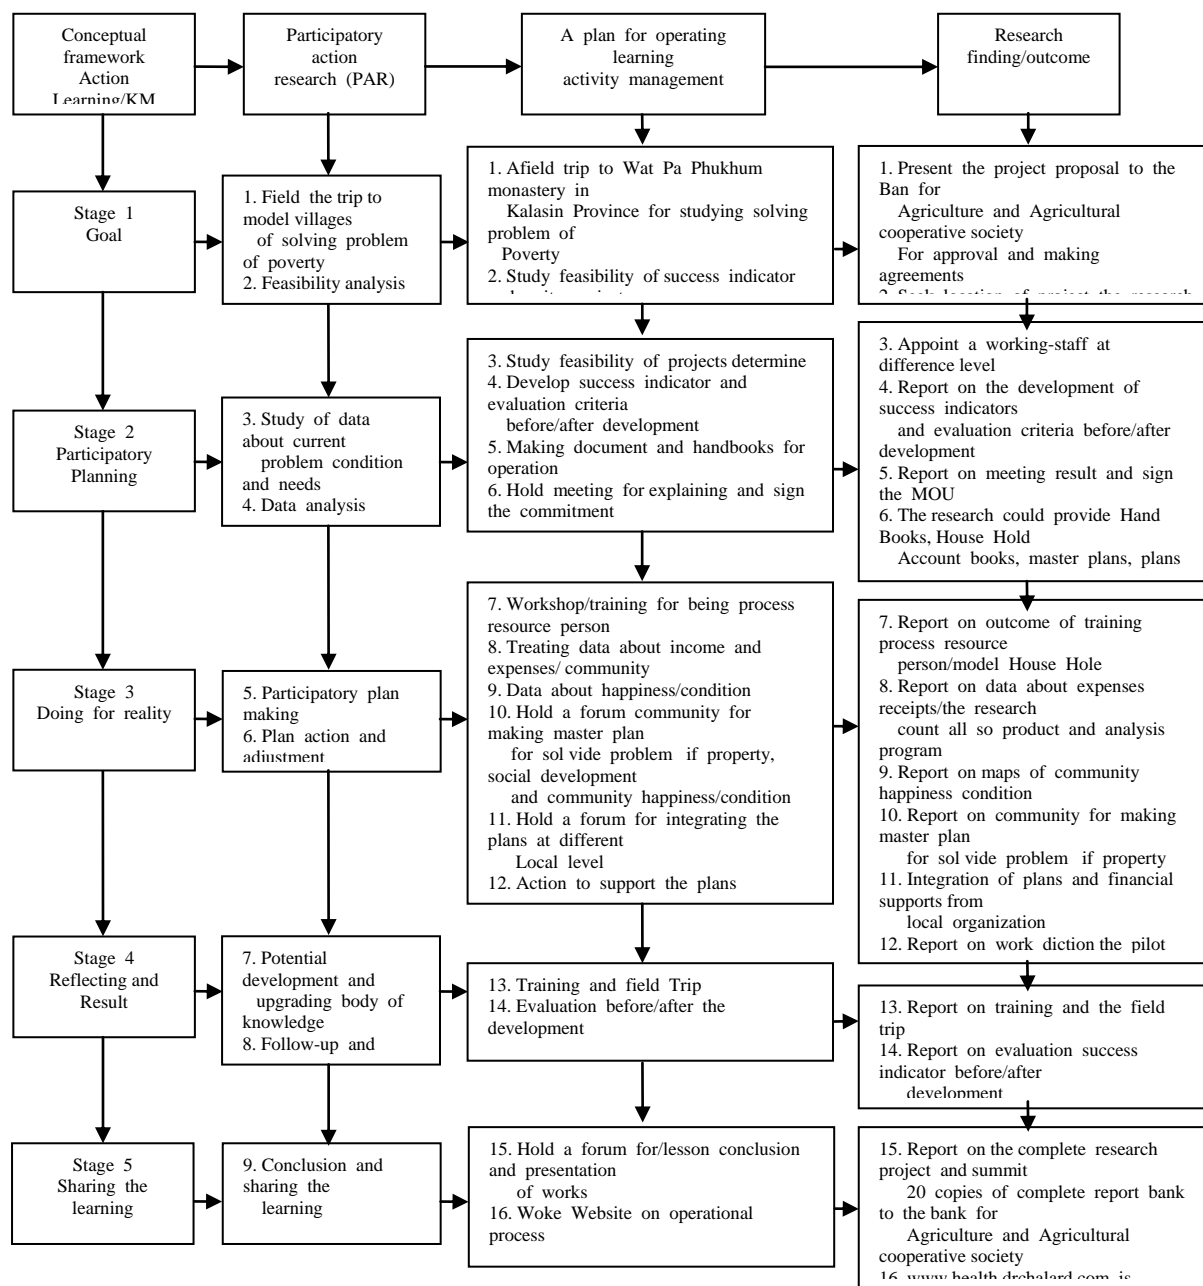

Figure 2 Model of Collaboration for Solving Problem of Poverty, Social Development and Community Happiness Condition in Maha Sarakham Province

The results of the study of the Project for a collaboration for solving problems of poverty, social development and happiness condition in Maha Sarakham province Phase 1 in 2011 are in accordance with the concept of poverty and development of economy society, and happiness condition. There were several

authors and organizations that presented articles. The following issues should be discussed.

1. For the definition of poverty factors of poverty, and the methods of solving of poverty that is to say, the operation of this project upheld the operational framework by building mechanisms of collaborative parties to develop method of solving of problem and happiness conditions which are appropriate to locality. Then the operation can generate mechanisms collaborative parties to develop method of solving problems of poverty and develop the society and happiness condition. Project work- staff were appointed based on the Maha Sarakham provincial Gender Number No. 98/2011. The following working mechanisms can occur. At the community level, there are working volunteers (CPHV) community public health household of volunteers is the goal of developing determination of learning activities together through the use of household accounts. Planning for life quality development and searching data about community happiness condition are instrument for solving problem of poverty at the household and community levels.

1.2 Party agencies at the sub district and district levels such as local Administrative Organization (LAO) are important mechanisms for work driving in terms of integrating work plans, supporting personnel, supporting budgets, enhancing and supporting the operational process, and in terms of personnel to academic knowledge, budget, and integration work plans into action

1.3 Party agencies at the provincial level enhances and support work plans, personnel and budget and drive operation at the policy level such as the provincial office, the provincial community development office, the provincial office of office and human security development, the office of provincial commerce, Higher educational institutions, Mahasarakham University and Bank for Agriculture and Agricultural could lead to solving problems of poverty social development and happiness condition in strength and sustainability.

9 Conclusion

The study results are incongruence with the concept of the results of the study conducted by Chaturong Boonyaratanasunthon and Kitti Phatanonthapatamadum (2007 : 253-254) Who gave the importance to an emphasis on solving problem of

poverty. The recommend increasing incomes from micro indicators such as GDP gross domestic product per head of physical macro-investment and infrastructure development

2.The development of data base from the community base to policy determination is for development at different levels. Having actual action data base of systems which community participation is made in the operational area. They develop programmed household accounting records. And then develop to be the website on project. There are details of incomes of expense and maps of community happiness condition. Evaluations are conducted before development to support the data as mentioned for analysis and synthesis. The determination of participatory policies and work plans for solving problems of poverty, social development and happiness condition is in the form of life quality development plan. The community master plan for solving problem of poverty, social development and happiness condition the pilot plan for solving problem of poverty includes keeping household account, list of debts and evaluation after development the data as mentioned can connect to be in information data base system of the parties mechanism agencies in work operation at every level of community, sub district, district and province. The plans for solving problems of poverty in all study areas the plan are pushed to be filled in the local development plans. The 3-year development plan of the local administrative organizations (LAO) are filled in the Expense Budget ACT of Fiscal year 2012 in the focus area of 6 district for 450,000 Bath. This is in accordance with the concept of Somchai Chitsuchon who believes that poverty is transient poor which may become chronic poor and poorest. That is to say, poverty can be cured by developing or changing correctly. That is to correct the cycle of poverty. There must be the actual action data base system, data about incomes and expenses for making maps of community happiness condition, evaluations before and after, development, analysis and synthesis, and making plans for solving problems with community participation.

3. Building the learning process manages. The body of knowledge of the community leading to solving economy, social and happiness condition problems. There is a learning-to-doing process of the collaborative parties for solving problems of poverty, social development and happiness condition, which is appropriate to local conditions. This process uses participatory action research. The

following are important stages of the operational process and outcome. Surveying data about current condition and problems concerning household accounts data about community happiness condition, data analysis, participatory plan making, action following the plan, follow ups and evaluation, developing potentials to upgrade the focus group's body of knowledge, summarizing lessons and learning sharing, organizing forum for summarizing lessons and presenting operational outcome of collaboration in solving problems of poverty, social development and happiness condition in Phase 1 (2011) in order to know

the project success, important lessons, problems and obstacles, and continuous operational plans.

The results of the study are accordance with the study conducted by Chalard Chantarasombat. (2004) on the concept concerning community study. He states there is an organization of community master plan. It begin from analyzing potential and determining guidelines for self-development, seeking instrument for determining popularize strategy, and other process.

The result of the study are also in congruence with the concept of Arisara Chuchat and others (1995) in relation to the process of developing by learning the concept of development : receiving experience identify experience, analyzing experience, planning, and acting There are important process of participatory development.

The results of this study are in accordance with the concept of basic principle of participation working. This concept is the concept of Therephong Kaeohawong (2000) and that of Praphon Piyarat (2000) concerning the stages of participation : decision – making participation, work operation participation in receiving benefit and evaluation participation. At the same time, actual participation consists of participation in seeking problem and causes of problem, participation in planning for doing activity, participation in investment and operation, and participation in follow-ups and evaluation. However the levels of participation include : decision – making level, collaboration level, and utilization level.

The results of the study are in accordance with the concept of the process of participation development by learning in the concept of Arisara Chuchat (1995) Their development consists of action to generate clear experience, and testing,

seeking, experimenting and action leading to learning new Things from new experiences. Identifying experiences, and stages identifying, explaining experience sharing, analyzing stage of beginning ; making understanding of experiences, concept of analyzing, and planning and identifying what to do next. There will be role in what have learned from experiences and in developing strategy.

The results of the study mentioned indicate that the project for collaboration for solving problem of poverty, social development and happiness condition, Maha Sarakham province in Phrase 1 (2011) upholds the principle of participatory development, aimed at building strength at the grassroots level. If there is a problem white operating work, the problem will be solved immediately. The community problems were used as major problems of operation.

The results of the study as mentioned are in accordance with the concept of participation in the shape of ladder steps of participation decided by Theeraphong Kaeohawong (2000) concerning 8-steps ladder of participation. These 8- steps are treatment step, explanations step, information step, discussion step, idea expression step, partnership step, agent-empowerment step, and controlled by people step. This project had 8-steps operation. At the same time there is a problem watch process. Attention was paid to formal and informal coordination in operation.

4.Success indicators for the project operation

For success in operation frame of operational issues, and success indicators for the project operation, there are studies and determination of frame of operational issues, and success indicators for the operation. Also, there are constructions of obligations, agreements accept ions of frame operational issues together to be used for evaluation before-after operational as indicators for work success.

The results of the study as mentioned are in congruence with Chalard Chantarasombat (2002) and others who conducted several projects and developed multi-dimensional indicators. Some examples are careers group such as production and quality of production, group management. For the project, social development and happiness condition in Maha Sarakham province, Phrase (2011), the indicators for development or operational outcomes are determined They are divided into the aspects of solving, social development and happiness condition. Also these aspects are divided into sub aspects, with a total of 73 indicators. All of these indicators are obtained from mutual agreement and approvals of the project participants. This

shows true responsibility based on the concept of participatory action research (PAR)

The collaborative parties enhance and support to solve problem of poverty as needed by the community through local administrative (LAO) from the learning by doing process. There are important stages of-the operational process and outcomes : participatory planning, real action, reflection, and learning sharing.

The results of the study mentioned are accordance with the writing by the Center for Information and Education Service, the article by ChoetsakChumnum (1997), the article by PhanthipRamsut (1997) the article by Rattana Buason (1998) and the writing by the Office of Human Resource Development Project, Krabi province. The writing emphasizing participation in every process based on the concept of participatory action research in supplement to utilization of the parties of enhance and support development for solving problem of poverty, social development and happiness condition. These is collaboration form local administrative organization, agencies in operation area, and other collaboration parties. It indicates that the operation by this project must use local potentials and must coordinate with the other agencies at every level.

10 Recommendations

1. Policy recommendations

For lessons from experience in conducting the project for participatory solving problem of community poverty in the part 1 year, policy recommendation are as follows.

Policy recommendation for the local Administrative organizations

The local administrative organization should made the community master plan of each community which lead to annual review in community forum and sub district in order to suit the changing situations. This will enhance and support the community plan to lead to action in a concrete forum and in continuity There will be a process and mechanisms for follow ups and evaluation to extend the lesson to other communities.

Policy recommendations for the work staff for provincial development strategies

The provincial development committee should bring the project into the plan in order to be the provincial pilot project for solving problems of debts and

poverty of the people, and enhance and support the project to generate continuous development in the pilot area and extended area to cover the whole province in the manner of community for solving problem of poverty in Maha Sarakham province to be successful.

3) Policy recommendations for Bank for Agriculture and Agricultural cooperative. For Agriculture and Agricultural cooperative should consider household accounts records of the farmness in each area for planning to enhance and support to be the property for loan guarantee for family development according to the plan for life quality development. Also the development of group activities should be considered supplementary careers to increase incomes in the community which are in accordance with community plan in each community.

2. Recommendation for development to solve problems of poverty

1) It is very necessary for working in the project for solving problems of poverty to build participation of all sections in playing their role in working together in the form of the collaboration parties. All sections must be able to work integrated in continuity.

2) All development organizations, agencies section, and invention of different instruments for leading process of poverty solving for villagers should suit for the target group and should be in accordance with the way of community life in order for the target group is lead to action in a concrete form.

3) Recording continuous incomes expense accounts and monthly analysis income expense accounts, and using analysis results for leading to planning will enable the target group to consider the self-development model in a appropriateness.

4) For community participation, in every process for community plans are made beginning from the process of committee appointment, working staff appointment, basic data survey, putting data into the system, data system making, community data base making ; data analysis for making community plan, development plan, activity plan and project plan together. These plans actually meet the needs of community.

5) For research and development for solving problems of poverty, participatory action research could be used for solving problem of poverty because it is research with development at the same time which can improve the operation

leading to success. While operating work, it takes community of participate in the process of development from thinking, decision – making, planning, action, evaluation, and receiving benefit

Structured Abstract

Purpose – The aim of the present study is to verify the presence and the evolution of (voluntary) environmental disclosure with reference to Italian firms. We have examined the documentation of listed firms both in 2006 and 2009, that have been chosen because they immediately precede and immediately follow the emanation in Italy of the legislative decree n. 32 of 2007 that introduced for the first time in Italy – at least in voluntary terms - the information about environment. Therefore, the analysis of the two years mentioned allows us also to verify whether and how firms operated after this new legislative indication.

Design/methodology/approach – We propose an approach based on multivariate regression analysis in order to assess the evolution and the determinants of voluntary environmental disclosure. The dependent variable is represented by the disclosure index, that we have estimated through the analysis of the corporate documents of the years 2006 and 2009. Independent variables are as follows: firm size, business industry, economic performance, financial situation, age, foreign markets, public shareholders, company ownership, audit, legislation and environmental performance.

Originality/value – The first contribution provided by our work is to realize, for the first time, a specific analysis on environmental disclosure of Italian firms. Moreover (second contribution) our study has extended this analysis to all the informative documents of the entities. For this purpose, besides the individual, we have analyzed the consolidated financial reports, the management reports, the sustainability reports and the reports on corporate governance, if present. Finally (third contribution) the present work allows to examine the effects of the introduction of a new legislation which requires (without obligation) environmental information in the document of the corporate financial annual report.

Practical implications – In contrast with the previous studies on this issue, the results of our analysis show an inverse (negative) and statistically significant relation between voluntary environmental disclosure and the level of minority shareholding, the presence of international audit firms (Big 4), environmental performance, profitability and quotation in foreign exchange markets. Finally, our analysis confirms the positive relation between environmental disclosure and firm size and with the presence of government shareholdings in the ownership structure.

Keywords – Voluntary environmental disclosure, disclosure index, sustainability, Italian listed companies, environmental performance.

Paper type – Academic Research Paper

1 Introduction

The aim of the present study is to verify the presence and the evolution of (voluntary) environmental disclosure with reference to Italian firms.

For this purpose we have examined the documentation of firms listed in Milan Stock Exchange both in 2006 and 2009. The choice of these two years is not random. 2006 and 2009 have been chosen because they immediately precede and immediately follow the emanation in Italy of the legislative decree n. 32 of 2007: through the modification of the article 2428 of the civil code, it introduced for the first time in Italy – at least in voluntary terms¹ - the information about environment. Therefore, the analysis of the two years mentioned allows us to verify not only the evolution of disclosure throughout time, but also whether and how firms operated after this new legislative indication.

The first contribution provided by our work is to realize, for the first time on the basis of our knowledge, a specific analysis on environmental disclosure in Italian firms. In fact from the empirical point of view the existing national contributions aim at a general survey on the existence of Environmental Management systems in corporate financial annual reports (Azzone et al., 1996; Azzone et al., 1997; Noci, 2000); other contributions aim at surveying the determinants of the firm's overall voluntary disclosure (Boesso and Kumar, 2007), the channels of diffusion of corporate Social Responsibility Disclosure (Vitolla and Rubino, 2012; Balluchi and Furlotti, 2013); the effects of disclosure strategies on the cost of risk capital (Bagnoli and Mantovani, 2009); other scholars aim at surveying the coherence between the information contained in the firms' strategic plans and those contained in the mandatory documentation (Avallone and Ramassa, 2009). Moreover (second contribution) our study has extended this analysis to all the informative documents of the entities. For this purpose, besides the individual, we have analyzed the

¹“The financial annual report must be accompanied by a relation of administrators with a reliable, balanced and complete analysis of the society's situation and the management's evolution and results [...] and also a description of the main risks and uncertainties the society is exposed to. The analysis [...] is coherent with the entity and complexity of the society's affairs and it contains – as much as it is necessary for the comprehension of the society's situation and the management's evolution and results - the financial results indicators, and if appropriate [from here the voluntariness indicated in the text], the non-financial results indicators which concern the firm's specific activity, including information about environment and employees”.

consolidated financial reports (with a specific reference to the supplementary notes and notes to the financial annual report), the report on management (with the innovations referred to in the legislative decree n. 32 for 2009), the sustainability report and the report on corporate governance, if present. Finally (third contribution) the present work allows to examine the effects of the introduction of a new legislation which requires (without obligation) environmental information in the document of the corporate financial annual report.

The prosecution of the work is structured as follows. Paragraph 2 shows the description of dependent and independent variables of our model and the hypotheses to be verified. Paragraph 3 describes the criteria for the selection of the sample. Paragraph 4 shows descriptive statistics and the matrix of correlation (univariate analysis). Paragraph 5 shows the multivariate analysis. Finally, the last paragraph (6) includes the conclusions.

2 Model variables: literature review and development of hypotheses

2.1 Dependent variable: the disclosure index

The mostly used disclosure index in international studies is obtained by the relation between the number of disclosure items effectively applied by each company to the total number of applied elements (Spero, 1979; Robbins and Austin, 1986; Wallace, 1987; Wallace et al., 1994; Meek et al., 1995; Wallace and Naser, 1995; Cooke, 1996; Inchausti, 1997; Cammferman and Cooke, 2002):

$$0 \leq I_j = \frac{\sum_{i=1}^n x_i}{n_j} \leq 1$$

Where n_j is the number of elements applicable to j-firm; n is the maximum number of applicable elements; x is the x-element of disclosure (elements vary from 1 to n).

Therefore, for instance, if the elements selected for the disclosure are 10 and the firm X highlights only 3 of them, the value of the disclosure index for that specific firm is equal to 0,3 (= 3/10).

From the description above it is clear that the first step in the calculation of the index is establishing how many elements must be applicable to disclosure. The indication of these elements is given by the guidelines of Global Reporting Initiative (GRI) (Clarkson et al., 2008) and the guidelines for ESG homologated by the European Federation of

Financial Analysts Firms (EFFAS). This led to individuate 31 elements which – according to the sources cited – should be included in the several corporate documents so as to give complete environmental information.

The presence of these elements in the documents of each firm has been verified.

For each firm of the sample three disclosure indexes have been calculated: a general disclosure index, a qualitative and a quantitative index (Wiseman, 1982; Freedman and Wasley, 1990). To each item it has been assigned a score in relation to the completeness of information in the documents examined; it has been distinguished among:

Detailed information: information is expressed in a clear, complete and systematic way in relation to the reference items: score equal to 1;

Generic information: information is given imprecisely and not completely in relation to the reference items and it does not allow a systematic comprehension of the phenomenon: score equal to 0,5;

No data: there is not any information in relation to the items, neither qualitative nor quantitative: score equal to 0.

In substance, at the level of general disclosure, for each item the minimum score assigned is equal to 0 if the item is not present in the documents examined, and the maximum score is equal to 2 if the item is present and is described in a detailed way from both quantitative and qualitative points of view. It derives that the maximum score obtainable from the total general disclosure index (qualitative and quantitative) is equal to 62 (31x2); the maximum score of the disclosure index respectively in the qualitative and quantitative versions is equal to 31.

In order to avoid problems of results' reliability and subjectivity, a team of three researchers has realized the score. The authors have defined the list of items and have instructed the three researchers who have carried out the analysis on the corporate documents, in order to individuate the presence of items. A preliminary verification of the scores assigned by researchers has been made on a sample of 3 annual documents.

2.2 Independent variables and formulation of hypotheses

Below we will indicate the variables selected in our study, the hypotheses developed with reference to each of them and the methods of measurement.

Firm Size

Among the variables which influence positively disclosure in general and specifically environmental disclosure, the principal international literature has included Firm Size (Patten, 1992; Gray et al., 1995; Deegan and Gordon, 1996; Adams et al., 1998; Al-Tuwaijri et al., 2004; Freedman and Jaggi, 2005; Brammer and Pavelin, 2008; Garcia-Sanchez, 2008; Stanny and Ely, 2008; Reverte, 2009). There are several reasons which led to this inclusion. Firstly, bigger firms afford considerable investments which make them more dependent on the capital market and on the problem of information asymmetries. But they can produce more information than those considered obligatory with lower costs than those afforded by small and medium firms (Mukherjee et al., 2010; Monteiro and Aibar-Guzmán, 2010). In fact big firms are provided with highly developed internal control systems, which provide the analysis and the study of supplementary information with respect to the information contained in the financial annual reports. The costs of production and diffusion of the information are considerably lower in big firms due to the minor incidence of fixed costs (Lang and Lundholm, 1993). It derives that most part of voluntary disclosure represents a sort of “obligatory information” for those firms which have a relevant role in the marketplace. Secondly, big firms which operate through branches and plants can obtain some benefits by providing additional information concerning their impact on the territory, the economic activity produced and the value realized for the areas where they operate, in order to obtain a “social and general appreciation” of their activity. Thirdly, the theory of legitimacy suggests that big firms must satisfy the social expectations of a large range of stakeholders, and for this reason they need to produce more information (Schipper, 1991).

Therefore the hypothesis to be verified is the following:

H₁: the level of voluntary environmental disclosure of firms tends to be higher the larger is the firm size.

As what concerns the measurement of the firm size, according to the principal studies on the issue (Zarzeski, 1996; Ahmad et al., 2003; Cormier et al., 2005; Brammer and Pavelin, 2008; Clarkson et al., 2008; Liu and Anbumozhy, 2009; Monteiro and Aibar-Guzman 2010; Mukherjee et al., 2010; Dawkins and Fraas, 2011; Galani et al., 2011; Wang et al., 2012; Zeng et al., 2012; Stanny, 2013) it has been used the natural logarithm of total assets.

Business Industry

The Business Industry is also a variable considered by the studies on environmental disclosure (Deegan and Gordon, 1996; Gray et al., 1995; Ho and Taylor, 2007; Brammer and Pavelin, 2008, Sinclair-Desgagné and Gozlan, 2003). The characteristics of the sector in which firms operate influence the quality of the information produced; this quality partly depends on the level of environmental sensitivity of the reference stakeholders (Sinclair-Desgagné and Gozlan, 2003). In particular, firms operating in sensitive sectors and having a high environmental impact (Cowen et al., 1987; Patten, 2002; Xianbing Liu and Anbumozhi, 2009; Salama et al., 2012) tend to produce more environmental information (Deegan and Gordon, 1996; Moneva and Llena, 1996; Sharma, 1997; Hoffman, 1999; Bowen, 2000; Patten, 2002; Brammer and Pavelin, 2008).

The hypothesis to be verified is the following:

H₂: the relationship between voluntary environmental disclosure and sensitivity of the sector is positive.

With reference to business industry we have adopted a binary variable which has a value equal to 1 if the firm belongs to a sector which is environmentally sensitive, and a value equal to 0 in the opposite case. The identification of the sectors has been taken from the Bloomberg database. Coherently with the classification proposed by Salama et al. (2012), several sensitive sectors have been considered: energy supply, paper and pulp, extraction and mining, contracting, chemicals, aerospace and defense, steel and auto parts, medical and telecom equipment, food processing.

Economic Performance

According to the stakeholders' theory of, even the economic performance of a firm influences positively the voluntary social and environmental disclosure (Cormier and Magnan, 2003; Ho and Taylor, 2007) and investments in social responsibility (Cho and Patten, 2007; Roberts, 1992). In regards to this it is possible to hypothesize that firms with a higher profitability have a higher possibility to invest their economic resources even for activities with higher social value and have the wish to provide this information in order to reduce the risk of adverse selection (Lang and Lundholm, 1993). In fact, most profitable firms have more resources for the writing of voluntary informative documents. Therefore, the hypothesis to be verified is the following:

H₃: The level of voluntary environmental disclosure tends to increase with the growth of the firm's profitability.

Profitability has been measured with the Return on Investment, calculated by the relation between operating profit and capital invested (Clarkson et al 2011; Dawkins and Fraas, 2011).

Financial Situation

According to some scholars, the level of environmental disclosure can be influenced even by the firm's financial situation (Zeng et al., 2012; Clarkson et al., 2008).

On one hand, it can be generally hypothesized that an indebted firm tends to provide more environmental information because its shareholders evaluate it even on the basis of its environmental performance and behavior (Al Arussi et al., 2009; Liu and Ambumozhi, 2009). On the other hand – especially during the periods of economic and financial crisis such as the one which characterizes Italy, due to the strong concurrence of eastern countries and to the adoption of the Basle 2 criteria (these have been completely applied from 2007) by the bank system – is highly probable that indebted firms destine their resources for the production of information for financiers (typically obligatory information) and disregard all other kinds of information (typically voluntary information). For these reasons, for our survey the following relation has been hypothesized:

H₄: the level of voluntary environmental disclosure tends to diminish with the growth of leverage.

The leverage has been measured through the relationship between financial debt and equity (Cormier et al., 2005; Déjean and Martinez, 2009; Malone et al., 1993; Tri Setyorini and Ishak, 2012).

Age

Generally speaking, it can be affirmed that a firm being on the market since much time has consolidated its control and reporting structures, and it can focus more on the enhancement of additional informative systems. In this sense, it can be hypothesized also that it could add to the ordinary and voluntary information a production which concerns general social responsibility and specifically environment. For these reasons, there should

be a higher environmental disclosure due to a more long-lasting permanence of the firm on the market (Monteiro and Aibar-Guzman, 2010).

Furthermore, without doubt the attention of public opinion on environmental effects increases especially when the firm joins the capital market. In fact, listed firms have a higher visibility and are continuously at the centre of the attention of mass media, money savers, etc. (Brammer and Pavelin, 2008; Cormier et al., 2005; Dawkins and Fraas, 2011; Fraser and Fraser, 2008; Guthrie and Parker, 1990; Reverte, 2009; Stanny and Ely, 2008; Tagesson et al., 2009). Therefore, the hypothesis to be verified will be the following:

H₅: the level of voluntary environmental disclosure of firms tends to increase with the increase of quotation age.

The firm's age is measured as the number of years from the first IPO (Liu and Anbumozhi, 2009; Xianbing and Anbumozhi, 2009; Zeng et al., 2012).

Foreign Markets

The studies concerning environmental disclosure have ascertained that the quotation in more financial markets produces the benefit of transferring the best practices on all the documents concerning the firm (Watts and Zimmerman, 1978; Ahmad et al., 2003). In particular, it has been verified that the quotation in those countries which joined the Kyoto protocol has favored the level of environmental disclosure (Freedman and Jaggi, 2011). Therefore we expect firms listed even on international markets more developed than the Italian market to produce wider environmental information (Reverte, 2009). The hypothesis to be verified will be the following:

H₆: the relationship between the quotation in international markets and firms' voluntary environmental disclosure is positive.

As what concerns quotation in foreign markets, a dichotomic variable has been introduced; its value is equal to 0 if the society is listed only in the Italian financial market; its value is equal to 1 if the society is listed even in other foreign markets.

Public Shareholders

Surveys on environmental disclosure have focused their attention on the different propensity of public firms to provide voluntary disclosure compared with private firms (Tagesson et al., 2009; Zeng et al., 2012). In particular, it can be affirmed that firms listed by the government or other public administrations should have a higher level of

disclosure compared with firms without any government shareholdings (Secchi, 2006; Tagesson et al., 2009; Zeng et al., 2012). In fact, in these firms there is a deep conflict among the parts which often represent unconverging interests. Politicians could be more interested in social issues, while managers and other shareholders are often focused exclusively on profit and value. In order to solve this conflict, managers tend to provide information useful to satisfy the needs of information of the different investors' categories.

Therefore the hypothesis to be verified will be the following:

H₇: the level of voluntary environmental disclosure tends to increase with the growth of public partners in the ownership structure.

The presence of public investors has been measured in terms of percentage of shareholding to the ownership structure.

Company Ownership

According to some authors, the level of disclosure is influenced by the level of concentration or diffusion of capital. In particular, in accordance with the agency theory, surveys have demonstrated that firms with a spread capital are more sensitive to external pressures, thus they tend to increase the level of voluntary reporting, in order to obtain the consensus and support of minority shareholders who don't participate actively to the firm and thus don't have any modality to know the listed society's activity (Cormier and Magnan, 1999; Cullen and Christopher, 2002; Cormier et al., 2005; Brammer and Pavelin, 2008).

The hypothesis to be verified will be the following:

H₈: the level of voluntary environmental disclosure tends to increase with the increase of the level of diffusion of ownership structure.

The incidence of minority shareholders has been measured through the relation between the third parties' equity and the group's equity (Patten, 1992).

Audit

The firms certified by big international independent audit firms tend to realize a higher level of disclosure compared with the firms certified by local independent audit firms (Zauwiyah et al., 2003). The reason is that big audit firms have many clients (contrarily to small firms which usually depend on few clients) and they do not fear

contraposition requesting additional information (Firth, 1979; Malone et al., 1993; Wallace et al., 1994; Wallace and Naser, 1995). On the other hand, even the relation with auditors can be considered in terms of agency theory: firms audited by big audit firms (which can afford some risks for their auditing and consequently make pressure so as to obtain information) can reduce the agency costs by increasing disclosure (Watts and Zimmerman, 1986). Finally, big international firms tend to transfer best practices (even those concerning environmental information) in all the documents of the companies certified by them.

Therefore, the hypothesis to be verified will be the following:

H₉: the relationship between the level of knowledge of audit firms and voluntary environmental disclosure of firms is positive.

In order to verify the influence of the audit firm, we have referred to a dummy variable which value is equal to 1 if the audit firm is among Big 4 (PriceWaterHouseCoopers, KPMG, Reconta Ernst & Young and Deloitte & Touche); its value is equal to 0 if the audit firm is not among Big 4 (Baroma, 2013; Zorio et al., 2013).

Legislation

As we have mentioned in the introduction, our analysis has focused on two specific years: 2006 and 2009. These years respectively precede and follow the adoption of the legislative decree n. 32/2007 which for the first time introduced in Italy – although in a voluntary form – environmental disclosure. In particular, the decree has partly accepted the Communitarian Directive n. 51 of 2003 by modifying the content of the Management Report, which is the document that is associated with the financial report and the consolidated financial report (composed of the financial annual report, the profit and loss account and the integrative note). The introduction of the legislative decree n. 32 of 2007 implied the modification of the article 2428 of the civil code (which in Italy regulates the writing of corporate documents); after the modification, this latter article implies that:

“the financial annual report must be accompanied by a relation of administrators with a reliable, balanced and complete analysis of the society’s situation and the management’s evolution and results [...] and also a description of the main risks and uncertainties the society is exposed to. The analysis [...] is coherent with the entity and complexity of the society’s affairs and it contains – asmuch as it is necessary for the comprehension of the society’s situation and the management’s evolution and results -

*the financial results indicators, and if appropriate, the non-financial results indicators which concern the society's specific activity, including the **information about environment and employees**".*

Therefore the following hypothesis shall be added to the previous:

H₁₀: the level of voluntary environmental disclosure has increased after the introduction of the legislative decree n. 32/2007.

In order to verify the effects produced by the introduction of the legislative decree n. 32/2007 which explicitly took into consideration for the first time in Italy the information about environment, a dummy variable has been introduced; its value is equal to 1 for 2009 and 0 for 2006.

Environmental performance

The last variable considered in our analysis is environmental performance (Ingram and Frazier, 1980; Wiseman, 1982; Freedman and Wasley, 1990). Generally, the lower is the level of pollution produced by a firm the better is its environmental performance. In literature and in praxis, this performance is configured in several ways (Azzone and Manzini, 1994; Gilley et al., 2000; King and Lenox, 2002; Klassen and McLaughlin, 1993; Tyteca, 1996). Unfortunately it is only provided by few firms in their documents; however nowadays in Italy there is no database which contains this indicator (for example a Corporate Social Responsibility Database). Finally, the results obtained from the studies which relate environmental variable and disclosure are not univocal.

By modifying the indexes of environmental performance of Al-Tuwajiri et al. (2004) and Clarkson et al. (2008), but keeping the same formulation, we expect that – with the decrease of the pollution level – there will be an extension of environmental information. In fact, it should be logical that if a firm improves its environmental performance throughout time, by producing a lower pollution level compared with the other firms, it is concerned about providing this and other environmental information. Therefore, the further hypothesis to be verified is the following:

H₁₁: the relationship between the level of pollution and voluntary environmental disclosure of firms is negative.

For the measurement of environmental performance in terms of pollution, we have calculated the relation between the total emissions of carbon dioxide (in tons) and the company sales¹.

In table 1 (see the Appendix) there are the variables examined in our study and the sign of the relation expected by the empirical verification.

Table 1 – Esplicative variables

Esplicative variables	Symbol	Measurement	Predicted Sign
Firm size	NLA	LN Total Assets	+
Business Industry	BI	Sensitivity of the sector (dummy)	+
Economic Performance	ROI	Return on Investment	+
Financial Situation	L	Financial debts/Equity	-
Age	AGE	Listing Age	+
Foreign Markets	MKT	Quotation in foreign markets (dummy)	+
Public Shareholders	GOV	Percentage of shares of public authorities in the ownership structure	+
Company Ownership	MI	Equity of third parties/Equity of the group	+
Audit	AUD	Big 4 (dummy)	+
Legislation	D	Year 2006 or 2009 (dummy)	+
Environmental Performance	EP	CO2/Sales	-

3 Sample selection

For the verification of the hypotheses developed in the previous paragraph, we have selected a sample of firms listed at Milan Italian Stock Exchange on 31/12/2006 and 31/12/2009. We started from the total of the firms listed at the Milan Stock Exchange in 2006 and 2009. We excluded financial brokers, insurance firms and soccer firms because they represent a different balance structure. We excluded also firms listed after 31/12/2006 and those which made the delisting during the period 1/01/2007-31/12/2009. We eliminated 4 firms which documents were not available for the periods considered. Finally, we eliminated all the firms which do not provide any note on environmental

¹Firms measure their pollution level in different ways. The level of carbon dioxide emissions is only one of them. We have chosen it because it is accepted by international literature as an objective measurement of atmospheric pollution by firms (Tyteca, 1996, 1997; Färe et al., 2004) and because it is the measurement used by most of the firms listed in Milan Stock Exchange in the period analyzed.

performance. In this way we have obtained a sample of 20 firms. For each of them we have calculated the disclosure index in 2006 and 2009

4 Descriptive statistics and univariate analysis

Before making the multivariate analysis on which the hypotheses introduced must be verified, we show in Table 2 (see the Appendix) the analysis of descriptive statistics and in table 3 the univariate analysis of dependent and independent variables.

Table 2 – Descriptive statistics

Kurtosis	2.678367	2.885105	2.253807	3.748264	5.913105	2.818831	1.806447	3.772817	3.006599	11.52490

IAG is the general disclosure index; IQN is the disclosure index in the quantitative version; IQL is the disclosure index in the qualitative version; LNA is the natural logarithm of assets; ROI is the return on investment; L is the leverage (financial debts/equity); AGE is the number of years of quotation; GOV is the percentage of shares of public authorities in the ownership structure; MI is the percentage of minority interests (Equity of third parties/ Equity of the group); EP is environmental performance (CO2/Sales).

From the analysis of descriptive statistics, first of all it can be noticed that from 2006 to 2009 there is: an improvement of three average disclosure indexes ($IAG_{20,2006} = 0.290$; $IAG_{20,2009} = 0.415$; $IQN_{20,2006} = 0.264$; $IQN_{20,2009} = 0.357$; $IQL_{20,2006} = 0.316$; $IQL_{20,2009} = 0.473$); an increase of average debt ($L_{20,2006} = 119.430$; $L_{20,2009} = 140.824$) and a reduction of average profitability ($ROI_{20,2006} = 10.024$; $ROI_{20,2009} = 6.058$). In substance, it would

seem that, despite a period of economic crisis and the introduction of the new legislation, firms improved their voluntary information even with reference to environmental issues.

Furthermore, this has been carried out despite a worsening of environmental performance ($EP_{20,2006} = 0.891$; $EP_{20,2009} = 0.934$); this datum would make us reflect on the will to motivate some productive and strategic choices. Finally, it must be highlighted that in the passage from 2006 to 2009 there is (on average) a reduction of the participation of both minority shareholding ($MI_{20,2006} = 15.047$; $MI_{20,2009} = 10.592$) and government shares ($GOV_{20,2006} = 12.450$; $GOV_{20,2009} = 10.300$).

The Table 3 shows the correlation matrix (see the Appendix).

IAG is the general disclosure index; IQN is the disclosure index in the quantitative version; IQL is the disclosure index in the qualitative version; NLA is the natural logarithm of assets; BI (business industry) is equal to 1 if the sector is considered as sensitive and 0 in the opposite case; ROI is the return on investment); L is the leverage

(financial debts/equity); AGE is the number of years of quotation; MKT is equal to 1 if the society is listed even in other countries and 0 if the society is listed only in the Italian financial market. GOV is the percentage of shares of public authorities in the ownership structure; MI is the percentage of minority interests (Equity of third parties/ Equity of the group); AUD is equal to 1 if the audit firm is one of the BIG 4, and 0 in the opposite case; Dt is equal to 0 for 2006 and 1 for 2009; EP is environmental performance (CO2/Sales)

The correlation matrix analyzed with reference to the disclosure indexes calculated highlights the following situation. The general disclosure index (IAG), contrarily to expectations, has a negative and statistically significant relation with the presence of the firm even in foreign markets. The same index highlights also a positive and statistically significant relation with the presence of government shareholdings in the firm. The quantitative index (IQN) and the qualitative index (IQL), similarly to the general index, have a positive and statistically significant correlation with the presence of government shareholdings in the firm.

Furthermore, only the quantitative index (again similarly to the general index) shows a negative and statistically significant relation with the presence of the firm even in foreign markets. Furthermore it is interesting to remark that the quantitative index always highlights a positive and statistically significant relation with the firm size measured by the natural logarithm of assets; while the qualitative index shows a negative and statistically significant relation with return on investment (ROI).

Finally, with reference to explicative variables, the correlation matrix would seem to exclude possible situations of collinearity. For each case, in the following multivariate analysis the collinearity test (VIF test) has been carried out.

Obviously the univariate analysis does not consider the potential impacts produced from explicative variables examined as a whole. For this purpose, in the following section a multivariate analysis has been carried out.

5 Multivariate analysis

In order to verify the hypotheses introduced in paragraph 2, a multivariate analysis has been carried out by relating environmental disclosure indexes (general, quantitative and qualitative) with the explicative variables identified. The regression can be synthesized with the following multivariate model:

$$\begin{aligned} \text{IAG, IQN, IQL} = & \alpha + \beta_1 \text{NLA} + \beta_2 \text{BI} + \beta_3 \text{ROI} + \beta_4 \text{L} + \beta_5 \text{AGE} + \beta_6 \text{MKT} + \beta_7 \text{GOV} \\ & + \beta_8 \text{MI} + \beta_9 \text{AUD} + \beta_{10} \text{Dt} + \beta_{11} \text{EP} + \epsilon \end{aligned}$$

where:

IAG is the general disclosure index; IQN is the disclosure index in the quantitative version; IQL is the disclosure index in the qualitative version; LNA is the natural logarithm of assets; BI (business industry) is equal to 1 if the sector is considered as sensitive and 0 in the opposite case; ROI is the return on investment; L is the leverage (financial debts/equity); AGE is the number of years of quotation; MKT is equal to 1 if the society is listed even in other countries and 0 if the society is listed only in the Italian financial market; GOV is the percentage of shares of public authorities in the ownership structure; MI is the percentage of minority interests (Equity of third parties/Equity of the group); AUD is equal to 1 if the audit firm is one of the BIG 4, and 0 in the opposite case; Dt is equal to 0 for 2006 and 1 for 2009; EP is environmental performance.

Before making the regressions, the multicollinearity among the explicative variables has been verified through the use of VIF (variance inflation factor). In addition, also robust standard error clustered at firm level (HAC) has been used. Even the normality of the sample has been verified, in relation to its size, through the Jarque-Brera test. Regressions have been done by using OLS model. In fact, the Breush-Pagan test has verified that this model is preferable to the random-effects panel model; the Hausmann test has verified that random-effects panel model is preferable to fixed-effects panel model (the test's results are indicated in the following table).

Table 4 highlights the results of the regression (see the Appendix).

Table 4 – Multiple regression Pooled OLS

$$(1) IAG = \alpha + \beta_1 NLA + \beta_2 BI + \beta_3 ROI + \beta_4 L + \beta_5 AGE + \beta_6 MKT + \beta_7 GOV + \beta_8 MI + \beta_9 AUD + \beta_{10} Dt + \beta_{11} Co2_S + \epsilon$$

$$(2) IQN = \alpha + \beta_1 NLA + \beta_2 BI + \beta_3 ROI + \beta_4 L + \beta_5 AGE + \beta_6 MKT + \beta_7 GOV + \beta_8 MI + \beta_9 AUD + \beta_{10} Dt + \beta_{11} Co2_S + \epsilon$$

$$(3) IQL = \alpha + \beta_1 NLA + \beta_2 BI + \beta_3 ROI + \beta_4 L + \beta_5 AGE + \beta_6 MKT + \beta_7 GOV + \beta_8 MI + \beta_9 AUD + \beta_{10} Dt + \beta_{11} + Co2_S + \epsilon$$

*, **, *** indicate the significant at the 0.10, 0.05 and 0.01 levels respectively.

IAG is the general disclosure index; IQN is the disclosure index in the quantitative version; IQL is the disclosure index in the qualitative version; NLA is the natural logarithm of assets; BI (business industry) is equal to 1 if the sector is considered as sensitive and 0 in the opposite case; ROI is the return on investment; L is the leverage (financial debts/equity); AGE is the number of years of quotation; MKT is equal to 1 if the society is listed even in other countries and 0 if the society is listed only in the Italian financial market. GOV is the percentage of shares of public authorities in the ownership structure; MI is the percentage of minority interests (Equity of third parties/Equity of the group); AUD is equal to 1 if the audit firm is one of the BIG 4, and 0 in the opposite case; Dt is equal to 0 for 2006 and 1 for 2009; EP is environmental performance (CO2/Sales)

From the analysis of table 4 it can be noticed first of all the goodness of the adaptation of the model proposed. The three regressions in fact give a high value of r-square ($r\text{-sqIAG} = 0.620767$; $r\text{-sqIQN} = 0.718171$; $r\text{-sqIQL} = 0.521371$). Again, always at a general level, it must be reported that the values of P-value (F) attest the significance of the models used and considered on their whole (that is, all the variables simultaneously).

Looking at the analysis of the single variables, it is appropriate to focus on the variables which led to contrasting results (and statistically significant) compared with what is asserted by theories and empirical verifications carried out by previous studies, thus even by our hypotheses of signs prediction.

First of all there are three variables for which the coefficient is statistically significant with reference to all the three indexes realized, and it has a sign opposite to the one which has been hypothesized. The first one of these variables is *MI*; it measures the incidence of minority shareholding, and thus the diffusion of the equity. According to the main studies, it has been hypothesized that with an increase of minority shareholding, business management – coherently with the agency theory – would tend to provide more information so as to avoid external pressures. On the contrary, differently from the results of the previous studies (Cormier and Magnan, 1999; Cormier et al., 2005; Brammer and Pavelin, 2008), from our regressions the coefficient's sign is negative. An explanation

could be that the more information is provided to a multiplicity of investors mainly interested in the economic return, the higher is the risk that in a period of crisis these would liquidate their own investments or direct them toward other more profitable purposes. Even the variable *AUD* assumes a different sign from what hypothesized. It is a dichotomic variable which value is equal to 1 if the society which makes the external auditing belongs to Big 4; its value is equal to 0 in the opposite case. Even in this case, we would have expected a positive direct relationship with disclosure. In fact it can be hypothesized that firms certified by Big 4 suffer a stronger pressure for providing information, and that within it there is also environmental information in accordance with international best practices.

On the contrary, our regressions show a negative sign of the coefficient (despite a significance of 10%) in which the higher value is assumed by qualitative disclosure ($\beta_{IAG} = -0.285$; $\beta_{IQN} = -0.241$; $\beta_{IQL} = -0.329$). It can be hypothesized that this sign is due partly to the fact that during periods of crisis, firms certified by Big 4 are already sufficiently involved in providing only accounting information, which is useful to reassure investors and markets; for this reason they could tend to disregard environmental (voluntary) information. The third variable which assumes a sign different from the one hypothesized – with a level of statistical significance equal to 1% for the qualitative disclosure index and global disclosure index, and with a level of 5% for the quantitative disclosure index – is EP; this is measured by the relation between the carbon dioxide emissions and company sales ($\beta_{EP, IAG} = 0.039$; $\beta_{EP, IQN} = 0.026$; $\beta_{EP, IQL} = 0.053$). In this sense, it could be supposed that, differently from what has been hypothesized previously (par. 2.2), firms which improve their environmental performances (reduction of the relation CO_2/S) consider this information as sufficient and they do not recognize the need of providing other disclosure.

There are also variables with a coefficient's sign different from the one hypothesized but which is statistically significant only for one of the indexes calculated. With reference to foreign markets (MKT), for example, from the model it can be deduced that the presence of the firm even in foreign markets (MKT) has an inverse statistically significant relationship (this too at 10%) only with the quantitative disclosure index; this presumably indicates that firms listed in foreign markets are not interested in including voluntary environmental information in their documents because they do not need to appear attractive for the international market, which has been already conquered.

With reference to all the three indicators calculated, the sign hypothesized is confirmed by both the firm size and government shareholdings. Therefore the result related to the dimensional variable ($\beta_{LNA, IAG} = 0.0402$; $\beta_{LNA, IQN} = 0.0428$; $\beta_{LNA, IQL} = 0.0377$) seems to confirm both the hypothesis that bigger firms can make a wider non obligatory disclosure due to the scarce incidence of the disclosure in terms of costs on the overall amount of corporate costs (Patten, 1992; Gray et al., 1995; Deegan and Gordon, 1996; Adams et al., 1998; Al-Tuwaijri et al., 2004; Freedman and Jaggi, 2005; Brammer and Pavelin, 2008; García-Sánchez, 2008; Stanny and Ely, 2008; Reverte, 2009), and the hypothesis coherent with the theory of legitimacy that bigger firms have a higher propensity for provide information in order to satisfy the wide range of stakeholders (even environmental stakeholders) who require information (Bansal and Clelland, 2004; Hasseldine et al., 2005). The result of the variable GOV on the contrary seems to confirm both that firms with government shareholdings respond to the public sensitivity toward the issues concerning welfare, and that corporate management undergoes pressures of public partner to provide this information.

The dichotomic variable D_t (which value us equal to 0 in 2006 and 1 in 2009) is statistically significant with positive coefficient in relation to the global and qualitative environmental disclosure index; this shows that environmental disclosure improved qualitatively in 2009 after the introduction of the legislative decree n. 32 of 2007.

Finally, the belonging to an environmentally sensitive sector (BI), the corporate debt rate (L), and the quotation age (AGE) do not have any statistical significance with the three indexes calculated.

6 Conclusions and further possible developments of the survey

In the present study we have analyzed the level of voluntary environmental disclosure in Italian firms listed in Milan Stock Exchange. For this purpose, we have considered the two years after the introduction of International Accounting Principles IAS/IFRS for the firms listed: 2006 and 2009. The use of these specific two years has allowed us to verify not only the evolution of environmental disclosure throughout time, but also the effect produced by the introduction of the legislative decree n. 32 of 2007, which modified the article 2428 of the civil code and introduced for the first time in Italy the information concerning environment.

The results obtained confirm the positive and statistically significant effect produced on the level of voluntary environmental disclosure (except for quantitative disclosure) from the emanation of the legislative decree n. 32 of 2007. Afterwards we have verified – in contrast with the previous studies on the issue – an inverse (negative) and statistically significant relation between the three indexes of environmental disclosure and minority shareholding, the presence of international audit firms (Big 4) and environmental performance. The contrasting results compared with international literature have been confirmed also with reference to the relation between profitability and the qualitative environmental disclosure index, and between quotation in foreign markets and the index of quantitative environmental disclosure index. Finally, our analysis confirms the positive relation of environmental disclosure indexes with firm size and the presence of government shareholdings in the ownership structure.

Despite the contributions of the literature concerning environmental information described in paragraph 1, it is our duty to express some reflections about two limits of our analysis. Firstly, the number of the sample analyzed is quite scarce (only 20 firms). This problem could be solved by consolidating the praxis of providing information even on environmental performance. It has been chosen an indicator of atmospheric pollution (CO₂ emissions) which, despite it is accepted internationally as a measure of firms' environmental performance, is not provided by Italian firms yet, although they are listed. In addition, in Italy there is no database which could allow a ranking of the firms concerning Corporate Social Responsibility.

Also, our analysis describes the determinants of voluntary environmental disclosure of only listed Italian firms. In a future our work could be enriched with the contribution provided by comparative analysis, at least at the European level.

Structured Abstract

Knowledge has many different characteristics and scholars in epistemology, economics and management have dealt with them ever since knowledge has emerged as the leading source of firms' competitive advantages. New product development requires new ideas and new ideas are stemming from knowledge. Knowledge originates from tacit knowledge (Polanyi, 1964). Therefore, firms need to enact tacit knowledge (Wieck, 1977). Enactment takes different forms depending on the context of knowledge and organizational characteristics. The paper is an attempt to integrate knowledge creation theory and practices. The paper conducts an in depth literature review on the nature of knowledge and knowledge creation structure and investigates how The Dow Chemical Company uses a knowledge creation structure to elicit tacit knowledge and exploit knowledge for new product development. The Dow Chemical Company is known as one of the leading innovative firms in the world. We believe that this case enriches research on knowledge creation and new product development although it has limitations in generalizing its findings and practices. In solidifying the knowledge-based theory of the firm we need a multi-dimensional approach such as a survey, case study and theory development as Nonaka (1994) advocated.

Design/methodology/approach - We propose an approach to investigate a practice of leading knowledge creating in terms of knowledge creation theories. The Dow Chemical Company is known for its innovation in new products and we use the example of knowledge creation in the Dow Chemical Company in the U.S.

Originality/value - This mythology provides evidence of effects of knowledge creation structure on the outcomes of knowledge creation and new product development.

Practical implications - Variations in structure of knowledge creation offer opportunities in selection of the market process. Investigating links between theories and practices will provide improvements in theories and practices. Therefore, this paper can offer opportunities for practitioners and theoreticians to improve practices and theories.

Key words - knowledge creation, knowledge management, knowledge-based theory of the firm, stakeholder management.

Paper type - Research and practical paper.

1. Introduction

Knowledge has emerged as the most important source of a firm's sustainable competitive advantage. Considering the importance of the subject, it is not surprising to witness a plethora of research, with a number of different perspectives from which researchers and practitioners have approached the management of knowledge. One notable recent development is that scholars in knowledge management began to study the nature of the firm from the perspective of the knowledge-based theory of the firm (Grant, 1996; Kogut and Zander, 1992; Nonaka, 1994; Spender, 1996).

Economic theories of the firm are concerned primarily with predicting the behavior of a firm's response to external market and internal agency-managerial issues. The knowledge-based theory of the firm, in particular, views the primary role of the firm as integrating the on-site knowledge resident in individual workers. The primary task of management, from the perspective of the theory of the firm, is establishing the coordination necessary for this knowledge integration. This over-emphasis and increasing focus on macroscopic structure and collective conceptualization ignores microscopic issues associated with individual workers' creation and sharing of knowledge.

Obviously managers have been making deliberate efforts to manage the knowledge of their organizations' work force. According to Hislop (2009), they use a wide range of methods in knowledge management, such as structuring organizations in particular ways, or using particular culture and people management practices and incorporating information and communication technologies (ICT). The choice of these methods may depend on the nature of knowledge, and the use of a particular ICT is applicable to explicit knowledge management. However, when different types of knowledge vary, the implication for organizational structure to integrate such knowledge is not a trivial issue.

This paper focuses on knowledge creation with an inter-active perspective between the structure and individual (agent) behavior in organization. Also, in particular, this study assumes that tacit knowledge is a key element in knowledge creation. Structures of organization and cultures are applied to knowledge creation, which converts tacit knowledge into explicit knowledge. Many studies on knowledge creation have focused on the effects of structures on knowledge outcomes. Recently, scholars are beginning to pay attention to knowledge creation at the micro level of individuals (Felin, *et al.*, 2009).

This micro approach to knowledge creation relies on the belief that knowledge is personal, subjective, context specific and embodied in individuals (Felin & Foss, 2006; Nonaka, et al., 2003). How do organizational structures and cultures affect an individual's behavior and interactions? How do they elicit tacit knowledge from individuals? Studies on the effects of structures and cultures on individuals' decisions about knowledge sharing/hoarding (macro-micro), interactions among individuals (micro-micro), and individuals' activities and knowledge outcomes (micro-macro) are proposed as micro foundations of knowledge creation. However, there is a dearth of research on the micro perspective (Felin & Foss, 2005, 2006) and the integration of the macro-micro (structure-agent) approach. This study is an attempt to study the micro foundation of knowledge creation and the integration of a structure-agent approach.

The study consists of 6 sections. Section two builds the theoretical background and section three discusses a structure-agent approach. We discuss the knowledge creation model in section four and section five evaluates The Dow Chemical Company's knowledge creation practice. Section six concludes the paper.

2. Theoretical Background: The Need for Integration of Organization and Individuals

Most knowledge scholars agree that knowledge has multi-dimensions such as tacit and explicit knowledge (Kogut and Zander, 1992; Lam, 2000; Nonaka and Takeuchi, 1995; Polanyi, 1964); ontology of knowledge (Lam, 2000); dispersed knowledge (Hayek, 1945; Tsoukas, 1996); individuals and the institution (Coleman, 1986, 1990; Felin and Foss 2005, 2006; Mahnke and Foss, 2007; Nelson and Sampat, 2001); knowledge sharing among

employees (Argote and Ingram, 2000); processes of reflexivity and direct social interaction (Bourdieu, 1977,1990; Nonaka and Takeuchi, 1995; Tsoukas, 2009); access costs to knowledge (Mokyr, 2000); communities of practice (Brown and Duguid, 1991; Cook and Brown, 1999; Gusman, 2009); and the evolution of knowledge creation practices (Bourdieu, 1977; Nelson and Winter, 1982; Popper, 1982).

Characteristics of tacit and dispersed knowledge have been discussed most frequently in knowledge and capability creation because understanding them is essential in knowledge management. Tacit knowledge is available and can become an important source of competitive advantage when the company mobilizes it for innovation in products, processes and services. Polanyi's (1966) statement on tacit knowledge tells the complexity of the issues in knowledge creation. He states that we can know more than we can tell (p.4). According to Schön (1983), tacit knowledge is rooted in action, procedures, routines, commitment, ideas, value and emotion. The embeddedness of knowledge in individuals and action is one of the central characteristics of tacit knowledge and this characteristic of tacit knowledge requires an approach, which integrates individuals and organizations.

Organizations create knowledge and convert the knowledge into organizational competence; individuals in organizations create knowledge. Felin and Foss (2006) introduce a new framework where the micro-level explanation improves on the collective level explanation by using Coleman's (1990) framework as a tool. Felin and Foss (2006) argue that the theory relies on individual factors, and potential intervention occurs at the individual level. They show one example of capabilities development by the hiring of particular individuals from other organizational settings (Song, Almeida and Wu, 2003). The model used in our paper is adopted from the Felin and Foss's framework as shown in Figure 1.

3. A Structure-agent integrative approach

Based on the general framework proposed by Felin and Foss (2006), we propose a comprehensive model of knowledge management with a macro-micro integrative approach. A Polanyi (1969) point out tacit knowing is indispensable in discovery of and all knowledge "is either tacit or rooted in tacit knowledge" (Knowledge and Being, 1969, p. 195). Personal knowledge is personal, subjective and context-specific (Argote and Miron-Spektor, 2011;

Hislop, 2009; Nonaka et al., 2000a, 2000b). A context includes the organization and the environment in which the organization embedded (Argote and Miron-Spektor, 2011; Nonaka et al., 2000a, 2000b). Knowledge creation involves knowledge conversion from tacit to explicit and combination of explicit and explicit knowledge. Knowledge creation also involves interactions (socialization) among individuals because firm's knowledge is often created by a team. Nonaka et al. (2000a, 2000b) argue that a firm creates knowledge through the spiral of socialization, externalization, combination and internalization (SECI), and a firm exists when the knowledge conversion rate of the firm is higher than that of the market in the long run. Figure 1 represents the framework which combines contexts, structure, interactions and reflections of knowledge creators. Each component of the model is explained in the following sections.

We modified Felin and Foss' (2006) framework and Figure 1 is a modified version of Felin and Foss model. Our model includes factors affecting knowledge creation from individual, organizational and external environmental levels.

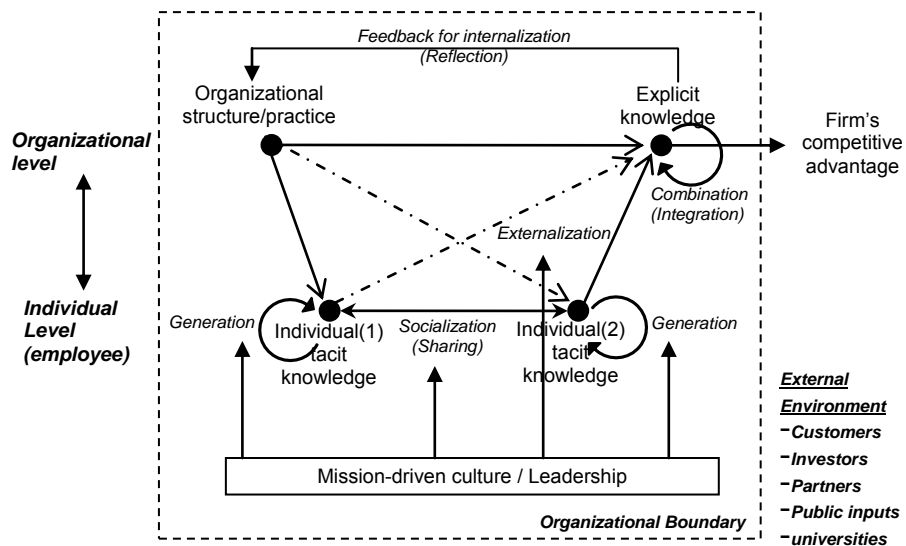

Figure 1. Conceptual Framework: Micro-Macro Integrative Approach to Knowledge Creation

3.1 Organizational structure

Organizational structure is an important component of knowledge management. The primary goal of any economic organization is to produce the output customers want at the lowest possible cost (Brickley et al., 2001). Firms need to change products, processes, services and management systems as customers' demands and technologies change rapidly in the global economy. A key input for these changes is knowledge. One of the propositions in knowledge management is that knowledge is abundant, but the ability to use it is scarce. The firm's ability to capitalize on the available knowledge is a major source of sustainable competitive advantage.

However, there are two challenging complications for making use of the available knowledge. First, knowledge is dispersed and embedded in individuals (Hayek, 1945; Polanyi, 1964, Tsoukas, 1996) and it is costly to wring out knowledge from individuals. Second, there are incentive problems for managers as well as agents in knowledge creation. Managers might not have the proper incentives to obtain true knowledge, and agents also might not have appropriate incentives to share and transfer their tacit knowledge. Hislop (2005) points out that the subjective, socially constructed and culturally embedded knowledge is open to dispute. He argues that managers might exert power or influence over different groups/individuals to develop incompatible and contradictory analyses of the same event. The organizational structure, organizational culture and trust among agents can influence agents' knowledge sharing/hoarding decisions. Therefore, the organizational structure is a control variable for knowledge creation.

Knowledge creation involves the conversion of tacit knowledge into explicit knowledge and a combination of explicit knowledge (Kogut and Zander, 1992; Nonaka and Takeuchi, 1995). Thus knowledge creation needs to address problems of dispersed knowledge and incentive incompatibilities. Knowledge scholars such as Foss and Mahnke (2005) raise the following questions:

How can employees be induced to make their human capital firm-specific when this puts them at risk? What are the complications of knowledge creation in teams? Do individual incentives enable or impede knowledge creation in teams? (Foss and Mahnke, 2005, p. 86).

Organizations need to effectively address these problems when designing their organizational structures for knowledge creation. There are numerous alternative structures to solve these problems and firm's knowledge outputs may differ depending on organizational structures: functional, divisional, matrix structure and/or project team. Brickley et al. (2001) includes three important components of organizational design that are determinants of the success or failure of the firm: 1) The assignment of decision rights, 2) The method of reward, and 3) The structure of systems to evaluate the performance of both individuals and business firms (Brickley et al., 2001, p. 281).

The appropriate organizational structure depends on the types of knowledge the firm needs to create. In general, the organizational structure of knowledge creation tends to be a project team. This project team or community of practice is self-organized, voluntary and less hierarchical. The structure of the team tends to vary among organizations, and research needs to investigate how organizational structures affect individuals' knowledge sharing/hoarding decisions and interaction among individuals.

The research that focuses on links between the organizational structure and individuals' behavior has been drawing more attention from scholars lately (Weick 1977; Coleman, 1986; Felin and Foss, 2005, 2006; Foss and Mahnke, 2005; Nelson and Sampat, 2001). Bourdieu's structure and habitus framework (1977, 1990) might be appropriate in establishing a relationship between the organizational structure and individual behavior. The objective structure might encourage individual agents to develop dispositions of imagination, empowerment and creative thinking if the culture of the firm is conducive to developing such dispositions. An integrative approach to governance and competence as proposed by Felin and Foss (2005, 2006) can be tested empirically by examining Foss and Mahnke's (2005) ten refutable propositions. Nelson and Sampat (2001) argue that physical and social technologies co-evolve. Their view on shared culture for economic progress might be applied to the relationship between structure and individual behavior in knowledge creation.

Our view involves a strong belief in the importance of shared culture in molding what people think is appropriate to do, but at the same time a belief that in many cases at least individual and group process winnow out grossly inferior or self destructive practices, and when new challenges or opportunities arise, there can be major changes in institutions which allow significant economic progress (Nelson and Sampat, 2001).

Social technologies in Nelson and Sampat are akin to organizational structure. The importance of social capital in the formation of intellectual capital is well documented by Nahapiet and Ghoshal (1998). Therefore, both cultural capital and social capital (Bourdieu, 1977, 1990) can be mobilized in knowledge creation.

Organizational practices, embedded in the given organizational structure, play a critical role in effective and efficient management of the entire knowledge creation and sharing processes within a firm. They may include knowledge-enhancing human resource management programs, such as training and selection, participative work design, performance appraisal and feedback, and incentive schemes that promote active learning initiatives. Generally, these organizational practices are designed to provide employees with ownership rights to remedy agency-managerial costs and to maximize their initiative behaviors, such as active participation in knowledge creation and sharing at the workplace.

Ownership of an asset or a firm entails two rights: 1) the right to participate in the control of the asset or the firm, and 2) the right to appropriate the residual earnings for the asset or the firm (Hansmann, 1988; Hart and Moore, 1990). Based on this notion of ownership, Ben-Ner and Jones (1995) suggest that employee participative work organization is defined in terms of rights employees hold to claim for financial returns and/or to participate in decision making within the firm. These two rights vary in degree and level, depending on the nature of employee participation arrangements.

We suggest that a given company's knowledge creation processes are strongly supported by those organizational practices that provide employees with these two participatory rights (i.e., ownership in control and financial returns) and those supportive practices which make them complete and genuine.

3.2 Individual identity: knowledge generation

At the individual worker level, given the structural setting within the organization, we suggest that such variables as personal traits, work attitude including job satisfaction and organizational commitment, trust among organizational members, and pre-existing knowledge may play a critical role in facilitating generation of knowledge for the organization. This self-learning process either may remain tacit or become externalized into an explicit state of

knowledge which promotes knowledge-sharing behavior. Among these variables, trust in particular enables cooperative behavior, promotes collaborative-based forms of organization, reduces interpersonal conflict, facilitates rapid formulation of an ad hoc work group, and encourages effective reactions to crises (Rousseau et al., 1998).

3.3 Mutual interaction at the individual worker level: sharing & integration

In order to identify management practices that may encourage and sustain such knowledge sharing, we first analyze the socio-psychological nature of this behavior. The concept of the collectivistic tendency of the employees could be defined as the social tendency of in-group perception in the workplace (Earley, 1993; Hofstede, 1980; Wagner and Moch, 1986). Specifically, the collectivistic tendency means that “individuals view and identify themselves through a small number of memberships in groups” (Earley, 1993, p. 321).

Once successfully completed the self-learning process will in turn successfully transfer to mutual learning in which groups of individual workers promote elements of individual and group characteristics based on personal traits and organizational culture and climate.

3.4 Organizational reflection: organizational feedback

The organizational structure is remade by the success or failure of previous actions and the organization improves organizational structure by reflexive feedback from individuals. Bourdieu's Notion of habitus (1977, 1990) provides the practical skills and dispositions necessary for individuals to navigate the knowledge creation process within a given organizational structure. Thus it resolves the antinomy between objective structure and individual subjective structure (see Figure 1). Problems in organizational structure will surface as individuals engage in knowledge creation under a given organizational structure. In this way firms accumulate knowledge about problems of the organizational structure. Popper's evolutionary epistemology (1982) offers a theoretical framework for changes in organizational structure; he argues that “all organisms are constantly, day and night, engaged in solving-problems” (p. 110). He states that problem-solving is always preceded by methods of trial and error; his fundamental evolutionary sequence of events is $[P1 \rightarrow TS \rightarrow EE \rightarrow P2]$, where P1=initial problem, TS=tentative solutions, EE=error elimination, P2=new problems.

Tentative solutions eliminate errors for the initial problem, but new problems might appear as individuals engage in knowledge creation under the new organizational structure. Therefore, a new organizational structure emerges as individuals in the company interact and eliminate errors in the current organizational structure. Giddens' structuration theory (1984) offers a good framework for feedback between structures and agents. We expand Giddens' theory in the discussion section.

3.5 Mission, culture, and values

Organizational mission, culture, and values may complement the structural setting for the knowledge management process of the given company. Organizational culture is believed to be the most significant input to effective knowledge management, and organizational learning in that corporate culture determines values, beliefs, and work systems that could encourage or impede learning and knowledge creation, as well as knowledge sharing (Alavi and Leidner, 2001; Gold, Malhotra, and Segars, 2001; Leonard, 1995; Schein, 1985).

Particularly in the age of the knowledge-based economy, where information asymmetry problems prevail, cultures and values may work as secret ingredients for the final success of the entire organizational learning process.

3.6 Leadership

The long tradition of leadership theory and research has only recently begun to address the role of leadership in knowledge management, despite its importance to organizations in the information age. Consequently, with very few exceptions (e.g., Berson et al., 2006; Lakshman, 2007; Viitala, 2004), information and knowledge management as key leader functions have not been systematically explored until recently (see also Bryant, 2003; Politis, 2001).

We suggest the importance of the role of leaders in knowledge management, as their role directly affects the strategic organizational support system as well as member behavior in association with various aspects of knowledge management within the organization. In particular, a leader's genuine character, which provides members with trust and vision, will play a critical role in shaping effective leadership for the knowledge management process within a company.

3.7 Stakeholder perspectives: relationship with external environment

Knowledge creation and integration also emerges from the collaboration of organizational participants and stakeholders such as customers, investors, partners, suppliers, public agencies, local community, etc. Nonaka and Toyama (2003, p. 8) emphasize the importance of boundary crossing in their analysis of knowledge “Ba”:

Ba is not limited to the frame of a single organization but can be created across the organizational boundary [. . .] as a joint venture with a supplier, an alliance with a competitor, or an interactive relationship with customers, universities, and communities. (Nonaka and Toyama, 2003, p. 8)

When expanding strategic perspectives from an internal organization to an external environment, many studies have shown that an organization managing for stakeholders results in better performance (Berman et al., 1999; Hillman and Keim, 2001; Sisodia et al., 2007). However, not much research systematically studies how a particular type of stakeholder strategy leads to the firm’s competitive advantage. Recently, Harrison et al. (2010) provided a rationale for including stakeholder theory in the discussion of firm competitiveness and performance. Specifically, it explained factors that facilitate acquisition of knowledge about stakeholder utility functions and offered a knowledge-based analysis of how firms with stakeholder management strategy can enjoy sustainable competitive benefits. Therefore, this paper follows the roadmap of stakeholder management provided by Harrison et al. (2010), including four perspectives: 1) Primary stakeholders, 2) Relationship characteristics, 3) Knowledge about stakeholders’ utility functions, and 4) Potential advantages.

Table 1. An Integrative Model of Knowledge-Creation: List of major macro or micro components and corresponding measurement variables

Components	Measurement Variables
organizational structure	Employee investment in firm-specific capital Team size, shirking and free ride Team-based incentive, individual incentive or combination Organization of team: self-selection or assigned? Evaluation system Reward system Ratio of specific to general learning investment Use of high-powered incentives to firm specific learning Effect of up-or-out rules versus up-or-stay rules for investment in firm-

	<p>specific capital</p> <p>Resolving incentive conflicts in knowledge creation by means of incentives, and/ or promotion rules and / or deferred payment and / or access</p> <p>Firms' sponsoring certified acquisition of general skills as a form of merit pay to induce higher employee investments in firm-specific human capital</p>
Organizational practices	<p>Employee participation in decision-making (e.g., Suggestion System, Team, TQM, QC, etc.)</p> <p>Employee participation in financial returns (e.g., Incentive Pay, Merit Pay, ESOP, Profit Sharing, Gain Sharing)</p> <p>Supportive programs (e.g., Training and Development, Job Design (Job Enrichment, Job Enlargement, Job Rotation, Performance Appraisal, Information Sharing, Technological Support)</p>
Individual worker characteristics	<p>Level of consciousness of own work process</p> <p>Job commitment and motivation</p> <p>Organizational commitment</p> <p>Pre-existing knowledge</p> <p>Personality</p> <p>Trust (self and others)</p>
Individual worker level mutual interaction	<p>(Perceived) <i>instrumentality</i> of mutual learning</p> <p>(Perceived) <i>valence</i> of mutual learning</p> <p>Social ties (spirit of cooperation)</p> <p>Culture</p> <p>Group identification (value)</p> <p>Communication</p>
Conversion of tacit to explicit knowledge	<p>Technology</p> <p>Motivation and inspiration</p>
Reflection of explicit knowledge	<p>Technology</p>
Organizational culture	<p>Sense of community (e.g., growing together)</p> <p>Admitting making mistakes</p> <p>Caring for human relationships</p> <p>Valuing stakeholder relationships</p> <p>Emphasizing triple bottom line (i.e., financial, social, and environmental performance)</p> <p>Thickness of culture</p>
Leadership	<p>Charisma</p> <p>Passion and Compassion</p> <p>Vision</p> <p>Lived value and consistency</p> <p>Humility</p> <p>Forgiving and love</p>
Stakeholder Relationship	<p>Trustworthiness</p> <p>History of fair distribution of value: Distributional justice, reciprocity</p> <p>History of stakeholder influence on management decisions (salience, procedural and interactional justice)</p>

4. Discussion

Despite its theoretical contribution, the study of Knowledge Management has suffered in its applicability to the real world. The relatively unknown mechanism concerning how knowledge creation actually happens within a given macroscopic organizational structure and culture, with microscopic individual worker attitudes and behavior, and interactive processes at the macroscopic organizational level each warrant further study.

This paper develops an integrated model which incorporates both the macro and micro levels of components, providing a relatively more complete picture of the knowledge creation process at the workplace. The long debated issue of “methodological individualism” versus “methodological collectivism” carries a profound question: “What is the relationship between the micro and macro levels? Do we always need to invoke micro-level explanatory mechanisms when trying to explain some macro-level phenomenon?”

Our proposition is that the knowledge creation process is a classical example which requires an integrative approach. Indeed, the literature in strategic management and organization theory has made significant contributions in its focus on the firm’s rational choice regarding design of organizational structure, and corresponding managerial practices provide a systemic view of how an organization as an entity should behave. However, organizations are made up of individual human beings. Knowledge is inherent in individuals initially; thus all knowledge creation starts with an individual employee’s self-learning process. This elementary truth has been lost in the increasing focus on structure, with negative consequences for theory-building, empirical work, and managerial practice.

We also believe that addressing the integrative frame of the structure-agent approach (or, multiple level analyses) presents some advantages, especially in the post-industrial knowledge based economy. With the increased risk of information asymmetry and agents’ moral hazard behavior in this era of complex technology and environment uncertainty, it is rather naive to believe that structural arrangement alone will provide perfect control and monitoring. Therefore, understanding the microscopic individual worker level is necessary to complete the macroscopic structural analysis of the knowledge creation process.

Extending the analysis to the microscopic individual worker level should also include external stakeholders as well. Our model in that sense is an open and dynamic system approach, which includes interactive participation in knowledge creation and sharing from external stakeholders such as customers, investors, partners, academic community, and others. We believe that knowledge management is going through a new era which includes active external stakeholder participation; thus knowledge management warrants further study in line with the stakeholder management paradigm.

We employ several theoretical frameworks for our discussions. First, Polanyi's (1966) tacit and explicit knowledge are the basis for discovery of knowledge. Second, Whitehead's (1929) process and reality offer a framework for the knowledge creation process. Third, the social theory (Bourdieu, 1977, 1990; Giddens, 1984; Coleman, 1986, 1990; Sewell, 1992) is suitable for the analysis of the relationship between the structure and individual (agent) behavior. Fourth, dynamic managerial capabilities integrate theories and practices to create and maintain a firm's competitive advantage (Bourdieu, 1977; Helfat et. al, 2007) and develop a knowledge creation model (Nonaka and Takeuchi, 1995; Kogut and Zander, 1992).

4.1 Tacit and explicit knowledge

The traditional definition of knowledge is "justified true belief" (Nonaka, 1994; Kimball, 1999). Belief is personal and private. We therefore need justification for knowledge and this justification is external (Kimball, 1999) and objective. Polanyi (1962) recognizes the indispensable role belief plays in all knowing.

We must recognize belief once more as the source of all knowledge. Tacit assent and intellectual passions, the sharing of an idiom and of cultural heritage, affiliation to a like-minded community: such are the impulses which shape our vision of the nature of things on which we rely for our mastery of things. No intelligence, however critical or original, can operate outside such a fiduciary framework (Personal Knowledge, 266).

Polanyi's statement includes many important aspects of current knowledge creation debates, such as belief, sharing and vision. How does a knower form belief? Polanyi (1966) argues that "our body is the ultimate instrument of all our external knowledge" (p. 15). We may probe things outside by a sentient extension of our body. Our awareness of our body for

attending to external things comprises focal and subsidiary awareness. Focal awareness, the object of our attention depends on subsidiary awareness. Polanyi (1969) pointed out that “focal and subsidiary awareness are not two degrees of attention but two kinds of attention given to the same particulars” (Knowledge and Being, 128). He uses recognition of a countenance as an example. Mitchell (2006) summarizes Polanyi’s example: the particular features of the physiognomy are subsidiarily known, and the integration of the particulars such as the nose and eyes produces the recognizable face, which is the focus of our attention. According to Mitchell (2006), “Polanyi’s most significant insight concerns the basic operation of mind: all knowing consists of the integration of subsidiary and tacitly sensed particulars into a focal and articulated whole” (p. 70). Polanyi identifies the object of our attention, the subsidiaries of our attention, and the knower as the triad (three components) of his tacit knowing. The knower integrates the subsidiary and the focal awareness into the active process that constitutes tacit knowing. However, the triad is not permanent and the knower can dissolve the triad by looking differently at the subsidiaries.

Polanyi (1969) pointed out that tacit knowing is indispensable in discovery of knowledge and all knowledge “is either tacit or rooted in tacit knowledge” (Knowledge and Being, 1969, p. 195). If all knowing is either tacit or rooted in the tacit, the knower is indispensable in knowing. The knower integrates subsidiary elements within a focal whole; therefore, explicit knowledge is rooted in tacit knowledge and tacit knowledge is the origin of knowledge. The knower acquires tacit knowledge by experience (indwelling) and engages in discovery of knowledge. Individuals’ efforts contacting hidden reality leads to a discovery of new knowledge. Polanyi (1966) argues that indwelling is the proper means of knowing (p. 16). An individual in Figure 1 is indwelling in her job and is gaining experiences, acquiring intuition for a discovery of new knowledge through her experiences. For Polanyi, intuition is making a guess and guessing correctly. He uses the notion of intimation of hidden reality. Individuals who are indwelling in their jobs develop a good intuition and easily detect the intimation from the hidden reality. As the knower (employee) cumulates tacit and explicit knowledge, the knower improves the discovery of knowledge. In the same vein, Cook and Brown’s (1999) generative dance between knowledge and knowing explain how the interplay between knowledge and knowing can generate new knowledge and new ways of knowing. Polanyi

(1966) indicates that there are many particulars of hidden reality; they are inexhaustible. Therefore the discovery of knowledge from the hidden reality can be continuous. The discoveries of Nonaka and Takeuchi's (1995) kneading for bread making and Orr's (1996) knowledge sharing among service workers for Xerox copy machines provide paradigmatic examples of this discovery of knowledge.

The organization needs a process that can wring out tacit knowledge and encourages employees to engage in the discovery of knowledge.

4.2 Process of knowledge creation

We can adopt Whitehead's process philosophy for the process of knowledge creation. Whitehead's philosophy is known as very complex. Scholars help us comprehend his main themes (Mesle, 2008; Sherbune, 1966). Whitehead (1929) contends that our world and our lives are dynamic and interrelated. Reality itself is a vast macro process embracing a diversified manifold of micro processes, novelty, innovation, and the emergence of new focus as inherent features of the cosmic scene. Whitehead, known as the philosopher of organism focuses on "becoming" and sees the world as organic. Reality in Whitehead's universe is interconnected, relational, and dynamic.

For Whitehead, "all knowledge is conscious discrimination of objects experienced" (Whitehead, 1933, p. 176). He argues that knowledge is the subjective form of the interplay of knower with known. Whitehead also indicates that the notion of mere knowledge is a high abstraction, and that conscious discrimination itself is a variable factor present only in more elaborate occasions of experience. The basis of experience is emotional and sensual. He accepts that "all knowledge is derived from, and verified by, direct intuitive observation" (Whitehead, 1933, p. 177). According to Desmet (2009) "Whitehead's analysis of sense experience stems from the idea that our experience is a stream of experiential moments in which each moment is initially determined by its past" (p. 4). Desmet points out that a vague feeling of all past things exercises a causal influence on the present moment, so that the past is preserved in the present and the past affects the future.

Whitehead attempted to integrate the theory, experiment and sensual experience (Desmet, 2009). He places emphasis on experience and distinguishes three modes of perception in each

of our perceptual moments of experience: the pure modes of causal efficacy, presentational immediacy and the mixed mode of symbolic reference (Whitehead, 1929, pp. 120-121). Applying this model employees perceive immediate presentation and efficient cause for their observations, forming perceptions on the interplay between causal efficacy and presentational immediacy. As there are possibilities of errors in symbolic reference on the interplay between causal efficacy and presentational immediacy, employees' conscious reflexive monitoring of errors can be valuable for knowledge creation. Therefore, new knowledge based on employees' experience requires verification and sharing experiences among employees. Employees' experiences present many selection alternatives for knowledge creating firms.

Creativity in Whitehead (1929) likewise has a parallel in knowledge creation. Knowledge scholars such as Nonaka and Takeuchi (1995) follow Whitehead's philosophical tradition of integrating the phenomenal and noumenal world. Mesle (2008) points out that Kant distinguishes between the noumenal worlds – the world as it is itself - and the phenomenal world - the world as actually experienced by us. The question is this: if we cannot know anything about the noumenal world, how can we know that the noumenal world exists or that it does or does not include space, time, causality, and substance? According to Mesle, Whitehead argued that the world “out there,” the world “in itself” does have space, time, and causality and that we can know this because we experience ourselves as part of that larger causal world through perception in the mode of causal efficacy (Mesle, 2008, p. 61). Our sense experience is unique and involves interpretation, as Mesle (2008) makes it clear:

Every act of experience has its own unique perspective, its own “actual world.” No two events arise out of exactly the same spatial-temporal situation. Much less do any two moments in a human life arise out of exactly the same context? Certainly, no two people share the same biography. Furthermore, each new experience involves interpretation of the received data. Mesle (2008, p. 59)

From this perspective, every employee's experience offers a perspective on the actual world, and every interpretation involves an interpretation of that world. Thus diversity of employees' experience and interpretations of the actual world are sources of creativity, and as Whitehead states creativity is the principle of novelty:

Creativity is the universal of universals characterizing ultimate matter of fact. It is that ultimate principle by which the many, which are the universe

disjunctively, become the one actual occasion, which is the universe conjunctively. It lies in the nature of things that the many enter into complex unity. "Creativity" is the principle of novelty. (Whitehead, 1929, p. 21)

Whitehead's concept of concrescence illustrates how the new entity becomes concrete by many entities growing together. Fiser and Stumpf (2012) point out that Whitehead visualized reality as a continual process in which actual entities are constantly becoming. Creativity then is the ultimate principle by which the many enter into complex unity.

The experiences of employees, customers, and competitors, reported as data, can be a basis of new knowledge creation. The experiences of these stakeholders present many possibilities (eternal objects for Whitehead), and the organization needs to establish a process to identify and select the relevant possibilities. When a good selection is made, the result is profitable for the organization. For Whitehead, "there are two species of process, macroscopic process, and microscopic process. The macroscopic process is the transition from attained actuality to actuality in attainment while the microscopic process is the conversion of conditions which are merely real into determinate actuality [i.e., it is concrescence]" (Whitehead, 1929, p. 326). However, current scholars argue they are species of one process. According to Sherburne (1966), Whitehead's process is the creative thrust from many to one, producing a novel entity that is other than the many that gave rise to it, and thus part of a new many that in turn is productive of new novel entities. This rhythmic alteration between many and one is a process. Experiences of many stakeholders in the organization contribute to the creation of a novelty. Therefore, the stakeholders in knowledge creation (see Figure 1) need concrescence because they are all connected, as in Whitehead's philosophy of organism or process.

Argote's (2011) organizational learning model includes the task performance experience as sources of knowledge. She states that "experience is what transpires in the organization as it performs its task" and "experience interacts with the context to create knowledge" (p. 1124). The context has two dimensions: environmental context and latent organizational context. Our model in Figure 1 includes both dimensions. A new innovation in product, process and service may require knowledge from employees, suppliers, customers and competitors, as well as other relevant stakeholders. In the long-run the organization cannot grow at the cost of stakeholders. This requires the formation of a network with relevant stakeholders and

collaboration among stakeholders has become increasingly important in knowledge creation and new product development.

One must understand the principle of creativity to see how concrescence and transition of fluency are species of one process. Sherburne (1966) points out that the notion of creativity is crucial to an understanding of process. Whitehead (1933) states that “creativity is the actualization of potentiality, and the process of actualization is an occasion of experiencing” (p.179). The basic presupposition of Whitehead’s system is becoming and ongoing. In this framework, an organization’s knowledge creation is becoming of its new product, process and service that make the organization ongoing. Thus the process of knowledge creation is actualization of the experiences of stakeholders in the organization.

Similarly, the knowledge and dynamic capabilities creation models by Nonaka and Takeuchi (1995), Kogut and Zander (1992) and Zollo and Winter (2002) have some common characteristics of becoming, and methods of converting experiences to new products/processes/services. Hargadon and Fanelli (2002) argue that “the conversion of latent knowledge to empirical knowledge refers to the application of knowledge latent in individuals to generate a physical or social artifact” (p. 295). They further explain that “the conversion of empirical knowledge to latent knowledge refers to the reflexive experience of individuals within the organization” (p. 295), arguing that the generation of new knowledge or the successful replication of old knowledge depends on the cyclic interaction between latent knowledge and empirical knowledge. This cyclic interaction continues in the ongoing process of knowledge creation.

In a similar vein, Bhaskar (2008) introduces two dimensions in knowledge production: the transitive dimension (the production of knowledge from and by means of knowledge) and the intransitive dimension (the independent existence and activity of causal structures and things). Bhaskar (1975) points out that knowledge in the transitive dimension is socially produced and the objects of knowledge in the intransitive dimension exist and act independently of men although their existence and/ or activity depend implicitly or explicitly upon men. He argues that scientists try to discover the reasons for things and events, patterns and processes, sequences and structures and they need to understand both ‘a concept of the transitive process of knowledge-production and intransitive objects of the knowledge they

produce: the real mechanisms that generate the actual phenomena of the world, including as special case our perceptions of them (p. 62)'. Bhaskar argues that science must be conceived as an ongoing process of transformation, continually or essentially in motion, in an attempt to capture (i.e. penetrate and describe) the stratification of the world. In capturing the concept of the ongoing process of transformation Nonaka and Toyama (2003) propose dialectics in knowledge creation. According to them dialectics is a method of thinking and acting and a way/process to approach a reality to find truth in it. They point out that the dialectic tries to approach the elusive 'absolute truth' through the process of examining and denying the series of 'relative truth,' although the absolute truth may never be found or may never exist. They emphasize the process is more important than reaching the absolute truth or not. Therefore, knowledge creation is dynamic and in motion.

4.3 Structures and agents

The sources of new knowledge elucidated by Polanyi (1966) and Whitehead (1929) are tacit knowledge and lived experience; personal knowledge and employees' experiences are sources of this knowledge. Knowledge is created by a team in an organization as team members interact in the knowledge creation process. This raises several issues in team production. The structure of the organization is designed to address these issues because it has effects on their behavior. Giddens' structuration theory (1979, 1984) may offer a framework for explaining the relationship between structure and agent in knowledge creation, as it is concerned with understanding the activities of knowledgeable human actors and the structuring of social systems.

We argue that Giddens' duality of structure (1979, 1984) can be adopted for the analysis of the actors and structure of knowledge creation. For Giddens (1979, 1984), structures are rules and resources. He regards the rules of social life as "techniques or generalizable procedures applied in the enactment/reproductions of social practices" (1984, p. 21), considering three dimensions of social structure in his structuration theory: signification, legitimation and domination. In knowledge creation, the signification (meaning) structure is shared rules, concepts and theories which actors can draw on to make sense of knowledge creation; each actor makes sense of what others say and do in his interactions with other

members by interpreting them. Each actor also receives intimation from reality, as stated by Polanyi and Whitehead. Sharing and communicating with team members can be helpful in making sense of and drawing meaning from each actor's experience and the intimation that each actor is receiving from the hidden reality. As interactions with team members clarify concepts and theories, they help create new knowledge.

Macintosh and Scapens (1990) draw on Giddens' structuration theory as their framework for management accounting. According to Macintosh and Scapens, legitimation involves the moral constitution of interaction. They argue that the legitimation structure is mediated through norms and moral codes which sanction particular behaviors, and they further point out what comprises the legitimation structure:

It comprises the shared sets of values and ideals about what is to be regarded as virtue and what is to be regarded as vice; what is to count as important and what is to be trivialized; what ought to happen, what not to happen (Macintosh and Scapens, 1990, p. 460).

Since Knowledge is tacit and lived experience (Polanyi, 1962; Whitehead, 1929) and locked in the human mind (Kim and Mauborgne, 1998), the decision to share or hoard knowledge has been the classical dilemma for exploiting knowledge in an organization. Therefore, creating shared sets of values and ideals among actors in an organization is crucial for organizational knowledge creation. This legitimation structure lays a theoretical ground for the importance of inter-personal trust among members in a knowledge creation team.

Giddens argues that domination depends upon the mobilization of two distinguishable types of resources (1984, p. 33): Allocative resources and authoritative resources. Allocative resources refer "to material resources involved in the generation of power, including the natural environment and physical artifacts; allocative resources derive from human domination over nature" (Giddens, 1984, p. 373). Authoritative resources refer to "non-material resources involved in the generation of power, deriving from the capability of harnessing the activities of human beings; authoritative resources result from the domination of some actors over others" (Giddens, 1984, p. 373). According to Macintosh and Scapens (1990), both types of resources facilitate the transformative capacity of human action (power in the broad sense), while at the same time providing the medium for domination (power in the narrow sense). They further point out that power in its broad sense is the ability to get

things done and to make a difference in the world. Because employees or subordinates can exercise significant power in the knowledge creation process managers' domination over employees tends to be more congenial than domineering because of this nature of knowledge. A study by Srivastava et al (2006) found that empowering team leaders and employees relates positively to both knowledge sharing and team efficacy.

Giddens' focus on the understanding of human agency and social institutions uses human agents and actors interchangeably. According to Sewell, Jr. (1992), Giddens places a great deal of weight on the notion that actors are knowledgeable, defining knowledgeability as "everything which actors know (believe) about the circumstances of their action and that of others, drawn upon in the production and reproduction of that action, including tacit as well as discursively available knowledge" (p. 375). Actors become knowledgeable about knowledge creation structures as they develop a set of dispositions on structures, which Bourdieu (1977) refers to as habitus. For Bourdieu (1977), habitus is a system of dispositions (lasting, acquired schemes of perception, thought and action). The individual agent develops these dispositions in response to the objective structure that the individual encounters. He argues that agents inculcate objective social structures into the subjective, mental experience of agents. Because a habitus tends to favor the particular social arrangement of society and reproduce the very structure of society, Bourdieu insists that sociologists must pay conscious attention to the effects of their own position on distortion or prejudice. This reflexivity can impel sociologists to correct their biases and prejudices. Ösbilgin and Tatli (2005) review Bourdieu's work and argue that his work can contribute to organization and management studies in three substantial ways:

- through (1) offering a conceptual framework for a multilevel research agenda in organization
- and management studies, (2) presenting an epistemological and methodological framework
- for tackling issues of reflexivity in the research process, and (3) proposing a methodological
- and epistemological way to overcome the dualities between structure and agency and

- objectivism and subjectivism (Ösbilgin and Tatli, 2005, p.855).

Therefore, the reflexivity of individuals can be a key factor contributing to knowledge creation.

Similarly, Giddens addresses issues in the interplay of agents' action as well as social structures in the production, reproduction and regulation of social order. For Giddens (1984), the duality of structure means that structures shape actors' practices, and their practices reproduce structures. Reflexive monitoring of an agent's action and interaction helps recognize intended and unintended consequences. Agents address problems of adverse unintended consequences that can lead to changes in structures.

Giddens refers the actions taken by individuals to agency. These actions taken by individuals (agency) take place as a continuous flow of action. Macintosh and Scapens (1990) sum up Giddens' agency and structures and present them as a figure (see Figure 2). Agents are purposive and know a great deal about why they act in the way they do. They can and do provide rationales for their actions and interactions. However, although many of the consequences of agents' behavior are intended and known, other consequences may be both unintended and unknown. In their reflexive monitoring of action in social settings, agents rely on both their discursive and practical consciousness and are motivated by an unconscious need for ontological security. (Macintosh and Scapens, 1990, p. 4)

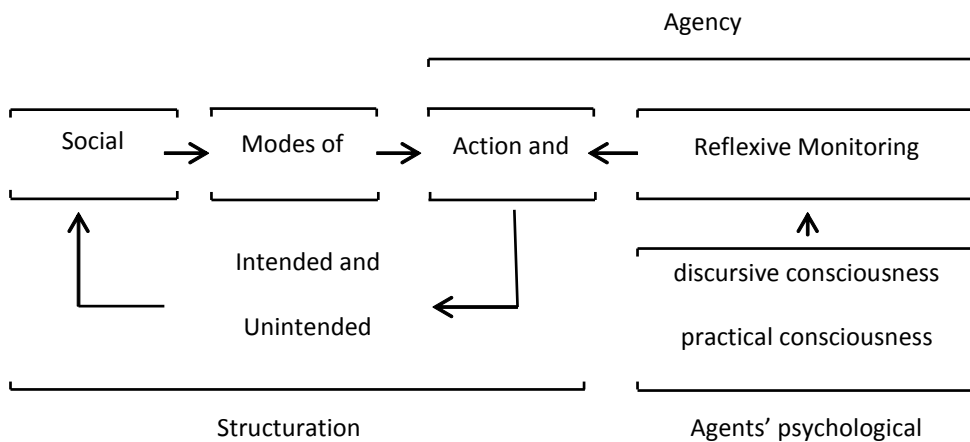

Figure2. Agency in structuration. Macintosh & Scapens, 1990

At the discursive level of consciousness, agents are able to give reasons for their behavior, and at the practical level of consciousness, agents understand what to do in social situations based on stocks of knowledge they acquired. The practical level of consciousness has an affinity to Bourdieu's habitus. Acts have unintended consequences and unintended consequences may systematically feed back to the unacknowledged conditions of further acts. Therefore, structure is dynamic, a continually evolving outcome and matrix of a process of social interaction (Sewell, Jr. 1992). Agents are empowered by structures, both by knowledgeability of structures and by the access to resources that enable agents to enact structures. Therefore, reflexive monitoring of actions and interactions leads to making changes in structures and agents' behavior.

Giddens uses the concept of routine in organizations to provide a sense of ontological security and trust on the actions and interactions among agents. Giddens (1984) refers to routinization as "the habitual, taken for granted character of the vast bulk of the activities of day-to-day social life; the prevalence of familiar styles and forms of conduct, both supporting and supported by a sense of ontological security" (p. 376). Actors' reflective monitoring and organizational routine make the transformation of structures in social settings dynamic and stable. The organization needs to make continuous changes, but at the same time needs to maintain stability to stem the flux and uncertainty of actions. Fuchs (2003) attempts to integrate Giddens' structuration theory to the theory of social self-organization, Fuchs (2003) pointing out that "Giddens' structuration theory fits well into the framework of a theory of social self-organization that stresses the role of human actors as creative beings" (p. 133). Fuchs argues that "the interactions between components result in new properties of the system that cannot be fully predicted and cannot be found in the qualities of the components. Microscopic interactions result in new qualities on the macroscopic level of the system" (p. 135). Changes in structures on the macroscopic level of a system are caused by actions and interactions of conscious knowledgeable actors.

Giddens' structuration theory provides a framework for knowledge creation structures and agency. If we assume that there are two employees in a knowledge creation team, both have tacit knowledge and lived experiences from their respective jobs. They have acquired knowledge from customers, investors, partners, competitors and the scientific community.

Therefore, individuals engaged in knowledge creation are knowledgeable, conscious and reflexive. Individuals can also anticipate possible future states, based on their abilities to detect intimation from the hidden reality in their fields (Polanyi, 1969). They can anticipate change in technologies, markets and regulations. A knowledge creation team consists of individuals with these traits who participate in knowledge creation. According to Fuchs (2003), creativity is the ability to create something new that seems desirable and helps to achieve defined goals. Based on anticipation of the future, the knowledge creation teams design/create new products, processes and services and provide solutions to problems. Individuals' participation in knowledge creation can be regarded as a micro-foundation; their interactions result in new knowledge. Thus a new knowledge creation structure may emerge from actions, interactions and reflexive monitoring of individuals.

Structures enable and constrain actions and interactions of individuals. In Figure 1, the knowledge creation structure affects individuals 1 and 2. Individuals are affected by mission, culture and leadership in the organization and take purposeful and strategic actions to enhance their utility, forming dispositions to navigate structures (Bordieu's habitus). Individuals further develop dispositions for enhancing their knowledgeableability in organizational structures as well as organizational environments.

4.4 Structures and agents' personal traits

According to Borghans et al. (2011), "there is a growing interest by economists in personality psychology to better understand the diversity of responses of agents to similar circumstances" (p. 315). We have discussed the possible effects of diverse structures on agents. Borghans et al. argue that agents may respond differently within the same structure, as responses depend on personality traits. Psychologist Roberts defines personality traits as follows:

Personality traits are the relatively enduring patterns of thoughts, feelings, and behaviors that reflect the tendency to respond in certain ways under certain circumstances. (Roberts, 2009, p. 140)

Psychologists measure five big factors of personality traits: extraversion, agreeableness, conscientiousness, neuroticism and openness to experience. Almlund et al. (2011) show that

personality plays a powerful role in predicting life outcomes; they also argue that personality changes over time and personality changes are influenced by structures. This result is in line with Bourdieu (1977, 1990) and Giddens (1984). Knowledge management studies should examine these carefully. Structures of knowledge creation may change the personality of employees over time, and management plays a key role in guiding personality traits to a positive and productive direction.

Baer et al. (2008) have shown that personal traits of team members affect team creativity.

They argue that teams composed of individuals high on extraversion, openness to experience, neuroticism, and agreeableness, and low on conscientiousness should be more likely to possess the potential to experience creative synergies. Their arguments suggest that personality traits can be an important factor in forming knowledge creation team.

5. Practice of knowledge creation

Feldman and Orlikowski (2011) point out that practice theory as it is practiced in relation to organizational phenomena is an emerging field. They situate practice theory in relation to three ways of studying practice: “an empirical focus on how people act in organizational contexts, a theoretical focus on understanding relations between the actions people take and structures of organizational life, and a philosophical focus on the constitutive role of practices in producing organizational reality” (p. 1240). According to Bourdieu (1977) “practices are no more than executions Or the implementing of plans” (p. 96). Executions or implementing plans involve activities and Hislop (2009) defines practice as purposeful human activity. How does a firm implement knowledge creation plans? We can study practices of a firm to answer this question. We examine a knowledge creation practice of The Dow Chemical Company from a theoretical knowledge creation perspective. It would be interesting to learn how a leading innovative firm creates knowledge and competency. This section is based on an in-depth interview with Mr. Whiteman who is the president of Dow Global Technology, Inc.

5.1 Knowledge creation structure

Knowledge creation structures may vary depending on organizations (place) and time. However, knowledge creation structures today converge more easily because of the globalization of the world economy as well as information and communication technology. The currently emerging knowledge creation structure, called “ideation”, is defined as “the process of generating or conceiving ideas and concepts that may be useful for attaining some desired state or outcome” (Briggs and Reinig, 2007, p. 1). Simpson (2008) defines it more simply and concretely: “Ideation is the systematic search for targeted opportunities, and new markets, and new services” (p. 1). Park et al. (2011) have illustrated typical processes that knowledge creating companies follow in developing new competency.

The Dow Chemical Company, a leading innovative firm in the world, offers a practice for knowledge creation. Section five examines a knowledge creation practice based on the case of The Dow Chemical Company (Whiteman, 2013).

5.2 Structure in Mobilization of Tacit and Explicit knowledge

Argote and Miron-Spektor (2011) point out that experience interacts with the context to create knowledge. They categorize the context into two categories: organizational and environmental. We adopt their framework with some modification as shown in Figure 1. According to Argote and Miron-Spektor (2011) the organizational context includes structure, culture, technology, identity, memory, goals, incentives, and strategy. The environmental context includes outside of the organization such as competitors, clients, institutions, and regulators. We discuss The Dow Chemical Company’s knowledge creation from the organizational and environmental context.

Structure in Internal knowledge Mobilization (organizational context)

The Dow Chemical Company has established an Idea Central, which is a database. When an employee or a group of employees has an idea, he/she can post it to the Idea Central. All employees are encouraged to propose ideas. Dow believes that no ideas are bad ideas; it creates the culture that all ideas are appreciated and valued. Employees who work for Dow learn from their daily experiences in dealing with customers and suppliers or in their labs. Dow obtains tacit knowledge from them and from all functions, ages and regions in the world,

since it is a global company. Variations and diversity of ideas are crucial sources of knowledge creation, because they can be combined to create new knowledge. Therefore, Dow management encourages employees to express diverse ideas and create an environment for diversity. The variations in experiences by Dow employees in all functions, regions and ages are key sources of knowledge creation.

Tacit knowledge is a prime source of new knowledge creation, as Polanyi (1966) argued. Tacit knowledge is acquired through lived experiences and employees receive intimation from the realities of their daily job. Tacit knowledge of their experiences can be momentarily realized, but will be lost if employees do not capture it at that moment. The process of Idea Central helps employees capture tacit knowledge. When the Idea Central is placed in the organization, employees develop dispositions, as Bourdieu (1977, 1990) advocated. The Idea Central of Dow Chemical is also a device to utilize dispersed knowledge (Hayek, 1945), since Dow's employees are dispersed around the world.

Structure in External Knowledge Mobilization (environmental context)

Dow Chemical also has scouting departments whose jobs are obtaining knowledge from outside sources such as academic journals, conferences, universities and government agencies (NIH). Employees in a scouting department also search out information and knowledge from suppliers, customers and competitors. Dow Chemical arranges a license agreement with those who have patents, if the patent is deemed necessary for Dow. Scouting, designed to obtain knowledge from outside of Dow Chemical, is divided into many different specialties, such as engineering and science, and acquires external knowledge from various sources (see Figure 1). This knowledge creation practice of Dow provides evidence of Nonaka and Toyoma's (2003) boundary crossing. Chesbrough (2003) refers to this as the open innovation system which is the use of purposive inflows and outflows of knowledge to accelerate innovation. Chesbrough (2003) argues that open innovation saves time and costs compared to closed innovation.

External sources of knowledge have been gaining importance in the knowledge economy. Apple Company, for example, is known for offering strong incentives to small companies and individuals with new knowledge. If knowledge from external sources is adopted in Apple products, a significant portion of the additional profit generated by adopted external

knowledge is offered to the firm or the individual who supplied the knowledge. This is a strong incentive to the supplier of knowledge, because Apple Company has a large market and this creates value for both Apple and knowledge suppliers. Apple Company acquired multi-touch sensing capabilities from FingerWorkks (Isaacson, 2011) and Google acquired Android.

5.3 Screening

Screening at Dow Chemical is done on a monthly basis. A cross-functional team consisting of four or five members from various functions goes through all proposals posted in the idea central. This team makes judgments on ideas, based on deeper analysis of diverse proposals placed by employees from all over the world. The team initially selects the ten best proposals from the Idea Central and then narrows the list down to a few ideas for funding. Dow saves all proposals for future use. Some proposals may not be buyable at the time of screening, but they may become value generating ventures in the future, as the economic environment changes (e.g., technologies and market conditions). Since all proposals are stored in the Idea Central and they are accessible by Dow employees, the Idea Central serves as effective organizational memories. Therefore, costly knowledge assets that Dow created are not lost ‘on the spot,’ and the Idea Central mediates the problem stemming from the lack of coherence, over time decision making raised by Nonaka et al. (2006). Dow can also make use of knowledge assets stored in the Idea Central by combining with future proposals for creating new products, processes or services. Screening can be regarded as a validation process of new knowledge because knowledge is “verified true belief”.

5.4 Basis for screening (how to screen)

The way that Dow Chemical screens proposals is interesting. Dow’s screening method is like putting pieces of a puzzle together. Dow maintains that sustained profitability of any business is only possible with all three advantaged positions. The first piece of the puzzle is technology advantage. Does Dow have a patent or patents for the proposed idea? Patents that need to be evaluated are composition, process, and application patents. If they do not have

them, they need to solve that puzzle by contacting patent holders for license agreements or a joint venture. The second piece of the puzzle is operations advantage which includes low cost raw materials, low capital options, process experience, synergistic cite, supply chain and regulatory constrains such as environmental health and safety regulations. They assess raw material requirements as well as accessibility of required raw materials and facility and capital. Costs of acquiring them need to be competitive. The third piece of the puzzle is market channels, which includes customers, brand names, reputation, synergistic sales, channel partners, market sales forces and meeting requirements of regulatory agents such as Environmental Protection Agency (EPA) and Food and Drug Administration (FDA).

There are smaller puzzle pieces within the three large pieces. In assessing each piece of the puzzle, limitations or constraints are analyzed. If Dow is missing technology pieces, they may develop them within the organization or acquire them from outside. Dow needs to assess the availability of raw materials, facility and capital as well as missing pieces of the operations puzzle. When they find missing pieces (constraints) they have to solve them. The market channel piece of the puzzle is figuring out customers, brand names and sales forces. They also examine market penetrability; some markets are very difficult to penetrate because newcomers have insurmountable barriers to overcome. When all the missing pieces of the puzzles are found, they put them together to create value for Dow. Dow will benefit from the entire value pie when Dow put together all pieces of the puzzle. Figure 3 is a graphical presentation of this screening process.

Once Dow has established the new competency at competitive levels, competitive advantage depends on recognizing new business opportunities and recombining these capabilities and unexploited proposals at the data central as emphasized by Helfat et al. (2007) and Argyres (2011). Argyres argues that “organizational economics can offer insights into features and processes that can promote or hinder opportunity recognition within organizations (p. 1141).” According to Argyres “governance choices are endemic to any capability development process, because such processes involve structuring incentives, allocating authority, and stimulating information flow (p.1142)”. Structuring incentives and allocating authority can influence knowledge creation and sharing knowledge.

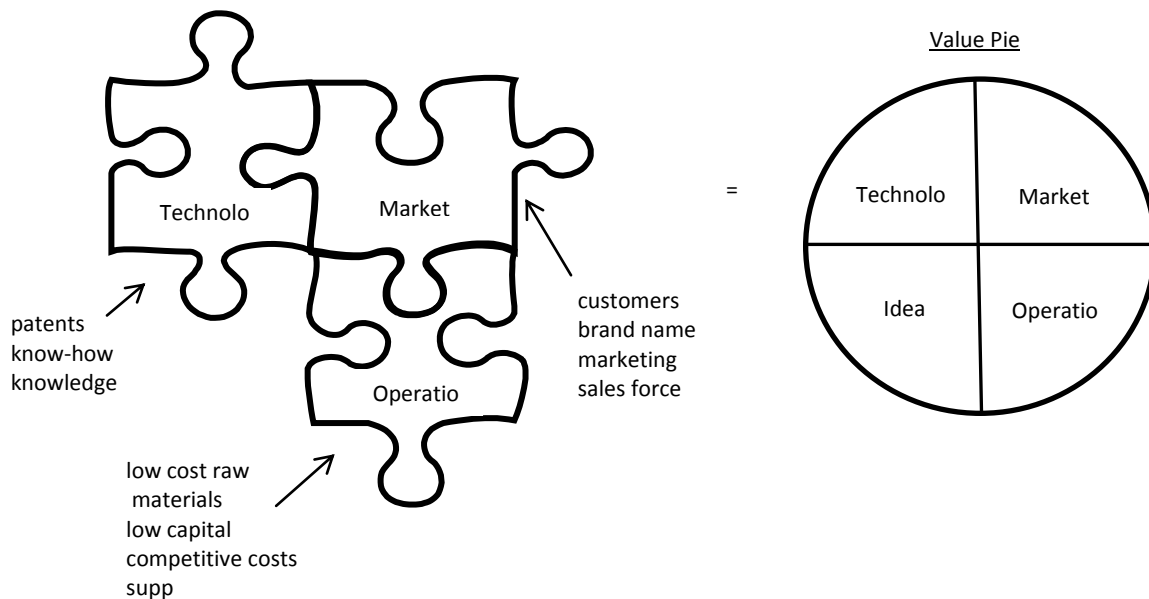

Figure 3: Screening process

It is hard to make judgments about what pieces of the puzzle can or cannot be found, and even if the pieces are found, the cost structure may not be competitive enough to embark on the project. They learned the hard way not to waste time and resources for a project that has missing pieces, or is too costly or impossible to find. Appropriate structures are established based on experiences of failures to prevent future failures. This establishment of structures is an example of the realization of theories of Giddens' structures and agents (1984) and Bourdieu's reflexive feedback and self-monitoring (1977, 1990). Therefore, the knowledge creation process is emerging and ongoing, as Whitehead advocated (1929). This process also supports the proposal made by Spender (1996) that knowledge is the basis of a dynamic theory of the firm.

5.5 Collaboration

What can Dow Chemical do with ideas when they cannot overcome constraints or find missing pieces of the puzzle? Dow figures out factors that the company is missing in the puzzle. Dow then decides to make them internally or to fill them from outside. They license

out (sell) ideas to those who have the capabilities to use them or form a joint venture. Dow Chemical searches for a firm that needs the knowledge that Dow has and negotiates a license agreement. A joint venture agreement is another solution for utilizing their ideas. They form a joint venture by connecting a network of companies which have pieces of the puzzle (technologies, ideas, and operation). They can find small companies who have good ideas or Dow's missing puzzle pieces and establish joint ventures. This example shows that innovation capabilities are distributed across firm boundaries, and managers combine distributed innovation capabilities to create a new capability through structures which coordinate the contributions of the various participating firms (Coombs and Metcalfe, 2002). Coombs and Metcalfe (2002) argue that we need to consider how the capabilities perspective can be extended to embrace a multi-firm perspective on innovation. They further argue that capabilities themselves become an important unit of analysis which is not coterminous with the firm. Madhok (2002) points out that "the reasons for collaborations between firms is to combine synergistically two sets of complementary but dissimilar resources and capabilities in a manner which will generate returns that will either create a market transaction or complete internalization"(p.277). Dow Chemical recognizes that advantages frequently occur in different organizations. Therefore, collaboration is critical because each organization has a unique pile of "advantaged" puzzle pieces. There are many possibilities in finding matches with other collaboration partners who have technology, operations and/or market advantage that Dow Chemical does not have. Dow can buy, sell, create, and trade pieces with collaboration partners. Possible collaborations partners are universities, large companies, small and startup businesses, market specialists and incumbents. Finding optimum partners is crucial for the success of collaboration. Dow has developed good strategic mixes for acquiring advantage in collaboration (Whiteman, 2013). The practices of Dow's scouting, collaboration and joint venture can be regarded as an of open innovation system (Chesbrough, 2003). The openness of technology sharing economizes costs in new product development by accomplishing the economy of scale and scope as Chesbrogh (2003) argues. According to Chesbrough (2003) open innovation is the use of purposive inflows and outflows of knowledge to accelerate internal innovation, and expand the markets for external use of

innovation, respectively. We can see that Dow's practice is a good example of open innovation.

However, the cross-firm structures for new capabilities innovation need to address governance issues on opportunism. Firms need capabilities to write contracts that efficiently deal with opportunistic behavior. Joint ventures among many firms require trust among the participating firms. Past experiences help build trust and reputation within the industry. Once a firm is known for taking advantage of participating firms and not sharing ideas, other firms are likely to avoid future joint ventures. Building a good reputation can be a strategic asset in the long run, because business dealings are ongoing and repeating.

Once the value pie is created, they split it based on contributions or strengths of each participant (see Figure 4 for a value pie). The initiating or proactive company can secure a better share of the value pie. This example shows that the governance choices of the firm (Williamson, 1991, 1999; Argyres, 2011) are involved in any capability development.

Dow forms over 100 joint ventures in a year, and having good intuition for what consumers would like to have is a key factor for success in joint ventures, as well as in Dow's new product development. Firms can search to find an addressable market and its size and explore market needs based on voices of customers (VOC). As von Hippel (1988) indicates, customers and suppliers are the most important sources of innovation. Voices of customers provide information on market needs. However, managers' intuition on what consumers want plays a key role in the success of a new product. The cofounder of Apple Company, Steve Jobs, was known for his good intuition on consumers' preferences and Steve Jobs and his designer, Ive, worked to simplify new design. Apple's first brochure proclaimed "Simplicity is the ultimate sophistication," and Steve Jobs had aimed for the simplicity that comes from conquering complexities, not ignoring them (Isaacson, 2011, p. 343). Samsung (a Korean chaebol) is taking a different track and values consumers' knowledge and experiences (Chen, February 11, 2013). Knowledge about what consumers want is a hidden reality and managers/knowers capture intimation from that hidden reality. Their intuition is a key element for the success of a new product. Dow's success rates are known to be 20-30 percent. This example shows how the network form of organization emerges as an adaptation to

changes in the environment for knowledge creation (Hana and Freeman, 1984; Leventhal, 1997).

Dow Chemical's practice for new product development illustrates an integration of macro-micro approaches. The Idea Central (macro level) structure is designed to solicit tacit knowledge from individuals (micro level). The variations in knowledge creation structures among organizations may have a different impact on individuals, and individuals' responses to the same structure may differ based on personal traits. If an Individual's ideas are verified by a team and the project proposed by an individual becomes a new competency by team efforts (meso level), interactions among individuals result in new qualities on the macroscopic level of the system (Fuchs, 2003). Interactions among individuals from cross-functions lead to new knowledge and competency creation in Dow. Variations of ideas offer opportunities for the organization to recombine them for new competency (Schumpeter, 1934; Kogut and Zander, 1994; Nonaka, 1994; Nonaka and Takeuchi, 1995). This example of Dow's knowledge creation illustrates how to engage in knowledge creation activity and how this knowledge evolves over time (Levinthal, 2006; Winter, 2006). Dow Chemical's idea central can be seen as a *ba* (a knowledge creating place: Nonaka and Kono, 1998, Nonaka et al., 2000a, 2003). *Bas* may vary depending on the contexts of knowledge creating firms and the market selects a good *ba* and the selected *ba* retains good characteristics of the *ba*. Variations in knowledge creating *bas* will continue in the market and the knowledge creating firm is, therefore, dynamic. According to Nonaka and Toyama (2003) *ba* can transcend time, space, and organization boundaries to create knowledge. A knowledge-based view of the firm regards the firm as a knowledge creating entity and a firm in this view is changed from an entity of being to an entity of becoming (Nonaka and Toyama, 2002, 2003) as seen in Prigogine's scientific view of the world (2003).

Collaboration saves precious time in developing new products, processes and services. Collaboration may be a better practice in a high-velocity economic environment because firms can bring new products to the market quickly. Nonaka et al. (2000b) point out that building one's own knowledge comes with cost, i.e. time. Building up knowledge assets through a firm's own knowledge creating process takes time, and hence costly (Nonaka et al. 2000b). Teece (2000) argues that the opportunity cost is especially high when the industry

that the firm is in is a high velocity economic environment. If the firm develops the missing puzzle pieces by themselves, they may fall behind the market competition.

Incentives

The intervention of managers to create knowledge can be made at both institutional and individual levels (Abell et al., 2008). First, managers need to provide opportunities for agents to interact. Managers and individuals together design an institution to be conducive for dialogue and interactions. Second, for diversity of ideas, managers need to hire individuals from many different universities and institutions and provide incentive systems for individuals and groups to acquire and share knowledge. When agents acquire useful knowledge (genotype) and skills, firms develop technology (phenotype) based on useful knowledge and knowledge sharing (intensity of knowledge), as Mokyr (2000) argues. When agents accumulate more knowledge and develop dispositions of imagination and creativity, the firm will have easy access to knowledge and creativity (Mokyr, 2000), because knowledge is stored in agents who supply knowledge and skills to the firm. Therefore, developing an incentive system for agents to constantly acquire knowledge and skills is crucial in building the dynamic capabilities of the firm. Individuals' choice of the organization, and their acquiring and sharing knowledge, depends on firm characteristics. As discussed before structuring incentives and allocating authority are important in knowledge creation and sharing.

Because managers at Dow appreciate diversity and create a culture for employees to supply many different ideas, it rewards those who produce the most ideas as well as the best ideas.

6. Conclusion

This paper attempts to integrate structure-agent approaches in knowledge creation. As firms design structures to create knowledge, individuals develop a set of dispositions in response to these structures. Thus structures influence individuals, and based on these structures knowledge outcomes may depend on individuals' actions, interactions and creativity.

The Idea Central has emerged as a model knowledge creation structure to elicit tacit and dispersed knowledge from employees and stakeholders. The Idea Central continues to change as knowledge creation teams reflect and consciously self-monitor structures and knowledge outcomes (see Figure 1). As actions and interactions of members in knowledge creation teams generate nonlinear knowledge outcomes, individuals in such teams tend to develop dispositions to acquire new knowledge through their work experiences and interactions with stakeholders. When they become conscious of knowledge creation, the reflexive self-monitoring employees in today's knowledge economy are valuable in both knowledge creation and changing organizational structures.

Structured Abstract

The objective of this paper is an analysis of the strategy of gaining knowledge through social capital and sustainable development in tourism companies so they can modernize and compete with constant improvement. We will see how effective this strategy is for the benefit of companies in terms of reducing costs, leveraging technology while feeding knowledge of indirect or direct customers. Aspects of social capital and sustainable development as the approach of several authors are briefly mentioned.

Purpose – The purpose of this paper is to conduct a critical analysis of the importance in the twenty-first century presents a new approach to strategic management based on knowledge from the perspective, of resources and dynamic capabilities, as an explanation of the role critical that these intangible assets presented in today's organizations from the implementation of a particular model of governance of existing knowledge on those, Grant (1996), Spender (1996), Bueno and Salvador (1996), Bueno et al (2006), to overcome the current economic crisis affecting many countries, areas and organizations in the global economy.

Design/methodology/approach – We propose an approach work is carried out with a proposal for a study of exploratory character. Social responsibility and commitment to the ecosystem as a social strategy to assist in the socioeconomic development of the organizational environment and as a facilitator for its own sustainable development. Eljkington (1994), Bueno (2011), Leon (2011a), Leon (2011b), Parrish (2010). The exploratory analysis in the tourism sector and in hotel companies that compose it, as evidence of the importance of the new management approach considered, given the nature and character of the business model and its relation to environment performance of this industry and its companies. Bueno (2011).

Originality/value – This methodology puts in evidence the methodology carried out will show that this knowledge based on their relationship to socioeconomic sustainability, its still emerging approach given its character by emergence time, requires more research efforts and empirical evidence, therefore work shows a value of exploratory character and originality evident within current approaches of strategic management and the knowledge economy, although it emergente. Por results will corroborate the formulated inductive approach, leading rebuttal to some of the guesswork exposed and organizations concerning the tourism sector.

Practical implications – The outcomes of the application as indicated, regardless of the overall importance of an analysis of intangible assets and dynamic capabilities that facilitate sustainable economic development in organizations, especially the variables that make up the main concepts the capital of the same, focusing on corporate social responsibility and environmental commitment, stresses that the results are important for designing a management model oriented entity mentioned sustainable development based on existing knowledge in the same in their strategic application in the hotel industry, for example the Tourism sector as previously indicated.

Keywords – economic sustainability, environmental sustainability, intellectual capital, knowledge management, social capital.

Paper type – Academic Research Paper

1 Introduction

Knowledge is the primary resource and the ability to create value in today's economy and that is basically related to the human capital of the organization, so that tourism can be seen, given its value chain and production processes, as a human capital intensive sector and generator of social capital which lay a solid foundation on how it facilitates sustainable development of organizations in the sector. Similarly, social capital benefits the collective learning and innovation in order to protect the cultural and natural heritage, facilitates access to markets, strong confidence of tour operators achieving greater intervention and control thereof, as well as power their economic, social and cultural dynamics.

The World Commission on Environment and Development (Brundtland Report, 1987) provides a catalog of "Requirements for Sustainable Development", in this exposes a political and institutional system to ensure the effective participation of citizens in decision-making. In turn, the World Tourism Organization in 2001, poses in which success depends on the community of interest between business, civil society and

governments. In this sense, it is justified that the strategic direction based knowledge facilitates sustainable economic development organizations. (Leon, 2011a y 2011b).

According to Spender (1996) knowledge is a complex concept when building a dynamic knowledge-based theory of the business concept. In addition, if the knowledge of the company is the most essential resource and in turn resides in a specialized form among members of the organization, then the essence of organizational capability is the integration of the expertise of individuals (Grant, 1996).

In general, by social capital theory we know that people use their social resources in order to obtain mutual cooperation, achieve goals without them would be very difficult to achieve.

Regarding sustainable development, the tourism industry must be familiar to some extent market forces competing and betting on responsible tourism. Sustainable development contributes significantly to employment generation and productive occupations. The idea of using indicators of sustainable development is the purpose of using them for policy, planning and management in the destinations. Keep in mind that sustainable management practices are applicable to all forms of tourism in all types of destinations, as well as to ensure durability should ensure harmony between the three principles of tourism development: environmental, economic and sociocultural. In summary should give optimal use of environmental resources, respect the socio-cultural authenticity of host communities, and ensure long-term economic activities.

2 Preliminary Issues

Tourism is one of the sectors which has been affected by the New Technologies of Information and Communication, I touched by meeting all impositions brought about the so-called Knowledge Society.

Thus, it should be noted that the tourism sector is facing today a new context, a different scenario was used, since the demands of the market are now completely new. Therefore, companies and tourism organizations have found it necessary to reorient their way of managing your business and also the method to capture new customers.

The capital, established social networks, have a special role here that try to develop through these pages.

In this new context, which has been a paradigm shift from the previous dominant model, companies and tourism organizations need to have a rigorous quality information on the activities performed.

In summary, the information and knowledge about the client (your current customers and your potential customers) are factors that must be known to be increasingly competitive in the market. To assume success and competitiveness all these new factors characteristic of the knowledge society and business tourism organizations (just as has happened in other companies) have adopted a model of knowledge management.

3 The importance and relevance of social capital in companies and tourism organizations: a sociocultural approach to tourism business within the knowledge society

As mentioned by Lozano, (2008), one of the defining characteristics of humans is that by nature is a social species, and therefore makes the individualistic behaviors that increasingly characterize our society and culture tends to create imbalances and conflicts between individuals, groups and organizations.

From a purely economic perspective , companies and tourism organizations operate as a criterion of competitiveness. A while now , these organizations have been including in its model address the growing role of social capital. This concept is relatively new. We say it is relatively new for the old theories about this concept have been made in the last two decades of the twentieth century. The so-called Theory of Social Capital has given great results in the study of businesses and organizations. Among the early research on this topic would include those developed by Leana & Van Buren , 1999; Tsai & Ghoshal , 1998) and can also be noted that of Nahapiet & Ghoshal (1998 : 243), the authors defined social capital as " the sum of the actual and potential resources derived from the relationships in a network." Thus, these thinkers analyzed how social capital makes facilitator for the creation of new companies and organizations intellectual capital. This is a very extensive process , since as the social capital is more important and has more networking , more benefits may be obtained , as has been seen performing tourism businesses currently.

There are three dimensions of social capital, which thereupon apply to tourist organizations (Giraldo, A et all 2013) as shown in Figure 1.

- structural: it implies the connection between the actors, the social interaction. Enjoy certain advantages those contacts that have an actor belonging to a social structure. Bueno and Merino (2007) express the structural capital refers to a body of knowledge and intangible assets arising from action processes which are owned by the organization and who stay in it when people leave.
- Relational: relates to interpersonal relationships such as trust and reliability, ie, the assets related to social interaction. Bueno and Merino (2007) state that relational capital is a set of skills that are added to the organization and the people as a result of derivative that preserves relationships with market players and society value.
- cognitive: According to Bueno and Merino (2007) Knowledge and ability to generate it by the people, they are useful for the mission of the organization. Furthermore, according Ribeiro et al (2005) would be shared meaning systems (corporate culture). With regard to corporate culture, it should be noted that there are many theories and many contributions by the authors. Point out here for Hofstade and Hofstade (2005) who mentioned that the factors that are part of or included directly in the organizational culture (and can be applied to organizations in tourism) are those mentioned below:
 - Organizational culture is broad, it is global, that is, is holistic..
 - Organizational culture is heavily influenced by history.
 - Organizational culture is also related disciplines, eg anthropology.
 - Organizational culture is socially constructed, so that is in some way a product of the society in which the concrete is immersed Tourism Organisation.
 - Organizational culture is, to some extent, difficult to change, it is difficult to transform.

Figure 1. Aspects of Social Capital.

Meanwhile, Putnam (2000) believes that social capital are the features of social organizations, and this has a special role as trust, norms and networks that can improve the efficiency of society by establishing the possibility of perform coordinated actions of character.

4 The management of knowledge in a tourist organization

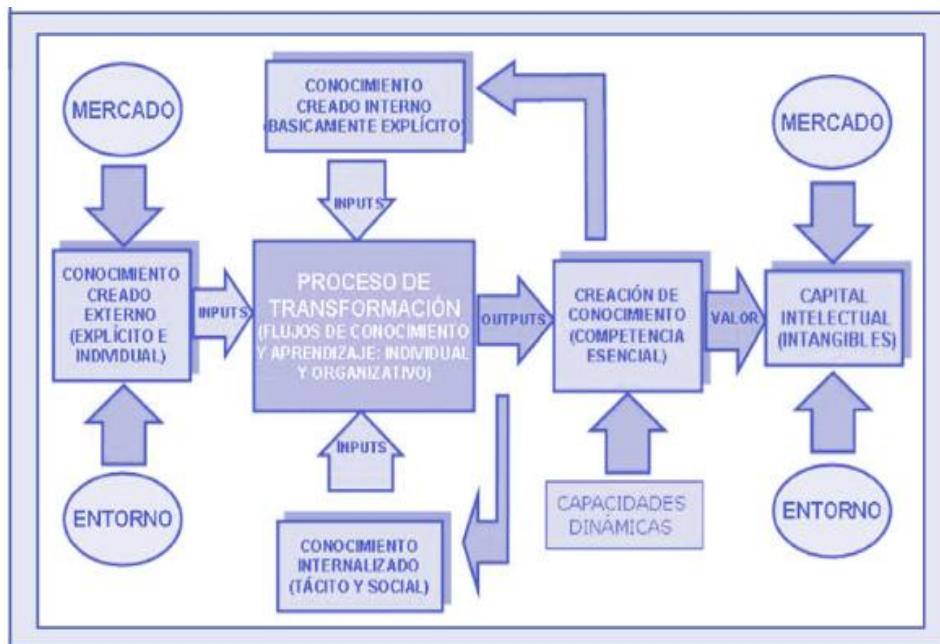

The management of knowledge can be effectively applied to all branches of the economy, economic activity, and how could it be otherwise also organizations in tourism. This is because organizations especially in tourism and hotels are immersed in an environment increasingly changing.

The management of knowledge is responsible for effectively take advantage of using the knowledge gained by the organizations (in our case analysis tourism businesses such as hotels). This knowledge is a valuable raw material, hotels and tourism in general organizations can use to your advantage to increase efficiency and profitability. They can use it, in short, to attract more customers or to retain customers who already have.

It is therefore absolutely necessary to sharpen and enhance organizational learning, where it has a special role technology and a specifically peculiar way the New Technologies of Information and Communication. In fact, the world of hotels in the XXI century could be understood but a detailed study of the impact is, for example, Internet.

To retain customers, hotels and tourist organizations usually need to know thoroughly what the tastes of the customers are, with the aim to propose a business strategy. So, offer a quality service, which will allow the customer loyalty and have, ultimately, more market presence.

Bueno (2003) presents "The Knowledge Creating System" which includes the new creation system based on knowledge value and represents a "knowledge factory". Overall, the entries are the kinds of knowledge absorbed in the company or the market, then there is a transformation of external and internal knowledge of the organization; Finally, where the outputs are the result from the creation of new knowledge is exhibited in figure 2.

Figure 2. Creating Knowledge System.

5 Empirical analysis

As mentioned above, due to the changing environment faced by organizations character from recent years, especially in technological achievement, they must be guided according to organizational knowledge management to achieve significant product innovation processes and services; so that their organizational structures make changes in their thanks to the knowledge they get from their customers asking for some innovations and business needs. Also, due to the economic crisis facing the tourism sector Racing obtain high occupancy rates high without lowering its cost, so the only tool you have is to

offer great customer service from obtaining knowledge about their tastes, needs and preferences (Journal of Research in Innovation Management and Technology 2008).

These changes have affected you from the point to the more general in the tourism industry, primarily in hotels. This can easily be seen to remember that since the act of opening the hotel room, such as finding hotel have changed radically. Currently, for these activities are used magnetic cards to open room, used the GPS to get to the hotel, among other things; this thanks to the New Technologies of Information and Communication (Rodríguez 2011).

However, it was also notable that some of these emerging changes have not been supported by certain changes in the organizational structure of the companies, and this can create a weak foundation in your organization. So to achieve these become more competitive with the requirements of the sector, should enjoy flexible organizational structures.

A series of studies on the new organizational structures focused on the tourist sector, were adopted as a measure to prevent the above (Bueno, Salmador y Rodríguez, 2004; Bueno, y Salmador 2006 y 2008; Bueno y Merino 2007; Bueno, Salmador y Reyes 2011).

The key to creating a new organizational structure in the tourism sector is to consider an analysis of the value chain and the same customer and the benefits that businesses can get from their customers (Rodríguez 2011).

Analysis of the value chain, consider the activities that makes a company but may be made by others that are more efficient when done by and in turn reduce costs and variables. Also, take into account the activities that can be performed by a self-service by customers thanks to new technologies, and thus rid the company of the same.

In terms of learning and knowledge management, organizations need to perceive and understand the needs and customer relationships. In this way, this would contribute significantly to the company because now the competition is huge, thus increasing the offer of hospitality services and products such as low demand due to the crisis. Therefore, according to Bueno and Merino (2007) in a complex society and knowledge-based economy, innovation is your goal and challenge, and for that we must know and learning to do and also know how to manage intangible and knowledge that generates them. Figure 3 shows most clearly.

Figure 3. Competitive Strategies.

Knowledge can be obtained through opinion polls aimed at customers or based on an analysis of the history of the extras hired by clients which reflect the tastes and preferences of both the same generic type or medium. Moreover, knowledge can also be obtained through a process of learning specific tastes, needs and preferences of customers as they return to enjoy the amenities (Rodríguez, J. 2011).

In relation to sustainable development in tourism organizations, sustainable management practices can be applied in any field of tourism. According to the World Organization Turimo (OMT) the sustainability encompasses the basics of tourism development: environmental, economic and sociocultural.

1. Environmental Resources: You must give optimum use so that conserve natural resources and biodiversity.
2. Economic activities should ensure viable economic activities in the long term as well distributed which stable employment opportunities and income benefits and social services are obtained for host communities.
3. Sociocultural Authenticity: must maintain cultural assets and traditional values.

Source: prepared.

Figure 4. Sustainable Development.

Parrish (2010) discusses research on organizational design necessary for sustainability-driven entrepreneurs to succeed in a competitive market context. This, because it is expected that more entrepreneurship contributes to sustainable development as a general purpose social.

Thus, the new organizational structure demonstrates its importance, given the nature and character of the business model and its relationship to the performance setting of this industry and its companies. The following table summarizes generally the objectives and expected results.

Table 1. Objectives and expected results.

Expected goals	Dissemination of information and tacit knowledge
	Collective learning
	Competitive advantages
	Trust, cooperation and solidarity
Expected Results	Innovation
	Sustainable development
	Improved productivity levels
	Cost reduction and economic growth

Source: Prepared

As already noted, tourist organizations operate in changing environments and have to constantly adapt to change. Therefore, Leon, R. (2011) establishes the importance of an early warning system in the process of developing a strategy at a time of uncertainty.

Here is to briefly reflect a structural example of a tourism organization. Some authors, for example, Rodríguez Antón et al (2000) that said the tourism organizations can adopt a hipertrébol structure, which is the result of a combination of the latest innovations in organizational structures that are concerned, ie the hypertext structure (Nonaka and Takeuchi, 1995) and cloverleaf structure (Handy, 1995). Thus, the structure combines both hipertrébol character organizational structures, but is more advantageous. Thus, in the tourism sector in addition to obtaining customer knowledge, considers knowledge of employees to achieve an interaction between their bodies, and in turn filling sustainable development to preserve all the natural, social and intellectual aspects of tourism development.

In this regard, note that a business system (and, therefore, also a system of business tourism) is flexible in nature, as the figure shows forth below:

Source: Rodríguez (2011)

Figure 5. Organizational Structure Hipertrébol

In relation to the structures of hypertext nature, and again according to Rodríguez A., Rodríguez P. Morcillo and Casani (2010) are designed or planned taking into account the importance of the project teams, in order that companies (in our if tourist organizations) have the ability to constantly adapt to change and especially to the specific needs and variables of different types of customers.

6 Conclusions

Analysis of the concept and role models and intellectual capital management processes were observed known knowledge, that in order to make manifest an analysis model and address the basic variables or intangible assets that make up the main elements the social capital of the organization, if the corporate social responsibility and commitment to the ecosystem or relations with the social partners in response to how to take responsibility for protecting the environment in which the company competes.

An exploratory analysis in the tourism sector and in hotel tourism companies that compose it, as evidence of the importance of the new management approach considered, given the need to adapt to the new demands of technological innovations in products and services by was performed customers as of the same companies.

The hipertrébol structure was exposed Nonaka et al. As a case or empirical approach to knowledge management for sustainability of organizations or tourism enterprises.

In general, it is beneficial for the tourism industry to adapt to these new series of studies on the new organizational structures of companies created but obviously focusing on the tourism sector. Therefore, it is useful to design procedures that automatically increase the transmission of knowledge in order to create a solid foundation to contribute to business performance strengthen the quality of its services and products to turn your customers fidelicen. Finally, it was observed that social capital greatly favors the tourism industry mainly in its skill base value in the form of innovation; all this in the context of sustainable development in the sector, where there is a relationship between the tourist and the community with equanimity benefits for both

Structured Abstract

Purpose – The purpose of this paper is to present a new paradigm for knowledge structure and understanding, based on *the triple helix* metaphor. This new perspective departs from *the known-unknown* paradigm based on *the iceberg* metaphor of explicit and tacit knowledge. Also, we would like to demonstrate the power of the new paradigm in promoting organization sustainable development.

Design/methodology/approach – My approach is based on a metaphorical analysis of the knowledge concept, and on a theoretical construct based on a new perspective. Cognitive science demonstrated that our thinking and understanding of the real world is based on conceptual metaphors. Knowledge has no referent in the real world and requires metaphors to be conceptualized, defined and used. Today, the most frequently used metaphors are the following: *knowledge as a resource*, *knowledge as flow*, and *knowledge as an iceberg*. These metaphors are based on rational knowledge and Newtonian thinking. The new paradigm is based on the metaphor *knowledge as energy*, and on thermodynamics.

Originality/value – This new paradigm is much more powerful than the previous ones since it allows transformations of different forms of knowledge into other forms of knowledge in an interactive way. The construct of the triple helix of knowledge is not just an extension of the iceberg model but it represents a completely new vision. The new paradigm has got an increased practical value since it correlates better with the knowledge management and leadership, and as a consequence, with the sustainable development of organizations.

Practical implications – Since *the known-unknown* paradigm focuses on rational knowledge, it is best suited for managers in their decision making. Leadership implies not only rational knowledge but also emotional knowledge and spiritual knowledge, and thus it correlates much better with the new construct of *the triple helix* than *the iceberg* model. Also, organizational culture is based mostly on emotional and spiritual knowledge and its role in promoting sustainability can be better understood by using the new model of the triple helix of knowledge.

Keywords – Knowledge metaphors, Explicit knowledge, Tacit knowledge, Emotional knowledge, Spiritual knowledge.

Paper type – Academic Research Paper

1 Introduction

Lakoff and Johnson (1999) demonstrate that human mind is intrinsically metaphorical, based on the recent findings of cognitive sciences that can be summarized as follows: a) the mind is inherently embodied; b) thought is mostly unconscious; c) abstract concepts are largely metaphorical. “The fact that abstract thought is mostly metaphorical means that answers to philosophical questions have always been, and always will be, mostly metaphorical. In itself, that is neither good nor bad. It is simply a fact about the capacities of human mind” (Lakoff and Johnson, 1999, p.7). Thus, metaphors use human experience and our mind imagination in explaining the reality that is our environment. “They guide our perceptions and interpretations of reality and help formulate our visions and goals. In doing these things, metaphors facilitate and further our understanding of the world” (Cornelissen et al., 2008, p.8). Applying this assertions to the concept of knowledge Andriessen (2008; 2011) showed that *knowledge* is an abstract concept whose structure and meaning depend on the metaphor used in explaining it. Since there is a practical infinite spectrum of potential metaphors we can use for knowledge, we may understand the large variety of interpretations for this concept. People coming from different fields of activity, with different individual experience and theoretical background try to explain knowledge from their own perspective.

The purpose of this paper is to present a dynamic perspective on knowledge based on a new metaphor – knowledge as energy, and on a new theoretical background – thermodynamics. In the next section I will present some of the most used metaphors in explaining the concept of knowledge, i.e. *knowledge as a resource*, *knowledge as flow*, and *knowledge as an iceberg*. Then, I will present the attributes of the new metaphor, *knowledge as energy*. Based on this latter metaphor I will introduce the concept of multifield structure of the organizational knowledge, and the concept of triple helix of knowledge. Finally, I will show how the new perspective on knowledge enhances the contribution of knowledge management to the development of a sustainable firm.

2 Knowledge metaphors

The relevance of knowledge metaphors comes from our interpretation of knowledge, organizational knowledge, and knowledge management. “The fact that we can only reason about knowledge through metaphors is not a bad thing (or a good thing), it is inescapable; that’s how the human mind works” (Andriessen, 2008, p.5). A simple

metaphor is composed of two semantic domains that are partially overlapped. The *source domain* contains the known concept and its attributes, while the *target domain* contains the less known concept and its attributes. The intersection of these semantic domains represents the common attributes the metaphor highlights and transfers from the source domain to the target domain. Not all attributes from the source domain can be transferred to the target domain, and not all attributes from the target domain can be found in the source domain. However, constructing and using a metaphor is rather fuzzy since it is up to the user to decide how much of the source domain can be transferred to the target domain, and to draw the semantic interface between the two domains (Lakoff and Johnson, 1980; Andriessen, 2006; Andriessen, 2008; Andriessen and Van den Boom, 2007; Gentner et al., 2001).

2.1 Knowledge as a resource

This is the most frequently used metaphor, since it is a direct extension of managerial experience and understanding of the organizational assets. Knowledge is considered a physical resource, with some of the attributes of physical objects. Some examples from literature will illustrate this metaphor. For ease of interpretation I will emphasize the knowledge metaphors by using italics.

“A somewhat less structured form of *accumulated knowledge* is the discussion database, in which participants record their own experience on an issue and react to others’ comments” (Davenport and Prusak, 2000, p.146).

“The realization that *knowledge* is the new *competitive resource* has hit the West like lightning” (Nonaka and Takeuchi, 1995, p.7).

“Codification can be defined as a process of *storage, indexation and distribution of formal knowledge* independently of any context” (Janicot and Mignon, 2012, p.6).

“Just as food and manufactured goods can be packaged and sold, there are ways *to package knowledge* for commercial benefit, using the intellectual property laws” (Sullivan, 1998, p.143).

It is evident that managerial thinking assigns to *knowledge* attributes transferred from the physical resources. Thus, knowledge can be *accumulated, stocked, stored, distributed* and *packaged*, although knowledge has no physical attributes. Knowledge is an intangible resource, yet it is considered like being tangible and separated from the knowledge worker (Bolisani et al., 2012). Unfortunately, in many practical situations managers with

less theoretical understanding of the metaphorical thinking extend towards the knowledge domain the attributes of tangibility and linearity, reflecting this way an extension of the Newtonian logic.

2.2 Knowledge as flow

There are two metaphors closely related: *knowledge as a fluid* and *knowledge as flow*. Both of them reflect a Newtonian logic applied to fluid flows. Objects are static and have fixed geometries, while fluids that flow are dynamic and have changeable geometries. Fluids can be accumulated and stored in reservoirs, and then they can be distributed through channels or piping systems. The most important attribute that is transferred to knowledge is the fact that fluids flow naturally downward, from a higher altitude toward a lower altitude. They may flow upward through pipes, but only as a result of some mechanical work done by pumps. These attributes of *fluid flows* have been transferred to *knowledge*, as we can see in the following examples from literature. I emphasized the metaphors through italics.

“This idea, describing the movement of knowledge from tacit to explicit, begins to depict *knowledge as a fluid* and dynamic realm” (Allee, 1997, p.45).

“For this free *flow of knowledge* to prevail, the organizational culture must be extraordinary” (Davenport and Prusak, 2000, 109).

“By addressing *the knowledge flow* process at this point, you can assess where the *flow of knowledge* is breaking down. People who don’t know anything about KM suddenly get it when they see how *knowledge should flow*” (O’Dell and Hubert, 2011, p.31).

The mechanical model of fluid flows have inspired many authors in explaining the concept of knowledge and how organizational knowledge actually works. For instance, Nissen (2006, p.XX) conceives knowledge as a fluid flowing through an organizational piping system: “To the extent that organizational knowledge does not exist in the form needed for application or at the place and time required to enable work performance, then *it must flow* from how it exists and where it is located to how and where it is needed. This is the concept *knowledge flows*”. There are at least two important differences between the metaphors *knowledge as a resource* and *knowledge as flow*:

- a) In the first metaphor the source domain is composed of discrete objects that are with given and fixed geometries. In the second metaphor, the source domain contains a fluid that represents a continuum with a changing geometry.
- b) In the first metaphor the source domain is static. In the second metaphor the source domain is dynamic, an important attribute that is transferred to the target domain where knowledge is defined.

2.3 Knowledge as an iceberg

The dyad of tacit knowledge-explicit knowledge developed mostly by Nonaka (1991; 1994), and Nonaka and Takeuchi (1995) shows that knowledge is not like a homogeneous object or flow. Knowledge is composed of two parts: a visible part reflecting the explicit knowledge and a hidden part reflecting the tacit knowledge. This conception comes from *the knowledge as an iceberg* metaphor. Explicit knowledge is represented by the part that is above the water and can be seen. Tacit knowledge is represented by the iceberg part that is under the water and it cannot be seen by an observer that is not in the water. As explained by Nonaka and Takeuchi (1995, p.8), “Tacit knowledge is highly personal and hard to formalize, making it difficult to communicate or to share with others. Subjective insights, intuitions, and hunches fall into this category of knowledge. Furthermore, tacit knowledge is deeply rooted in an individual’s action and experience, as well as in the ideals, values, or emotions he or she embraces”. Explicit knowledge is the rational knowledge people can communicate and share with others based on a certain language and culture. Explicit knowledge can be codified, stored in knowledge bases, retrieved, transferred, and disseminated through different communication channels.

The iceberg metaphor could be also an excellent visual representation of the *known-unknown* paradigm. The *known* component is represented by explicit knowledge since that is the knowledge an individual is aware of, while the *unknown* component is represented by the tacit knowledge. The unknown knowledge is larger than the known knowledge, like the two parts of the iceberg separated visually for an external observer by the water surface. However, the iceberg is just a huge physical object, without any inner dynamics or transformations. That means that explicit knowledge cannot transform itself into tacit knowledge or vice versa as the Nonaka model of knowledge creation shows (Nonaka and Takeuchi, 1995).

2.4 Knowledge as energy

Both previous metaphors were based on the Newtonian logic and linearity. However, knowledge is intangible and nonlinear. This new metaphor was proposed by Bratianu and Andriessen (2008), and further developed by Bratianu (2011). This metaphor contains *energy* in the source domain and *knowledge* in the target domain. Energy has totally different attributes than objects. First, energy is a field that means a non-substantial and continuous entity. Such a field cannot be seen and cannot be touched, which means that it is intangible. Also, the energy field is nonlinear and non-homogeneous. Second, energy manifests in several forms that have the property of transforming one form into another. For instance, mechanical energy can be transformed into heat, and vice versa. These transformations are based on thermodynamics principles, and not anymore on the Newtonian logic. However, we have to emphasize the fact that thermodynamic principles state that energy cannot be created and cannot be destroyed. It can be only transformed from one form into another one based on the conservation laws. This attribute of energy will not be transferred to the knowledge domain since knowledge can be created, can be destroyed, and does not remain constant with respect to any transformation. The metaphor *knowledge as energy* is a complex metaphor, composed of the following four metaphors:

Metaphor 1: *Knowledge as energy*.

Metaphor 2: *Cognitive knowledge as mechanical energy*.

Metaphor 3: *Emotional knowledge as thermal energy*.

Metaphor 4: *Knowledge dynamics as energy thermodynamics*

I will explain each of these above metaphors in the followings.

Metaphor 1: Knowledge as energy. The source domain contains energy that is not anymore an object. Energy is a *field*, that means a non-substantial, nonuniform, and nonlinear entity spread as a continuum in space. This attribute of being a field is very important since it is not anymore related to tangible things. Just think at the gravity field. We cannot see and cannot touch the gravity field, yet we feel it any time we jump. In conclusion, the main entailment from the source domain is *the field* characteristic of knowledge.

Metaphor 2: Cognitive knowledge as mechanical energy. The source domain contains mechanical energy, and the target domain contains cognitive knowledge. Mechanical energy contains both potential energy and kinetic energy, and cognitive knowledge contains both tacit and explicit knowledge. The dynamics between potential

energy and kinetic energy from the source domain can be mapped upon the target domain, where we have tacit knowledge and explicit knowledge.

Metaphor 3: Emotional knowledge as thermal energy. This is a new element of the knowledge metaphor that changes the functional paradigm from dynamics to thermodynamics. That is because thermal energy has different properties than mechanical energy. It is a different form of energy. While mechanical energy is ruled by the Newtonian logic, thermal energy is ruled by the thermodynamics principles. Mechanical energy has only one dimension, while thermal energy has two dimensions: an *extensive* one that is a quantitative property, and an *intensive* one that is a qualitative property. To measure the intensity of a thermal field we define *the temperature* as the main property, and use thermometers as measuring instruments. *Emotional knowledge* is a new form of knowledge that is different than the cognitive knowledge. I will discuss about emotional knowledge in the next section of this paper.

Metaphor 4: Knowledge dynamics as energy thermodynamics. This is the most difficult metaphor to explain since it requires a very good understanding of thermodynamics. The main idea is that in the source domain we have the transformation of mechanical energy into thermal energy, according to thermodynamics principles. That means that we can map this characteristic from the source domain upon the target domain, and admit that cognitive knowledge can be transformed into emotional knowledge and vice versa. This constitutes a very important idea that differentiates this metaphor from all the other metaphors that have been used in knowledge management so far. We will discuss more about the practical implications of this metaphor in the next section of the present paper.

3 The triple helix of knowledge

3.1 Fields of knowledge

The most important entailment transferred to the target domain in the metaphor *knowledge as energy* is the attribute of *field*. Energy is a field, and thus knowledge can be conceived as a field. When we analyze and map all the knowledge from an organization, we may distinguish between different fields of knowledge.

Introducing a new metaphor for knowledge based on analogy with energy, Bratianu and Andriessen (2008) changed the explicit knowledge-tacit knowledge dyad into the

cognitive knowledge-emotional knowledge dyad. Furthermore, this dyad can be transformed into a triad composed of *cognitive knowledge*, *emotional knowledge*, and *spiritual knowledge*. Thus, organizational knowledge may be conceived as being composed of three fields of knowledge: *the field of cognitive knowledge*, *the field of emotional knowledge*, and *the field of spiritual knowledge*. These fields are non-substantial, nonlinear, nonuniform, and have the property of transforming from one form into another form of organizational knowledge in a certain context. That means that any organization has a multifield structure of knowledge (Bratianu and Orzea, 2013a). This multifield structure is a helix composed of cognitive, emotional and spiritual fields of knowledge that are in a continuous interaction and transformation. Thus, we can discuss about a triple helix of knowledge.

3.2 *The field of cognitive knowledge*

Cognitive knowledge is “the most important component of the organizational knowledge since it represents all the explicit knowledge from employees and the embodied knowledge in the organizational documents, processes and intellectual property. It is the knowledge that fuels the managerial decision making process, and the knowledge used for data bases creation“ (Bratianu, 2013, pp.214-215). Many philosophers considered that it is the only form of knowledge we have, and that is fully rational knowledge. We may recall the Cartesian expression *Cogito ergo sum!* that made history. Rational knowledge became the source of all scientific knowledge and technology development. European education has been developed on this objective and scientific knowledge. Even today many university courses and textbooks base decision theory on mathematics and logic, which means rational knowledge. Cognitive knowledge has been also heavily supported by experts coming from information theory and information technology since they operate with data and information that is grounded in the rational mind.

Aristotle is one of the firsts philosophers that made a difference between rational knowledge (*episteme*), operational knowledge or know-how knowledge (*techne*), and process knowledge or know-why knowledge (*phronesis*). “The concept of *phronesis* is generally understood as the ability to determine and undertake the best action in a specific situation to serve the common good.... It goes beyond analytical, scientific knowledge (*episteme*) and technical knowledge or know-how (*techne*) and invites judgments and

decisions made in the manner of a virtuoso social actor” (Nonaka, Toyama and Hirata, 2008, p.14). Ryle in his seminal book *The concept of mind* published in 1949 made a clear distinction between knowing *how* and knowing *that*. Knowing *how* is related to learning by doing and getting experience, which quite different than rational thinking. Polanyi extended the concept of knowing how to *tacit knowing*: “My search has led me to a novel idea of human knowledge from which a harmonious view of thought and existence, rooted in the universe, seems to emerge. I shall reconsider human knowledge by starting from the fact that we can know more than we can tell” (Polanyi, 1983, p.4).

A dominant theory in knowledge management developed mainly by Nonaka (1991; 1994), Nonaka and Takeuchi (1995), and Nonaka, Toyama and Hirata (2008), based on findings of Ryle and Polanyi, is that of the knowledge dyad composed of tacit knowledge and explicit knowledge.

Thus, cognitive knowledge contains both rational knowledge as explicit knowledge and tacit knowledge. For this dyad the most suited metaphor is that of *an iceberg*, as previously discussed.

3.3 The field of emotional knowledge

Unlike the European tradition based on the Cartesian dualism of body and mind, the Japanese tradition is based on the theory of oneness of body and mind. “For the Japanese, knowledge means wisdom that is acquired from the perspective of the entire personality. This orientation has provided a basis for valuing personal and physical experience over indirect, intellectual abstraction” (Nonaka and Takeuchi, 1995, p.29). That means that emotions and feelings carry with them a specific type of knowledge we may call *emotional knowledge*. In the Nonaka theory, emotional knowledge is a part of tacit knowledge without any individualization. However, cognitive science demonstrated that emotional knowledge is an important component of our knowledge structure, and that it plays an essential role in making decisions (Damasio, 1999; Damasio, 2003; Damasio, 2012; Goleman, 1995; Goleman, 1998; Hill, 2008; Kahneman, 2011; LeDoux, 1999).

Kahneman (2011) states that our mind works with two thinking systems: System 1 – is a fast body reaction system, which has been developed during human being history for survival; System 2 – is a slow thinking system based on rationality. The first system represents an emotional processing of all incoming sensorial signals, through emotions and feelings. Being very fast, this system has an important impact on the decision making.

As Hill (2008, p.2) remarks, “Breakthroughs in science have revealed that people are primarily emotional decision makers”.

Damasio (1999) explains the biological support of emotions and feelings and their relation to our conscious mind. “For the purpose of investigating these phenomena, I separate three stages of processing along a continuum: *a state of emotion*, which can be triggered and executed nonconsciously; *a state of feeling*, which can be represented nonconsciously; and *a state of feeling* made conscious, i.e., known to the organism having both emotion and feeling” (Damasio, 1999, p.37). All of these states carry with them emotional messages towards the brain and the nervous system, that are processed by the emotional intelligence to find adequate solutions to environmental problems. Emotions are processed and remain within the nonconscious zone of our brain, but they manifest themselves in the body state and our facial expressions. The primary emotional states are the following (Hill, 2008, p.84): happiness, surprise, anger, fear, sadness, disgust. It is interesting to note the fact that there is only one positive emotion – happiness, and only one neutral emotion – surprise. All the others – anger, fear, sadness and disgust are negative emotions. Also, it is interesting to see how emotional states of happiness, anger and sadness influence our decision making and risk evaluation: “The difference between these three emotions, however, is that when we’re happy we tend to take a risk even if the reward is low. With *fear*, the risk is considered low because danger already exists. With *sadness* we feel like we’ve got nothing to lose” (Hill, 2008, p.85).

Emotional intelligence represents the class of *intrapersonal* and *interpersonal* intelligences in the multiple intelligences framework developed by Gardner (2006). In this framework, Gardner defines *an intelligence* as “a biopsychological potential to process specific forms of information in certain kinds of ways. Human beings have evolved diverse information-processing capacities – I term these ‘intelligences’ – that allow them to solve problems or to fashion products” (Gardner, 2006, p.29). In other words, rational knowledge is processed by linguistic and mathematical intelligences, while emotional knowledge is processed by emotional intelligence. This idea is very well expressed in the definition of *emotional intelligence* by Mayer, Salovey and Caruso (2004, p.197) as being “the capacity to reason about emotions, and of emotions to enhance thinking. It includes the abilities to accurately perceive emotions, to access and generate emotions so as to assist thought, to understand emotions and emotional

knowledge, and to reflectively regulate emotions so as to promote emotional and intellectual growth”.

3.4 The field of spiritual knowledge

Spiritual knowledge, spiritual intelligence, and spiritual intellectual capital are some new concepts researchers started to promote in the space of organizational dynamics and managerial thinking (Branson, 2011; De Geus, 1999; Zohar and Marshall, 2000; Zohar and Marshall, 2004). This type of knowledge has been integrated by Nonaka in his model of tacit knowledge, but without any identification characteristics. However, its importance for decision making and companies growth and learning makes it necessary to consider spiritual knowledge as a stand-alone knowledge field, and to consider it a third component of the triple helix of knowledge.

Spiritual knowledge is an important component of the spiritual capital of any organization. As Zohar and Marshal stated, “Our spiritual capital is our shared meaning, our shared purpose, our shared vision of what most deeply matters in life – and how these are implemented in our lives and in our behavioural strategies. It is the capital that is increased by drawing on the resources of human spirit” (Zohar and Marshal, 2004, p.27).

Spiritual knowledge represents the content of the vision and mission of any company, and employee aspirations and their social responsibility for their doing. International statistics show that many companies die before their 50th anniversary since their top management focuses only on the profit maximization and economic objectives. Profit should not be the purpose of any business, but a necessary limiting condition of its development. The purpose of any business should be to create value for society, and wellbeing for employees. According to Aries de Geus (1999, p.9), “corporations fail because the prevailing thinking and language of management are too narrowly based on the prevailing thinking and language of economics. To put it another way: companies die because their managers focus on the economic activity of producing goods and services, and they forget that their organization’s true nature is that of a community of humans”.

4 The triple helix of knowledge and sustainability

The triple helix is formed of cognitive knowledge, emotional knowledge and spiritual knowledge. Each form of knowledge can be transformed into another form of knowledge, similar to the thermodynamic transformation of one form of energy into another form of

energy. Spiritual knowledge contains shared values and beliefs, and a sense of meaning of the whole organization. It is knowledge about *what I am*, and *what my organization is*. It is about the existential purpose of any organization, and the role played by people in creating a future. Spiritual knowledge is processed by spiritual intelligence and the process yields spiritual capital. According to Zohar and Marshal (2004, p.4), “Spiritual intelligence’s sense of meaning, values, and purpose generates spiritual capital. Spiritual capital’s wealth of meaning, values, and higher motivation are necessary to sustainable capitalism and a sustainable society”.

Sustainability is based on strategic thinking (Bratianu, 2007) and a system of organizational values that drives the decision making process. The dynamics of the triple helix of knowledge oriented on the long term thinking by the organizational values is one of the main requirements for developing organizational learning, and finally of a learning organization (Örtenblad, 2011; Senge, 1999). For Senge (1999, p.14). The fundamental meaning of a learning organization is “an organization that is continually expanding its capacity to create its future”. That means to go beyond the *adaptive learning* and to develop a *generative learning process* that enhances the capacity of organization to renew its intellectual capital (Bratianu and Orzea, 2013b). By developing this dynamic capability, such an organization becomes a *sustainable organization*.

5 Conclusions

The purpose of this paper is to present a new paradigm of understanding knowledge – the triple helix of knowledge that is based on the metaphor *knowledge as energy* and on thermodynamics principles. The triple helix is a dynamic construct composed of three fields of knowledge: cognitive knowledge field, emotional knowledge field, and spiritual knowledge field. Cognitive knowledge field contains basically rational knowledge that represents the most important component today in managerial decision making. Emotional knowledge field contains knowledge generated by emotions and feelings, and becomes important in leadership and in organizational culture. Spiritual knowledge field contains knowledge about our existence and organization vision, mission and values.

The triple helix of knowledge is important not only because of its constituents, but also because there is an internal dynamics based on thermodynamics: each form of knowledge can be transformed into another form of knowledge. Due to these transformations the organizational entropy is increased and learning and innovation are stimulated. Learning

and innovations are two driving processes for intellectual capital renewal, which contributes directly to the firm's sustainability. Thus, the new perspective on knowledge can be related directly to the process of sustainability.

Structured Abstract

Purpose – In this paper, we are interested in the knowledge that is “wasted” in organizations, that is existing relevant knowledge that is overlooked in the process of knowledge conversion. Given the competitive pressure firms are facing in today’s business environment, a waste of knowledge is not only costly but also dangerous. This means that we consider knowledge from a knowledge at risk perspective. Having this in mind, the purpose of this paper is to review research on knowledge waste in organizations to establish our current body of knowledge regarding this topic.

Design/methodology/approach– The study consists of a systematic review of 77 peer-reviewed articles addressing knowledge waste in organizations.

Originality/value – To the best of the authors’ knowledge, no systematic literature review on this topic has previously been published or presented.

Practical implications– The topic seems to be a promising field for intensive research and offers a variety of future research avenues. In view of practitioners, the study’s finding may enable an increased awareness towards the areas where existing knowledge is at the mercy of “waste”. This can assist practitioners to better cope with risks related to this waste and, therefore, better exploit the (limited) knowledge base available.

Keywords – Knowledge waste, Intangible assets, Knowledge management, Systematic review, Knowledge loss

Paper type – Academic Research Paper

1 Introduction

Among the different knowledge management activities (e.g. knowledge identification, knowledge creation, knowledge dissemination etc.), it seems that knowledge creation is viewed as more important than the other activities. Markus (2001), however, stresses (she talks about reuse) that the effective reuse of knowledge should take a stronger role, as it is clearly associated with organizational effectiveness. In the same vein, researchers have highlighted the link between the reuse of knowledge and developing competitive advantage (Szulanski, 1996). Consequently, one can assert that a strong consideration of existing knowledge can help firms to improve performance and thus sustain competitive advantage. Having this in mind, in this paper we will focus on knowledge that is not used. More precisely, we are interested in the knowledge that is “wasted” in organizations, that is existing relevant knowledge that is overlooked in the process of knowledge conversion (Ferenhof, 2011). Given the competitive pressure firms are facing in today’s business environment, a waste of knowledge is not only costly (Bolisani et al., 2013) but also dangerous. As initiatives, which are, after all, repeating already existing knowledge instead of creating new knowledge or recombining it in new ways, can result in situations in which valuable resources and time are bound and thus not available to other more important business operations. Consequently, this may be damaging not only for the company concerned but also for the economy, as continuously reinventing the wheel blocks from developing. In sum we look at knowledge from a knowledge at risk perspective, i.e. addressing situations in which knowledge that is not used becomes a liability or a risk (Durst, 2012). Against this background, the purpose of this paper is to review research on knowledge waste in organizations to establish our current body of knowledge regarding this topic.

2 Theoretical background

The relevance of knowledge assets as fundamental strategic factors of business success has been widely recognized (Barney, 1991; Drucker, 1993; Grant, 1991). In fact, more and more organizations attribute their competitiveness to their knowledge assets and specifically their exploitation, and consider knowledge as their distinguishing feature

(Nonaka and Takeuchi, 1995). In such a situation, a suitable management of knowledge assets has become a strategic role for company success.

According to Wiig (1993), knowledge management consists of seven activities: 1) creation, 2) sourcing, 3) compilation, 4) transformation, 5) dissemination, 6) application and, 7) value realization. Thereby, many studies have described ways of converting knowledge into value for organizations. One of them is the SECI model proposed by Nonaka and Takeuchi (1997) that involves four main activities: externalization, socialization, combination and internalization. The aim of this model is to extract the tacit knowledge from the people, converts it into explicit knowledge, archive it in the company, then make other people learn it, internalize it, so that it becomes tacit again. This sounds simple in theory, but in practice these processes are not that straightforward. Indeed these processes are accompanied by mistakes and disruptions, so instead of taking advantage of the knowledge available it is “wasted”.

In order to improve this situation, particularly the activities of sourcing, compilation and application, many frameworks and models have proposed to use ontologies to address this issue. For example, Lee *et al.* (2006) state that ontology in conjunction with Semantic Web Technologies may help represent and share various types of engineering change-related knowledge in specific contexts. On the other hand, Sherimon *et al.* (2012) highlight that ontologies have the potential for enabling true knowledge sharing and reuse among heterogeneous agents, both human and computer. Picking up this idea, Zhang *et al.* (2012) suggest the use of ontology for modeling Product Service System (PSS) in order to perfect prototyping for design knowledge management and knowledge reuse, and to integrate more methods which are suitable for designers, such as the roadmap.

Others authors (e.g. Aubry *et al.*, 2011; Buttler and Lukosch, 2013; Komi-Sirviö *et al.*, 2002) applied the idea of lessons learned (LL) to deal with the issue. LL can be defined as documented knowledge gained from experience, successful or otherwise, for the purpose of improving future performance (Buttler and Lukosch, 2013). Komi-Sirviö *et al.* (2002) support the creation and maintenance of a LL database as an effective means to store and share knowledge in the organization. Aubry *et al.* (2011) confirmed that LL-related activities are a good means to transfer knowledge. In project-based organizations (PBOs), for example, the individuals collect and use LL in order to prevent reinvention of the wheel or repetition of mistakes (Aubry *et al.*, 2011; Buttler and Lukosch, 2013). Knowledge reuse is applied for knowledge sourcing, compilation and dissemination. It

focuses on the ability to locate and use knowledge previously generated (Watson and Hewett, 2006; Wee and Chua, 2013; Zhang *et al.*, 2013).

Consequently, different actions have been created to manage knowledge in a better way, but those actions could be improved (i.e. being more effective) if one would focus on the wastes of knowledge that occur during the life cycle of knowledge management (KM) as presented by Wiig (1993).

2.1 Knowledge Waste

According to Ferenhof (2011) knowledge waste can be described as any failure in the process of knowledge conversion, better known as spiral of knowledge creation of Nonaka and Takeuchi (1997). Thereby Ferenhof proposes that the waste can present itself in different ways: reinvention, lack of system discipline, underutilized people, scatter, hand-off, wishful thinking.

I) Reinvention is a type of waste that happens if the organization does not reuse the designed solutions, components, projects, experiences or knowledge acquired previously (Bauch, 2004). After project completion or expiry of maintenance contract, it is the knowledge that was not internalized and put in use, or it is simply forgotten over time. This may lead to efforts that can be equated with “reinventing the wheel” which reveals themselves as repeated projects, mistakes or recurring issues (Almarshad *et al.*, 2010). So instead of reusing good practices, supporting innovative practice, and preventing the reinvention of the wheel (Aubry *et al.*, 2011) rather likely outcomes are wasted activities and reduced project performance (Cheng, 2009; Dani *et al.*, 2006). As the effective transfer of knowledge is considered as one of the key success factors (Cheng, 2009), this knowledge reinvention must be avoided. Consequently, if an organization can succeed in reusing its knowledge assets, resources can be invested in continuous improvements of existing knowledge stocks instead of wasting them into efforts of reinvention (Fong, 2005).

II) Lack of system discipline covers a number of factors related to the clarity of objectives outlined in the organizations. More precisely it covers unclear goals and objectives; unclear rights, roles, responsibilities and rules; poor delivery dates; insufficient willingness to cooperate as well as incompetence or lack of training (Bauch, 2004).

III) Underutilized people refer to employees that are not using their skills and expertise in full. Often this is a consequence of missing roles and responsibilities given to them, when in reality, they could assume much more if the process was designed more effectively (Locher, 2008).

IV) Scatter refers to actions that make knowledge become ineffective because of flow disturbances, which is basically the disruption of interaction required for teamwork. This category can be divided into two sub-categories: communication barriers and poor tools. Communication barriers directly prevent knowledge flow occurrence. They include: a) physical barriers such as distance, computational incompatible formats, etc.; b) social barriers such as the corporate class systems and management behavior that prevent the flow of communication and knowledge, and c) skill barriers that are people who are not capable of transforming data into usable knowledge (Ward, 2007). Poor tools, on the other hand, refer to the assumption that tools should support the flow of knowledge and not stifle this flow, as users assume that these tools are the only solution. These users seek to take shortcuts, copy unsuitable operating modes, and therefore cause failures by forcing the use of tools without properly analyzing their relevance and suitability. By insisting on using these tools, processes end up in a death spiral, i.e. the more one tries to improve the processes the worse the failures (Ward, 2007). Or, to put it another way, the scattered knowledge results in knowledge leakage, and knowledge leakage results in organizational inefficiency (Hu, 2008).

One example of scatter is highlighted by Cheng (2009), who states that knowledge from one project can be separated and scattered in different phases and owned by different participants. This is imaginable in temporary virtual organizations as well as in consulting firms. Those firms normally fail to capture and transfer knowledge that is scattered on those phases and thus increases the likelihood of waste, such as "reinventing the wheel". According to Padova and Scarso (2012), large enterprises also scatter knowledge objects. For these authors, this is demonstrated by the number of documents the firms continuously create and store. It is difficult to access knowledge that is scattered across different projects, processes, trades, and people (Hu, 2008). In the same vein, Lijuan (2011) highlights that the main objective of KM implementation is to manage knowledge which is scattered throughout business activities or hidden in the minds of staff effectively.

V) Hand-off occurs when one separates knowledge, responsibility, action and feedback. It results in decisions made by people who do not have enough knowledge to make the decision effectively or do not have the opportunity to accomplish it. As subcategories we have useless information and waits can be specified (Ward, 2007). According to Ward (2007) information is useless if it does not help in understanding the customers, because the information would not add value to the flow, innovation, and improved decision-making. Instead it would actually be created to fulfill someone's own interests. Waits, on the other hand, normally occurs through the establishment of standard conventional sequencing of activities, which creates a batch processing and causes slow processes. A single path to follow, instead of multiple streams or paths of information and a large variation of work in the batch cause the waste of scatter (Ward, 2007).

VI) Wishful thinking means to follow the subject's own reasoning, based on interests, wishes rather than on facts or rationality, or decision-making is based on one's own perception of reality respectively. For Ward (2007) this means operating in the dark, blindly making decisions without consistent and backing data. This aspect can be divided into specification test and discarded knowledge. Specification test is a practical conventional pattern. It cannot highlight whether a good or service is ready for commercialization, it is statistically impossible to execute enough tests to be confident that there are zero defects (Ward, 2007). On the other hand, discarded knowledge happens for a number of reasons. For example, teams and superior focus on the product or service launch, thereby leaving aside the capture of knowledge; specification tests do not say much so the information can't be used next time and, above all, few people know how to turn the data into usable knowledge (Ward, 2007).

In conclusion, the authors of this paper believe that the (negative) consequences of knowledge waste are high. The organization is in a continued reinvention process and loses valuable financial and non-financial resources. For example, the waste of knowledge may reduce the time resources available to innovation, thus challenging firm's competitiveness (Baxter *et al.*, 2008). Another consequence could be that the firm fails to offer high quality solutions (Demian and Fruchter, 2009). Additionally, any investments in KM activities would be very difficult to justify, as one of the main reasons for disappointment regarding these investments is assigned to missing knowledge reuse (Liu *et al.*, 2013). Given the role of knowledge as the most important strategic factor for firms

(Spender 1996) such waste needs to be understood by both the academic and practitioner communities.

3 Methodology

In the review process, the authors adopted the principles of a systematic review as recommended by Jesson *et al.* (2011) namely: 1) Mapping the field through a scoping review, 2) Comprehensive search, 3) Quality assessment, 4) Data extraction, 5) Synthesis, and 6) Write up.

First, a research plan was developed comprising the research questions of interest, the keywords, and a set of inclusion and exclusion criteria. The paper's aim was to determine the current status of research on knowledge waste.

We conducted two different researches, the first one focused on understanding the definition of knowledge waste and loss that may occur in companies. The query of this research was "knowledge AND (waste OR discard OR fling OR toss OR "toss out" OR "toss away" OR "chuck out" OR "cast aside" OR "dispose" OR "throw out" OR "cast out" OR "throw away" OR "cast away" OR "put away" OR "missing" OR "squandered" OR "stray" OR "straying" OR lost OR loss OR "knowledge waste" OR "knowledge loss" OR "waste of knowledge". The second query used "knowledge management" AND (reinvention OR "lack of system discipline" OR "underutilized people" OR scatter OR hand-off OR "wishful thinking" OR "knowledge waste" OR "waste of knowledge" OR "knowledge reuse". Additionally, inclusion and exclusion criteria were specified. The inclusion criteria were: peer-reviewed academic papers, English language and the databases Compendex, Scopus and Web of Science. Grey literature such as reports, books and non-academic research; and other languages than English represented exclusion criteria. Moreover, an excel data sheet was produced consisting of key aspects related to the research aim. In the given case these were: name of author(s), year of publication, research aim/objectives, theoretical perspective/ framework, method, main findings, and name of the journal.

Second, once all relevant issues had been specified, two of the authors accessed the databases and looked for suitable articles. The first search had been carried out on June 04, 2013 and resulted in 139 hits. The second search took place on March 10, 2014 and resulted in 370 hits; resulting in total number of 509 hits.

The third step consisted of two procedures. Firstly, the authors jointly worked through the abstracts to make sure that they actually covered the pre-defined scope. This procedure yielded a final selection of 339 articles. Secondly, the 339 papers were divided among the authors. Subsequently the authors entered the relevant data regarding the research purpose in the excel sheet. Then the authors jointly went through each data entry and discussed the content. In the case of possible reservations on the part of the author who had not read the article, the authors went through the article in question. This procedure resulted in a further reduction of the number of papers. In the end, the authors reached a final selection of 77 articles, which fulfilled the criteria, set and thus represented the basis for analysis. This approach helped to alleviate the risk of any inconsistency in the analysis and the conclusion drawn from there.

Fourth, the final excel sheet was jointly discussed involving all authors. This discussion enabled the authors to categorize the findings under themes, which in turn, helped to clarify what is known about knowledge waste and to which areas the body of knowledge is limited. Fifth, the final stage of the review process was devoted to writing up the findings.

4 Presentation of findings

Among the 77 papers that formed the basis for our analysis, the oldest publication is from 1997 and the most recent ones are from 2013. Most papers were published in 2008, 2009, 2012 and 2013, which suggests that the topic is of great interest and relevance.

In the sections below we present our analysis concerning the following aspects: general observations which outline the research methods applied. After that, the study's main findings according to the themes identified are presented.

4.1 General observations

With regard to the methodology, the most common method applied is the case study approach. This is followed by surveys and model approaches. Other methods such as ethnography (e.g. Demian and Fruchter, 2006), mixed methods approaches (e.g. Aubry *et al.*, 2011) or experiments (e.g. Chakrabarti *et al.*, 2007) are less frequently used.

The 77 papers were published in different journals which can be assigned to the fields of operations, technology and management; information management; sector studies;

general management; entrepreneurship and small business management; and organization studies. This suggests the topic interests a broad audience.

4.2 Body of knowledge regarding knowledge waste

We summarized the main findings of the investigated studies under eight broad themes:

- Factors hampering/fostering knowledge reuse
- Framework
- Implementation/Best practice
- Knowledge management
- Knowledge reuse in different contexts
- ICT solutions
- Theory development
- Consequences of knowledge waste

Factors hampering/fostering knowledge reuse

Twenty-two papers can be assigned to this theme. Regarding factors hampering knowledge reuse the studies highlighted the financial situation of the organization and the management's too strong integration into day-to-day business (Durst and Wilhelm, 2012), failure to provide learning benefits (Chauhan and Bontis, 2004), novelty of problems, conditions within organizations (e.g. social norms), types of available knowledge, and methods of reusing knowledge (Petter and Randolph, 2009), overall costs involved (Watson and Hewett, 2006). As regards factors supporting knowledge reuse, social knowledge networks (Demian and Fruchter, 2006), development of social capital (Balatti and Falk, 2002), integration in the people's practices (Hsaio *et al.*, 2006), the contribution of the owner/managing directors as creator and driver of KM activities (Wee and Chua, 2013), existence of a knowledge manager (Adamson, 2005), motivated people and clear internal structures and communication channels (Nielsen, 2012), alignment of reusable knowledge items with company strategy (Liu *et al.*, 2013), willingness of people to contribute valuable knowledge (Watson and Hewett, 2006) were mentioned.

Framework

Seventeen papers were assigned to this theme. Based on their findings the authors of those papers proposed frameworks intended to improve knowledge reuse in organizations or knowledge management in general. For example, Ficet-Cauchard *et al.* (1999) propose a tool (CBR module) that aims at assisting knowledge reuse. Thereby the focus is on helping the individuals concerned to better retrieve existing data when addressing new but similar business tasks. Lettice *et al.* (2006) proposed a measurement framework to capture the importance of knowledge reuse in the new product development process. Sherimon *et al.* (2012) highlighted in their work the significance of ontologies for knowledge reuse.

Implementation / Best practice

Five papers were placed under this theme. Those papers report the implementation of certain knowledge management activities intended to reduce the danger of “reinvention” (e.g. Soon *et al.*, 2010) or to improve collaborative knowledge management which in turn can help in knowledge creation and transfer (Dave and Koskela, 2009).

Knowledge Management

Seven papers were assigned to this theme as they address issues aimed at improving knowledge management activities in organization in general. For example, Shang *et al.*, (2009) develop a model that shows the contribution of dynamic capabilities to knowledge management.

Knowledge reuse in different contexts

Two papers were assigned to this theme (O’Leary, 2001 and Majchrzak *et al.*, 2004). O’Leary (2001) investigated knowledge reuse for the matter of problem solving in the consulting field. Majchrzak *et al.* (2004) studied knowledge reuse in the context of radical innovations.

ICT solutions

Sixteen papers proposed ICT solutions to better cope with knowledge reuse. For example, Fruchter and Demian (2002) described a prototype corporate memory system that allows the finding of knowledge, the exploration of the knowledge’s evolution

history and the exploration of the project context. Barros *et al.* (2004) demonstrated the usefulness of risk archetypes and scenario models as suitable means to knowledge retrieval and reuse.

Theory development

Seven papers were aimed at developing a theory of reuse and related fields respectively. Markus (2001) highlighted the role of knowledge management systems and knowledge repositories. Daugeliene and Marcinkeviciene (2009) proposed the inclusion of the brain circulation phenomenon in the study of knowledge management and specific knowledge management activities. Whereas So and Bolloju (2005) discussed the contribution of the theory of planned behaviour to the study of knowledge sharing and reuse.

Consequences of knowledge waste

One paper was assigned to this theme. McQuade *et al.* (2007) highlight different areas where knowledge can be wasted or even worse lost. The authors mainly draw attention to a loss of expertise in interpersonal communication skill.

7 Conclusions

Against the background of the growing concern of both scholars and practitioners regarding the implementation knowledge management initiatives, the aim of this study was to pay particular attention to the knowledge that is “wasted” in organizations, that is existing relevant knowledge that is overlooked in the process of knowledge conversion. Even though many studies have focused on knowledge reuse but they have not highlighted the topic from a knowledge at risk perspective meaning situations in which knowledge that is not used becomes a liability or a risk (Durst, 2012). Accordingly, the purpose of this paper was to review research on knowledge waste in organizations to establish our current body of knowledge regarding this topic. To do so we conducted a systematic literature review to identify suitable articles. A final set of 77 articles formed the basis for our analysis.

Our review makes clear that the body of knowledge regarding knowledge waste in organizations is still limited. The main findings were categorised into eight broad themes: Factors hampering/fostering knowledge reuse, framework, implementation/Best practice,

knowledge management, knowledge reuse in different contexts, ICT solutions, theory development and consequences of knowledge waste

The findings suggest that the existing literature provides only fragmented insights into knowledge waste in organizations. Given the importance of knowledge to company, a better understanding of this aspect is very important. Our present study clearly underlines that the topic still calls for more research, which in turn offers scholars a variety of research avenues.

We consider the following future research directions as promising: 1) the development of method to measure knowledge waste in organizations, 2) the expansion of studies on the financial and non-financial impact of knowledge waste on companies, 3) the provision of more empirical work that demonstrate the impact of different approaches and techniques, e.g. lessons learned, ontology on the reduction of knowledge waste in organizations.

The present study is not without limitations. A complete coverage of all the articles considering the issue of knowledge waste could not have been achieved, given the search proceeding chosen. So it may have left out papers that also addressed the topic but used a different language. Yet, it seems reasonable to assume that the review process covered a large proportion of the studies available. Finally, this paper proposes some research directions which are not exhaustive but represent initial stages.

Abstract:

The transition from an economy based on production towards a knowledge-based economy has highlighted the crucial role of Intellectual Capital (IC) in the firm's financial performance. Intellectual Capital is a business resource that includes know-how, patents, internal and external relationships. IC is widely acknowledged as one of the most critical resources which organizations rely on to improve their efficacy and efficiency, and hence help to improve the value creation and competitive advantage (de Pablos, 2003). There are several empirical studies that examined the quantity and the nature of IC information disclosure in annual reports in different industries and countries (Guthrie and Petty, 2000; Olsson, 2001; Brennan, 2001; Bontis, 2003; Bozzolan et al., 2003, 2006; Abeyssekera and Guthrie, 2005), but few studies have analyzed the ICD in the financial sector. The choice to focus on the banking sector is linked primarily to the fact that it represents an interesting stream as these companies fall under high-intensive IC, just thinking of the use of highly specialized human resources in the economic and financial field. This study aims to analyze the nature and extent of information on intellectual capital in the sustainability reports of companies belonging to the banking industry with two main purposes: to observe a sector often set aside despite its important role in the economy and to reply to the growing demand for longitudinal analysis in the field of intellectual capital (Mention, 2011). The first objective is achieved by identifying the presence or absence of information on intellectual capital in the sustainability reports; while the extension (number of times of calling an item) of disclosure has measured with the frequency of reporting an item within the report with reference to a single banking institute. The second purpose of the paper is achieved by taking into account two years, 2006 and 2012. The industry in which the analysis is conducted is peculiar in that it is a knowledge-intensive industry that has undergone deep changes over the last decade, who have given more importance to intellectual capital as a resource source of value and competitive advantage. The empirical analysis is carried out by analyzing the social reporting of the listed banks on the Milan Stock Exchange through the content analysis for the years 2006 and 2012, in order to capture the effect of Basel II on the level of corporate information.

Design/methodology/approach – The content analysis is used to examine the level of Intellectual capital disclosure in the sustainability reports. The empirical data were drawn from of Italian listed companies that operate in financial sector in years 2006 and 2012.

Originality/value – This research expands on previous studies of voluntary intellectual capital disclosure (ICD), as it is the first study that focuses on measuring intellectual capital using the content analysis and an IC index in the banking sector.

Practical implications – This study helps management identify relevant intellectual capital elements to disclose.

Keywords – Intellectual capital, financial institutions, sustainability reports, banking

Paper type – Academic Research Paper

1. Introduction

The process of globalization and market integration, increasing competition, the development of IT and the internet, the prevalence of soft elements, intangible and human factors that have characterized the last few decades, have changed the sources of value and competitive advantage (Cordazzo, 2007; Tayles et al., 2007; Petty & Guthrie 2000; Goh, 2007) and have changed the way companies operate. The assets that create value and create a competitive advantage to the company are no longer the machinery and equipment as intangible assets (Roos et al., 1997; Teece, 2000; Bontis, 2002), such as knowledge, information, the skills and competences (Roos et al., 1997; Quinn 1992; Nonaka and Takeuchi, 1995; Edvinsson and Malone, 1997; Choo and Bontis, 2002). The value of a company, therefore, depends not only on what can be accounted for, but also the not capitalized intangible assets, such as intellectual capital (Swart, 2006; Bernard et al. 2003; Teece, 2000).

Intellectual capital (from now will be used IC) is now recognized as one of the most important sources of value and competitive advantage (Edvinsson and Sullivan, 1996; OECD, 2006; Ordonez de Pablos, 2003). Indeed, Pulic & Bornemann (1999) state that "this new economy [...] Intellectual capital. Has become the one and only competitive advantage of a firm". The value of companies, in other words, derived from intangible assets such as customer relationships, business agreements, procedures and processes adopted, organizational skills, know-how gained, brand.

The new international context has also influenced the banking sector deeply changing the competitive environment (Gardener and Molyneux, 1993; Matthews and Thompson,

2008). Banks appear special for several reasons. First, they offer a wide variety of services (Bhattacharya and Thakor, 1993), accept deposits and make loans, may purchase bonds (Matthews and Thompson, 2008); provide financial intermediation services similar to other financial institutions and offer service of liquidity and payment. It is the quality of services provided to customers that makes the difference and this depends on the intellectual capital within the bank (Giant & Previati, 2009). Financial industry is, in fact, intellectually-intensive (Mavridis and Kyrmizoglou, 2005) and the competitive advantage binds primarily to intangible assets and intellectual capital, because, as stated by Watkins (2000), banking products are easily replicable and lack of adequate forms of protection.

Factors for a long time underestimated and lightly managed, such as the strength of the relationship of the bank, its brand, the corporate culture and the values of human resources have become, with increasing competitive pressures and the progressive deterioration of profit margins, clear strategic priorities of these organizations. In such a context, the organizations, on one hand, and stakeholders, on the other hand, are interested in disseminating information on intellectual capital, the first, and to have information, seconds. External communication on intangibles, in fact, enhance the image, visibility and reputation of the bank, generating positive effects on performance.

In addition, through most complete and articulated disclosure, it complies with the provision of the law laid down in the third pillar of Basel II, which drives in order to increase the disclosure of both qualitative and quantitative nature for stakeholders. Given, therefore, the importance of intellectual capital, it is important to determine whether the companies have changed their practices in response to the disclosure of such changes.

The existing literature has analyzed the extent and nature of intellectual capital generally with a cross-country approach. Among these studies (Guthrie and Petty, 2000; Bukh et al, 2005; Bontis et al. 2003; Goh and Lim, 2004; Ordonez, 2003), those focusing exclusively on the financial sector and banks in particular are still limited (Khan and Ali, 2010; Mention, 2011; Abdifatah Haji and Mubaraq, 2012). The present paper fits in this last field. The aim of the contribution is, in fact, to study the nature and extent of the information of the components of intellectual capital (human capital, structural and relational) in the Italian banking sector companies.

The choice of the banking sector for the analysis has different motivations. In the first place, it represents an interesting field of research, given the type of activity, a high content of knowledge, which characterizes them. In addition, this sector, like others, has

been affected by deeply changes that have created the necessity to develop different skills than in the past, making the management of intellectual capital one of the vital aspects of these organizations.

The management of intellectual capital has become in the new context more complex and characterized by a high degree of uncertainty, one of the driver to deal with the negative results that have characterized the sector as a result of the profound changes in the competitive environment. Banks, in other words, were pushed to expand the range of its powers, to apply innovative approaches, as well as to adopt strategic and organizational structure more dynamic and oriented to the strategic management of intangible resources. Even an external element should have an influence on the level of disclosure or the advent of Basel II and specifically the third pillar entitled "Market discipline". The objective of Basel II is to increase the disclosure of both qualitative and quantitative nature of the stakeholders¹, in particular on issues related to the operational risk management (such as procedures and policies related to operational risk management processes and information systems aimed at monitoring operational risk, or aspects of structural capital). These characteristics mean that the banking sector will come up as an interesting area to conduct research on intellectual capital (Mavridis and Kyrmizoglou, 2005; Goh , 2005; Reed et al., 2009).

Italy was chosen for two reasons. First, banks are a central sector in the Italian economy and should develop their information on intellectual capital; second, knowledge on intellectual capital in Italian companies are limited (Bozzolan et al., 2003; Bozzolan et al., 2006) and absent knowledge on the banks.

The analysis is conducted using the method, most widely used in the literature of similar studies, of content analysis. The nature and extent of information on intellectual capital are analyzed by examining the social reporting. The information thus obtained were summarized in an indicator of disclosure at the corporate level and subcategories. The main objective of the analysis is to evaluate, over time, the nature and the extent to which firms in the banking sector publicly provide information on their intellectual capital as a whole and for sub-category.

¹ *More specifically, the purpose of the third pillar is to "Encourage market discipline by Developing a set of disclosure requirements wich allow market Partecipants To assess key pieces of information on the scope of application, capital, risk exposures, risk assessment procedures, and hence will the capital adequacy of the institutions "(Basel II, p. 226-228).*

Compared to the existing literature, this paper allows to get an overview of intellectual capital disclosure with reference to Italian banks, context not yet investigated in spite of its dominant role in the economy; answers the question of longitudinal type information in terms of intellectual capital reporting (Mention, 2011) and highlights the relationships between the different components of intellectual capital. The paper is complementary to the studies of Bozzolan et al. (2003) and Bozzolan et al. (2006), who analyse intellectual capital disclosure in Italy with the exception of the financial sector, thus bridging the gap in the literature.

This paper is organized into three parts. The first part consists of introduction, definition of intellectual capital and literature review. The second part examines the research objective and the methodology. The last part analyzes data and presents findings. Conclusion, limitation of study and ideas for further research are also described in the last part.

We used the methodology of multiple case studies to quantify the level and the quality of voluntary disclosure of intellectual capital of financial companies. The remainder of this paper is structured as follows: Section 2 focuses on definition of intellectual capital and literature review. The second part examines the research objective and the methodology. The last part analyzes data and presents findings. Conclusion, limitation of study and ideas for further research are also described in the last part.

2. Theoretical background

2.1 Defining Intellectual Capital

There are several definitions that try to explain intellectual capital, since the beginning of its research (Brooking 1996; Edvinsson and Malone, 1997; Sveiby, 1997; Lev, 2001; Lev and Zambon, 2003). Stewart (1997) defines intellectual capital as "knowledge, information, intellectual property and experience that can be put to use to create wealth", whereas Bontis (1998) describes intellectual capital as "a set of intangibles (resources, capabilities and competences) that drives the organizational performance and value creation". Sveiby (1997) asserts, instead, that "Intellectual capital includes all employees, organizational knowledge and their abilities to create value added and led to sustainable competitive advantage", whereas Edvinsson e Malone (1997) define intellectual capital as the own of knowledge, information, intellectual property, technology, organizational,

personal and professional skills that provide the company a competitive advantage in the market.

Numerous frameworks have been developed to classify and monitor intellectual capital (Brooking, 1996; Marr et al, 2004; Sveiby, 1997; Bontis, 1998) and the literature agrees in identifying intellectual capital as the combination of human resources (human capital), structural (structural capital) and relational (relational capital) of a company (Sveiby, 1997; MERITUM Project, 2002).

Human capital is the set of knowledge, skills, abilities, level of education, experience, talent, innovation, motivation, creativity, leadership, business skills, managerial skills, culture and business philosophy, managerial attitudes, individual and group experience, ability to face and solve problems. This section included skills (including knowledge and abilities); the attitude (motivation, leadership quality management) and intellectual agility (the innovative skills of the members of the company) (Bontis et al. 1999; Bontis, 2002; Daum 2003; Dubra, 2010).

Structural and organizational capital is know-how encoded within the corporate structure, the capacity for innovation, the efficiency of production processes and business consistency with the objectives of the corporate culture of the business, the degree of alignment and cohesion of the management and the structural capacity to meet and enhance their human resources, technologies, procedures, risk assessment methodologies, software, databases, patents, communication systems (Bontis, 2002; Daum 2003).

Finally, *relational capital* is the relationships established with the market and with their customers. It is therefore a wealth outside the company, is not inherent in the corporate structure. Included in relational capital are corporate image, network, long-term contracts, collaborations and cooperations (Bontis, 2002; Daum 2003).

The interaction of these three key elements generates value; management tends (more or less consciously) to enhance positive interactions between these elements extending the "area of value creation." In this sense the intellectual capital is more than the simple sum of these resources (Bontis, 1996; Bontis, 1998; MERITUM Project, 2002), in fact, closely interrelated with each other.

2.2 Why banking sector?

Banks are service companies with a high content of knowledge (knowledge-intensive) (Eurostat 2005), which essentially operate through human resources with high

professionalism and operational processes which involve a major effort in the development and transmission of information (Rebora, 2003). In Italy they play an important role and, in fact, dominate the Italian financial system, representing at least 85% of the entire financial system (International Monetary Fund, 2012).

The sector, as well as in other countries, has undergone a big change that began as a result of deregulation, technological change and globalization. The development of new technologies has reduced costs and has changed/improved the quality and variety of services that the bank can provide customers (Berger et al., 2010), facilitated the development of new products and new channels to provide services, new banking and management costs (Beccalli, 2007), but at the same time has encouraged the presence of new entrants (Gardener and Molyneux, 1993). On one hand, deregulation and financial globalization, opening up to the international flow of capital, have increased the competitiveness and led to the introduction of new virtual services. On the other hand, the progressive reduction of barriers to entry (direct consequence of deregulation) and the greater ease of specialization within the field, parallel to the standardization of financial products and the rapid evolution of demand, have contributed in decisive extent, to raise the threshold of profit financial intermediaries, making it more complex and critical management of banking. Banks have, therefore, had to deeply rethink themselves seeking new business strategies (from a balance-sheet activities to off-balance, greater involvement in the capital market), new models of doing business (e-banking, mobile banking, role of technology), new business models (subcontracting, outsourcing, strategic alliances) and M & A. These changes have affected the nature and activities of the banks and created the need to develop new skills and competencies (human capital), but also in terms of organizational change processes and technologies (structural capital) and relationships with stakeholders (relational capital).

Intellectual capital in banks has its own specific such as: high and strong relation with customers, trust and reputation as the basis of competitive advantage, the information component of the production and distribution processes; the relational nature of long-term relationship with customers; the necessity for a rapid adaptation of the behavior of people in the light of the new product/process; the relevance of the service and assistance in the competitive policies of differentiation; the centrality of the participation of people to service system of the industry (Campbell, 2010).

Increasing competitive pressures, arising from the phenomena mentioned above and

the increased complexity of the management of banking activity can thus be considered as determinants of the reasons for the increasing orientation to the strategic management of intangibles in the financial services. In banks, the main role is played by human capital. Human capital is difficult to develop and managers must always seek to motivate employees in order to reduce the propensity to leave the bank.

Aside from the human contribution, banks face other typical characteristics of knowledge-intensive activities, such as technology and the frequent interaction between employees and customers. Still, banking activity implies a close relationship with customers, which is largely based on the integration of information and communication technologies to the development of new products and services, as well as for automation of process. The increasing automation in the manage of banking operations has a direct impact on the role of technology and, at the same time, however, raises concerns about security issues (confidential information, information accessibility, etc.) and processes for managing operational risks (operational risk management process). Operational risk is defined by Basel II as the risk of losses achieved in inadequate internal processes, human error, failures in operating systems or due to external events.

Operational risk affects all the operations of banks and thus implies the need to pay due attention to structural capital (procedures, processes and information systems theory to identify, monitor and mitigate operational risk). Accordingly, we expect that banks provide an extensive information on these aspects in order to demonstrate their act to develop and use this form of capital. In the banking sector another important aspect is the central location of the customer, identifying it as a key success factor (Cabrita & Bontis , 2008). With the advent of new ways of carrying out the business activity, such as online banking, banks could benefit from this by developing new services and / or products. Still critical to the bank is the quality of relationships with the supervisor, with the supervisory bodies (Bank of Italy, Consob, with reference to Italy). The reputation and trust-based relationships are other intangible factors (Castelo Branco & Rodrigues Lima, 2006).

Finally, an external element, the advent of Basel II, and in particular, the third pillar entitled " Market disciplines ", should have an influence on the level of disclosure. The objective of Basel II is to increase the disclosure of both qualitative and quantitative nature for stakeholders. More specifically, the purpose of the third pillar is to " Encourage market discipline by Developing a set of disclosure requirements which allow Market participants to assess key pieces of information on the aim of application, capital , risk

exposures, risk assessment procedures, and hence will the capital adequacy of the institutions " (Basel II , p. 226-228). These changes are reflected in the structural capital , and in particular we expect a greater disclosure of those items that are more directly related to the *operational risk manangement* (such as procedures and policies related to operational risk management processes and information systems aimed at monitor operational risk).

Each element of intellectual capital is, therefore, a critical resource for banks that must be managed internally, but should also be disclosed in order to build a good reputation (Toms, 2002; Xifra and Ordeix, 2009). On the other hand a good reputation helps to maintain a sustainable competitive advantage.

2.3 Literature review

Essentially two are the main field of study related to intellectual capital: studies that measure intellectual capital in economic-quantitative terms and studies on intellectual capital disclosure directed to highlight information on intellectual capital in the same way that the economic-financial information can influence the decisions of a potential investor (Rees and Sutcliffe, 1994).

Focusing on the latter topic, as our contribution falls in it, the first study is Guthrie and Petty (2000). The authors develop a framework of characteristics/attributes of intellectual capital, derived from Sveby's Intangible Asset Monitor to encode and analyze the annual reports of 20 listed companies in Australia for the year 1998, with the purpose of determining the level of the IC discolsure (ICD) in the Australian context. From this study many others start, generally focused on a single country, some analyse the presence of information on intellectual capital, others also the extension and others the quality of disclosure (Guthrie & Petty, 2000; Abeyesekera, 2000; Brennan, 2001; Bozzolan et al., 2003). Generally the analyses are cross-industry even if sometimes the analysis focuses on a particular sector (Shareef and Davey, 2006; Scheneider and Samkin 2008). Limited are those that include banks in their sample analysis (Williams, 2001; Abdolmohammadi, 2005; Bontis, 2002; Goh and Lim, 2004; Guthrie and Petty, 2000; Oliveras et al., 2008; Vandemaele et al. 2005; Vergauwen and Alem, 2005; Oliveria et al., 2010; Khan and Khan, 2010) or focused only on the banking sector (Khan and Ali, 2010; Mention , 2011; Haji and Mubaraq , 2012).

Banking activity, in fact, is a high-knowledge business services and its characteristics are suitable to be analysed in terms of IC, which represents a critical resource in the process of corporate value creation. The activities of banks requires human resources with a good education, qualified and continuously updated (Alvesson, 2000), generally involves relationships with customers and rely, in large part, to the development of new products and services, integration of information and communication technologies (ICTs) (Mention & Bontis, 2012).

Khan and Ali (2010) are the first authors to present a study that analyses the annual reports to assess the ICD in 20 listed banks in Bangladesh in the period 2007-2008. The framework of analysis is Sveiby (1997) as modified by Guthrie and Petty (2000). The authors, in order to take into account the characteristics of the banking sector, insert other items, such as "banks recognition for services", "banks market share", "banks reputation for services" and "number of training for employooyee." The method of analysis is the content and the items used are 21. The data are qualified with the value of "0" if the information is absent and "1" if the information is present and the unit of analysis is the word count. The information that prevail are those on human capital (65%) followed by those on the relational capital (20.8%), and those relating to structural capital (14.2%).

The second study is Mention (2011), who examines the practices of voluntary reporting on intellectual capital by analyzing the annual report of five European banks. The analysis is conducted over a period of nine years (2001-2009) through the content analysis, that identifies for each of the three categories (human capital, structural capital and relational capital), five subcategories² and different indicators.

The framework used is Guthrie and Petty (2000) modified to take account of the peculiarities of the banking environment. The information acquired are qualified with the value "0" if absent, "1" if qualitative and "2" if quantitative in nature. The unit of analysis is the text unit. The analysis shows an increase in all categories of intellectual capital in the period and on average it should be noted that the category of majour interest is human capital (43 % of the information), followed by the relational capital (34%) and then structural capital (23%).

² *Human capital constitutes: knowledge, Skills, Attitudes, talent management e training policies; capitale strutturale: Intellectual property, information systems and infrastructure, management process, corporate culture, innovation capabilities; capitale relazionale: Bran, customers, distribution channel, business partnerships, corporate actions*

The third study deals with the ICD in the banking sector is Haji and Mubaraq (2012), who examines, for the period 2006-2009, the annual reports of 20 Nigerian banks. These authors do not adopt a specific framework of reference even if they adopt the classic division of intellectual capital. The researchers identified 44 items and qualify the information with "0" if absent and "1" if present. The most consistent information are those relating to structural capital (average 36%), followed by those on human capital (34%) and then by the relational capital (30%).

All studies above cited were conducted in other countries; the absence of previous research justifies exploratory approach of this study, recommended in those situations in which knowledge about a particular topic are limited (Selltis et al., 1976).

In the three studies mentioned, the method of research is content analysis³. This method, in fact, is the most appropriate in studies of disclosure of intellectual capital in annual reports, social reporting and other corporate documents (Yamagami & Kokubu, 1991; Guthrie & Petty, 2000; Unerman, 2000; Brennan, 2001; Bozzolan et al. 2003; Oliveira et al, 2006; Beattie and Thomson, 2007; Cordazzo, 2007; Vergauwen et al, 2007; Abeysekera, 2008 Abeysekera & Guthrie, 2005; Oliveras et al, 2008).

3. Research objective and methodological approach

Objective of this study is to investigate the amount and the type of intellectual capital information (human, relational and structural capital) reported in the sustainability reports of Italian banking firms.

The analysis is conducted on a voluntary reporting documents, such as new forms of corporate disclosure, that may be useful to provide information based on intellectual capital (Zambon, 2003; Cordazzo, 2005) for the years 2006 and 2012. Specifically, the analysis is carried on the sustainability reports.

The methodology of analysis, in line with the existing literature, is content analysis, which is a useful method to extract information (April et al., 2003), which allows to identify the different components of intellectual capital and to understand, analyze and describe information about the intellectual capital in the documents selected for the

³ Another common method of analysis in the study of intellectual capital is the VAICTM analysis. The methodology VAIC is instead used to measure the intensity with which a company produces value-added based on the efficiency of intellectual capital (P. Stale, Stale S., S. Aho) and its goal is to measure efficiency in 'use of intellectual capital (Pulic, 2000). The VAIC leads to determine a summary of the efficiency of the enterprise and efficiency of intellectual capital.

analysis. The objective of this method can be found to represent the behavior of organizations in terms of intellectual capital disclosure⁴.

This method consists in classifying the information contained within the document analyzed within a predefined category of items identified with the intent to capture aspects of intellectual capital that you want to analyze. The basic assumption of content analysis is that the amount of information available reflects the importance of the information (Krippendorff, 1980). The application of content analysis involves the classification of the information available in the various categories in line with a predefined schema or identified criteria (Guthrie and Petty, 2000; Abeyesekera, 2008). The application of content analysis involves reading the document of social reporting and coding of information based on the framework identified.

In the contribution we have chosen to examine the level and extent of information on intellectual capital in the documents of voluntary reporting, in particular in sustainability reports, available on the website of the banks. It is, in other words, interested in analyzing the voluntary disclosure on IC, as it is considered important in order to provide a complete view of the firm (Campbell and Rahman, 2009). The research analyzed the need for information to decision makers reveal that market participants consider important and useful information on the IC to make investments (Abhayawansa and Guthrie, 2010).

The items used to make the analysis follows the pattern for intangibles of Sveiby (1997), who identifies the internal structures (structural capital), the external structures (relational capital) and employee competence (human capital). To take account of the purpose and object of the analysis, the items of analysis have been modified according to the sector analyzed, in order to have a better convergence with the item that much more likely to be reported by banking institutions (Guthrie & Petty, 2000). In this context, useful references are Mention (2011), Shih et al. (2010) and Ordonez (2003), as will be specified. The content analysis, following the literature (Krippendorff, 1980; Weber, 1990), was developed in the following steps: a) definition of the unit of analysis; b) defining the categories and c) development of an unambiguous coding rules.

a) Definition of the unit of analysis

With regard to the first phase, the existing literature identifies as a unit of analysis a word, a sentence or paragraph. Milne and Adler (1999) believe the word is not reliable,

⁴ Krippendorff (1980) afferma che la content analysis è "research technique for making replicable and valid inferences from data according their context"

because it has a different meaning depending on the context of reference of the sentence and is therefore considered the most appropriate sentence for this type of analysis. However, since a sentence may contain more information, including on different aspects of intellectual capital in order to avoid bias in the analysis could be considered the unit of text as the unit of analysis; in this case, the different information needs to be captured for the different components of intellectual capital.

Items have been investigated focusing on information and not on the expression of the single word. Therefore the research has sought and counted the information expressed in the sustainability reports concerning each single item. Have been deleted the double information on the same item and information contained in the table and charts have been counted only in case if they supply an additional information not explained in the body of the report.

b) Defining the category

In this paper, intellectual capital is defined and analyzed using three broad categories: human, structural and relational capital.

Human capital consists of the set of skills and knowledge of employees which can be further improved with training. It includes also experiences that can be developed with training programs. Human capital can be analyzed at micro level (individual) or macro level (enterprise).

Relational capital is linked to the organization and its relationship with external elements such as customers, suppliers and shareholders. Examples of relational capital in banks are customers, brand loyalty, customer satisfaction, strategic alliance and coalitions.

The structural capital can be, instead, defined as a knowledge created by an organization and which can not be separated from the same.

Consistent with the existing literature (Bontis, 2003; Guthrie and Petty, 2000; Striukova et al. 2008) for each category were identified sub-categories (items) and indicators (Table 2), trying to capture the most important aspects with regard to context analysis.

The selection of items is the most critical aspect (Marston and Shrivess, 1991, Bukh et al., 2005) and in order to make this choice less subjective, items were selected taking into account the items identified in Mention's study (2011). Mention (2011) identifies a framework of analysis with reference to the study of Shih et al. (2010) on human capital

in financial institutions and the study of Guthrie and Petty (2000) for the structural capital and relational adapting the items according to the the banking sector. These items have been integrated with the indicators identified by Ordonez (2003) and subsequently with indicators derived from the study of some sample documents.

Table 1 – Framework for analyzing IC reporting

c) The coding process of intellectual capital information

Consistently with Oliveria *et al.* (2010), manual coding was preferred because software-assisted searches for words, sentences or portions of pages are insufficiently robust to capture the nature of the IC information disclosed (Beattie and Thomson, 2007). In order to collect the items on intellectual capital sustainability reports have been read in full, without resorting to the "Search" function in PDF documents analyzed.

The data was first coded by category and then by subcategory. In line with the purpose of this study to concentrate on the qualitative character of intellectual capital disclosure, repetitions were ignored.

In order to identify the level of disclosure, the information was coded in a dichotomous way, whose value was set at "1" if the item is present and "0" otherwise. It was made this choice in order to avoid areas of subjectivity that tend to be present when the assignment of the value includes a weighing (Williams, 2001).

The extent of disclosure was measured by counting the frequency of the presence of the three categories and their subcategories. The frequency, in fact, indicates the importance of a particular element (Krippendorff, 2004).

Finally we constructed a Disclosure indexes (ICI) (Haniffa and Cooke (2005); Ghazali (2007)). ICI calculate "the number of information-related items that a given report contains based on a predefined list of the possible items" (Bukh et al., 2005). The total disclosure score was computed as the unweighted sum of the scores of each item (Cooke, 1989). All items were considered relevant to all firms. The formula to calculate ICD_i is the following:

$$ICD_i = \frac{\sum_{j=1}^n D_{ij}}{n}$$

where D_{ij} assumes the value of 1 if were found information on the item and zero otherwise and "n" is the maximum number of items reported in the document.

The use of disclosure indices in studies of accounting and reporting of business practices is widely used (Marston and Shrivs, 1991, Guthrie et al., 2004), as these studies represent an aspect of the quality of disclosure that may be captured by a measure "sum" (Beattie, 2002; Bukh PN, 2005). To mitigate the main problem of content analysis (accuracy of information), the collecting data was conducted on sustainability documents separately by all the three authors and then compared where it showed discrepancies.

4. Sample and data

Listed banking sector firms in the Italian Stock Exchange are initially selected to represent the sample of the study. However data of some companies have been omitted because they are not fulfilling the sampling requirements of this study. Under such requirements, companies should have published their social reports for 2006 and 2012. In line with this requirements, thirteen firms have been excluded from the sample and four retained.

The selected document for the analysis is the social reporting. The banks listed on at 31/12/2012 were seventeen, but only six draw up documents of voluntary reporting in five years. None of the analyzed banks draw up a real intellectual capital reports. All documents used are freely available online.

Table 2 - sample

SAMPLE SELECTION PROCESS	NUMBER OF FIRMS 2006	NUMBER OF FIRMS 2012
Total financial firms listed in FTSE MIB	17	17
Firms with sustainability reports	5	10
Total sample	4	

The final sample consists of 4 companies, one (Monte dei Paschi Group) was excluded because of its Sustainability Reports 2012 could not be compared with 2006 because it consists only indicators and do not disclose narrative part.

Therefore our final sample consists of the following companies: 1) Unicredit Bank, 2) Credito Valtellinese, 3) Ubi Bank and 4) Carige Group.

5. Results

5.1 Descriptive Analysis

Only 24% of the companies draw up sustainability reports in the period time considered.

In banking sector, the main role is played by human capital and relational capital; in fact the examined companies disclosed information mainly on these type of resources while the lowest incidence occurs on structural capital both in 2006 and 2012.

Table 3 – Descriptive statistics for the sample

Number of sample companies	17
Number of companies that have a sustainability report	5
Number of intellectual capital attributes in model	136
Average number of attributes reported per company	60 in 2006 and 64 in 2012
Minimum number of attributes reported by any one company	47 in 2006 and in 2012
Maximum number of attributes reported by any one company	72 in 2006 and 91 in 2012

Source – our revision

Table 4 displays the number of human capital, relational capital and structural capital reported by the four aforementioned institutions over two-year period, 2006 and 2012. As illustrated in the table, the level of information disclosed follows an ascendant trend. To a certain extent, this observation supports the proposition that disclosure of intellectual capital increases over time, especially after the entry into force of the third pillar of Basel II (market discipline).

In absolute terms, relational capital consistently ranks first in this study, unlike what is reported in the study of Mention (2011), both in 2006 (716) and in 2012 (837); human capital holds the second place (261 in 2006; 488 in 2012), while structural capital lands on the third on (161 in 2006 and 168 in 2012). This result highlights the importance for the banking sector of the relational capital: this means trust and credibility from its customers and in general from its stakeholders.

In relative terms, the ranking indicates that relational capital is most disclosed, followed by human and then structural capital, which is consistent with prior studies (e.g. April et al., 2003; Guthrie and Petty, 2000; Oliveras et al., 2008; Striukova et al., 2008).

Table 4 – Intellectual capital in the examined reports.

	2006	%	2012	%
Human Capital	261	24%	488	33%
Structural Capital	161	14%	168	12%
Relational Capital	716	62%	837	56%
Intellectual Capital	1150	100%	1493	100%

Source – our revision

Taken a closer look at the importance of each subcategory (table 5), it can be observed that the top five subcategories are “Training policies” for human capital, just to show the importance in this particular sector of the professional and learning training, the updating of the employee; “corporate culture and identity” for structural capital, to indicate the importance of some values, as trust, credibility, etc.; “Customers”, “Business partnership” and “Corporate action” for relational capital, to highlight that the relationship with customers and stakeholders are crucial for an institution. Corporate action refers to all initiatives in which banks are involved in, especially in no-profit organisms, or to promote cultural and sport events.

It can be observed also a low level of disclosure of intellectual property, innovation capabilities and management process. A possible explanation for this may reside in the fact that banks may be hesitant to pursue patenting over their financial institutions in

Europe due to the legal uncertainty surrounding the patentability of business methods and computer programs.

Table 5 – Disclosure per subcategory, given in absolute term and relative disclosure level provided

Cat.	Subcategories	2006	%	2012	%
HC	Employee's profile	36	3,14%	32	2,14%
	Knowledge	21	1,83%	22	1,47%
	Skills	35	3,05%	39	2,61%
	Attitudes	19	1,66%	18	1,21%
	Talent management	92	8,00%	196	13,13%
	Training policies	70	6,10%	181	12,12%
SC	Intellectual property	6	0,52%	3	0,20%
	information system and infrastructure	30	2,61%	26	1,74%
	Management process	3	0,26%	0	0,00%
	Corporate culture/identity	115	10,02%	123	8,24%
	Innovation capabilities	7	0,61%	16	1,07%
RC	Brand	23	2,00%	37	2,48%
	Customers	128	11,15%	191	12,79%
	Distribution channel	83	7,23%	109	7,30%
	Business partnerships	125	10,89%	181	12,12%
	Corporate action	357	31,10%	319	21,37%
IC	Total	1148	100,00%	1493	100,00%

As regards disclosure per items, it could be observed, consistently with prior literature, that for human capital few and sometimes none information are reported for overtime, employee's experience, team work, language, problem solving, creativity or proactivity of the employee; whereas the most informations reported are gender distribution, internal communication, recruitment policies and training programs. As concerns structural capital, very few informations are reported for licenses, copyright; whereas the major informations disclosed are corporate value and vision. Finally, as regards relational capital information relates to shareholder value are not present, whereas informations relates on sponsorship, environmental protection measures, relation with suppliers, collaboration and multichannel bank.

5.2 Intellectual capital in the four case studies

The case studies, as defined above, concern the analysis of sustainability/social reports of four financial listed companies. These reports have been prepared in accordance with the Global Reporting Initiative 2002 (GRI2) for 2006 and with the Global Reporting Initiative 2006 (GRI3) for 2012.

Unicredit, compared to the other banks' reports, can be used as an example of best practice in the field of sustainability reports, as it constitutes of many pages with a reach and detailed description of all chapters considered in the GRI, obtaining for all years a score of A+ as level of application.

The series of events over the past 10 years pushed countries and financial institutions to promote sustainable growth. The first years of the new millennium have been marked by an increasing attention to issues of sustainability. The last decade was marked by the subprime mortgage crisis and insolvency of many banks that have given rise to a unprecedented global recession. The next debt crisis European sovereign, together with the erosion of the reputation of the financial sector, has undermined public confidence in banks' ability to support the real economy. This has led to an increasing focus on long-term viability of the financial sector, as well as on professional conduct of banks and their ability to be responsible corporate citizens.

The research for information on intellectual capital according to the identified framework has identified the following results, articulated in human capital, structural and relational.

a) Human Capital

Human capital section of the Italian firms in sustainability report is sufficiently complete. Informations less widespread in the analyzed documents are origin country of employee, overtime, experience and expertise and problem solving. These results are coherent with Oliveira *et al.* (2010) and Mention (2011) results, according to whom the most reported items are: training policies and internal communications. Only Unicredit Bank provides information on social dialog, promotional initiative for gender balance, leadership development initiatives.

In general, the most reported items are referred to workers' relationship and training; this means that information concerning aspects as health, safety and training programmes are more highlighted. Unicredit is the company that provides the most information pertaining to human capital, follow Ubi Bank.

c) Relational Capital

The relational capital is the area of intellectual capital which companies both in 2006 and 2012 pay the most attention. Companies seem to acknowledge that their customers and in general stakeholders are a critical source of wealth, and that by building a positive image with stakeholders they can acquire an important intangible element – a good reputation. Reputation is inherent to the financial services and it is highly influenced by human capital and structural.

6. Conclusion and future research

Considering the peculiarities of the banking sector, its being knowledge-intensive and the changes that have affected the industry, this study analyzes the level of information on intellectual capital of the banks listed on the Milan Stock Exchange. Practices regarding

disclosure of intellectual capital in Italian banks was conducted using content analysis, which allowed us to examine and define the extent and the content of the information provided in the documents of social reporting.

The study shows that the relational capital, as shown in previous works, predominates followed by information on human capital and structural capital then. Either way, the information level is quite high. Analyzing the trend shows a substantial increase in information related to capitale human and relational capital and the structural remains almost constant.

The results have implications for policy and management . At the level of policy Basel II drives to provide more information, particularly on intellectual capital, but to date there are no specific references on how to provide such information and this can make it difficult to implement the prediction of a balance of intellectual capital, especially if it is not mandatory. Therefore it would be desirable to develop a framework for this report may be directed to the preparation of the document and its comparability over time and somehow assure the reader about the goodness of the information contained therein. From the management point of view to an enterprise knowledge-intensive management of intellectual capital is essential. Prepare a report like this can bring benefits in terms of transparency, trust and reputation. So how management uses time and effort to identify its key resources so should communicate outside.

This research expands on previous studies of voluntary intellectual capital disclosure (ICD), as it is the first study that focuses on measuring intellectual capital using the content analysis and an IC index in the banking sector. Moreover, this paper contributes to the existence literature mainly in three ways: first, we analyze the quantity and the quality of IC disclosure in the financial sector; second we choose Italian banks; third, we compare the information disclosed in the annual reports and in the sustainability reports of the firms belonging to the sample.

The study certainly has limitations and the principal is to be attached to the use of content analysis, unaccurate the subjectivity of interpretation even though there is a list of predefined items, secondly, the sample size does not allow to generalize the results even if it is recognized that judgmental or purposive approach offer comparable results to the use of probabilistic methods with small samples (Thietart, 2003), even if our goal is not to generalize the results to the case of an exploratory study. The study is exploratory in nature and its goal is to expand your knowledge with reference to a sector that is still

largely unexplored.

Regarding the future of the research, it could be useful accompany the content analysis of questionnaires to firms in the sample. This is because, as already mentioned, the technique of content analysis suffers from subjectivity. In other words, the content analysis involves the application in the trial of an attribute information to the intellectual capital and at the same time it is difficult to decide whether a paragraph in a document contains specific information on intellectual capital. In addition to reading a document, typically hundreds of pages with lots of information and involves fatigue and tuner can easily result in a view but this information is not. Still content analysis is static and identifies what is happening at a certain time not identify themselves but the long-term strategy.

Structured Abstract

Purpose – The purpose of our study is to investigate whether companies with higher voluntary IC disclosure are more likely to have a MBV gap larger than one, after controlling for the intellectual efficiency of the firms. Additionally, we aim to investigate – for the first time to our best knowledge – on the effectiveness of voluntary IC disclosure in improving the market valuation process, by testing the effects of additional IC information on the gap between market value and intrinsic value of firms characterized by higher incidence of IC components (mostly non-recognized on balance sheet).

Design/methodology/approach - The empirical analysis is based on non-financial companies that are listed on the Milan Stock Exchange throughout the period from 2008 to 2011. To compute the extent of IC disclosure provided by companies, we build three IC indexes which consider specific IC categories: the internal structure, external structure and human capital (Guthrie and Petty, 2000b). In order to measure the corporate IC components, we follow the Pulic's approach (Pulic, 2000a,b), by calculating the VAIC and its three components: capital employed efficiency (VACA), the human capital efficiency (VAHU), and the structural capital efficiency (STVA), respectively. To estimate the intrinsic value of firm, we follow the Ohlson (1995) and Frankel and Lee (1996) approaches, by using the analysts' earnings forecasts as applied by Barth et al. (1998).

Originality/value - This study contributes to the extant literature on the role of IC information for the efficiency of financial markets in two respects: by enhancing the understanding on the important role of information concerning internal structure of IC in the market valuation process; by testing - through a new analysis approach - the supposed greater accuracy of market valuation process in presence of higher information transparency. The investors' assessment is much more accurate as the market value reflects the intrinsic value of the firm. Therefore, this approach checks on the effectiveness of corporate IC voluntary disclosure in improving the accuracy of investors' assessment, by testing whether firms with an intrinsic value more than book value which

are characterized by higher incidence of IC components are more likely to have a MBV larger than one, when they disseminate more information on IC resources.

Practical implications - This study has practical implications for various parties, such as investors and other stakeholders. It gives evidence on the important role played by voluntary IC disclosure in reducing information asymmetries between the internal and external parties' valuation of companies, primarily increasing the information held by agents in the investment community. This, in particular, in an institutional setting like Italy characterized by companies with dominant shareholders, where the information asymmetries exacerbate the agency conflicts between dominant (controlling) shareholder and minority shareholders. Moreover, the findings contribute to shed light on the effectiveness and determinant role of voluntary IC disclosure practices (in annual reports) in improving the market assessment of high tech companies, thus reducing the possibilities of underestimation of their (more hidden) value creation drivers.

Keywords – Market value, VAIC, Voluntary Intellectual Capital Disclosure, Firm Value, Market Assessment accuracy.

Paper type – Academic Research Paper

1. Introduction

The development of new business sectors and, in particular, the rise of the “new knowledge economy” have led to an increased emphasis on intellectual capital (IC) (Stewart, 1997; Thurow, 1999; Guthrie and Petty, 2000a; Petty and Guthrie, 2000; Guthrie *et al.*, 2001; Bontis, 2001). Indeed, intangible and knowledge resources are increasingly emerging as the new competitive drivers for creating value in global business markets (Stewart, 1997; 2001; Sveiby, 1997; Marr and Schiuma, 2001; Skoog, 2003; Marr *et al.*, 2004; Guthrie *et al.*, 2006; Sharma *et al.* 2007; Oliveiras *et al.*, 2008; Yi and Davey, 2010; Schiuma, 2011). As stated by Stewart (1997), “Intellectual capital is intellectual material-knowledge, information, intellectual property, experience, that can be put to use to create wealth”.

In particular, IC can be viewed as a part of the resources (input) invested by companies to gain competitive advantage and, thus, improve financial performance (output), contributing to increased corporate value and firm wealth (outcome) (Cheng *et al.*, 2010; Molodchik *et al.*, 2012; Naidenova and Parshakov, 2013). Consequently, the more a firm is characterised by technological advances and rapidly increasing IC (i.e., a knowledge-based firm), the more its financial performance and its equity attractiveness for shareholders are driven by its IC resources (Naidenova and Parshakov, 2013). However, the treatment of intangibles in current accounting systems fails to recognise the “new” intangibles (Wallman, 1995; Mortensen *et al.*, 1997; Stewart, 1997; Lev and

Zarowin, 1999; Hedlin and Adolphson, 2000; Petty and Guthrie, 2000; Zambon, 2003; Bozzolan, 2003; Garcia-Meca et al., 2005; Oliveira et al., 2006; Bontis, 2003; Guthrie et al., 2006), such as staff skills and abilities (Stewart, 1997; Lee, 2011), organisational procedure, databases, strategies (Nazari, 2010), customer relationships, etc. (Wong and Gardner, 2005). Indeed, these “soft intangibles” (IC) do not meet the accounting definition of an asset, and consequently, they cannot be recognised in financial statements (Wayne, 2001; Bozzolan et al., 2003). Therefore, financial statements do not contain all intangibles assets that contribute to create company value and the market-to-book value (MBV) gap would reflect the inability of financial statements to take into account the value of IC (Lev and Zarowin, 1999; Mouritsen et al., 2001). In this context, the disclosure of IC would so have a strategic importance to shareholders (Marr et al., 2003) because it integrates traditional financial information, providing more comprehensive information, which enables investors to better interpret the financial indicators (Graaf, 2013) and to reduce the perceived risk associated with the entity (van der Meer-Kooistra and Zijlstra, 2001). Consequently, narrative reporting of IC allows companies to provide broader information on which the users can base the valuation of a firm, facilitating a more accurate valuation (Darrough and Stoughton, 1990; Bukh, 2003; Garcia-Meca et al., 2005). Amir and Lev (1996) found that financial information and non-financial information combined together can better explain market value. Since then, further studies have showed the important role of IC information for the efficiency of the financial market (for a literature review, see Abhayawansa and Guthrie, 2010).

The purpose of our study is to empirically explore whether companies with higher voluntary IC disclosure are more likely to have a MBV gap larger than one, after controlling for the intellectual capital efficiency of the firms. Additionally, we aim to investigate – for the first time to our best knowledge – on the effectiveness of voluntary IC disclosure in improving the market valuation process, by testing the effects of additional IC information on the gap between market value and intrinsic value of firms characterized by higher incidence of IC components.

Because the relations examined likely differ across industries, we present separate findings for firms in the high-tech and traditional non-financial firms. The empirical analysis is based on non-financial companies that are listed on the Milan Stock Exchange throughout the period from 2008 to 2011.

To compute the extent of IC disclosure disseminated by companies, we build three IC indexes which consider specific IC categories: the internal structure, external structure and human capital (Petty and Guthrie, 2000).

In order to measure the corporate IC components, we follow the Pulic's approach (Pulic, 2000a,b), by calculating the VAIC (Value Added Intellectual Coefficient) and its three components: the capital employed efficiency (VACA), the human capital efficiency (VAHU), and the structural capital efficiency (STVA), respectively. To estimate the intrinsic value of the firm, we follow the Ohlson (1995) and Frankel and Lee (1996) approaches, by using the analysts' earnings forecasts as applied by Barth et al. (1998).

The results give empirical evidence that high tech companies with higher value creation efficiency of human capital are more likely to have a market-to-book ratio larger than one. On the contrary, for traditional companies, the value creation efficiency of physical and financial capital employed primarily influences, in a positive direction, the probability of a MBV larger than one. The findings from our further analysis showed that in addition to specific IC performance, also the voluntary disclosure on internal structure of intellectual capital (non-financial information) seems to have an important role in the market valuation process, especially for the high tech companies, mostly characterized by a higher incidence of "soft assets". For the high tech companies, the results also suggest that investors prefer to base the assessments of relational capital resources (external structure of IC) directly on the corporate financial performance. Our final analysis reveals that a greater disclosure on IC appears determinant in improving the market assessment of high tech companies characterized by higher IC performance. For traditional companies, the findings show that investors tend however to incorporate the value drivers of these companies, regardless of disclosure on IC resources, maybe basing their valuations mainly on financial information as well as on other types of information channels (like the analysts). This study contributes to the existing literature in a number of ways. First, the paper gives evidence that the different weight of IC components in companies leads to their different relevance in the market valuation process, showing a tendency to a rational behaviour of the financial market. In fact, the investors' assessment results more based on the value creation efficiency of human capital for high tech companies, whereas for traditional firms strictly reveals the value creation efficiency of physical and financial capital. Second, this study contributes to the extant literature on the role of IC information for the efficiency of financial markets in two respects: by enhancing the understanding on

the important role of information concerning internal structure of IC in the market valuation process; by testing the supposed greater accuracy of market valuation process in presence of higher information transparency through a new analysis approach. The investors' assessment is much more accurate as the market value reflects the intrinsic value of the firm. Therefore, this approach checks on the effectiveness of corporate IC voluntary disclosure in improving the accuracy of investors' assessment, by testing whether firms with an intrinsic value more than book value which are characterized by higher incidence of IC components (mostly non-recognized on balance sheet) are more likely to have a MBV larger than one, when they disseminate more information on IC resources. The remainder of the paper is organised as follows: Section 2 provides the specific hypotheses to be tested. Section 3 describes the research design and method. In Section 4, the results are presented and discussed. In Section 5, conclusions are drawn.

2. Research hypotheses

The significance of IC in explaining the gap between the market and book value of companies is debated in the literature, representing one of the most popular theory on IC (Galbraith, 1967; Bontis 1996; Stewart 1997; Sveiby, 1997, 2010; Edvinsson and Malone, 1997; Lev and Zarowin, 1999; Andriessen, 2004; Dumay, 2012).). Figure 1 shows the theoretical framework we developed for the research hypotheses of this study. According to previous studies in the field, IC can be subdivided into three main structural components: internal structure (structural), external structure (relational) and human capital (Stewart, 1991, 1997; Bontis, 1996, 1998, 1999; Edvinsson and Sullivan, 1996; Sveiby, 1997; Edvinsson and Malone, 1997; Roos et al., 1998; Guthrie and Petty, 2000b; Bontis *et al.*, 2000).
