Purpose – This paper extends from the hypothesis that in many economic sectors competitiveness is based on intangibles. Knowledge and innovation are premises of social development and provide critical resources to local economies. Therefore countries with sizeable resources in human capital are likely to provide higher standards of living (Romer, 1989). Our argument draws on Richard Florida's theory and intends to test the hypothesis according to which the city, in order to maintain its knowledge intensity, must develop a beneficial and attractive urban climate likely to retain creative workers - it must promote creativity and support innovation.

Design/methodology/approach – Our research is exploratory and proposes results from a first test of relevant attraction factors applicable to Montréal. We applied a qualitative approach based on semi-structured interviews. The investigation examines artistic careers and the features offered by Montréal to visual artists. The survey was conducted largely in the Plateau and Mile End districts. The interview guide has four sections that focus on the career path of highly qualified and/or creative workers, on the city's strengths and weaknesses, on creativity-enabling aspects and on the city's features that contribute to retention. Also examined is the influence of self-managed artists centres on the network of stakeholders on the territory

Originality/value – Richard Florida's theory (2005-2002) has attracted the attention of many cities, but has not been tested much. It is interesting to test as Richard Florida's theory considers that the city, in order to maintain its knowledge intensity, must develop an attractive urban climate likely to retain creative workers - it must promote creativity and support innovation - and it must offer not only good quality of life but scores of career opportunities, especially in the arts sector which can be seen as a source of

innovation. The idea is also that the creative workers and amenities would then attract knowledge workers.

Practical implications – The test of this hypothesis can have important implications in terms of city management, city infrastructure development as well as factors of attraction to develop in order to attract knowledge workers and creative workers.

Keywords – Creative class, creative workers, artists, local development, cities

Paper type – Academic Research Paper

1 Introduction

This paper extends from the hypothesis that in many economic sectors competitiveness is based on intangibles. It is generally understood that knowledge and innovation are premises of social development and provide critical resources to local economies. Therefore countries with sizeable resources in human capital are likely to provide higher standards of living (Romer, 1989). Our argument draws on Richard Florida's theory and intends to test the hypothesis according to which the city, in order to maintain its knowledge intensity, must develop a beneficial and attractive urban climate likely to retain creative workers - it must promote creativity and support innovation - and it must offer not only good quality of life but scores of career opportunities, especially in the arts sector which can be seen as a source of innovation. Focus is also set on artistic careers since a number of authors believe that careers in the arts, although boundaryless and unsettled, are forerunners of careers of the future and typical of jobs likely to develop in many other sectors (Menger, 2002).

In addition, the city must promote the development of training institutions to prepare workers, quality cultural infrastructures, dense networking and social coherence discernible in its ethnic and cultural diversity and in the cooperative measures implemented toward social development. Basically, Florida's theory is that creative workers (artists, including professionals and others) tend to be attracted to and remain in so-called 'cool' cities where the population is open to multiculturalism and tolerant of gays and lesbians (Tremblay and Tremblay, 2006). It follows that the success of an urban region in the generation and retention of creative activity depends on the quality of space and on such factors that promote good neighbourhood and social cohesion in the community.

We have dealt elsewhere with our criticism of Florida's theory (Pilati and Tremblay, 2007) and do not wish to revisit the issue in full detail here; our intent here is essentially to test the assumption empirically. While Florida's ideas has often been criticised on their theoretical foundations (Shearmur, 2006), the particulars still remain to be tested and deserve a reality check for two reasons: first, because of their wide dissemination, and second, because they have hardly been submitted to empirical investigation according to a number of authors, namely Shearmur (2006) and Kotkin (2000). Kotkin (2000) and Kotkin and Siegel (1999) claim that talents (the authors reject Florida's creative class concept) are first and foremost concerned with the cost of living in the city, commuting between home and work, and the range of family recreation amenities offered by the city and that Florida's theory does not stand. It thus appeared interesting to determine which are the driving factors of attraction for artists in particular; other groups were analysed in other research (Tremblay and Darchen, 2010). In this paper, we will briefly expose the general context of the research, mainly as concerns globalization, then look at the concepts that underpin our research, that is those of creativity, creative class, etc. We will then go on to look at the situation of artists in Montréal and in the province of Québec, our methodology and finally some results of the research.

2 The context of globalization and arts/culture as a source of economic growth

Globalization has had major impacts over the last decades, although it is not the only force at hand, technology and management strategies also having impacts, as delocalization and relocalization do for example. These international trends to delocalize, relocalize and rationalize have impacts on neighbourhoods, cities and regions and major problems have appeared over the recent years, industrial activity being attacked in many developed nations, as industry moves to low-cost countries. and nations look for new sources of economic development and growth.

Globalization and management strategies have thus put forward a *new model of knowledge-based capitalism* that underlines the role of high tech activities, but also more and more over the last years on creative activities and services (Miles & Green, 2010; Musterd & Murie, 2010). This new model is based largely on *multiple networks* (Castells, 2004), which develop across international borders and actually increase the porosity of borders (Castells, 1997, 1998; Amin & Thrift, 2002).

These reconfigurations place cities and mega-cities at the forefront of the movement and transformations related to globalization (Scott, 2001). In such a context, we can see that some parts of the population are successful in integrating social and economic networks (Scott, 2006b; Sassen, 1996; Soja & Scott, 1986), while another part of the population is excluded from such networks and prevented from benefiting fully from their citizenship (Castel, 2008).

Cities are therefore witnessing the concentration of power in certain spaces at the expense of others (former industrial and manufacturing zones, working class neighbourhoods). Many of these former industrial and manufacturing districts are the object of revitalization activities, and many of these rest upon the so-called creative activities and services. It is the interest in these transformations that lead us to question the major factors of attraction of the creatives and knowledge workers, in cities in general, and in Montreal in particular in this specific research.

3 Knowledge City and Creative City

The Italian economist Pier Luigi Sacco (2005) claims that creativity plays a fundamental role for economic and social enhancement in a given territorial system; creativity may ‘enhance the competitive advantage of businesses, develop new social forms and contribute to a social process of knowledge accumulation’.

The US author Richard Florida puts forward the idea that a creative city is based on talent, technology, and tolerance, but his argument is contested on the grounds that his notion of talent resides rather exclusively within an elite, that is mainly people with high levels of education, or artistic groups. While many researchers as well as city managers accept the importance of creation for revitalizing urban neighbourhoods, the debate on creation and innovation in urban settings has been focused on the strategy of the “creative class”, proposed by Florida (2002), which has been highly criticized and provoked strong opposition from the excluded and deprived to strategies of city development centered on cultural creation (Tremblay and Tremblay, 2010).

In *The Rise of the Creative Class*, Florida classifies all knowledge workers in the ‘creative class’, which adds up to a rather disparate party of all ages found in every population strata. Florida (2002) and the Catalytix team conducted an investigation of the creative economy in 24 of the largest regions of the United States and Canada. The authors contend that ‘creatives’ account for 30% of the workforce in the U.S. The creative

class is structured as follows: one ‘very creative’ core or class, and generic creatives ‘by profession’. According to the Catalytix team of authors, the whole creative sector includes four large occupational clusters designated under T.A.P.E. (the acronym stands for Technology, Arts and culture, Professional and managerial activities, and Educational activities). T.A.P.E. also includes persons who work in the information sector, life sciences, computer hardware and software, mathematics, and in other activities like architecture, design, arts and entertainment. This group embodies society’s cultural capital and a *modus vivendi* endowed with values in individualism and meritocracy. In addition, the authors emphasize above all the virtues of competitive, open, challenging and flexible work in a context that Florida has labelled *cool space* in order to underscore *sensemaking* and interaction among individuals (Pilati and Tremblay, 2007).

Florida’s creative class theory has drawn a lot of attention and much criticism from many social scientist as well as urban scientists. The ‘creative class’ is often seen as an advanced alternative community, an avant-garde of pioneers absorbed in a fascinating creative calling that entails empowerment, and more importantly for urban development issues, that is instrumental in creating amenities and activities to attract knowledge workers and thus foster urban economic development.

Many consider that this creative class concept does not add anything to the traditional concept of human capital (Shearmur, 2006; Tremblay and Tremblay, 2006). With the elite considered as the source of creativity and diversity, Florida calls for huge investments in cultural and artistic amenities to make the city attractive for the so-called creative class, who would in turn stimulate innovation and economic growth.ⁱ

According to Menger (2002) ‘the arts are a testing field for flexibility’. This will be confirmed in our data as we will see that our interviewees, all of them artists, are often employed on a part-time "as required" basis and must therefore live by contractual flexibility standards. Moreover, the unfolding of an artist’s activity is usually a cycle of work periods and more or less extensive job insecurity episodes.

4. Montreal, City of Creatives

Montreal seeks to be recognized as Canada’s creative and cultural metropolis (Bellavance and Latouche, 1999). According to Stolarick, Florida and Musante (2005), Florida *et al.* (2005), a Canadian creative class is established in three large urban city-regions: Montréal, Toronto and Vancouver. In this study, the three Canadian cities rank

first among the 24 North American cities for the concentration of the very creative core. This core class is believed to have undergone an impressive growth in recent years in both the U.S. and Canada. In Canada, creatives would be approximately 4 350 000 according to the definition, that is 28% of the active population. Stolarick *et al.* (2005) have determined that in the Montréal region creative class resources amount to a substantial ratio with 450,000 persons, ahead of the services sector, at least according to their definition. Of course, the exact boundaries of the creative concept remain disputable and largely intuitive, but the figures are nevertheless worthy of note if only because the arts sector, generally regarded as a marginal sector, is suddenly given significance in conjunction, of course, with other creative sectors.

Data conveyed in the Canadian study on the arts by Hill Strategies Research (2006) confirm that there is, in the largest Canadian cities, a rather high concentration of artists, that artists' average income is relatively high and that growth in the arts sector is remarkably significant. Three cities (Montréal, Toronto and Vancouver) account for the largest number of artists, that is 38,400 artists or 29% of the 130,700 artists in Canada. In Québec, artists are concentrated mainly in Montréal (36% of the provincial artistic workforce) and Montréal ranks third in terms of headcount in Canada (1.9% compared with the 0.8% Canadian average); Toronto ranks first. Montréal numbers 10 075 artists and the headcount has grown by 24% or 2,000 persons between 1991 and 2001 (Hill Strategies Research, 2006). This growth, however, is the least of the three large Canadian cities (Vancouver 57% and Toronto 35%) and is lower than the Canadian average, 29%. At 50%, the rate of growth of artists in Montréal is the highest in the three Canadian major cities where Vancouver records 23% and Toronto 36%.

Further, according to a *Hill Strategies Research* study (March 2006) Montréal accounts for the largest number of artists, second only to Toronto: in terms of producers, directors, choreographers and similar professions, then second for musicians and singers, for authors, editors and writers, and finally for actors. Indeed according to Bellavance (2004) the arts sector owes its development first and foremost to the substantial growth in the number of artists in Québec, in Canada, and in the Western world. Bellavance notes that this field has witnessed in the last decade not only 'a diversification in the practices but also an acceptance –if not an institutionalisation of contemporary art and of its aesthetics which now prevails' (Bellavance, 2004:2). Thus a diversification of disciplinary competencies is developing and the movement is toward new technologies

and even toward new artforms (new arts). Bellavance also notes that this combines with ‘increased tolerance if not a definite recognition of creativity and innovation values that coincides with the institutional acknowledgement of the legitimacy of the aesthetic of modern time mainstream. From the fine arts in the traditional sense (and in the disciplinary sense), the movement has taken us to contemporary visual arts (in the multidisciplinary sense)’.

From 1991 to 2001¹, Montréal accounts for the largest number of artists in Québec with an increase of 24% over that period. It is notable that neighbourhoods such as LaSalle (47%), Verdun (33%) and St-Hubert (30%) have also witnessed a considerable increase of their artist population. Nevertheless, it is in Montréal that the largest number of artists is to be found. Montréal artists also have the highest average income among the artists in 21 cities of the province. The gap in income, however (i.e., the percentage difference between the average income of artists and that of the local active population) is the lowest (7%) among the cities in the province (Hill Strategies Research, March 2006, p. 34). Let us now examine the method of our research.

5. Methodology

Our research is exploratory and proposes results from a first test of relevant attraction factors applicable to Montréal. We applied a qualitative approach based on semi-structured interviews. The investigation examines artistic careers and the features offered by Montréal to visual artists. The survey was conducted largely in the Plateau and Mile End districts.² The interview guide has four sections that focus on the career path of highly qualified and/or creative workers, on the city’s strengths and weaknesses, on creativity-enabling aspects and on the city’s features that contribute to retention. Also examined is the influence of self-managed artists centres on the network of stakeholders on the territory as well as the importance of the above as they relate to Florida’s bohemian index, i.e., the weight of openness in values and standards on human capital attraction and retention. In this regard, *The Flight of the Creative Class* (2005) claims that immigration plays a decisive role in the attraction of the best talents who, in turn, provide a definite competitive advantage to a city-region. In order to demonstrate that a flow of

¹ We have not found such an analysis with more recent Census data , for 2011, but the same districts appear to be developing still,

² From here on, the paper is an adaptation and translation of a paper published in French in the *Revue canadienne de science régionale* ,in Canada.

immigrants from all origins is a critical element of a city's capacity to attract international talent, Richard Florida makes reference to North American cities and indicates that the presence of immigrants from many places and in high numbers favours some Canadian cities. The mosaic of ethnic and racial groups is seen as positive, since no particular group dominates (Florida, 2005). Immigrants bring along more than just their specialised skills, and therefore immigration policies should be designed to sustain the entry of newcomers. Immigrants actually bring along their networks of contacts in both the economic and creative areas. In this paper, we deal with issues that pertain to the social fundamentals at work in the attraction and retention of talented persons, including the characteristics of the urban employment market likely to alleviate the risks associated with the lack of a job or revenue and that can deflect or change a career path and artistic career.

6. Artist careers: results from our research

In the wake of enquiries by Menger (2002) as well as Florida (2004a, b, and 2005), we have focused our attention on artistic careers in the hope to somehow corroborate their conclusions with this exploratory field study.

6.1. Employment or career opportunities

From the start we have observed that artists seek stimulating work and employment that brings them professional development. At the outset of a career, the professional opportunities offered to artists are based on a series of contracts, most of them in the arts sector. As the career unfolds and where a voluntary rerouting may occur, artists prefer to remain in the same artistic domain, but often don't have the choice in order to earn a living. Where the change is not deliberate, artists try to develop other activities that have some artistic overtones, for example teaching or management in the artistic field, as is the case in self-managed artists centres¹. This aspect is accounted for in a study by Bellavance (2005) in which we learn that an array of arts-related jobs such as teaching and other unrelated employment opportunities take up a lot of time in the professional life of artists and, of course, in their income.

In 2000, at the time of the Statistics Canada census analysed by Bellavance, (2005), one (1) artist out of three (3) was engaged in activities such as teaching art or commercial arts-related practices or activities (photography, commercial drawing and other related

work). Similarly, Martin (2005) observed that young interviewees who had relinquished their artistic career sought another professional status, mostly teaching. At the onset of a career, establishing oneself in Montréal is the most important step for most artists in search of a context and an ambience that are receptive to creative experimentation which, according to our interviews, is encountered in Montréal.

Several Montréal features are attractive to artists in terms of employment market: a dynamic artistic and cultural context that offers year-round activities, the possibility to experiment a wide variety of art forms, the availability of affordable work space as well as continuously renewed calendar of events launched throughout the city. This bubbling diversity of activities provides artists with countless opportunities for exposure and for the display of their work. For long term career opportunities, however, where artists must move from Montréal, our respondents state that they would nevertheless prefer a life in cities that offer even more opportunities such as Toronto and New York, in North America, or London and Berlin, in Europe. Artists acknowledge that in terms of career opportunities, an artist in one of those cities would be granted better recognition than artists living in Montréal. According to one artist (MB, 2006) ‘artists who pursue their creative work over a long period of time, say in France, become *artiste d’État*, commercial artist in the United Kingdom, and a contact artist in Germany’. Our respondent MB adds that in the latter cities ‘there is a larger population - there are specialised platforms and broadcasters - and of course prestigious institutions the likes of which are not found in Montréal’.

Another artist, (ML), compares Berlin and Montréal. According to this respondent, ‘Berlin is probably quite similar in terms of quality of life, but in terms of career opportunities, the outlook is more vigorous’. One more interviewee, (CD) likewise compares Montréal to a neighbouring American city, New York. In terms of quality of life, she says that ‘Montréal is much better’ but she also states, although she hasn’t lived in New York, ‘that in terms of professional development someone well positioned would perform more and better’. And in a Montréal-Toronto comparison she adds ‘of course there are more opportunities given the size of the population; there is a larger number of specialised agents and distributors of art, and prestigious institutions in Toronto. Obviously there is more work available in Toronto, if only in the museums, but the cost of living is higher there than in Montréal, which limits the access to work space and thus,

creativity to a certain extent. Then, in Toronto, one must live and work in English only and that's a drawback' for many.

Other artists hold that Montréal is clearly deprived of cultural and artistic structures, that Montréal is at times unreceptive to investments intended for that sector. Many consider that Montréal's infrastructures have been largely ignored except for a few recent investment in the Montreal Symphonic Orchestra's new hall. Indeed as Toronto is 'credited with the existence of 19 symphonic orchestras compared to only 4 in Montréal and with 58 theatre companies while Montréal accounts for only 33, this certainly legitimizes the shape of this new urban cultural order' (Latouche and Bellavance, 1999:2).

It appears that Montréal may be attractive mainly due to the lower cost of rent, for home and for working space, and for career entry opportunities. In terms of career advancement, however, many respondents consider that Montréal does not have enough institutions, structures and networks to support a genuine artistic career without individuals having to resort to other contingent jobs just to survive.

6.2. Career promoting networks

Artists deem that one of the features that a city can contribute to minimise job-loss or low-income related risks is the establishment of a stakeholders' network on the territory. An active and dynamic cultural environment certainly helps to create this network which is growth-sustaining for artistic communities and careers¹. One artist (MJL) says that she 'was lucky enough to access well-established networks in the artistic community and in the underground community, and benefit from the strong interconnections among the different people who crowd these social networks'. Another artist (CB) holds the same opinion, 'I think that a network is really vital', she says. She believes that 'the availability of a good professional network provides a safety net of sorts when you become involved somewhere and when you change jobs, activity or even change locations. Your skills are known and never lost for that community and it is helpful for job hunting elsewhere'.

To develop and maintain a network of contacts is an efficient strategy to put into action both the expectations and the objectives of a career. But this network is of rather limited scope in the Montréal metropolitan area and is not set to envision career

¹ We also conducted a research on the links between the Business and Arts sectors, with Elisa Cecilli, student from the Arts Management program at the University of Trento. See the research note on our website (www.telug.ca/chaireecosavoir).

expectations beyond Montréal or the province of Québec. One artist (MB) testifies that ‘it’s all about occupational choice; opportunities do come by and I try to follow up on them through multiple contacts at different levels. I’m an artist, but also a coordinator and a commissioner and this allows me to meet a lot of people who, if they appreciate my personality or my work, are all potential collaborators [...]. Alliances are indeed strategic because if you want to persist in that sector you’ll have to work with these people one day or the other anyway. So there are a few actors in the sector who’ve turned their back to the community, but they’re now completely isolated’. The function of the network is therefore a career-influencing factor. Although the community is relatively small, it seems valuable to remain in contact and above all to be well perceived.

6.3 Artistic career plans, expectations and challenges

Many artists among our interviewees have stated that Montréal possesses valuable assets to which the artistic community will cling. A substantial number of artists definitely prefer Montréal over other cities as their home base to fulfil their future career plans and expectations. Career goals are focused on the potential for a full-time career as a professional artist, which is not always easy or even viable. In self-managed artists’ centres, however, artists are likely to meet and exchange with a score of actors from different backgrounds, whether artists, co-ordinators, facilitators or commissioners. It is this very aspect that encourages and promotes the creation of alliances or the execution of joint projects. For artists, the lack of funding is the most critical issue or challenge, and indeed artists are often under financial pressure. They nevertheless do as best they can to manage this hurdle through the design of new artistic endeavours, project support activities, fund raising policies and including a diversification of their occupational activities into teaching and/or the management and facilitation of networking in the artistic sector.

One artist (ML) contends that ‘there is a lack of capital, I mean there is money but the question is how and where is it invested. Change is frightening, and what I’m saying here may be upsetting [...]. Nevertheless, money is available to artists who want to perform, and the cost of living isn’t that bad. We can have access to production workspace, studios...’. An investigation into the 1999 figures on the financial standing of artists substantiates that the sale or the rental of works of art ‘is not necessarily the main source of revenue yet it is the most often mentioned source among all incomes’ (Bellavance,

2005:iv,xiv). All artists have widely diversified income but as Bellavance puts it, ‘most artists are likely to develop diversified income strategies’ (ibid.). The earnings accrued directly from their practice are usually rather lean.

According to Hill Strategies Research (2006), Montréal displays the lowest income differential between artists and the rest of the working population among the three large Canadian cities. In Montréal, the \$CD 26,200 average income places the city tenth among Canadian urban centres and the differential is the lowest with the overall average income. Montréal is nevertheless credited with a distinct personality and an ever-growing potential that artists do acknowledge. Artists identify Montréal’s uniqueness as an essential qualifying feature: a good place to live on a permanent basis. There are factors and features that make Montréal unrivalled. Montréal is the second largest French-speaking city in the world. The pace is smooth and easy, facilitation is available for establishing knowledge networks and there is an open-minded gay community. Indeed artists, in keeping with Florida’s studies, consider that the city is tolerant, that it acknowledges the expression of multiple cultural profiles and that it welcomes diversity. In the following paragraphs, our interviews and reference documents are analysed to identify those factors deemed most important and which make the city attractive enough to attend to its large number of artist.¹

6.4. Montréal’s attraction and retention factors

Artists assert that the quality of life in Montréal is extraordinary and that the cost of living and other amenities are beyond compare. Montréal offers artists a quality of life better than what is provided in other North American cities for the same price. Economy of scale is repeatedly mentioned, as well as low-cost access to culture which benefits both the public and the artistic community.

According to several interviewees, Montréal’s singularity would be that of talent and creativity. As one City of Montréal cultural development agent puts it, ‘Montréal is unlike other cities to which it is readily compared, for example Toronto, where tremendous efforts are made in terms of cultural facilities with renowned architects and unthinkable buildings worth millions, including a recently added opera house (Centre for the Performing Arts), all things that may be envied, including the Film Festival, yet Montréal

¹ Given the limits in number of pages for this conference paper, we cut out a good number of citations, available in the French version of the paper. See Pilati and Tremblay (2008). See also Tremblay and Pilati (2008) for other elements on the creative city.

has always been recognized by its trait, singular, original, distinctive and French-style *joie de vivre*. [...] Think of a little big city like Montréal, I think it ranks 26th in size among North American cities. It's easier then to pinpoint our distinctiveness as the second largest French-speaking city in the world. And yes there is one singular quality to Montréal, but we're not saying that it is a private or exclusive quality. We differ in that sense, culturally, which makes us unique, but for us the issue is enhancement, not misfortune'.

Compared to other large North American cities, Montréal offers a rather safe environment. One artist (CD) believes that 'the best is yet to come which will provide a little more splash, so to speak. What I like about Montréal is that it's a good place to live. [...] the city is rather safe, and that, for me is another good point'. To this, artist (MB) adds tolerance as an outstanding feature of the city, one that ranks highly creativity and experimentation.

6.5 Less attractive job market

We also surveyed our participating artists on the less attractive characteristics of Montréal. For many of them, Montréal lacks a more authentic and original cultural policy, strategy. Some believe that in order to read Montréal as a genuine, internationally renowned cultural metropolis, Montréal should facilitate creative freedom, within and outside the framework of the cultural industry. One artist speaks of 'the loss of historical information; some things are done not only in Montréal, I'd say the are done in many other cities as well, think only of everything that happens in the entertainment district, one can see so many projects pop up and quickly dissolve'. Montréal appears to be a rather underdeveloped market for contemporary art. The city is therefore less attractive for artists in this sector regardless of the low cost of rent. Whereas low costs are conducive to production, many aspiring contemporary artists state that the distribution of their production is problematic.

6.6. Creativity enhancing aspects of Montréal

Montréal's alternative and underground culture is important for the artistic and cultural landscape and this factor is deemed significant for artists in the development of their creativity. For example, one artist (MJL) underscores the importance of alternative magazines; another artist (CB) goes into more detail concerning Montréal's artistic and cultural context. She says 'it's more like the underground somewhat, these neighbourhood

initiatives that really make the city come alive, for me at least. Diversity also, of course. So for me, in Montréal's culture, this is what counts, what's interesting. Montréal's music scene is very much appreciated internationally. The public is eager and pop music – all of the underground scene, is quite recognised internationally'. We may gather therefore that all artistic segments contribute to the liveliness of Montréal's artistic system.

According to many artists, the urban dimension itself is another significant factor in their creative ability. One of them (CB) says: 'that's the feeling I may have of a network, it imparts meaning in Montréal's artistic community. In many neighbourhoods of the city, there is a community spirit. And somehow to be part of this is a stepping stone to visibility. But to have a window on the street is even better, it is among the very first criteria. [...]' Yet another artist (EG) says that Montréal is a city that is both a village and a metropolis in all its districts, a city that is on the average three-story high [...]. For one's creativity, Montréal is convenient whether a village or a city, and a very large city it is in terms of geographic surface area on this island. Village and large city remain one; public transportation ensures proximity; even when you must take the subway or the bus, it's easy and convenient... taxi rides are inexpensive and the road system is accessible. Proximity is everywhere and that makes for easier creativity.'

Further, artists claim that creativity benefits from a flexible work environment which includes the possibility to access collective spaces with relaxation and socialisation facilities. Montréal offers several such creative spaces in specific city districts, in depressed sectors, or in sectors under reconversion. Without specific input toward territorial planning, creatives would seek for large buildings which can be used for creative projects (Florida, 2004a,b). They invest both in culture and in creativity and they change neighbourhoods into 'creative ecosystems'. These spaces are then adapted to the needs of artists who, in terms of facilities, have a preference for open, well lit, quiet working environments with high ceilings.

One artist (MJL) confirms this and says that for her work she really needs well lit spaces in natural light: 'you see something, when I think of the closet I was given to work at the university, lit with a single neon tube, I never went there, wasn't interested in such an environment either to think or to create; anyhow, it was just a wall and that's it. I quite like wide horizons that give me the impression of being part of the action, in this case an urbanscape seen from the roof where so many things happen [...] ...it's a chance to be able to work in collective workshops, not alone in a cubicle, I was in a huge space, we

were in open workshops and could speak to each other and having had that opportunity I have a different understanding of ‘contacts’... (end of quote).

According to the Hill Strategies Research report on the most creative neighbourhoods in Canada, Montréal supports 5 of the 10 most creative districts in Canada. The Plateau Mont-Royal neighbourhood is considered Canada’s top creative district with 605 artists in a total workforce of 7,560, that is an 8% concentration; quite similarly, the neighbouring district of Mile End has a 6.1% concentration of artists. Such concentration no doubt breeds a setting favourable to creativity and the artists concerned agree that they collect there precisely for that reason. It was also noted that adjoining neighbourhoods such as Mile End have begun to develop in a similar manner because of their proximity to Plateau Mont-Royal and because rents have not yet begun to rise, while they have in the Plateau for some decades.

7 Conclusions

Florida’s creative class theory has drawn a lot of attention and much criticism from both the right and the left. The ‘creative class’ is often seen as an advanced alternative community, an avant-garde of pioneers absorbed in a fascinating creative calling that entails empowerment and self-direction, and that is instrumental in creating amenities and activities to attract knowledge workers. Some of the criticism aimed at Florida’s theory address specifically what some designate under elitism since the less creative population or the economically disadvantaged are not suitably taken into account. In this paper, we did not discuss this issue, and instead we made an attempt at testing the validity of the theory on the attraction factors at play between cities and the talented.

This research initiative has revealed that visual artists display a profile seemingly close to Florida’s and Menger’s contention. Florida does not stress the artistic employment issue enough, and rather highlights to the importance of cultural and artistic amenities to attract other knowledge workers. The employment and market realities require a substantial measure of individual responsibility and activation in order for artists and cultural groups to make a living. Indeed, the talented and the creatives increasingly cope (like many others, dare we add, and not always through choice, cf. Tremblay, 2007) with intermittent employment and the risks inherent to possible career changes.

What is revealed according to Menger (2002) are the ‘paradoxical learnings on artistic work’ whereby some of the main and most significant transformations in work and

employment systems today are: empowerment, intensive involvement in the activity, high self-reliance, work flexibility and choice of context, and for a large number of artists, psychological and social rather than monetary gratification. This of course is the bright side, which we did find in our interviews with the creative artists. However, the same self-reliance and flexibility may however mean insecurity, especially in the less creative sectors.

In the artistic sector, however, the non monetary rewards supply 'an insular basis to the ideological glamour associated with artistic work' (Menger, 2002:53). Artists handle a much more important and powerful capital that relates to the symbolic components acting upon the individual's identity. Artists undertake this activity which is riskier than employment in other sectors, but success may at times yield extraordinary rewards. Artists benefit from their learning potential and from their ability to educate through the multiple exchanges carried out during the activity. Moreover, experimentation happens to result not only from organisational provisions but also and mostly from social relations in self-managed artists centres. As Menger (2002) puts it, pioneer spirit speaks to entrepreneurship, and the creation of a network and work alliances provides its organisational model to other connected fields. However, it remains to be seen to what extent these artistic and cultural groups are indeed the source of attraction for knowledge workers, as Florida has proposed. We have highlighted here the factors of attraction for creative workers, but have in other works looked at the factors of attraction for knowledge workers and there may not be so many relations between the two groups. (Darchen and Tremblay, 2010)

Abstract

This paper studies the antecedents of individual improvisation in the ad-hoc co-improvisation context. The paper explores how the intra-personal factors self-efficacy and intrinsic motivation, and the inter-individual or other-focused psychological factor of positive affect are related with individual improvisation in ad hoc co-improvisation event. This is important for two reasons. First, improvisation is an increasingly important ability of individuals, teams and organizations working in various forms of temporary settings. Second, it is important to understand, what the simultaneous effect of both intra-personal (self-efficacy and intrinsic motivation) and the situation related inter-individual (other-focused) factors are for one's improvising. The study explores the relationships of these variables through the SEM-PLS path model with a data sample of 70 respondents collected from four co-improvisation workshops. The results indicate, that self-efficacy relates with individual improvisation. In addition, the positive affect moderates the relationship between intrinsic motivation and individual improvisation, and that this interaction effect is significant, strong and negative. The study contributes on the discussion of the antecedents of temporariness and suggests improvisation as a promising approach for individuals to deal and cope in such emerging conditions.

Keywords – Individual improvisation, self-efficacy, intrinsic motivation, positive affect, PLS

1 Introduction

In rapidly and unexpectedly changing economy (Eksted et al. 1999; Bakker, 2010) temporary forms of organizing have become as increasingly relevant (Bakker, 2010; Mayerson, Weick, Kramer, 1996; Kanter, 1989) as firms need to integrate highly specialized and distributed expertise and knowledge (Tsoukas, 1966; Tsoukas and Chia, 2002) into tasks to respond to the emerging problems and grasp the opportunities. Such

temporary conditions (Mayerson et al. 1996) require different orientation and abilities from the participating members compared to stable organization conditions. This study proposes an individual improvisation as an individual ability and purposeful behavior to deal in dynamic conditions of temporariness and ambidexterity, and, in other words, in the ad hoc social interaction with other experts.

In temporary forms of organizing number of actors work together over a limited (Goodman and Goodman, 1976; Grabher, 2002, Mayerson et al., 1996) and short period of time (Lanzara, 1983; Grabher, 2004; Bakker, 2010). In such conditions the participants neither know each other nor their expertise, and they often have minimal, if any, time for socialization (Lindkvist, 2005). Likewise, such situations lack stable structures, pre-determined roles, shared organizational or team culture (Mayerson et al., 1996; Lindkvist, 2005; Weick and Roberts, 1993), routines (Mayerson et al. 1996), memory (Moorman and Miner, 1997; 1998) as well as conventional sources of trust (Mayerson et al., 1996). Instead, the conditions and the antecedents of such ad hoc teams unfold and are built in real time interaction by the participating members.

Individual improvisation is seen as a near and overlapping construct with individual creativity (Amabile, 1996; Leybourne and Saddler-Smith, 2006; Montuori, 2003) and individual innovative behaviour (Moorman & Miner 1998; Fisher and Amabile, 2009), but represents a more dynamic dimension of these constructs. As an innovative and rule-breaking behaviour improvisation represents real-time responsiveness (Fisher and Amabile, 2009) and ability of an individual to cope in complex and ambiguous settings (Weick, 1993; Montuori, 2003). Therefore, we see individual improvisation as an increasingly important individual behaviour, and possibly even a skill required by modern employers (Friedman 2014a, 2014b).

However, empirical and especially quantitative studies on individual improvisation are scarce (with the exception, see Magni, Proserpio, Hoegl, and Provera, 2009; Hmileseski and Corbett, 2006) and it is not yet clear, what antecedents enable individual improvisation to occur in ad hoc team conditions. For example, Mayerson et al. (1996) argue that without paying attention to, and managing the conditions of unfolding temporary settings, the participants are likely to act more like in permanent conditions, which thereby can limit exploration and suggestion of novel ideas and solutions and risk taking.

To respond to this shortage in the literature, the study at hand examines individual improvisation as the ability of an individual to deal in temporary and ad hoc team conditions. More detailed, the study explores both the intra-individual (psychological) and interpersonal (other-focused) antecedents of an individual improvisation in temporary creative conditions. Hence, intra-individual factors of self-efficacy and intrinsic motivation, as well as the interpersonal factor of positive affect are studied as antecedents of an individual improvisation in an ad hoc co-improvisation context. An interest is thereby paid on whether the individual improvisation is more as a stable attribute of an individual, or is it more an issue influenced by the situation or both. This is, to what extent the situational factors, such as perceived influence and the experienced positive signals of the other person (Bligh, Pearce and Kohles, 2006) affect individual improvisation within temporary team context. What does it take to improvise in an ad hoc team, where two individuals improvise together?

The data was collected from four workshop sessions with working adult students. Data (N=70) was collected via survey in 2013-2014 from experts who had several years of work experience from different industries and fields. We explored the causal relationships between the dependent (individual improvisation) and independent variables (self-efficacy, intrinsic motivation, positive affect) as well as the moderation effect of positive affect between intrinsic motivation and individual improvisation using PLS path model analysis, which is a suitable method for explorative analysis as well as in cases of small data sets.

The paper provides evidence of the antecedents of individual improvisation in ad hoc expert tasks i.e. in conditions that are becoming increasingly common and relevant for firms operating in a global knowledge-intensive context. The results indicate that positive affect, displayed as perceived bodily passion, moderates the relationship between intrinsic motivation and individual improvisation, and that the moderation effect is negative. In addition, self-efficacy affects individual improvisation in ad hoc co-improvisation.

The study provides novel findings by introducing the other-focused elements, such as perceived positive affect, to the discussion of the antecedents of individual improvisation. In addition, the study explores the simultaneous effect of both intra-personal and inter-individual factors on individual improvisation in an ad hoc co-improvisation situation. As a practical contribution, the study suggests that organizations should take more advantage of novelty, diversity and emergence in their knowledge creation and innovation activities.

Against the common understanding, it may actually be easier to collaborate informally with completely novel individuals, rather than with those well-known individuals whom one already knows and may have learned to avoid any controversial issues.

2 Theoretical background and hypotheses

2.1 Individual improvisation in co-improvisation

Individual improvisation is an ability of an individual to deal in complex and unexpected situations (Magni et al. 2009; Magni, Provera and Proserpio, 2010; Vera and Crossan, 2005; Weick, 1998; Montuori 2003) in a creative, contextual and professional manner. It plays an important role in collective creative processes like in team improvisation (Vera and Crossan, 2005), organizational improvisation (Moorman and Miner, 1998) and innovation (Fisher and Amabile, 2009), in fostering processes of new product development (Eisenhardt and Tabrizi, 1995; Moorman and Miner, 1998), product design (Sutton and Hargadon, 1996), implementation of new technology (Orlikowski, 1996; 2002), in start-up firms (Baker, Miner and Eesley, 2003), entrepreneurship (Hmieleski and Corbett, 2006) as well as in institutional entrepreneurship (Fliegstein, 2001). Hence, it is a dynamic behavior and ability of individuals to orient and act in conditions of complexity, temporariness and ambidexterity.

The context of this study is ad hoc co-improvisation, which is understood as a form of team improvisation, where the number of actors improvises together. Such co-improvisation concerns to carry out the open ended task without script and preplanning, in shared and emerging leadership and responsibility under mutual support (Vera and Crossan, 2005; Sawyer and deZutter, 2009; Weick, 1993; Koppett, 2001). Indeed, an ad hoc co-improvisation is demanding and it requires special kind of abilities and orientation from improvising individuals. In co-improvisation the real time responsiveness (ability to cope with lack of time and to respond to emerging situations) and the elements of team improvisation (Vera and Crossan, 2005; Weick, 1993; Johnstone, 1979; Koppett, 2001), such as presence, acceptance and agreement, openness, imagination, bricolage, building on others, shared responsibility and leadership, mutual support for others, scaffolding and mutual trust are fundamental basis for co-improvisation (Vera and Crossan, 2005; Johnstone, 1979; Koppett, 2001; Spolin, 1977). Hence, we argue that in the co-improvisation context the antecedents of successful individual improvisation demand the other-related factors to be considered.

To our knowledge few quantitative studies are available examining the enablers of individual improvisation. Magni et al. (2009) found that team cohesion moderated the influence of team behavioral integration on individual improvisation. Behavioral integration was operationalized constituting of communication and experience, knowledge and perspective sharing among team members. Hmieleski and Corbett (2006) found that propensity for improvisation was a significant predictor of entrepreneurial intentions. Leybourne and Sadler-Smith (2006) found that individual improvisation mediated the relationship between individual intuition and project outcomes. Finally, the study of Vera and Crossan (2005) found interaction effect of team improvisation and contextual factors influencing on innovation.

Hence, the current research of individual improvisation is scarce and it suffers from some gaps. First, although, being highly ad-hoc and complex by its nature, individual improvisation is less studied phenomenon in temporary and ad hoc co-improvisation context. Less is known what factors enable individual improvisation to occur as well as how temporariness effects on its occurrence. This refers to the lack of studies examining how temporariness effect on the behavior of the group members (Bryman, Bresnen, Beardswort, Ford and Keil, 1987), antecedents of team dynamics (Bryman et al 1987, Saunders and Ahuja, 2006; Bakker, 2010) and common creative process (Bryman et al 1987, Saunders and Ahuja, 2006; Sonnenburg, 2004). Second, the team improvisation studies (Vera and Crossan, 2004) measure improvisation and its enablers as team level constructs. Third, the scales of individual improvisation are underdeveloped especially in terms of the antecedents of individual improvisation in situation of co-improvisation. The current scales of individual improvisation measure the individual characteristics, i.e. intra-individual attitudes and propensity of an individual to improvise (Magni et al., 2009; Hmieleski and Corbett, 2006, but pay less attention to the other-related factors and social interaction essential in team and co-improvisation.

Aiming to extend the understanding of the individual improvisation in temporary context we draw from the current research in individual creativity and individual innovative behavior as close constructs to individual improvisation. We take as a starting point the assumption that similar kind of factors may predict all these individual level phenomena. The current literature suggests that both the more stable personality factors or traits and the situation-specific factors affect an individual willingness to contribute to stimuli (Amabile, 1996; Grant and Berry, 2011; Leybourne and Sandler-Smith, 2006;

Magni et al., 2009, Magni et al., 2010). We also adopt the view suggested in recent studies, that self-interested or intrinsic motivations and the other-related or prosocial motivations are positively related (De Dreu and Nauta, 2009; Grant and Berry, 2011). In the following we discuss the antecedents of improvisation related self-efficacy, intrinsic motivation and positive affect more detail and state the hypotheses.

2.2 Self-efficacy

From individual psychological factors the improvisation related self-efficacy is already identified as predictor of individual improvisation (Magni et al., 2009; Magni et al., 2010; Hmieleski and Corbett, 2006) in organizational team context. One's belief in his or her ability to succeed in particular situations (Bandura, 1997) is captured via construct *self-efficacy*, which thereby predicts individual's performance (Bandura, 1986; Shea and Howell, 2000; Tierney and Farmer, 2002). High levels of self-efficacy indicate increased motivation to put efforts, time and energy to particular activities even under stressful situations and obstacles (Bandura, 1997; Denti and Hemlin, 2012). In contrast, in opposite case it indicates the likelihood of an individual to avoid such efforts, which means to stick on the orders (Magni et al. 2010) preventing the rule-breaking behavior and exploration of novel solutions. For individual improvisation to occur, it is obvious that the high level of improvisation related self-efficacy predicts in individual ability to deal with emerging events and in temporary context where fast action is a necessity for performance. Thereby, we state the hypotheses:

H1: Individual improvisation related self-efficacy predicts individual improvisation in ad hoc co-improvisation.

2.3 Intrinsic motivation

The relatively stable personality trait of intrinsic motivation is a key driver of creativity (Tierney et al., 1999; Elsbach and Hargadon, 2005; Grand and Perry, 2001; Amabile, 1983; 1988; Shalley et al., 2004). It describes one's orientation or level of enthusiasm, enjoy and passion for opportunities and activities of generation of novel insights, ideas and solutions (Tierney et al., 1999; Amabile, 1988). The intrinsically motivated individuals feel themselves positively affected (Silvia, 2008; Grant and Berry, 2011), which stimulates creativity (Amabile, 1996) and engagement into complex and

unfamiliar tasks (Gagné and Deci, 2005; Grant and Berry, 2011). Current literature suggests that the orientation of an individual for creativity is partially shaped by the context (Amabile, 1983; Tierney et al., 1999), but the stronger effect is provided by the stable nature of intrinsic motivation (Tierney et al., 1999). An intrinsic motivation has been found to be related with cognitive flexibility (Amabile, Barsade, Mueller & Staw, 2005), psychological engagement and individuals ability to deal with complex and unfamiliar tasks (Gagné & Deci, 2005; Grant and Berry, 2011), which all are essential characteristics also for individual improvisation to occur. In fact, Hmieleski and Corbett (2006) measured one's proclivity for improvising with a large single construct constituting of three dimensions: creativity-bricolage (Tierney et al, 1999; Vera, 2002), pressure-stress, and action-persistence (Unger and Kernan, 1983; Moorman and Miner, 1998). We thereby state the following hypotheses:

H2: Intrinsic motivation for creativity predicts individual improvisation in ad hoc co-improvisation.

Whereas intrinsic motivation is considered as the key source of individual novelty (Amabile, 1996; Grant and Perry, 2011), the other-related factors refer to the importance of the others (Grant and Perry, 2001) for co-improvisation. Therefore, the less studied predictors of individual improvisation are the other-focused psychological factors, which refer to the inter-personal, social and situational affects emerging in interaction between the co-improvising participants. In other-focused factors attention is on the others, i.e. one's perceptions of the other person's behavioural cues, gestures, and signals (De Dreu, Weingart and Kwon, 2000). The perceptions captured from the other person behaviour and responsiveness may represent positive affect (Erez and Isen, 2002), which can increase one's enthusiasm and passion, expression of ideas openly (Erez and Isen, 2003; Staw and Barsade, 1993), acceptance of the ideas of the other person and building on them, and encourage one to throw into improvisation. In fact, we propose that the other person's visible (perceived) positive affect leads to mutual co-creation. This is because positive affect is contagious and the visible positive affect makes another person see the opportunity, and thereafter take action (here increase one's individual improvisation) (Erez and Isen, 2002). In the following we refer to positive affect by discussing the construct of psychological presence introduced by Kahn (1990, 1992), that we measure as entrepreneurial passion by Chen et al., (2009).

2.4 Positive affect

The experienced *positive affect* such as interest and passion has been demonstrated as a critical factor in idea generation, problem solving and innovation (Isen 1999, Amabile et al. 2005). Positive affect may manifest in intensive psychological, cognitive and bodily presence displayed in person's aliveness from concrete and bodily to abstract cognitive and emotional indicators. *Bodily presence*, maintaining the eye contact and fullness of the speech provide physical cues for being present, while cognitive presence is signalled through active participation in a social interaction (Kahn 1990, 330; see also Goffman, 1961). In the entrepreneurship context Chen et al (2009) describe passion as an intense affective state toward a specific target displayed by cognitive and behavioural manifestations. First, it enables intensive focus and full use of energy on the current task, critical for ad hoc expert tasks within specific time limits. Second, it makes the expert's motivation and interest visible in verbal and non-verbal display, energizing the other expert in social exchange. In general, the interactions with one another among team members influence and impact on team members' behaviour, beliefs, attitudes and contributions (Blingh, Pearce and Kohles, 2006; Weick, 1979). We thereby propose the following hypothesis:

H3: *Perceived positive affect predicts individual improvisation in ad hoc co-improvisation.*

The intrinsic motivation is considered as relatively stable intra-individual trait, while the positive affect represents the situation-specific affect. Hence, the interaction effect of these factors to individual improvisation may vary between individuals. In fact, it is likely that relationship between the intrinsic motivation and individual improvisation is stronger for some people than for others, which assumption leads us to explore the possibility of moderation effect in the relationship between the variables in consideration. For example, Grant and Berry (2011) found the other-focused factor of prosocial motivation strengthening the relationship between intrinsic motivation and creativity (independently rated). The moderating variable influences on the strength and direction of the relationship between the predictor (intrinsic motivation) and the outcome (individual improvisation) (Baron and Kenny, 1986; Frazier, Tix and Barron, 2004). Likewise, Erez and Isen (2002) found positive affect interacting with task conditions while effecting on motivations. Hence, it is likely that the effect of positive affect is not equal across the people (Erez and Isen, 2000). We thereby state the following hypotheses:

H4: Perceived positive affect moderates the relationship between intrinsic motivation and individual improvisation in ad hoc co-improvisation.

3 Methodology

3.1 Case description

Our workshops were consciously planned to study both the individual and team antecedents of individual co-creation and action in ad hoc conditions. Hence, we built a situation where the team members (two individuals in each) were strange to each other. This refers to conditions of temporariness (Goodman and Goodman, 1979; Mayerson et al., 1996; Laranza, 1983). As a task they carry out an imaginative and creative task (which is outside their familiar fields and therefore new to them) within short period of time (25-30 min). In fact, they have to improvise together to carry out the task in given time. We were interested about both the intrapersonal and inter-individual antecedents of such ad hoc team work.

3.2 Data collection and analysis

The data was collected via survey from four workshop session in two university centers of continuing education in 2013-2014. The respondents (N=70) were experts with several years of work experience from different industries and fields. In the workshops they worked in pairs with the person with whom they were not familiar with. To analyze the data, we test the causal relationships between the dependent and independent variables using PLS analysis. The PLS is preferred method as it deals non-normally distributed data well (Bontis, Booker and Serenko, 2007), it deals with relatively low sample size (Hair, Ringle and Sarsted, 2011) and it allows multiple predictor variables and multiple outcome variables in the model (Baron and Kenny, 1986; Frazier et al, 2004). The minimum sample size for PLS-SEM should equal with “the ten times the largest number of formative indicators used to measure one construct” (Hair et al., 2011). In addition, it is preferred for exploratory studies aiming to extend the existing theory (Hair et al., 2011), and suggested also for moderation effect studies to overcome possible unreliability in measurements (Baron and Kenny, 1986; Frazier et al., 2004). The data based on the

perceptions and experiences of the respondent's is often non-normally distributed, the PLS was appropriate method for analysis

3.3 Measurements

Dependent variable: Construct *individual improvisation* was measured by five items scale adopted from Magni et al., 2010, who modified it from the team level scale of Vera and Crossan (2005). A sample item is “*I can deal with unanticipated events on the spot*”. The construct was captured by five-point Likert-type scale.

Independent variables: In assessing the improvisation related *self-efficacy* we used a three-item variable (Magni et al., 2009; Zhao et al., 2005) captured by a five-point Likert-type scale. A sample item was, “*I am confident; I can deal with unanticipated events on the spot.*” The construct *intrinsic motivation* was measured with the five item scale (Tierney et al., 1999) captured by a five-point Likert-type scale. The sample item was, “*I enjoy finding solutions to complex problems*”. The construct *positive affect* was measured with the scale of Davis (1980, 1983) captured by a five-point Likert-type scale. The sample item was, “*The person used a lot of gestures*”.

4 Results

4.1 Descriptive statistics

From the respondents (N=70), 58.6% (N=41) were female and 41.4% (N=29) male. The distribution of the education of the respondents was as follows: vocational college 2.9% (N=2), matriculation examination 7.1% (N=5), higher academic degree, 68.6% (N=48), and in the category of the other degree of education were 21.4% (N=15) respondents. The distribution of the age of the respondents was as follows: under 30 years, 22.9% (N=16), 31-50 years 67.1%, (N=47), over 50 years 10%, (N=7). From the respondents 32.9 % (N=23) had a work experience less or equal of 10 years, 40% (N=28) had a work experience between 11 to 20 years, and 27,1% (N=19) had more than 20 year work experience.

The data relied on self-report measures. We therefore assessed the risk of common method bias, and conducted a principal component analysis that incorporated all the items from all of the constructs using the Harman's one-factor test (Podsakoff et al., 2003) for each model. We investigated the solution in order to determine the number of factors

required to account for the variance in all the items. The largest factor accounted for 18.11 %, which suggests that common method bias is not a concern.

4.2 Measurement model

Composite reliability values of the constructs varied between 0.84 – 1.00, which exceeds the suggested value of 0.70 (Nunnally and Bernstein, 1994; Hair et al. 2011) and demonstrates high levels of internal consistency reliability (Appendix I, Table 3).

Table 3: Construct statistics and estimated loadings

	Mean	Sd	AVE	Composite Reliability	Cronbachs Alpha	Communality	Loadings
Intrinsic motivation	2.84	3.940	0.98	1.00	0.99	0.98	0.99-1.00
Improvisation	3.31	1.801	0.86	0.97	0.96	0.86	0.92-0.96
Positive affect	3.28	0.832	0.61	0.88	0.89	0.61	0.71-0.90
Self-efficacy	3.88	0.572	0.64	0.84	0.72	0.64	0.76-0.85

Convergent validity of the constructs based on the average variance extracted (AVE) value showed high levels of validity. AVE values of the constructs varied between values 0.51 – 0.98 (Table, 3 and Appendix I). The lowest AVE value (0.61) was on *positive affect* and the highest on *intrinsic motivation* (0.98).

To assess *discriminant validity* we compared the Fornell-Larcker criterion (Fornell and Larcker 1981) with cross loadings (Table 4). More specifically, we compared the square root of AVE (on the diagonal in table 4) with the correlations between the latent constructs. The all square root values of AVE were higher than the correlations between the latent construct variables. Hence, the discriminant validity was established (Hair et al. 2011).

Table 4: Correlation matrix and discriminant validity assessment

	Intrinsic motivation	Improvisation	Positive affect	Self-efficacy
Intrinsic motivation	0.98			
Improvisation	0.19	0.92		
Positive affect	0.24	0.33	0.78	
Self-efficacy	-0.02	0.17	0.03	0.80

4.3 Model analysis

We examined first (Model I, table 4) the direct paths from the independent variables of self-efficacy, positive affect and intrinsic motivation to individual improvisation. The model I showed that there exists path dependence from the independent variables to dependent variable, albeit all paths were non-significant (H1: $t=0.68$, H2: 0.87 , and H3: 1.06). The $R^2=0.147$ explained 14.7 % of the individual improvisation in ad hoc co-improvisation conditions.

Figure 1: The path dependence between dependent and independent variables.

In the Model II (Figure 2) we explored the moderation effect of the *positive affect* between the variable of *intrinsic motivation* and *individual improvisation*. The results (Figure 2) give a standardized beta of -0.055 from intrinsic motivation to improvisation, and 0.265 from positive affect to improvisation, and an interaction effect of -0.568 with a total R square of 0.424 . The $R^2=0.424$ of the model explained 42.4 % of the individual improvisation in temporal team creativity conditions. The interaction affect had an effect size of $f = 0.48$, which is strong as it exceeds the value of 0.35 (Henseler and Fassot, 2010; Cohen, 1988; 410-414). The results imply that there exists difference between individuals experiencing the positive affect in ad hoc co-improvisation situation. The

interaction effect of positive affect and intrinsic motivation is less important for the individuals with high intrinsic motivation than for the people with low intrinsic motivation. In other words, the individuals with low intrinsic motivation profit from positive affect in co-improvisation.

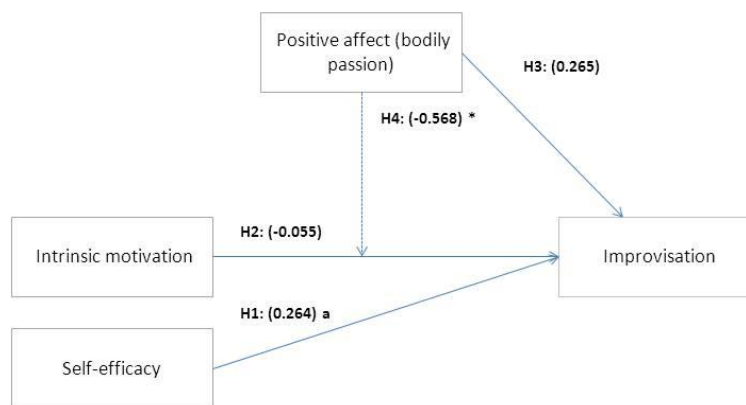

Figure 2: The interaction model.

In general, the R square value of 0.50 is considered as moderate and 0.25 as weak in marketing research (Hair et al., 2011). The judgment of R square, however, depends on the research discipline, and, for example, in consumer behavior the R square of 0.20 is considered as high enough (Hair et al., 2011). This study is explorative one and focuses on human behavior, and there exist few empirical quantitative studies concerning the antecedents of individual improvisation in temporary work settings, hence R square value of 0.42 can be considered at least as moderate.

In the model II the model analysis showed significance on the Hypothesis of H4 (t=1.80) at the significance level of 95%. Also, hypothesis H1 (t=1.29) showed some

significance at the significance level of 90 %. Instead, hypotheses H2 ($t=1.09$), and H3 ($t=0.50$) were non-significant.

Table 4: Testing the Model I and the Model II.

MODEL I	Path Coefficient	S.D.	Standard error	T Value
H1: Self-efficacy -> Improvisation	0.168	0.2455	0.2455	0.68
H2: Intrinsic motivation -> Improvisation	0.123	0.1400	0.1400	0.88
H3: Positive affect -> Improvisation	0.291	0.2455	0.2741	1.06
MODEL II: Moderation model	Path Coefficient	S.D.		T Value
H1: Self-efficacy -> Improvisation	0.295	0.1966	0.2044	1.28 a
H2: Positive affect -> Improvisation	0.228	0.2479	0.2432	0.92
H3: Intrinsic motivation -> Improvisation	-0.533	0.4603	0.1103	1.16
H4: Intrinsic motivation * Positive affect -> Improvisation	-0.996	0.7033	0.3150	1.80 *

Significance on the t-values (one-tailed):

a	*	**	***
90 %	95 %	97.5%	99 %
1.282	1.645	1.960	2.326
			2.576

5 Discussion

The following section discusses the findings of the study, the implications of them, as well as the ways in which the paper contributes to the discussion concerning the antecedents of individual improvisation in ad hoc co-improvisation.

In the direct path model (Model I) we found positive path dependence from the independent variables of self-efficacy (H1), intrinsic motivation (H2) and positive affect (H3) to individual improvisation. However, the path dependences were unexpected weak, which lead us to study the possible interaction relationships (Frazier et al., 2004). For that purpose, we draw from the current literature (Grant and Berry, 2011; Erez and Isen, 2002) to form the interaction effect of the constructs of intrinsic motivation and positive affect to individual improvisation. In fact, the assumption was that the situational and interaction related positive affect (Erez and Isen, 2002) and more stable attribute of an intrinsic motivation (Grant and Berry, 2011; Tierney and Farmer, 2002; Tierney et al., 1999) would vary across individuals (Erez and Isen, 2002).

The results provided support for the role of positive affect in moderating the relationship between intrinsic motivation and individual improvisation. More specifically, the moderation effect was strong ($f=0.48$) and negative. That is, the effect of the perceived positive affect is opposite to the effect of intrinsic motivation, and in other words, the higher the intrinsic motivation of an individual is, the weaker the effect of perceived positive affect is for individual improvisation to occur in ad hoc co-improvisation. Likewise, the lower the intrinsic motivation the stronger the effect of positive affect is.

The finding is novel, and it indicates that in the ad hoc co-improvisation situation both the intrapersonal (intrinsic motivation) and the situational factors, such as perceived positive affect play an important but opposite role for individuals' willingness to engage in such ad hoc and creativity demanding co-improvisation event. Indeed, the antecedents of individual improvisation in ad hoc co-improvisation seem to be to some extent individual-specific factors.

In addition, the results provided some support for the role of improvisation related self-efficacy (H1) for individual improvisation in ad hoc co-improvisation. The finding confirm both the previous studies that found self-efficacy as a predictor of individual improvisation (Magni et al., 2009) and in the more general context the studies presenting one's belief (self-efficacy) toward particular activity (in this case improvisation) predicting that performance (Bandura, 1997; Tierney and Farmer, 2002; Zhao et al., 2005).

5.1 Implication for research and practice

The findings of this study provide the following implications. First, it extends understanding of the factors affecting on individual improvisation in ad hoc co-improvisation situation by introducing the other-focused dimension i.e. the experienced positive affect affecting individual improvisation. Second, the implications of this study also contribute to the limited understanding of the antecedents of individual improvisation and the state of the current empirical measurements of individual improvisation. Indeed, the current scales of individual improvisation (Magni et al., 2009; Hmileseski and Corbett, 2006) lack the dimensions of the other-related factors, which have been proposed as fundamental enablers of co-improvisation (Koppett, 2001; Johnstone, 1997; Sawyer and deZutter, 2009). This is also what the results of our empirical study indicate. Finally,

in more general sense, the study contributes to the topical discussion and the less studied field of the conditions of temporary forms of organizing (Goodman and Goodman, 1976; Grabher, 2002, Lindkvist, 2005; Mayerson et al., 1996; Bakker, 2010). Such unique and unfolding conditions demand different kind of orientation, abilities and skills from participating individuals than the conventional organizational settings does, on which this study shed light by exploring the antecedents of individual improvisation in ad hoc co-improvisation event.

6 Conclusions

This study explored the antecedents of individual improvisation in ad hoc team improvisation settings. With a structural equation modelling (PLS) we explored the simultaneous effect of intra-individual factors of intrinsic motivation (Tierney et al, 1999; Tierney and Farmer, 2002; Amabile, 1998), self-efficacy (Magni et al., 2009; Bandura, 1997) and inter-individual factor of positive affect (Kahn, 1990, 1992; Chen et al., 2009) on individual improvisation in ad hoc team improvisation conditions.

The study contributes to the discussion of the antecedents of individual improvisation in ad hoc co-improvisation context in the following ways. First, although, being highly ad-hocratic and complex by its nature, individual improvisation is a less studied phenomenon in temporary and ad hoc co-improvisation context. This study shed light on the simultaneous effect of both the intra-personal and inter-individual antecedents of individual improvisation in ad hoc event. Hence, it provides evidence of the human behaviour and co-improvisation within conditions of ad hoc interaction and temporariness (e. g. Bryman et al. 1987; Saunders and Ahuja, 2006; Sonnenburg, 2004; Bakker, 2010). Second, the scales of individual improvisation are underdeveloped especially in terms of the antecedents of individual improvisation in situation of co-improvisation. The current scales of individual improvisation measure the individual characteristics, i.e. intra-individual attitudes and propensity of an individual to improvise, but pay less attention to the other-related factors and social interaction essential in team and co-improvisation.

The paper contributes to the discussion on expert tasks and innovation by exploring factors enabling improvisation in ad hoc tasks increasingly common in dynamic knowledge-based network economy. The practical implications of this study suggest first that organizations should take more advantage of novelty and diversity in their knowledge creation activities. Based on the group discussion after each workshop the participants

found that the exercise was useful and productive. Many were also surprised of the innovative outcomes and some of the participants noted that this exercise that was not based on their work-roles, related expertise and known colleagues, and that the exercise was actually more productive than the work-role related innovation activities. Based on our experience as participant observers, the survey data and qualitative “debriefing” discussions our first insights are that against the common understanding, it may actually be easier to collaborate informally with completely novel individuals rather than with those well-known individuals whom one already knows and may be have learned to avoid any controversial issues. Hence, organizations should emphasize more emerging interaction for flexibility and renewal.

7 Limitations and Future Studies

The key limitation of the study is that the sample size is still relatively low (N=70), which may cause some limitation especially in moderation effect analysis. We also believe that there are other potentially interesting factors impacting individual improvisation and co-improvisation, e.g. trust and related trust building mechanisms.

In a seminal article by Mayerson et al. (1996) the trusting behaviours are presented as mechanisms through which unfolding conditions of temporary settings can be managed. We believe that trust can be another facilitator for ad hoc expert tasks, although all of the sources of trust found in conventional context (e.g., familiarity, shared experience, reciprocal disclosure, threats and deterrents, fulfilled promises and demonstrations of non-exploitation of vulnerability) are not likely in temporary settings between strangers (Mayerson et al., 1996). The unfolding elements of temporariness, such as vulnerability, uncertainty, risk, and expectation could certainly be managed by trusting behaviour (Mayerson et al., 1999), and therefore, the future studies should focus on the trust related behaviours and the ways how trust unfolds in temporary interaction between participating members should be studied. Second, the more varied number of the other-related factors (perspective taking) should be studied as antecedents of individuals to cope in ad hoc and temporary conditions. Finally, individual and co-improvisation are promising approaches to understand the unfolding nature of temporariness, which studies should be continued.

Structured Abstract

Fashion worlds (Becker, 1988) describes the transition from Fordism towards a new type of economic model and supply chain in which creativity and innovation are favored (Leslie, Rantisi, 2010). The world of fashion design (Bourdieu, 1984) is one that is characterized as being cultural (Throsby, 2008) and creative (DCMS, 2001). It is worth considering that the transition from Fordism to a service oriented economy brings forth major paradigmatic changes (Boltanski, Chiapello, 1999). While observing major actors, a subculture is revealed that is resistant to standardisation and proposes instead development that is culturally, socially, economically, spatially and ecologically sustainable.

Purpose – The goal of our research is to highlight the role of creativity within the given sector as a cultural model for development as well as a contemporary social issue.

Design/methodology/approach – Our analysis of *Fashion worlds* in Montreal is based on participant observations (Peneff, 1996) and a survey (Blanchet et al., 1992; Beaud et al., 1997) which were conducted from 2009 to 2013 by semi-structured and open interviews (approximately sixty, 28 designers and 32 Intermediate Sectorial & Intersectorial Actors). The study was based on interviews and internal data (reports, corporate documents, press articles, etc.). The interviews were conducted in four rounds, all lasting between one hour and half to two hours each, and fully transcribed. The first round is based on a guide to trace the trajectories of Emerging Designer (ED) (semi-structured interviews); the second round takes place in open interviews aimed to collect the story of Renowned Designer (RD) and pioneers (DP) (Bernier, Perrault, 1987). The third round follows a guide developed towards Intermediate Sectorial Actors (ISA), Intermediate Intersectorial Actors (IIAS) and Political Intermediaries (IP) (semi-

structured interviews). Finally, the fourth round follows a guide geared towards Intermediate Promoter Industry (IPI) representatives (semi-structured interviews). Groups encountered are divided into two main categories: the first being fashion designers and the second being the actors from the sphere of influence and cooperation (media, sectorial and intersectorial NPOs, public/private actors...). We chose to adopt as part of our research a reflective and comprehensive position (Max Weber, Hamel, 2007; Bourdieu, 1992). Our methodology is qualitative (Deslauriers and Kérisit, 1997; Van Der Maren, J. - M, 1987). Our study on the trajectories of fashion designers crosses the macro, meso, and micro-levels. The three levels are interdependent (Simon, 2009; Cohendet et al, 2010) to capture careers in a territorial dynamic sector as well as at the individual level. We crossed levels of meso/micro analysis for the interpretation of our data to identify additional information, opposition, tension, etc. (Gurvitch , 1950, 1963) and grasp the dialectical nature of social reality (Gurvitch, 1962). We triangulated data (Jonsen and Jehn, 2009; Royer, 2007) from our various sources (interviews, official documents, information in social networks including Facebook, etc.).

Originality/value – Our study seeks to demonstrate that there is an ongoing effort to value and promote the creativity of local actors. The goals of creative industries evolve in the direction of sustainable industries, and this responds to the needs of territories to distinguish themselves from one another and to eventually exchange amongst themselves.

Practical implications – This study situates itself within an ongoing attempt in Quebec, where for several years the actors and intermediaries, political as well as from civil society, have thought together and sought the establishment of a local metropolitan cluster of fashion in which creativity and innovation are encouraged.

Keywords – Creative industries (CI), Fashion Designer, City, Globalization, Sustainable Development (SD).

Paper type – Academic Research Paper and practical Paper

1

¹ *Janus Paradox* (Latour, 2001 :12)

1 Introduction

Across the fashion industry different actors have had to re-evaluate their business models due to the contemporary state of globalization. With the outsourcing of production to countries with lower salaries and the closing of offices, there are now new rules of operation within capitalism (Boltanski, Chiapello, [1999], 2001). Whereas the fashion industry of Montreal previously enjoyed a significant reputation in North America, occupying the third position after New York and Los Angeles, it now confronts “two shocks in quick succession” (ISA.1). The first one came in 2003 with the opening of borders to “developing countries with North/South agreement [...], the poor countries” (ISA.1); the second came in 2005 with the “abolition of import quotas [...] the industry has completely collapsed!” (ISA.1). The elimination of trade barriers like tariffs and import quotas is achieved by most WTO countries in 2005. “This begins an irreversible process where there are significant losses of employment in the textile sector. In Quebec, several surveys suggest that losses range from about 8,000 to 15,000 jobs” (Ville-Montréal, 2004: 2). The manufacturing sector is the first to outsource their production given the fact that “they are the ultra-intermediaries in the supply chain” and the first affected by the price problematic (ISA.2) whereas the retail sector sees an explosion of “import products” (ED.1).

With this shift, “there is another world now” (ISA.3). The repositioning sector is organized around “comparative advantages such as creativity, expertise, and the proximity to the United States” (City-Montreal 2004: 15). The industrial restructuring context of the industry (Milstein&Cie Conseil Inc.¹, 2011) offers new opportunities. In order to distinguish itself and become more competitive, industry invites forth all the community stakeholders to produce a strategic plan. In this paper we show the specific role of the creative industries (CI) and how they adapt to this economic shift. To do this, we begin by presenting a literature review to introduce the contemporary global context of both industry and fashion, as well as that of CI and sustainable development (SD). In addition, we exploit the results of our survey highlighting adaptations to globalization (or sectorial distinctions) in the form of creative and sustainable solutions. We observe the construction of the creative and entrepreneurial identity in this trade (Dubar, 1991; Dubar

¹ The study shows that the post-industrial era is marked by an increase in the hiring of “white collar” workers.

et al 1998. Hughes, 1996), as well as a commitment within a given territory. We also propose that this highlights the meaning of creativity from an entrepreneurial point of view and not just from a creative one, and how this impacts on designers' and small businesses (SMBs) trajectories.

2 Theoretical/Analytical Framework

2.1 *The creation of a local fashion field (“champ”) and the fashion industry*

The history of fashion in Quebec begins in the 1920's and 30's with the establishment of the *Maison de Haute Couture* as well the presence of renowned local designers such as Ida Desmarais, Lucien Lacouture, Gaby Bernier, Angelina Di Bello, etc. who rely on Parisian fashion as a source of inspiration (Baril, 2004). The first Canadian Designers Association (ACC in French) is established in 1954 in Montreal. By coming together, designers legitimize their profession and contribute to a flourishing environment through events, with the support of the textile industry, the media, etc. Precursor designers such as Raoul-Jean Fouré, Jacques de Montjoye, France Davies, Marie France de Paris, etc. assist the newer generations of designers to succeed them. Two major historical events within Quebec society induce “major changes” (DP.1): The Quiet Revolution in the 1960's and the World's Fair in 1967 (Grenier, 1965). After this, culture and creativity emerge as identity issues and designers and small fashion businesses evolve within a local and international context facing the developments of CI as well as sectorial restructuring.

While the fashion industry struggles to legitimize itself (Bourdieu, 1984), it operates in a problematic industrial context, which creates a fragile configuration. Generating symbolic value goods, it is also addressing the market of commercial property. The fashion industry brands itself as different—an authentic, singular, and creative goo—and seeks to distinguish itself from a “standard production” (Boltanski, Chiapello, [1999], 2001: 597). The notion of the multitalented designer emerges, requiring expertise in different fields (art, artisan, commerce, etc.) which makes his legitimization complex. It can be argued that the fashion designer becomes an “interstitial” figure (Alandete, 2000 : 87) where art, artisan, culture, and commerce cross invoking the *Janus Paradox* (Latour, 2001: 12) which creates a dual identity (entrepreneur/creative). The SMB (small and medium sized businesses) of the sector thus emerge in a very particular context, articulating business and art/artisan. It is in this context that we observe the emergence of

CI. Regarding the dominant international fashion order, the creation of *mode d'ici* (local fashion) finds difficulties in placing itself, either enjoying a reputation or a consecration. Nevertheless, it is the expression of local cultural identity characterized for being branded *Made in Montreal, Made in Quebec*. Within this quest for recognition, we find the industry placing itself on larger issues such as societal development, but facing important challenges in the context of globalization.

To thwart the setbacks of globalization, professional strategies, creativity, innovation and original business models (niche markets and local manufacturing) are put in place. Moreover, the legitimization of the creative sector requires cooperation within a particular milieu, *the fashion world* on the one hand (Becker, 1988), composed of large firms but mainly of many SMBs and designer firms, and the support of intermediary actors (public and private) on the other. In regard to this, a commissioner of fashion is created in 2009: the Office of Montreal fashion (BMM). Also, the Fashion Week (MFW) promotes designers since 2000 and the Council of Quebec fashion designers (CCMQ) is structured in 2010. The sector's restructuring innovates by creating a roundtable of programs (2008-2011) thanks to government aid programs (Pro-Mode Strategy: 2007-2011) followed by a Fashion Work Group (2011-2013), bringing together key industry players (Martini, Lifson, 2013).

Consultation of stakeholders results in a report recommending the creation of a metropolitan cluster of fashion and the need for a cooperative effort of support for the industry, that is designers in particular. During these discussions, the agency Sid Lee proposed a strategy called "ingenious fiber" (Martini, Lifson, 2013: 44) to support the industry in its restructuring. The fact remains that "the designers are the trademark of the entire industry" (CCMM, 2013: 19), and because they make a creative profession, they belong to the CI (grouped statistically with the *architecture and design*, CCMM, 2013).

2.2 Creative Industries: Montreal, Creative City

A parallel second report emerges, and it sets forth a precedent. This report focuses on an extensive study CI of Montreal and relies on the existence of a creative environment (multimedia, architecture and design, the arts, media, and advertising) (DMC, 2001) a "growing sectorial ensemble" marked by the presence of cultural diversity and creative and dynamic capital (CCMM, 2013). The talent of creators and their leadership are the guarantors of a radiating and creative metropolis at a local, national and international

scale. CI generate over 91,000 jobs in Montreal (Région métropolitaine de recensement, RMR¹) constituting 4.6% of all jobs in the RMR. “Direct and indirect economic benefits” (CCMM, 2013: 3) amounted to \$ 8.6 billion. Moreover, these industries “create value in other sectors” and they play a role “in urban regeneration and social cohesion ”(ibid.). Observing a fragmented sector, mainly composed of small businesses (micro-enterprises) and self-employed workers, the report recommends the consolidation of “sustainable creative enterprises” and leaders (ibid.). Moreover, the disparity of local creative goods in international markets is an obstacle to development, which is why it the report recommended to exploit new distribution channels, visibility on the web 2.0, business alliances and the use of an entrepreneurial spirit. This issue of internationalization is important and is one of the main issues to be addressed by the small local businesses in order to remain active and sustain their activity over time. Our paper will show how designers and small firms deal with this issue.

Based on the notion of the “wave of maximizing the potential of creative industries” from Montreal, the report highlights three historical stages of “support measures”: A development wave qualified as “the *institutional* (started in the 1950s-1960s, focusing on culture and creative talent base in Montreal)”; the second wave “the *industrial* (started in the 1980s-1990s, focusing on technology as the base of creative companies),” and the third wave “the *collaborative* (started in the 2000-2010 focusing on creativity and the basis for new creative platforms)” (CCMM, 2013: 3). To complete the development process, six objectives are proposed: “maintain emphasis on talent, stimulate exploration, favor consolidation, value intellectual property, support commercialization, and strengthen the influence and positioning” (CCMM, 2013: 4) of the creative city. The issue of valuing a creative class (Florida, 2002) in the framework of a territorial revitalization (Pecqueur et al, 2009. Pecqueur, 2005) and urban development (Fontan *et al.*, 2003) is a thesis that, although viewed with caution, (Scott 2000, 2006. Tremblay et al, 2010) saw great success among urban policies (Stolarick *et al.*, 2005). Competition between cities is now based on the existence of talents capable of creativity and innovation (Landry, 2000). The report (CCMM, 2013) highlighted the benefits for the different structural actors and the importance of supporting these industries in a context of globalization. This will effectively increase the “territorial attractiveness” (Kahn², 2010 : 642-643) through

¹ The metropolitan area consisting of the cities of Montreal, Laval, Longueuil and 79 other neighboring municipalities is home to 3.6 million people, and accounts of half of Quebec's GDP. (CCMM, 2013).

² Greffe (1999, 2002b, 2005) About his typology of impacts (effects) of the local culture and cultural policies.

economic benefits and the “image effect” (*ibid.*) of the cultural metropolis. Therefore, the city is distinguished by developing its creative talents (Pilati, Tremblay, 2008 ; Pecqueur, 2006), by being simultaneously an Anglophone and a Francophone "young city" (ED.2), by offering a favorable environment: low cost rents and quality of life (ED.1), and it has a “superb fine reputation within the Canadian context” (ED.3). However, the assertion of a creative class within an “uncertain horizon” (Menger, 2009) confronting a global crisis, the deregulation of capitalism (Boltanski, Chiapello, [1999] 2001) is not unproblematic. In this regard, the theme of project work (*travail par projets* ; cf Menger, 2002) to ensure a stable income (Consultancy work, cumulation of 2 jobs, etc.) is a feature of the so-called nomadic creative career which presents many risks (Tremblay, 2003 ; Cadin *et al.*, 1999, 2000).

Amongst the strategies which contribute to build a reputation and image, fashion design is exposed (as for the museum exhibition of designer Denis Gagnon in the Museum of Fine Arts of Montreal, october 2010) publicized and supported by various local actors, and it is more and more assimilated to “heritage works” (De Certeau, 1974: 167), invested by a political and cultural will to organize its influence and visibility. Conventions with various international organizations, in Australia, Europe, UNESCO etc. seek to legitimize all creative sectors and provide a common definition of the creative economy including fashion (Throsby, 2008) even if it is characterized by an utilitarian aspect in its production (Menger, 2010 ; Alandete, 2000). Since the 1980s, cultural policies redefine the field of culture “in its redevelopment by its high content of creativity, culture [...]it] is the area where are sought and implemented qualities that are also a resource for the economy as a whole” (Menger, 2010: 214). In the United Kingdom, CI include *industrial design, advertising, fashion, software and IT services*, which are “included in the scope of public cultural action” (*ibid.*). The city of Montreal, in 2006, joined the Creative Cities Network and became “UNESCO City of Design” (UNESCO, 2006). Distinguishing itself on the world stage, it addresses the challenges of the transition from one social status to another where *nothing seems definitive* (Boltanski, Chiapello, [1999] 2001). “The Montreal metropolitan region therefore ranks among the top 10 North American creative cities” (CCMM, 2013: 31), and ranked 4th in the sub-sector of architecture and design (including fashion) “with 5.4 jobs per 1000 jobs” (*ibid.*: 32) behind Vancouver, Toronto and San Francisco.

The case of Montreal seems to provide a “redefinition of culture” (Menger, 2010) on matters concerning the governance and the organization of culture (*the Festival of design and fashion, the Jazz festival, Quartier des Arts, etc.*). We believe that the local politico-economic dynamics with regards to the creative industry (film, fashion, video games, performance and circus arts), play a significant role regarding contemporary issues of the city, which challenges creativity within a context of crisis, in a society maintaining a complex relationship to globalization (Culture-DD12¹, 2012: 15). Montreal assumes a *creative metropolitan identity*, which values local talents and is active in the development of *urban competitiveness within the new economic era* (Fontan, 2006), while at the same time aspiring to a more global image. “Because the hands are elsewhere and that the head is all that remains in developed countries, we see a boom of studies on innovation management” (Giusti, 2011: 149), but also on the Creative City, its meaning and its possible contribution to local development and globalization (Tremblay and Tremblay, 2010).

The city becomes place of identity affirmation and reputation building for the designers and small fashion firms (Agenda 21, 2012), and it informs us about the changes in relations between culture, environment, society and the economy. The *Creative society* reached a turning point and expresses a new spirit of capitalism linked more towards the idea of service than production, and where the role of creativity calls out the paradox of the “artist critique” (Boltanski, Chiapello, [1999], 2001: 632). In other words, goods produced in response to a demand of authenticity (e.g. eco-products) nevertheless obey the spirit of capitalism (*ibid.* ; Greffe, 2010).

2.3 Culture and Development : Rethinking Social projects

Particular attention placed on CI questions the role played by creativity in development. More broadly, it seeks to assess the relationship between culture and development in the same way that established relations between “environment and development” and between the economy and the environment in the Brundtland Commission (Rapport Brundtland, 1984), which coined the expression *sustainable development* in its report and was “politically adopted by the world in the Earth Summit in Rio de Janeiro in 1992” (Agenda21, 2012: 2). In 1995, “Our Creative Diversity” (UNESCO, 1996) sponsored by UNESCO at the Global Culture Commission, explores

¹ Cit. Edgar Morin

the nature of this relationship. “Culture is [...] the vehicle through which behaviors are transmitted, while at the same time is a source of dynamic change, creativity and freedom and hopeful promises” (UNESCO, 1996: 11). It is up to societies to adopt “new ways of living [...]”. It is also important to promote different development paths, being aware of the influence of cultural factors on the way companies design their future and choose the means to achieve them” (*ibid.*). “Creative diversity” (*ibid.*: 20) intervenes as a response to the de-industrialization of Western societies while creativity, acting as a powerful social engine (*ibid.*), explores engagement models incorporating contemporary cultural and economic concerns. Environmental issues are on the agenda, as is citizen consumption that is responsible and equitable within a given territory; this is what we find, for example, within the context of environmental ethics.

The sustainable development (SD) Law (LDD-Loi sur le développement durable), passed in Quebec (2006), qualifies SD as “development that responds to the demands of the present without compromising the capability of future generation to respond to their own demands (LDD, 2013: 10) and associates this with the objective of “fairness” or equity (Laganier *et al.*, 2002: 5). The LDD introduces “a vision which takes into account as being inseparable the environmental, social, and economic dimensions of development activities.” (Agenda 21, 2012: 2) and associates the notion of *interdependence* (Laganier *et al.*, 2002). Through the decree 763-2012 (4 July 2012), the LDD adds culture as the thirtieth goal. On the occasion of a cultural construction adopted by the Government on the 23 November 2011 (Agenda 21 of Quebec), the objective is formulated as a support for “the creation, production and dissemination in all sectors of the Quebec cultural system to ensure development” (Gov.QC, 2013: 3).

The addition of this fourth pillar to the other three (economy, environment and society) advocates for the values of an “innovative responsible” company making “sustainable development as a fundamental and dynamic engine” (*ibid.*: 62). This adds to “the debate on the role of culture, the local economy and the rich heritage” (Pascual Espuny, 2010: 14-15). In fact, since 1981, “Ignacy Sachs, founder of the notion of eco-development with Maurice Strong, introduced the cultural pillar to the conceptualization of sustainable development (Sachs, 1981: 139)” (*ibid.*). Through its objectives, SD can be integrated in the creative economy.

SD is thus integrated as part of a social project where there is reflection on the relationship of post-industrial and developed societies to globalization and observation of

the manners in which adjustments take place. After years of free trade, we are now in the context of a civic character interdependence, where each territory (city, region, etc.) must think of *new ways of doing things* while adhering to universal values.

The garment industry of Quebec has been transformed by globalization (Pilon, 2005 ; Metzger, 2003) and has not escaped the turmoil of other industrial societies. This is why in the second part of our paper, on the basis of our empirical study, we present the context to highlight how the industry is positioned today in developing such strategies of production relocation. We show how designers and small firm “creators,” as resources of sector and local value (creativity, ways, etc.) are embedded territorially (Simon, 2013) and how creativity and innovation must be considered as new development paradigms. The fashion design segment is to understand in the context of a creative ecosystem (Daidj, 2011) which bases its development between the CI and the garment industry, between the economy and culture. The concept of “*Think global and act local*” (St-Pierre et al., 2010) seems to fit sectorial strategies that put forward local actions in order to support the industry.

3 Creative Commitment : An alternative model between the economy and culture

“*Today, we produce little, but quickly [...] it has to be top design*” and “*it still requires a lot of skill, it is very demanding!*” (IP.2). This is the new fashion trend “*just-in-time,*” *hyper-designed, manufactured quickly,* must ensure locally the presence of “*design modes*” which ensure there is an “*active production.*” (IISA.2). With the industry’s crisis, the closing of many factories and the loss of skilled labor, training specialized labour becomes an important issue (ISA.2). We have discussed the positioning of designers on a local market (production, distribution, niches, etc.) ; we now discuss the specifics of the role of the creative within the fashion industry. While “*the future of Quebec*” seems to rely on its “*creativity*” (ED.5.3), the subculture of the creative industry remains problematic.

3.1 The Garment industry and creative industries

The local market of fashion design proposes products in which creativity, innovation, and sustainable development are highly valued. These may be everyday products, but they result from a process where the creative, the artistic, and/or the craft carry a signature and identity. These designers distinguish themselves from “*international*” fashion, being essentially a “*counter-fashion*” (RD.5), which does not mean they cannot have international success, on the contrary. Following international fashion trends leads “*dangerously towards the homogenization of creativity*” (RD.1) and this may be more characteristic of large firms as well as appropriate for them. On the contrary, for small designers’ studios, it is preferable to have a clear, original, local image, and to export this original creative product. (RD.5) situates herself “*outside what is fashionable,*” and claims “*a need for sustainability, long term use*”, ensuring “*timeless fashion*” and argues that her clothes are “*timeless collection pieces.*” (RD.5) also denounces the political marketing campaigns of “*creative companies*” that focus on catering to the already “*hyper advertised*” high-end luxury brands (e.g. Vuitton, Chanel, Armani, Dolce & Gabbana , etc.) which in turn, prevent small designers who have very little means for advertising. (RD.2) does not like that which is “*ephemeral*”: “*I prefer that it lasts for a long time.*” For her, a designer is someone who has “*guts, their own universe, and one who signs from A to Z*” his/her collection. It is the creative commitment that singles out Lacroix’s work and it for this reason that, “*a Christian Lacroix always looks like a Christian Lacroix, a Jean-Paul Gauthier always looks like a Jean-Paul Gauthier*” (*ibid.*). A truly creative work is a continuous exploration of one’s own creativity to propose unique pieces (RD.1).

While the design community is often perceived as “*a circle of artists*” by the industry (IISA.2), not generating significant business figures (IISA.2, ISA.3), it nevertheless “*showcases*” the creative (ISA.4). The precarious status of independent workers and small businesses, “*studio-designers,*” within the context of economic uncertainty make it difficult for fashion designers to have a career, as very few are “*chosen*” (IISA.2) “*Either you play the game, or you don’t... If you don’t play the game, you scrape the bread!*” The industry encourages designers to develop their own “*business sense,*” an entrepreneurial dimension to the trade. (IISA.2) believes that “*what is missing amongst fashion designers, is real entrepreneurial designers not just creative ones!*” But the paradox lies in the idea of opposing CI and traditional industries. Designers evolve within an industry that continues to favor outdated, traditional manufacturing models (ED.1) whereas the majority

of designers see themselves as part of the creative and/or cultural industries. Our study shows that almost half of the designers surveyed see themselves as being part of cultural industries (41%), and 34% as being part of creative industries, whereas 25% had no opinion on the matter. Clearly, a majority sees itself as operating within the creative domain (75% cultural and CI).

In order to develop local reputation, they can surely use the support of intermediary organizations, and a certain number of them do contribute to this. (Tremblay and Yagoubi, 2014).

3.2 Creative professions at a crossroads of fields

3.2.1 The identity in question

– The Janus Paradox : Creativity and Entrepreneurship

In a “*dream industry*,” such as fashion, we find ourselves in a world of seduction and competition (RD.1) to “*sell the dream*” (ISA.2). The designer is, thus, “*an entrepreneur who dreams*” (RD.1) who must continuously adapt to changes and new paradigms. We derive two ideal-typical figures which define the professional identity, that is the *designer-entrepreneur* and the *designer-creator*, which reflect the complexity of the creative profession, it is a “*difficult*” business (ED.6). “*Much of it is a dream [...]. You start from scratch and you believe in your project!*” In order to succeed, thus, one must master, “*both sides, the business side and the creative side*” (ED.5.4); the passionate side and, “*the rational side which tells me: it must be profitable, it has to sell!*” (ED.1).

Designers have, “*a brain split into two*” (ED.2) on the one hand there is the business (sales, *money making*) and on the other, the creative dimension (creation of the collection). Expressing the idea of a “*dual identity*” (ED.3) says: “*where can I situate myself? Am I an artist or am I a merchant? This is always the dilemma which afflicts us*” (DP.2). The success of the profession is not valued in the same way when considering, “*the artistic versus the financial aspect!*” (DP1), “*one must certainly be an entrepreneur and take into account the profitable side of the company [...], but one must as well have a creative side which is life rewarding although not necessarily always financially rewarding*” (DP.2). This paradox can be undone by the introduction of a dual business. This type of company experiences success by dividing the business into two well defined roles, making collaborators complementary to one another, for example,

while one takes care of the creative side, the other takes care of the entrepreneurial side, this is the case of (ED.12), “ *I have the opportunity of having another person, we are two. Two strong heads... I admire the people who start business by themselves, and are then capable of doing business while remaining creative at the same time*” (ED.5.4).

– *The designer-entrepreneur*

Despite the fact that the world of fashion calls for the creative and artistic dimensions, there is the sometimes hard realization of the entrepreneurial dimension. “*It is not just art, there is also a commercial dimension once there is a target market*” (ED.2). To do this job and to choose to have a collection, makes one an entrepreneur, “*when one is a designer in Montreal and one wants to get out of the more commercial industry, one does not really have a choice, one must be an entrepreneur!*” (ED.9.2). The entrepreneurial commitment requires that one have “*an investigative temperament,*” “*it is a matter of personality more than anything else*” (ED.1). One must, “*always be on the lookout for alliances [...]. One must look for possibilities at a commercial level, as a matter of fact!*” (ED.5.4). How does creativity combine itself with entrepreneurship, and are the two compatible? “*It is clear that it is not for everyone, to be both the boss of the company and the creator as well*” (RD.1).

– *The designer-creator*

Designers who identify themselves as being creative, generally distinguish themselves by participating actively in the cultural sphere. One of the possibilities that is available for them is to associate with the Métiers d’art (artisans) and receive aid from SODEC (Society for support to cultural industries) in the form of grants, funding, prizes, tax credits, etc. . The designer then has a double status: artist/craftsman (culture) and designer-entrepreneur (industry, economy). In order to associate themselves with the Métiers d’art, they must however demonstrate certain skills: treating the material, it being hand-made, having exclusive pieces, etc. However, the artisan aspect of the designers’ trade is controversial and is not viewed positively by all. Some designers fear the pejorative image of the artisan and “*want to stay away from this aspect of the trade for fear of being perceived as a granola-poor artist*” (DP2); “*it makes me think of people who do some crafts at home*” (ED.7). One designer (RD.1) member of the Métiers d’arts defends his position by saying that, “*the art of haute couture*” is “*born from that art of*

that which is hand-made". (ED.2) thinks all designers should master the traditional artistic basis of the business, which is the craftsmanship. *"To be a true master creator, comes from what you do with your hands, you have to love fabrics and love sewing, you have to have technique..."*.

3.2.2 Cultural Dimensions

– *The status of the artist*

The creative process of designers is comparable to other creative crafts: many designers demonstrate the need for self-expression, that which Yves Jean Lacasse called *"the artist in him/herself."* *"The fashion artifact, ultimately, becomes an excuse"* and the fashion design is not an end in itself (ED.3). The well-known designer Marie Saint Pierre explained to us that she could have been also an architect, artist, or sculptor. In choosing fashion design, she finds that this trade is a *"mixture of all three... In other words, there is the sculptural aspect of the garment, that of a certain beauty, of texture, and color [...] and then there is garment as a type of house as well, a sort of shelter that is close to the individual"*.

– *The creative business*

According to our findings, 31% of designers consider that they form part of a creative business, 27% believe their work is innovative and 25% that it is artistic. Despite the risky nature of the business, it is the creative aspect of the trade that keeps many designers attracted to the profession. The risk is high, especially during the first five years, and even if one's career is stable, risks may always come about. The trajectory of designer (ED.4), for example, reflects fifteen years of practice characterized by disruptions and successes etc. Eventually (ED.4) stopped designing despite his *"needs to create"* in order to find employment in another sector. Nevertheless, most designers argue that creativity and passion are the primary motivators within a profession that is difficult and uncertain (ED.9.2, ED.4), even if the *"creative aspect"* constitutes only 5 or 10% of the job. Without creativity, *"I would die!"* Mariouche (Harricana) explains: *"Without the creative element to compensate, I would be very unhappy"* (RD.2). The need for creation, the passion for the business, allows designers to *"believe, go, and even run!"* (ED.5.3). Passion is fed by the idea of avocation, of choice (ED.6); it acts as *"flame"* (DP.2) which feeds creation. *"I live my passion"* says (RD.1).

– *The rise of singularity* (Heinich, 2012)

Creativity is “*the precondition for the originality of the collection*” according to (RD.3). This idea of singularity, of distinctiveness through creation, enables a commercial brand and its creator to become renowned (RD.1). Denis Gagnon explains that his strategy is “*to be [...] as creative as possible*” and to “*go beyond marketing.*” Distinguishing one’s self is promising for success if the designer is accepted for his/her approach: “*I am different from others, and that is what makes me popular*” (ED.6).

The Niche : Designers choose “*a niche product in order to attract a certain clientele*” and gain visibility (ED.10). Local companies develop hyper-specialized niches and are overwhelmed by demand. (ED.3) uses the example of a “*small company*” that manufactures organic cotton and wool, which produces knitwear, coats, accessories, etc., “*quality crafts*” (L’Angéline, 2014). “*They have their own sheep, and the demand has become so large that local wool is no longer enough and thus they now have to import it as well*” (ED.3). (ED.11) seeks a more “*excentric*” niche, “*more high-end,*” “*more creative*”. (ED.8) seeks the “*low price look, the low price of the haute couture*” (ED.8). Some seek the unique piece market, for example the makers of corsets and sweaters (ED.4). (ED.7) speaks of the “*contemporary line!*” a collection that situates itself amidst “*big names like Prada*” and the “*manufacturers*” with garments ranging in price “*from 100 to 1000 dollars*” and which are nevertheless “*Quebecois creations.*” (ED.12) favors local production as well as the “*made in Montreal*” tag. (ED.10) works with natural materials and produces quality products with an eco-design at an average price. Two designers (ED.9.2) privilege the use of fair trade resources, “*organic cottons or fibers*” and develop their own color and silk-screen printing... “*We try working conceptually to avoid the H&M look.*” Ying Gao, researcher-designer has engaged in research and innovation, exploring modular clothing focusing on “*design work [...] conceptual work*” that is cultural and artistic.

The Style: The individualization process goes through the creation of a “*style, a label*” (ED.5.2). “*We recognize the designers through their creation and each year their clientele expects some novelty [...]. We recognize – a Marie Saint Pierre or a Rosie Godbout!*”(ED.5.4). Style is expressed in different manners: “*avant-garde*” (ED.12);

creation of a “*distinctive style*”, “*no trend*”, “*a classic stylized and sophisticated garment.*” (RD.4).

The signature: Once the approach and style are in place, the designer is required to brand his/her creations as an element of recognition: “*as you create your branding by staying on the same garment line and then the power repeat*” the people recognize the creators (ED.2). “*I think it's more in terms of aesthetics than they present that they become recognizable*” (*ibid.*).

7 Conclusions

In order for the creative industry to ensure sustainable social and cultural development, it became clear from our study that local community support is essential, both in terms of intermediation (intermediate sectorial, intersectorial and institutional) as is the support of the media (promoters, media, cultural actors) to encourage creative professions. “*In the Work Group as well as the Consultation Table, both large producers and large retailers recognize that creativity is essential*” to the development of the fashion industry (ISA.4), and particularly to SMBs who want to compete with larger organizations, but on their own field (creative design).

- *Intermediation: it is crucial to support a diversity of entrepreneurial business models in the industry – i.e. support commercial success at different levels from SMBs to large firms – and support products that are made in Quebec, or Canada.*
- *The media: promote the creativity of designers and support their recognition (image and media success) locally, nationally, but also internationally.*
- *Strengthen the image of the Creative City through talented designers: Montreal as a fashion city (BMM, Government, MFW). Promote Made in Montreal garments. All this supports the image of the local designers on an international scale.*

The local fashion industry illustrates a dynamic of resistance to globalization while simultaneously endorsing a particular sub-culture. In our work, we highlighted the similarities between the concerns of the traditional industry and those of creative industries, the latter offering a new model of legitimization and promotion of the creative emerging segments as well as the historical ones. In our view this requires the inclusion and participation of designers in their territory and in a wider view of sustainable development(SD). Fair trade fashion (specific materials: organic cotton, recycled fur, etc.) and local production (local subcontractors, jobs, quality control, etc.) and the “studio-

creators” favor sustainable economic and social development. This also supports the idea of encouraging responsible consumption: “It is important to underline the stubbornness of certain designers and certain brands to keep their production local. We believe that the issue of local consumption is not a temporary fad. The social value added to products is an integral part of the branding of several labels” (Villeneuve, 2007), and this goes at the local as well as the global scale. From a political and social perspective, the worlds of fashion are thus supported by stakeholder involvement and cooperation of the community (business but also clientele, media and intermediary actors).

It is for this reason that we can conclude and summarize that creative industries and sustainable development can be joined to attain the same objectives (Pascual Espuny, 2010). The political pillar cuts across all others and shows the local willingness to adhere to the vision also endorsed by other countries that engage local and fair practices.

Acronyms

Distrectual models and innovation: when creativity drives sustainable growth for the territory

Pamela Palmi

Department of Economic Sciences
University of Salento
Complesso Ecotekne, via per Monteroni, Lecce

Structured Abstract

Purpose - The topic of local development is more and more linked to the role of innovation and creativity as main drivers to implement processes for change, aiming to structural growth and consolidation (Gilbert, 2012). Within such a framework, a crucial role is played by the so-called district economies, which are rapidly taking new shapes, through the transition from the traditional Marshall models to fully developed local systems, which base their competitiveness on innovation and creativity. Such systems, generally referred to as “creativity districts” or “clusters”, are not always able to face the many complex challenges which are coming up on the socio-economical stage and require a strategic planning, both on a political and on an entrepreneurial level, in order to develop those competencies which are nowadays crucial to compete globally.

Design/ Methodology - We propose an approach quantitative. The present paper, starting from the evolutionary tendencies of the post-fordist districts, analyses the identity of the creativity districts (evolved new economical districts, Sacco 2006; Salvemini, 2008) and their relevant policies according to the Italian experience. A creative district or cluster is a geographic concentration of companies, usually small or medium enterprises, with an elevated degree of creativity and innovation, highly specialised, inclined to operate within scientific research centres, such as universities or public laboratories (Cesaroni, Piccaluga, 2003).

Approach/ Originally/ Value - This methodology puts in evidence the tendency of the production district of creativity to balance the activities of *exploration* and *exploitation* of the involved stakeholders, meaning the capacity to research and exploit new technological chances and to implement new technology within products and processes (March, 1991). In order to facilitate the relationships between the stakeholders and therefore the balancing of *exploration* and *exploitation* it is essential to analyse the capacity of the district to stimulate the development of the social capital among the organizations, which is the base of the mutual trust, often driven by the presence and activity as well as socio-cultural animation of associations and public institutions (Granovetter, 1985).

Keywords: Creativity district, Innovation, Exploration & exploitation, Absorptive capacity, Growth

Paper type: Academic Research Paper

1. The Analysis Model

This study aims at proposing an analysis model of creative production districts which may steer politics and strategies of different involved actors, in order to sustain growth and competitiveness at a national and international level.

More specifically, our work seeks to outline a vision in order to support integration of different expertise, so as to render the entire innovation process more effective and efficient. The proposed model essentially aims at balancing *exploration* and *exploitation* activities, identified as the ability to research and explore new creative opportunities, while conveying and incorporating new creativity within product and processes (March, 1991). Such abilities, assumed as being critical to guarantee competitiveness in the short and long term, are nevertheless hardly detectable inside a single economic actor, because they require different expertise and routines, often in conflict with one another (Gupta *et al.*, 2006). Therefore, their coexistence and balance may be efficiently reached inside an inter-organisational relationship space, where different actors of a creative district engage in *exploration* or *exploitation* activities, being mutually connected within an innovation and creativity production chain. Theory studies and empirical evidence (Rothaermel, Deeds, 2004; Lavie, Rosenkopf, 2006), mainly referring to technological districts (based on the aforementioned reasons, such considerations are also valid for creative districts, both because of the proximity and the interrelation between creativity and innovation, of the recurrent inclusion of technology in creative industries, and vice-versa), proved it reasonable to suppose that research centres and universities are mainly seeking to explore new solutions (*exploration*), while enterprises are more interested in industrial development and marketing of products and/or processes (*exploitation*). It is therefore necessary a right balance between these two typologies of institutionally different actors, in order to create conditions apt to favour both development and the deployment of creative and innovative solutions within districts.

However, in order to favour the establishment of cooperational relationships among actors, therefore balancing *exploration* and *exploitation* activities, it is necessary to foresee a series of integration procedures, as for instance co-localisation, relocating the workforce and the alignment of incentives among different actors, with the purpose of encouraging a real cooperation, and move beyond the mere logic of public funding (Albino, Messeni Petruzzelli, Rotolo, 2010). It is actually important to create a mutual trust environment, which has often proved essential to explain the success of partnership

activities. Under this perspective, associations and public institutions may play an important role, since they can serve as a guarantor or sponsor, easing the foundation of cooperation initiatives among actors in the same district (Smith, 2007), as well as the development of the fundamental value known as “social capital”, which has proved to be crucial for successful processes in local economies.

The expression “social capital” has at times been used as a synonym of *civiness* (Helliwell, Putnam, 1993), trust (Granovetter, 1985), or «cultural rules, unwritten in bold type» (Fukuyama, 1995), however in the course of time it reached always broader implications, attaining various cultural, political, infrastructural and environmental connotations. We can conclude that social capital is identified by a system of values, rules and social relations allowing individuals to pursue collective behaviours and represent a sort of facilitator in conveying knowledge, thereby easing its dissemination.

This translates into more chances for organisations to generate innovation, thus outsourcing information and knowledge (Laursen, Salter, 2006). The relation among social capital, cooperation, innovation and creativity has been the subject of treasured works in literature (Sacco, 2006), emphasising how enterprises located in high social capital areas are more inclined to innovation and creativity than others. Furthermore, seen from the perspective of relocating workforce and explore new markets, a recent study (Moretti, 2013) on the American experience, proves the existence of a new labour geography, geared towards *creative class* dynamics and profit-sharing (Florida, 2002; Amadasi – Salvemini, 2006) also applied to creative territories (Montanari, 2011).

In addition, high levels of social capital tend to increase the positive effects generated by investments in research and development, and the inclination towards innovation and creativity inside the same enterprises (Laursen *et al.*, 2012).

The *absorptive capacity* is the third element on which the proposed analysis model is based with reference to the district actors, where “ability” is the possibility to comprehend, acquire and use the knowledge deriving from the interaction with other organisations (Cohen, Levinthal, 1990; Zahra, George, 2002): this mind-set may be absolute or relative, where the latter refers to a specific relation in place, and the opportunity that partners have to successfully interact thanks to a cognitive and organisational proximity (Lane, Lubatkin, 1998).

The concept of *absorptive capacity*, introduced by Cohen and Levinthal (1990), concerns the capacity of organisations to identify, acquire and implement creative

knowledge from external actors. It is therefore a specific organisational skill, which may more precisely be defined in literature as «the ability to recognise the value of a new knowledge, assimilate and apply it to commercial purposes » (Cohen, Levinthal, 1990, p. 128); this skill must not be taken for granted, as it plays a crucial role in the cooperational dynamics among economic actors, and therefore in an effective mix of explorative and exploitative expertise (Zahra, George, 2002).

The organisational literature has highlighted the diverse factors that may contribute to strengthen organisations' *absorptive capacity*, such as: investments in research and development (Cohen, Levinthal, 1990); the presence of qualified human capital (Vinding, 2006); scientific research activities (Rosenberg, 1990; Dyer, Singh, 1998; Fabrizio, 2009), and relationships with universities and research centres (Gambardella, 1992; Cockburn, Henderson, 1998; Zucker *et al.*, 2002). However, the ability of a single organisation to interact with external actors does not solely depend on its “absolute” *absorptive capacity*, but rather on what has been later defined as the “relative” *absorptive capacity* (Lane, Lubatkin, 1998), aimed at analysing the measure of a successful interaction between two specific organisations. In this regard, there are three fundamental factors to explain how two economic actors may interact and exchange knowledge: a certain level of creative similarity (Mowery *et al.*, 1998); similar organisational structures (Burns, Stalker, 1961); shared values and routines (Prahalad, Bettis, 1996). What is defined as «creative, organisational and cognitive proximity » (Boschma, 2005) is therefore the foundation to build steady and long-lasting relationships among organisations, aimed at an effective and efficient integration of expertise and knowledge-sharing. This paper considers *absorptive capacity* as the ability of organisations to identify, acquire and implement creative and innovation knowledge owned by external actors.

In conclusion, another key element of the proposed model regards the actors' ability to connect the district on a global scale, therefore acting as *knowledge gatekeepers* or brokers between a regional and an international system, thereby enabling a gateway to the outside market, and access to new opportunities and technological solutions (Lazaric *et al.*, 2008). In this regard, the presence of multinational enterprises within the district may play a decisive role, guaranteeing an adequate level of international opportunities to the district system, which is therefore positioned inside the current global networks, nowadays the primary exchange place for the information and knowledge market.

Although from a different context and with different dimensions, a clear and well known example of this occurrence is furnished by the birth and growth of the Silicon Valley technological district in California: together with the propulsive thrust coming from Stanford University, it should be surely measured how the activities of multinational enterprises such as IBM, Lockheed and General Electric have significantly contributed to the success of such district in an international scale (Saxenian, 1994; Adams, 2005).

Figure 1 shows the proposed analysis model of creative production districts.

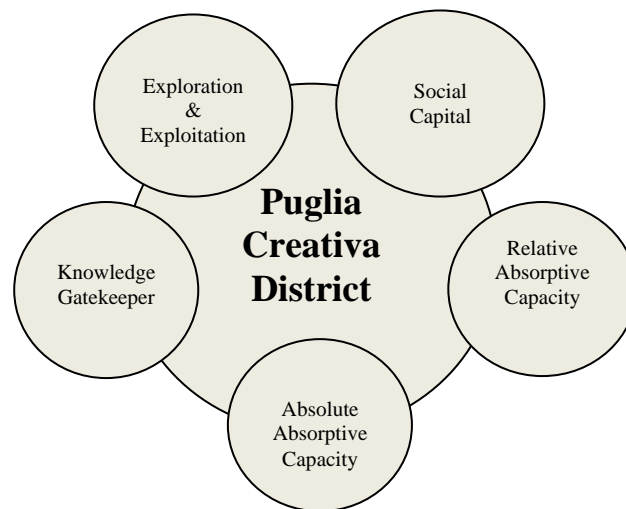

Figure 1 – Analysis Model of Creative Districts

2. Research Method. The Puglia Creativa District

We will examine the Apulian Creative District, adopting the analysis perspective of the theoretical model proposed in the preceding pages. In particular, we will study to which extent the various production chains (1. Cinema and Audiovision; 2. Performing Arts including Theatre, Music and Ballet; 3. Design; 4. New Technologies and ICT; 5. Multimedia and Broadcasting; 6. Training Services: Training, Culture, Creativity; 7. Visual Arts) are able to balance *exploration* and *exploitation* activities; the presence of institutions and/or associations aimed at strengthening the social capital; the *absorptive capacity* of different actors both in absolute and in relative terms; the presence of multinational companies operating as *knowledge gatekeepers*; and the level of creative complementarity among different actors operating inside production chains.

Before proceeding with the analysis of the production chains, or more appropriately of sectors constituting the examined district, it is necessary to define the *proxies* applied to measure different constructs. As regards the balance between exploration and exploitation, we refer to the diverse typology of actors within sectors, differentiating among public research institutions and enterprises. Through this distinction it is possible to consider universities and research centres as mainly concerned with *explorative* activities, while entrepreneurial actors mainly pursue exploitative objectives. This approximation, although rather simple, makes it possible to capture a different institutional direction for involved actors, as well as their *mission*, aimed at exploring new knowledge and creative, innovative and technological opportunities for entrepreneurial actors.

Previous studies have highlighted how the integration of explorative and exploitative approaches allows to effectively combine *upstream* value chain activities with *downstream* value chain activities, hence supporting creative innovation processes throughout the entire production chain (Rothaermel, Deeds, 2004; Lavie, Drori, 2012).

In order to assess the ability of the district to create and strengthen social capital among different actors, the presence of public institutions and/or associations in different sectors of the Puglia Creativa district has been evaluated. Such organisations, thanks to supporting activities and socio-cultural events, may stimulate a mutual trust environment among organisations, which has proved crucial in explaining the success of district economies (Valdaiso *et al.*, 2011). The *absorptive capacity* of actors in different sectors has been evaluated in “creative” terms, with reference to production “prototypes”, relevant to each single production chain¹.

Furthermore, in order to consider only those prototypes (and/or patents) developed by organisations located inside various sectors within the district (with the exclusion of

¹ In this regard, it is worth explaining the operative methodology applied to this work. As for the Movie sector, the prototype is represented by original scripts and film-direction productions; for the Performing Arts sector (Theatre, Ballet and Music), the prototype entails the production of original shows and/or designs, as well as original music productions whose copyrights have been registered at the Italian SIAE Copyright Authority; for Visual Arts, the prototype is a recognisable and patented format, or original formats of exhibitions including the publication of catalogues and/or original works of art created by artists with a recognisable format (which may not necessarily be patented, as it is unusual in this particular field, although it should at least be followed by the publication of a catalogue or otherwise clearly recognisable by its brand, logo or other form of identification); for the Multimedia sector, the production of services with specific copyrights; for the ICT production chain, the creation of new patents; for the Design production chain, the creation of brands and/or patents; for the Services sector, the creation of brands and/or patents.

prototypes developed in different locations and based in other extra-regional contexts), there is a reference to the home address of the first creator, using an approach which is largely employed in literature (Singh, 2008). We then proceeded to include in our analysis sample only those prototypes (and/or patents) whose first creator was an Apulian resident, in order to capture with a good degree of approximation the “creative” capital within the different district sectors. More specifically, as regards the absolute *absorptive capacity* in various district sectors, we mentioned the total amount of prototypes (and/or patents) regularly registered by all concerned actors. The relative *absorptive capacity*, on the other hand, has been measured taking into consideration the cooperation between enterprises coming from the same sector, regardless of the creation of co-production prototypes.

In conclusion, the existence of *knowledge gatekeepers* within production chains and their ability to be open to international markets has been analysed taking into account the cooperation with international enterprises inside various sectors. Such actors may indeed play a “bridging” role, connecting the local system with global networks in terms of exchange of information and knowledge (Lazaric *et al.*, 2008; Adams, 2005).

Practical/Implications

Within the current debate about the measures taken to restructure the district economies, creativity and innovation play a role more and more important (Salvemini, 2008, Sacco 2010). They are driving forces, able to set paths of growth and structural development (Gilbert, 2012). The model specifically investigates four factors, which in the organizational literature are considered as crucial in order to make the process of creative innovation more effective and efficient and thus to explain the success of the production districts of creativity and innovation. Such factors are: a) the capacity to balance *exploration* ed *exploitation*; b) the creating and consolidation of the *social capital*, through the presence and the activities of associations and public institutions; c) the development of *absorptive capacity*, both in absolute and in relative terms; d) the presence of multinational companies, able to connect the district on a global level, thus acting as *gatekeeper* between the regional and the international system.

By means of the model described above, all the sectors constituting the district Puglia Creativa were analysed: 1) Cinema e Audiovision; 2) Live Entertainment, including

Theater, Music and Ballet; 3) Design; 4) New Technologies and ICT; 5) Multimedia and Broadcasting; 6) Training Services: Training, Culture, Creativity; 7) Visual Arts. The relative position of each sector within the district, compared to the parameters identified in the proposed organizational model of analysis, was charted on a scale from zero to ten.

Source: own data elaboration.

Figure 2 – Comparison of Puglia Creativa District Sectors with Reference to Parameters Identified in the Analysis Model

The results provide a useful contribution for an analysis on the state of the district, on its current degree of development and on the future outlook. Such an analysis can contribute to the definition of the regional policies supporting a systemic view of the district, using as a starting point the solidity and the dynamic changes of the sectors which constitute the district itself. An in-depth analysis of each sector, taking into account strengths and weaknesses, can indeed help to define measures to develop the sectors themselves and furthermore to integrate them horizontally and transversally (as well as vertically) within the chain of creativity.

Structured Abstract

Purpose – In the current hyper-connected world, the success of a firm is increasingly dependent on the activities of other active players within the same environment. It is therefore important to understand how to orchestrate ecosystems made up of multiple organizations, institutions and other intermediaries to produce continuous streams of innovation. The paper suggests a potential orchestrator role for academics within this scenario.

Design/methodology/approach – The paper draws on the experience of an applied research centre in Italy. We begin by describing the research centre, the collaborative research processes through which it accomplishes its activities, how it funds them, and the interorganizational results that it has achieved in seven years of practice. Reflecting on the experience of this research centre, we underline not only the key role that academics can play as knowledge management experts, but also the specific research design allowing them to be effective in orchestrating ecosystem innovation.

Originality/value – The analysis of the research centre outlines two main rationales supporting the key role of academics within an innovation ecosystem. The first rationale is associated with the fact that academics are in an independent position, which is neutral and represents a middle ground between the different organizations that share knowledge to ignite and sustain innovation at an ecosystem level. The second rationale is associated with the levels of compliance and complementarity that academics have with the main purposes for which knowledge within an innovation ecosystem is created and leveraged.

Practical implications – Two ‘design’ choices seem necessary to materialize the potential key orchestrator role of academics: (i) the extensive use of multiple approaches of collaborative research; (ii) the creation and maintenance of a knowledge platform allowing academics to manage and to progressively diffuse and leverage the ecosystem-based learning mechanisms underlying each innovation effort.

Keywords – Innovation ecosystems, Orchestration, Knowledge management

Paper type – Academic Research Paper

1 Introduction

One of the reasons why most innovation initiatives fail is that organizations often lack a coherent ecosystem around them that is able to support and complement their innovation efforts (Adner, 2011). In fact, in the current hyper-connected world, firms are increasingly embedded in networks of interdependent activities carried out by external agents within the same ecosystems (Adner and Kapoor, 2010). On the one hand, these interdependencies underlie firms' ability to appropriate returns from investments in innovation (Adner and Kapoor, 2010). On the other hand, firms can exploit these interdependencies to sustain efforts of interorganizational innovation (Stadler et al., 2013).

Thus, innovation ecosystems require processes characterised by simultaneous cooperation and competition (Afuah, 2009), and an orchestration of the actors involved in the interorganisational efforts of innovation (Dhanaraj and Parkhe, 2006). It is therefore important to understand how to orchestrate innovation ecosystems—communities made up of multiple organizations, institutions and other intermediaries that collectively interact as unique systems to produce interorganisational streams of innovation (Kapoor and Lee (2013).

This paper draws on the experience of an applied research centre in Italy to suggest a potential orchestrator role for academics within these settings. We begin by describing the research centre, the collaborative research processes through which it accomplishes its activities, how it funds them, and the interorganizational results that it has achieved in seven years of practice. Reflecting on the experience of this research centre, we underline not only the key role that academics can play as knowledge management experts, but also the specific research design allowing them to be effective in orchestrating ecosystem innovation.

2 The ICT in Healthcare Observatory

Healthcare is a paradigmatic example of an industry in which most of the innovation efforts have to be extended at an interorganizational level to be effective (Angst et al., 2010). Moreover, in healthcare there is no single organisational actor able to create and extract value from the ecosystem around it (Dougherty and Dunne, 2011). In fact, healthcare organizations lack the incentives necessary to play this hub role, healthcare associations do not have enough legitimacy, and consultancy firms lack the necessary independence. Only supra-organizational entities (e.g. the Ministry of Health) would be able to orchestrate innovation initiatives at an interorganizational level. However, most of them have no resources and/or are ineffective in engaging healthcare stakeholders because they adopt only top-down, pro-

grams, which are unable to affect organizational behaviour in a significant way (Scalzo et al., 2009).

Within these settings, the ICT in Healthcare Observatory (IHO) is one the largest success stories in the relationship between Politecnico di Milano and the Italian healthcare stakeholders. Started in 2008, the IHO has created a virtuous loop among research, training, consultancy and communication, that in few years has allowed it to: (i) align the different perspectives on ICT's role within the Italian healthcare domain; (ii) transfer the urgency of collaboratively working on ICT-driven innovation in healthcare; (iii) legitimate IHO as the leading partner to be involved in national/regional projects of ICT-based innovation in healthcare; (iv) enhance the collaboration between the supply and the demand side of the Italian healthcare industry; and (v) become a reference point for all the healthcare decision makers regarding ICT issues. Table A.1, in the Appendix, outlines the main innovation initiatives instituted and led by the IHO. As depicted in the table, most of these initiatives (22 out of 32) have an interorganizational nature. Table A.2 outlines the main deliverables that the IHO produced as a result of its orchestrator initiatives since its inception.

The IHO conducts its activities according to the process depicted in Figure 1. A longitudinal approach is framed into a set of annual research projects, with public presentations of achieved results each year (Pettigrew, 1990). To increase the possibilities of effectively changing the way healthcare organizations view ICT in coping with innovation issues, public presentations are based both on academic- and practitioner-oriented deliverables—such as workshops organizations, papers in peer reviewed journals, articles in general press, etc. (Mirvis, 2008). The idea behind this approach is to increase not only the number of people interested in ICT-driven innovation in healthcare, but also the urgency of adopting ICT as a driver to solve the main issues faced by Italian healthcare practitioners.

Every year, the IHO weaves two main streams of collaborative research (Pasmore et al., 2008). The first is a Semi-Qualitative Research (SQR) led by IHO's researchers, and enriched with the involvement of the practitioners in the gathering and analysis of the data pertaining to the research problem. In the second, the Italian healthcare stakeholders themselves are the change agent (Schein, 2008), and—in the process of seeking help—they engage in a reflective Clinical Inquiry Research (CIR) with the help of the IHO.

Both streams of research are considered in a collaborative way. As depicted in Figure 1, research-driven SQR is more focused on formally inserting the tackled issues into the global discourse—with the aim of gradually switching from an exploratory (*theory generation*) to an explanatory (*theory confirmation*) perspective. The practitioner-driven stream is more fo-

cused on effectiveness during the practical implementation of the developing models, and aims to progressively expand its focus from *problem solving* to *change management*.

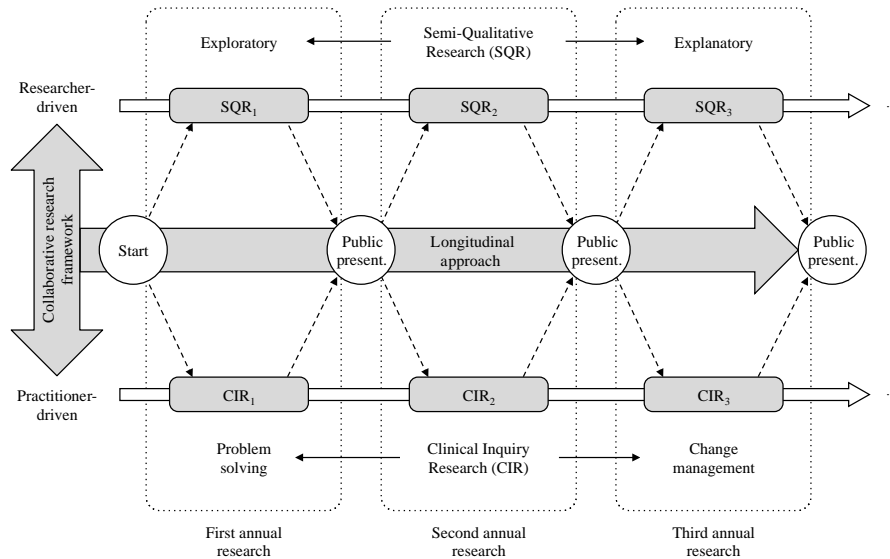

Figure 1 – IHO process to orchestrate the innovation ecosystems in Italian healthcare industry

2.1 Clinical Inquiry Research Stream

CIR is a well-defined collaborative form of research developed by Schein (2008). Clinical refers to the role that academics must play in helping a healthcare stakeholder to (Coghlan and Brannick, 2005): (i) emphasize in-depth observations of change processes, (ii) emphasize the effects of change interventions, (iii) benchmark the findings, and (iv) build theory and empirical knowledge through developing concepts that capture the real dynamics of the system. Gummesson (2000) recognizes that research conducted in this manner potentially enables the total solution to be studied rather than particular parts. Moreover, CIR can be used to initiate change and generate insights from theory development (Stebbins and Shani, 2009).

A distinguishing characteristic of CIR is in the setting of the activity. Unlike most other collaborative research approaches, with CIR the learning opportunity arises in a situation led by the client who needs help and, because of this, is more likely to reveal important data (Schein, 2008). Acting as a process facilitator, the researchers of the IHO help “clients” release resources through self-diagnosis and self-intervention (Stebbins and Shani, 2009). In order to attain a more suitable and sustainable research, the CIR stream of the IHO is framed into annual projects (CIR₁, CIR₂, etc.; see Table A.1 in the Appendix) that end with the presentation of the achieved results not only to the actor who

needed help, but also in broader research contexts such as during specific SQR meetings between academics and healthcare stakeholders, called advisory boards (see §2.2.3).

Business process analysis and mapping (Womack and Jones, 2003), face-to-face interviews and multi-participant interactive dialogues (Mikaelsson and Shani, 2004) are the main collaborative mechanisms utilized in each CIR of the IHO. Moreover, many data are obtained through the involvement of the organization assisted in the SQR process. Periodical meetings are performed in order to progressively share the achieved knowledge with the healthcare organization, orient the SQR process toward more interesting goals, and discuss the empirical as well as theoretical implications of the achieved findings.

2.2 Semi-Qualitative Research Stream

Every year, the IHO uses a combination of a quantitative panel of dynamic electronic surveys, several qualitative case studies, a series of focus groups called advisory boards, and an online community. The overall process of their utilization is depicted in Figure 2.

2.2.1 Electronic Survey

Every year, the IHO creates and delivers an electronic survey to a sample of more than 500 Italian healthcare CIOs from representative organizations of varying types, sizes and geographical areas. A response rate higher than 15% is always achieved (e.g. in the research process of 2012, 127 healthcare CIOs answered the survey—see Figure 2).

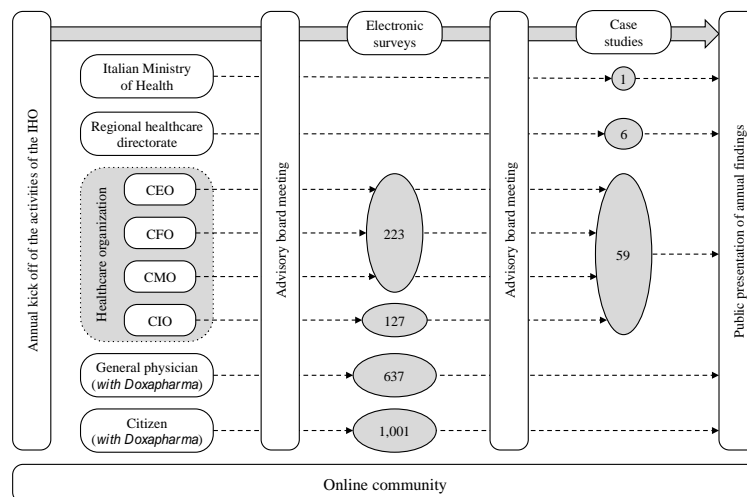

Figure 2 – Semi-Qualitative Research process adopted by IHO in the annual research of 2012

The survey is always designed with semi-closed questions, in order to balance usability and speed—with the possibility of expounding on each question. After positive results from pilot respondents and further refinement with the advisory board, the survey is made available via web in a form allows CIOs to nominate a collaborator able to answer a specific question (and to then review the answer given), and see specific sections of the survey only if specific threshold answers are provided. These dynamic features are responsible for higher response rates—even when using an extensive survey (e.g. 30 questions in 2012).

From a researcher viewpoint, the delivery through an electronic platform gives the possibility to analytically work on closed questions throughout data collection. The IHO is thus able to identify anchors to guide future data gathering, and detect connections between data for further theory generation (Forza, 2002). These preliminary concepts can be brought to the advisory board's attention, together with all the answers given to open questions.

Every year, the IHO delivers a second set of surveys to the Strategic Board—CEO, CFO and CMO—of the same healthcare organizations of responding CIOs, in order to cross-validate given responses. National and international healthcare associations, as well as technology suppliers in healthcare support IHO's research, and actively participate in its activities (Mohrman and Mohrman, 2011). Their contributions aim to not only economically sustain the research, but also push for a timely response on the part of the strategic board of the sample. The brevity of the survey given to CEOs, CFOs and CMOs allows a greater number of organizations to be used as a basis for conducting longitudinal research.

Starting from the annual research of 2012, the IHO has developed a partnership with Doxa-pharma, the branch focused on the healthcare sector of Doxa, the leading Italian institution in opinion pools, market research and statistical analysis. This partnership allows the IHO to run two yearly surveys on statistically-significant samples of general physicians (637 respondents in 2012) and citizens (1,001 respondents in 2012). The idea is that of progressively considering a comprehensive perspective on the topics tackled by the IHO.

2.2.2 Case Studies

The IHO performs a comparative analysis of more than 40 case studies every year (e.g. 66 in 2012). The selection of the healthcare organizations to be studied is based on: (i) the size of their ICT department (measured through the surveys, using the rate of Full Time Equiva-

lents (FTEs) in the ICT direction over the total number of organization employees), (ii) ICT strategic importance (measured through the surveys in budget terms), (iii) ICT projects—both those developed and those in progress—, (iv) advisory board suggestions.

Data is gathered through a series of semi-structured interviews given to the CIO of healthcare organizations of particular interest. A team of an experienced and a junior researcher of the IHO leads every interview, which is based on a consistent protocol, constructed according to survey responses, as well as an a priori analysis of the healthcare organization. All the interviews are digitally recorded, transcribed verbatim, summarized and interpreted through periodic meetings of the IHO in order to test concept reliability, share visions, as well as to formally group and compare key issues. If any information remains unclear and/or more data is needed, interviewees are re-contacted for additional clarifications. Finally, all interviewees are involved in reviewing the summarized interpretation.

A second panel of interviews is delivered to the strategic board—CEO, CFO and CMO—of the same healthcare organizations of responding CIOs, in order to cross-validate the given responses and achieve construct validity (Yin, 2003). Moreover, the IHO analyses multiple sources of evidence: healthcare organizations' internal documents, ICT schemes, websites, white papers, etc. Due to the specific nature of the Italian healthcare industry—in which many decisions are taken at a supra-organizational level (Scalzo et al., 2009)—the IHO performs case studies on the directorate of important and representative regional healthcare systems (6 cases in 2012) and on the Italian Ministry of Health (see Figure 2). When the combination of these sources does not add particular insights to data interpretation, the IHO stops their collection. The huge amount of available data allows better data triangulation (Jick, 1979), which further increases construct validity and enhances the confirmability as well as the credibility of the achieved results (Yin, 2003).

2.2.3 Advisory Board and Online Community

Coghlan and Brannick (2005) note that there are three distinct activities that merit special attention by the parties involved in a longitudinal and collaborative research like that of the IHO: defining the task, defining the process, and attending to the relationship. According to their vision, the IHO benefits from an advisory Board: a multidisciplinary focus group that advises and helps in directing the focus of SQR, in interpreting data, in anticipating future research issues and confirming results via social feedback (Mirvis, 2008). The group counts more than 50 representatives including: (i) C-levels of the main Italian

healthcare organizations, (ii) national and international healthcare technology suppliers, (iii) professionals from national and international healthcare associations, and (iv) healthcare experts. The advantages of working with this heterogeneous group are not only the ability to gain a clear perspective of real sector problems, but also the creation of a community of interest formed around the study—with unique opportunities to bring together the industry supply and demand, and stimulate innovation initiatives.

From a research viewpoint, the advisory board helps in improving both construct validity and dependability of the findings (Yin, 2003). The annual contribution brought to the research by the advisory board is organized around three face-to-face meetings (Figure 2). The first one deals with informal discussion about annual research objectives and priorities in the data gathering process. In the second meeting, initial results are discussed, and the advisory board suggests potential best practices on which to perform the annual case studies. In the last meeting, overall results and explanations are discussed to test, review and confirm them. In all meetings a couple of cases of effective ICT management are presented to share best practices and discuss how to concretize the potential of specific ICT-based solutions.

With the aim of offering further opportunities to discuss ICT's role in the Italian healthcare industry, the IHO has started an online community, which is used not only to discuss preliminary research findings, but also to share experiences, links and news on the topics of ICT and innovation in healthcare. The community helps the IHO in exploring new languages and new channels to be used in order to connect it to practitioners.

3 Academics as Orchestrators of Innovation Ecosystems

The experience of the IHO emphasizes that innovation is no longer solitary exercise, but a collective achievement involving permanent negotiations and new forms of collaboration/com-petition among different stakeholders (Afuah, 2009). The IHO recognizes that the interorganizational initiatives of innovation entail complex phenomena, which exceed the capacity of individuals and organizations to accomplish them (Porter and Powell, 2006). Only through a continuous interaction among many diverse actors—over long periods of time and with a considerable amount of uncertainty—is it possible to benefit from the use of ecosystems as a means to foster innovation (Dhanaraj and Parkhe, 2006; Dougherty and Dunne, 2011).

In this scenario, the IHO shows that academics can play an important role as 'orchestrators of innovation ecosystems', where—paraphrasing Dhanaraj and Parkhe (2006)—

orchestration is defined as the set of deliberate actions to create and extract value from an innovation ecosystem. There are two rationales supporting this consideration:

- The independence of academics within the innovation ecosystem;
- The compliance and complementarity that academics have with the main purposes for which knowledge within an innovation ecosystem is created and leveraged.

3.1 First Rationale: Independent Position

The first rationale explaining why academics hold a valuable position to orchestrate innovation ecosystems is associated with the fact that academics are in an independent position, which is neutral and represents a middle ground between the different organizations that have to cooperate in order to ignite and sustain interorganizational efforts of innovation. In fact, the IHO is composed of academics, and—as opposed to the other stakeholders present in the healthcare industry—academics tend not only to have no hidden agendas related to the promotion of a specific ecosystem configuration, but also to hold significant expertise in building trust and in serving as secure intermediaries between the different actors. Literature has repeatedly shown that, instead of writing lengthy contracts and exercising litigation options, it is better to rely on social interactions to coordinate the activities of an ecosystem and activate streams of joint problem solving within it (Dhanaraj and Parkhe, 2006).

Conscious of these peculiarities, the IHO has invested in being progressively perceived as an impartial and autonomous entity to be consulted in case of fact-checking and evidence-based decision-making. Almost all the interorganizational initiatives listed in Table A.1 have been activated and led by the IHO thanks to its reputation as an independent accumulator of data able to manage privacy issues and help practitioners in accomplishing their innovation decisions. For instance, a big region in Northern Italy asked the IHO for help in developing the guidelines with which to orient and govern the implementation of the electronic medical records of all the 33 public healthcare organizations operating within it (refer to CIR₅ in Table A.1), while the Italian Ministry of Health asked the IHO for data on the diffusion of electronic medical records within the Italian healthcare industry because—having strong relationships with all the providers of this ICT-based solution—as well as the majority of healthcare organizations utilizing it, the IHO ensured a detailed and unbiased picture of the real diffusion of electronic medical records that no other practitioner-oriented entity in the industry has been able to provide. This is coherent with the strategy that the IHO has historically pursued, which is based on two pillars:

- *Favouring interorganizational over organizational clinical inquiry research*: in this way the interest of a single actor does not achieve a predominant position within the ecosystem, biasing the perspective adopted by the IHO in supporting innovation;
- *Accepting only fixed, and small fees to sustain the accomplishment of semi-qualitative research*: in this way the dimension of an organization (and its financing capacity) does not influence the definition of the objectives of IHO research;

3.2 Second Rationale: Compliance to Innovation Ecosystems' Knowledge

The second rationale is associated with the levels of compliance and complementarity that academics have with the main purposes for which knowledge within an innovation ecosystem is created and leveraged. Leveraging on the works of Docherty et al. (2003) on interorganizational networks, it is possible to identify four types of innovation ecosystems to which academics can contribute as knowledge management experts: professional, learning, transformational and strategic. In the rest of the paragraph we describe these ecosystems, why the IHO's experience suggests that academics can be valuable orchestrators of interorganizational initiatives of innovation within them, and the key role of knowledge management.

3.2.1 Academic Compliance to Professional Innovation Ecosystems

Professional innovation ecosystems periodically bring together practitioners who gain some benefit from exchanging knowledge with like-minded peers in order to keep abreast of the latest developments in their fields (Docherty et al., 2003). Indirectly, these knowledge exchanges catalyse collective reflections on how accomplishing organisational and interorganizational initiatives of innovation, and provide opportunities to realise them. There are many professional innovation ecosystems in the Italian healthcare industry. Associations, consultants, and developers of ICT-based solutions organize several meetings to encourage debates among healthcare stakeholders around innovation. However, these meetings tend to be over-focused on specific topics, which are connected to the application domain of the meeting organizer. Moreover, the participants in these meetings tend to share the same beliefs, the same values, the same experiences and the same perspective of the future. Thus, it is often necessary to find incentives of thinking 'outside the box', in order to really keep up the pace with the multiple opportunities available to practitioners.

In this respect, the IHO shows that academics can be helpful in: (i) offering opportunities to share knowledge and expertise; (ii) initiating effective collaborative discussions about in-

dividual experiences; (iii) summarizing and formalizing the knowledge generated through peer interactions; (iv) guiding and bringing value to discussions; (v) helping to think outside the box; and (vi) maintaining the focus on mutual organizational interests. As an example of these capabilities consider the advisory boards periodically organized within the annual semi-qualitative research of the IHO (SQR₁–SQR₆ in Table A.1). These meetings are exploited not only to orient the research process of the IHO, but also to provide the Italian healthcare industry with unique opportunities to bring together its supply and demand side, and create moments to stimulate interorganizational initiatives of innovation. The online community has been created to offer further meeting occasions of this kind in a virtual environment, and to consolidate the relationships established face-to-face.

3.2.2 Academic Compliance to Professional Learning Ecosystems

The organizations in a learning innovation ecosystem aim to increase their knowledge by focusing on innovative sources of inspiration within the ecosystem to which they belong. Usually they interact through private/public meetings, purposefully reflecting on theirs and others' knowledge to identify learning opportunities related to organizational and interorganizational innovation issues. Progressively, formal and informal consortia emerge from this continuous reflection. These consortia influence existing knowledge management systems by creating a safe psychological climate that allows the learning anxiety behind the resistance to change to overcome (Schein, 2002). The Italian healthcare industry can be seen as a compound set of learning innovation ecosystems. It is sufficient thinking to the several work groups through which the Italian Ministry of Health coordinates the sharing of best practices among its regional healthcare systems.

The IHO suggests not only that academics are natural enablers of the learning processes underlying these groups, but also that the higher the moderation of academics, the more effective the activation of multiple streams of unbiased reflection around the practitioners' knowledge at both the organizational and the interorganizational level. With reference to the semi-qualitative research streams activated by the IHO, the number of participants in its workshops and public presentations (Table A.2) emphasizes IHO effectiveness in rendering as salient the learning potential related to the cases discussed within these events.

Practitioners can organize and lead learning innovation ecosystems as well—especially consultants and the supra-organizational entities like the Ministry of Health. However the learning atmosphere that they create is less of a safe psychological climate

than the one created by academics, who, in addition, are particularly effective in understanding the idiosyncrasies of the specific reality being addressed, in embracing a broad perspective, and producing more effective interorganizational knowledge. The advisory boards of the IHO are so effective in capitalizing on the past to better shape the orientation of IHO thanks to the safety perceived by the participants of these “closed events”, which are progressively exploited to present organizational and interorganizational cases of innovation in order to freely discuss them without the risk of public judgments

3.2.3 Academic Compliance to Professional Transformational Ecosystems

Transformational innovation ecosystems aim to transform their participants, whose development in terms of innovation is seen as integrally linked to the development of the ecosystems of which they are a part and/or with which they interact. Thus, the ecosystem acts as a tightly-coupled peer system, in which participants collaborate on directing, developing and deploying the knowledge that is necessary to enable the transformation processes. In Italy, all regional healthcare systems establish themselves as ecosystems of players focused on developing joint transformational processes within the innovation domain. These processes are of course oriented towards sharing professional knowledge (§3.2.1) and/or obtaining learning outcomes (§3.2.2), but their main emphasis is put on having the best conditions to ignite and sustain interorganizational initiatives of innovation.

The IHO shows that, in these cases, the healthcare stakeholders form transformational innovation ecosystems, and that academics can play key orchestrating roles within these ecosystems as knowledge management experts. For instance, the surveys that are delivered to all Italian healthcare C-levels each year provide the IHO with updated data regarding the overall priorities in ICT investments. During 2010, these priorities represented a common base for the development of an ICT-driven innovation plan for a regional healthcare system in Northern Italy (see CIR₆ in Table A.1). This plan has been developed with the healthcare directorate of the region, and the IHO provided this last one with critical inter-organizational knowledge regarding how to effectively enable and sustain the progressive digitalization of the whole regional healthcare system through: (i) the definition of the functional ICT areas and governance initiatives to be kept under control; (ii) a prioritization of the main interventions; and (iii) a set of indicators to monitor the impact of each intervention on the objectives of the regional healthcare system.

Academics are particularly effective in leading an interorganizational ecosystems transformation for two reasons. First, a transformation opportunity is seized and pursued if the relative ecosystem is able to maintain a delicate equilibrium among different interests, and a critical prerequisite to this equilibrium is the presence of a safe psychological climate avoiding any perceived risk of free riding during knowledge sharing. From this viewpoint, academics are the actors that have always manifested the highest level of independence. Second, academics have strong competences in systematically identifying potential directions along which to guide the joint transformational paths of the innovation ecosystem. These competences are the results of incessant literature analyses and of the exposure to the practices of other sectors.

3.2.4 Academic Compliance to Strategic Innovation Ecosystems

Strategic innovation ecosystems are formed to add value to business processes through mutual dependence on exchange relationships. As part of the strategic ecosystem, organizations engage in goal-oriented activities around shared problems, with the aim of dynamically achieving innovation objectives through the reduction of transactional problems. Starting from this viewpoint, it is possible thinking of Italian healthcare also in terms of as a set of inter-related strategic ecosystems aiming to find an overall configuration that allows the whole industry to disrupt their services without compromising the quality offered to patients. The complexity of the decisions taken within a strategic innovation ecosystem necessitates supporting the creation of ecosystem knowledge by: (i) decoding the choices made by each actor; (ii) assessing their efficiency and effectiveness; and (iii) integrating it to the interorganizational knowledge system of the ecosystem. The process is oriented to the production of explicit evidence, valuing mutual dependence during interorganisational relationships.

The experience of the IHO shows that academics can play key orchestrator roles within these settings. For instance, and with reference to CIR₁₉ in Table A.1, the IHO leveraged on its unique knowledge of all the 33 public healthcare organizations operating within a big region in the Northwestern Italy to assess the maturity of their information systems according to a model jointly developed with the healthcare directorate of the region (CIR₁₃), and based on a systematic literature review. The assessment has provided both the region and its public healthcare organizations not only with information regarding specific intra- and inter-organizational ICT-based functional areas requiring further development, but also with the joint objectives of: (i) progressively homogenizing the ICT-based solutions present in the healthcare system; (ii) reducing the costs of ICT management; and (iii) improving the quality

of the regional healthcare system through an ICT-based integration of its different care pathways. These ecosystem objectives are the result of a innovation process that academics easily activated and sustained thanks to their capabilities of realizing systematic literature review, maintaining a continuous relationship with different actors, and supporting the whole strategic innovation ecosystem in knowledge creation, extension, conversion and integration.

3.2.5 Potential Orchestrator Roles of Academics

The experience of the IHO demonstrates that academics can play several orchestrator roles in all innovation ecosystem types. More specifically, the main orchestration role of academics within an innovation ecosystem tends to change according to its nature:

- In professional innovation ecosystems academics provide meeting occasions for ecosystems actors, and help them in recognizing the innovation opportunities available within and to the ecosystem by enhancing the diffusion of ecosystem knowledge;
- In learning innovation ecosystems academics reduce the learning anxiety behind the resistance to change that each actor of the ecosystem tends to manifest, and help in arranging knowledge in order to better framing innovation opportunities at a ecosystem level;
- In transformational innovation ecosystems academics support the different innovation processes activated in the ecosystem through the constitution of the best conditions necessary to accomplish them and the systematization of interorganizational knowledge;
- In strategic innovation ecosystems academics orient each innovation process towards common valuable objectives, and contribute in actualizing each synergy present among all ecosystem actors by constituting an independent ‘knowledge hub’.

The IHO shows also an increasing interrelationship among the different types of innovation ecosystems. This interrelationship underscores how innovation arise from the combination of top-down and bottom-up forces, stemming from semi-autonomous entities that have to interact through complex and uncertain processes of collaboration-competition, and consistent with the main dynamic emphasis adopted by the innovation ecosystem to which they belong.

4 Two Prerequisites for an Effective Academics’ Orchestration

Even if academics have a tremendous potential to orchestrate innovation ecosystems, most of their initiatives are neither oriented toward achieving this goal (Knights et al., 2008), nor effective in attaining it (Bartunek and Schein, 2011). In fact, industries and universities

are governed by different belief systems, practices, and institutional logics, which comprehensively tend to ignite several tensions between academics and practitioners who try to jointly realise innovation. The basic step to manage these tensions is the nurturing of a continuous knowledge exchange between the two actors. However, this exchange is difficult to initiate and maintain due to the presence of diverse goals, motivations, and planning horizons.

Academics in the field of innovation management are aware of the necessity of bridging the gap between theory and practice, and understand the value of being part of (or leading) innovation ecosystems. However, their struggle caught in the middle of a conflict between career concerns and societal contribution, because most of the incentives within the academic domain are connected to peer citation pressures, and not in generating innovation. As a result, the attitudes and the interests of academics are progressively shaped, and their research endeavours are increasingly narrowed down to the point where they are no longer able neither to orchestrate complex phenomena nor to elucidate them. According to the experience of the IHO, two ‘design’ choices seem necessary to materialize the potential key orchestrator role of academics:

- The extensive use of multiple approaches of collaborative research, not only to increase the influence of academics in practice, but also (and especially) to support knowledge creation and exchange at both organizational and ecosystem levels;
- The creation and maintenance of a knowledge platform allowing academics to manage and to progressively diffuse and leverage the ecosystem-based learning mechanisms underlying each interorganizational effort of innovation.

The next two paragraphs deepen these choices, and start outlining a framework for clarifying the orchestrator role that academics can play within an innovations ecosystem.

4.1 Extensive Use of Multiple Collaborative Research Approaches

The IHO shows that the orchestration of innovation ecosystems requires academics a relentless exposure to large number of practitioners coming from different domains: the researchers of the IHO meet frequently with healthcare C-levels (CEOs, CFOs, CMOs, and CIOs), physicians, nurses, employees in the administrative offices of healthcare organizations, policy makers, providers of ICT-based solutions for healthcare, consultants, representatives of healthcare associations, delegates of regional healthcare directorates, deputies of the Italian Ministry of health, etc. In these complex, interrelated settings, the generation of knowledge no longer occurs—as historical happen (Christensen et al.,

2009)—only in the academic domain, but rather in a more distributed manner (Mohrman and Lawler, 2011). Thus, IHO researchers are increasingly becoming just one of the many players through which the actors in the Italian healthcare industry seek to find actionable knowledge to govern innovation initiatives at multiple levels of analysis.

In this increasingly competitive scenario, academics have to decide if they want to ‘stay in their ivory towers’, being increasingly marginalized as ineffective players, or seek out their orchestrator role, exploiting their strengths and establishing partnerships with other network players. The experience of the IHO suggests that an extensive use of multiple approaches of collaborative research allows the achievement and maintenance of a dynamic equilibrium providing academics with the capabilities to orchestrate innovation at an ecosystem level. In the next two sections we respectively explain why collaborative research seems necessary, and why multiple approaches of collaborative research are better than single approaches.

4.1.1 Why Collaborative Research?

Collaborative research implies research efforts that include an active involvement of practitioners in the following four phases (Van de Ven, 2007):

- *Problem formulation*: situating, grounding, diagnosing, and inferring the research by determining who, what, where, when, why, and how the problem exists. Answering these questions requires meeting with people familiar with the problem.
- *Theory building*: creating, elaborating, and justifying a theory. Developing this theory—as well as its plausible alternatives—requires conversations with knowledge experts from the relevant disciplines and functions that have addressed the problem.
- *Research design*: developing a model for empirically examining the alternative theories. Doing this well typically requires advice from technical experts in research methodology and from the people with access to data.
- *Problem solving*: communicating, interpreting, and applying the empirical findings regarding which alternative models better answer the research questions.

The engagement of practitioners in all these phases forces academics to extensively deal with them throughout the research process, not only providing opportunities to legitimize academics’ orchestrator role, but also allowing academics to aspire of having an impact on reality. For instance, the IHO started its online community to increase its dialogue with practitioners, gather research interests from a broad group of stakeholders, periodically stress the importance of following the suggestions derived from its findings, and provide tailored an-

swers to the practitioners willing to adopt the models jointly developed in its research processes.

Moreover, pushing academics outside themselves—to obtain and be informed by the perspective of practitioners—collaborative research fosters the generation and the validation of actionable knowledge, which not only provides a solid theoretical background through which supporting the development of a innovation ecosystem, but also simplifies the alignment with practitioners that is necessary to influence their actions towards common goals.

Finally, collaborative research is based on the value that “knowledge production” and “action” are not set apart as two separate processes, but synergistically support each other. In fact, collaborative research aims to understand the influence in complex systems of behaviours, actions, and purposeful design choices that are intended to manage the systems toward intended outcomes (Pasmore et al., 2008). Thus, academics can use collaborative research in multi-stakeholder settings to orchestrate innovation ecosystems—as clearly exemplified by the interorganizational initiatives led by the IHO (see Table A.1).

Collaborative research	Informed research	Insider/outside research*	Design/evaluation research	Action/intervention research
Description	Academics conduct and control research activities with advice of practitioners	Teams composed of insiders and outsiders co-produce knowledge	Academics develop and evaluate policies or programs for/with practitioners	Academics implement change to solve a practitioners’ problem
Purpose	Describing/ explaining	Describing/ explaining	Designing/ controlling	Designing/ controlling
Perspective	Dethatched outsider	Attached insider	Dethatched evaluator	Immersed change agent
IHO’s examples**	All surveys and case studies in SQR ₁ –SQR ₆	All advisory boards in SQR ₁ –SQR ₆	CIR ₅ , CIR ₆ , CIR ₈ , CIR ₁₃ , CIR ₂₁ , CIR ₂₂	CIR ₁₄ , CIR ₁₉

* Van de Ven called this typology of research “collaborative”; we have preferred the terms “Insider/outside research” not only to avoid a potential terminological confusion, but also because it captures the real aims of these research efforts: developing joint teams, in which one or more members are relative insiders to a setting and one or more members are relative outsiders, to conduct a collaborative study (Bartunek, 2008)

** Refer to §2 for a description of the specific Semi-Qualitative Research (SQR) and Clinical Inquiry Research (CRI) streams

Table 1 – Typologies of collaborative research’s approaches utilised by the IHO

4.1.2 Why Multiple Approaches of Collaborative Research?

Collaborative research contemplates a wide variety of approaches characterized by different degrees of collaboration. At one extreme, collaboration may be limited to access to an organization for data collection. At the other extreme is research that seeks not only to produce

knowledge but also to transform a system. In between these extremes there are several forms of collaboration that can be exploited by academics to orchestrate innovation ecosystems.

From this viewpoint, the IHO shows that multiple levels of collaboration are necessary, and that the more these different approaches of collaborative research are combined and simultaneously pursued, the greater the orchestration of interorganizational efforts of innovation. In order to explain why, it is necessary to generalize Van de Ven (2007), and classify the collaborative research approaches depicted in Table A.1 according to their purposes and perspectives. Purposes focus on whether the collaborative research is being undertaken to describe/explain or design/control the innovation ecosystem. Perspective refers to the degree to which academics relate to the research domain as external observers or internal participants. The intersection of these two dimensions generates four different macro-approaches of collaborative research, which the IHO concurrently uses to orchestrate innovation ecosystems. These macro-approaches are depicted in Table 1.

According to the experience of the IHO, the greater the concurrent presence and the balance among these collaborative research approaches, the greater the possibilities of exploiting the synergies among the relative orchestration modes. In fact, the interplay among the different collaborative research approaches provides multiple ways and levels to engage with practitioners in a comprehensive manner, which triangulates the relative knowledge according to the specific emphasis of the innovation ecosystem. For instance, most of the orchestration efforts of the IHO are placed not in enabling but rather in supporting interorganizational initiatives of innovation. To successfully support these initiatives, each year the IHO weaves semi-qualitative and clinical inquiry research streams. The combination of these different forms of collaborative research allows the progressive assembling of a transformational innovation ecosystem of practitioners and academics able to jointly assess, investigate and realize the strategic role of ICT within healthcare. More specifically:

- *Quantitative-oriented research activities*, like the surveys, provide the IHO with the detachment that is necessary to both deal with different healthcare stakeholders and objectively seize the innovation opportunities within and among them;
- *Qualitative-oriented research activities*, like the case studies, call for first hand involvement of IHO's academics, which however maintain the neutrality allowing them to construct meaningful perspectives for the innovation ecosystem to orchestrate;

- *Action-oriented research activities*, like the CIR or the advisory board, exploit the emergence of insights from the interaction with the social system to sustain the progressive transformation of the innovation ecosystem over time.

Adopting multiple collaborative research approaches, the IHO gradually understands the right emphasis to place on these different research activities, in order to combine their strengths and avoid their weaknesses based on the specific domain under consideration. The end result is a combination of real-time observations and retrospective analysis, which not only maximizes the probabilities of discovering short-lived factors that have a significant influence on the orchestration performance, but also provides the advantages of: (i) getting the “big picture” of the innovation ecosystem, and (ii) avoiding overcomplication and oversimplification during knowledge orchestration (Van de Ven, 2007).

4.2 A Platform to Manage the Network-based Learning Mechanisms

The experience of the IHO shows that to develop an innovation ecosystem it is necessary to change: (i) the viewpoint from which academics look at practice; (ii) the way through which the collaborations between academics and practitioners are established and maintained. Regarding the former, instead of simply viewing organizations as data collection sites and/or funding sources, academics have to view them as a learning workplace (idea factory)—where practitioners and scholars co-produce knowledge on important questions and issues by testing alternative ideas and different views of a common problem. Regarding the latter, Bartunek et al. (2011) suggest that for a successful collaboration among academics and practitioners it is necessary to: (i) widen the circle of involvement, so that everyone’s voice counts, creativity is easily sparked, and accountability is distributed across the whole network; (ii) develop and exploit joint academic-practitioner forums; (iii) connect individual practitioners and academics with each other; (iv) create academic–practitioner communities for action; (v) make sure that academic–practitioner interactions are fair.

While the experience of the IHO indicates that these actions produce dynamics of real engagement between scholars and practitioners, taken alone they are insufficient to maintain the intimacy with practice that academics need for an effective orchestration of an innovation ecosystem. In order to achieve this goal, the relationship between academics and practitioners has to be developed and nurtured over time. The IHO suggests that the configuration of a knowledge platform allowing academics to manage and progressively diffuse the ecosystem-based learning mechanisms underlying each interorganizational innovation increases the ef-

fectiveness of academics in orchestrating an innovation ecosystem. In the next two sections we explain why a knowledge platform seems necessary, and why the diffusion of a tapestry of ecosystem-based learning mechanisms increases the effectiveness of orchestration.

4.2.1 Why a Platform?

The IHO proves that academics can orchestrate innovation ecosystems by engaging themselves to multiple actors through collaborative research approaches. On the one hand these approaches hold tremendous potential for the advancement and application of knowledge as well as ecosystem alignment, on the other hand they are highly difficult to control in an experimental sense (Bartunek et al., 2011). In fact, the collaborative research accomplished in multi-stakeholder settings tends to exceed individual research capabilities, and asks for multiple research perspectives, researchers, methods and resources (Mohrman et al., 2008).

From this viewpoint, a promising avenue that the IHO is exploring is the constitution of a knowledge platform—a socially-engineered knowledge framework (Stebbins and Valenzuela, 2004) able to: (i) constitute a critical mass of researchers to convey several perspectives on the same innovation stimuli; (ii) jointly overlap different theoretical and empirical frameworks to successfully tackle these stimuli; (iii) manifest a unique identity during the interaction with practitioners; (iv) push academics out of their comfort zone, which tends to be over-focused on peer citation logics; (v) engage academics with practitioners in each phase of the collaborative research processes underlying an orchestration effort; and (vi) convey the innovation initiatives present within an ecosystem at a systemic level.

The IHO suggests three motivations to establish a knowledge platform in the context of multi-stakeholder research that is oriented towards the orchestration of innovation ecosystems. The first motivation is related to the fact that a knowledge platform strengthens the effectiveness of collaborative research in supporting any academic orchestration. In fact, a knowledge platform allows to easily work on the six motors proposed by Tenkasi and Hay (2008) to foster academic-practitioner collaboration (Table 2). These motors are enabled and improved by the presence of a knowledge platform, which not only collects in a meaningful, circumscribed niche of inquiry the efforts of the nine applied researchers working in the IHO, but also allows to efficiently allocate their resources, prioritize the different interventions, seize all exploitable synergies, effectively share best practices, and easily convey the different innovation efforts at a systemic level.

Table 2 – Motors used by the IHO to engage practitioners and orchestrate CI ecosystems

Motor	Definition	Relating theory to practice	Relating practice to theory
Scaffolding	Identifying problems of double relevance by including a platform that, while leading practical actions, ensures theoretical outcomes	Development of an annual research agenda derived from a detailed literature analysis	Adding practical elements exceeding the needs of the stakeholders helped through each CIR project to increase theoretical outcomes
Framing	Using theory to give direction to a broadly expressed innovation mandate, and practice to frame a niche in which to test/develop a theoretical model	Considering ICT as a lever that a healthcare system can use to overcome the conflict between quality improvement and cost rationalization	Slight adaptation of the research agenda according to practitioner needs (mostly in terms of focusing on specific ICT-based solutions)
Influencing and legitimizing	Using theory to influence and legitimise the need for certain kinds of actions, and using practice to legitimise a certain kind of theoretical model	Fostering the usage of ICT as a lever to dynamically balance exploration and exploitation within healthcare	Leveraging the idiosyncrasies of the different regional healthcare systems in Italy to study the variables moderating the significance of ICT
Sense making	Using theory to make sense of practice, and practice to re-inform theory	Paradoxical thinking to explore the necessity of balancing exploration and exploitation in healthcare	Necessity to switch from an organizational to a network-based unit of analysis to not conduct an abstract research
Demonstrating	Using theoretical rigor to demonstrate that a solution is empirical successful, and practical impacts to provide evidence supporting the veracity of a theoretical model	Quantification of the benefits (in terms of quality and cost) associated with the investments in ICT in healthcare	Application of an ICT adoption model developed through a group of cases on another group of healthcare organizations in order to refine the model and test its veracity
Turns	Reframing a theoretical element to make it more palatable to a practitioner audience; and reframing an empirical element with similar aims for an academic audience	Graphical and interactive presentation allowing healthcare practitioners to understand the frameworks of paradoxical thinking	Legitimizing the methods used by IHO – with a specific emphasis on the collaborative and qualitative ones (e.g., definition of the strategies to reduce informant bias)

A second motivation for exploiting a knowledge platform concerns the possibility to increase the dialogue between academics and practitioners. Periodically, the IHO brings the two together to discuss research findings and their practical implications, to identify key emergent problems, and to facilitate networking, so that healthcare stakeholders can share their experiences and learn from one another. Being a research centre emphasizing the importance of its domain, the IHO serves as a hub, providing a structure and a process by which practitioners and academics can continuously co-interpret interorganizational issues. As exemplified by IHO’s advisory boards, the knowledge platform serves as a “safe” container for what may become difficult conversations, and from which an orchestration process can be set up and sustained. By adhering to the IHO, practitioners and academics agree on committing to attending regular meetings, confronting on a periodical basis, and cyclically reflecting on interorganizational innovation issues. Literature (Van de Ven, 2007) suggests that this form of collaboration is especially effective: (i) in learning from

past experiences, (ii) in adopting a shared vocabulary for capturing multiple dimensions of a phenomena, and thus, (iii) in orchestrating interorganizational innovation ecosystems.

A final motivation for establishing a platform to orchestrate innovation ecosystems is related to the creation of an adequate research rhythm. The IHO shows that if academics aim to play a substantive role as interorganizational orchestrators they have to undertake rapid research processes, which balance rigorousness and timeliness. The former is oriented toward providing enough sophistication to ensure that the evidence on which practitioners will base their decision is soundly based (Hodgkinson et al., 2001), whereas the latter ensures that this evidence arrives in a timeframe compatible with the decision-making. A platform like the one established by each IHO substantially helps in truly excelling at both these competing demands. In fact, on the one hand, a platform provides academics with resources and time to collectively reflect on interorganizational issues, compare alternative network solutions, and explore different orchestration strategies. On the other hand, it forces academics to train their capabilities of conducting collaborative research more quickly, and in a way that addresses the changing realities faced by practitioners.

4.2.2 Why Ecosystem-based Learning Mechanisms?

Learning, in one or more variations, is an integral part of any innovation initiative. Starting from this consideration, each innovation ecosystems underline the comprehensive character of the learning endeavours, which academics can foster and use. More precisely, it is possible to distinguish between learning 'in' and 'from' an innovation ecosystem (Huzzard and Gregory, 2008). In fact, this last one can acquire not just the declarative knowledge of its specified learning target, but also procedural knowledge about the management of the ecosystem itself: its setup, maintenance and survival. For instance, the IHO generates insights of interest for the entire Italian healthcare industry both through the data collected by its surveys/cases as well as thanks to its events, which provide opportunities to jointly reflect on the best way to collaborate on shared innovation issues.

The IHO suggests that the effectiveness of a knowledge platform in orchestrating innovation ecosystems is connected to its capability to design, implement, spread, and leverage mechanisms through which to learn 'in' and 'from' the ecosystems themselves. In fact, the learning issues are often not formally given a clear priority on the management agenda in most organizations, and—since interorganizational learning is effective if its conditions

and process are systematically designed and implemented (Shani and Docherty, 2003)—academics are among the best designers and developers of ‘learning mechanisms’.

At the most basic level, learning mechanisms are formalized strategies, policies, guidelines, methods, tools, routines, and any other arrangement that is designed to promote and facilitate learning (Lipshitz et al., 2007). Although learning mechanisms can apply at individual, group, organizational and ecosystem levels, most of the literature on the topic assumes an organizational perspective, and identifies three main learning mechanisms: cognitive, structural, and procedural (Fredberg et al., 2011). Starting from this viewpoint, it is possible to talk about three Ecosystem-based Learning Mechanisms (ELMs), which the IHO concurrently uses in orchestrating innovation ecosystems (see Table 3 for some examples).

- *Cognitive ELMs*: language, symbols, theories, values and concepts for creating an understanding among all innovation ecosystem on the character, need, and priority of a new ecosystem status as well as the changes required to realize it (Docherty and Shani, 2008).
- *Structural ELMs*: interorganizational infrastructures that encourage practice-based learning within an innovation ecosystem—housing and enabling the knowledge exchange required for interorganizational innovation (Shani and Docherty, 2006).
- *Procedural ELMs*: institutionalized procedures, routines, and methods that facilitate ecosystem knowledge exchange, and establish the core routines to effect innovation.

The experience of the IHO emphasizes that a knowledge platform that focuses on nurturing a tapestry of different types of ELMs has greater possibilities to ignite and sustain ecosystem innovation. The higher the interrelatedness of the ELMs, and their coherence to the specific purpose of the innovation ecosystem, the more effective the orchestration by the academics. The IHO represents an effective knowledge platform to keep practitioners abreast of the latest developments in their fields because it provides them with: (i) network data on which to reflect (e.g. on ICT budgets); (ii) opportunities to house these reflections (e.g. the online community), and (iii) processes through which to facilitate them (e.g. the benchmarking among different hospitals).

5 Conclusions

Organizations are increasingly shifting from innovation initiatives centred on internal resources to those that are centred on sharing resources, knowledge and expertise in ecosystems (Adner, 2011). In these settings, most innovation efforts have to be designed and accom-

plished at an interorganizational level to produce outcomes. The experience of the IHO suggests that academics can effectively orchestrate these initiatives. In order to concretize their orchestration role, academics have to extensively engage with practitioners, and leverage on their independence/compliance to the different types of innovation ecosystems.

The best way to accomplish this task in an innovation ecosystem seems to be the organization of a knowledge platform combining multiple approaches of collaborative research. The balance of multiple approaches of collaborative research tends to increase academic possibilities of activating virtuous cycles between research, communication and community management, which allow academics to effectively serve as knowledge management experts, and conveys the different innovation efforts at a systemic level.

Table 3 – Examples of Ecosystem-based Learning Mechanisms (ELMs) enabled and led by the IHO

Ecosystem type*	Cognitive ELMs	Structural ELMs	Procedural ELM
Professional	Report with quantification of healthcare ICT budgets (derived from surveys) ^[FROM]	Online community and public presentations ^[IN]	Benchmarking among hospitals and among regional healthcare systems ^[FROM]
Learning	Report with investment priorities of healthcare CIOs (derived from surveys) ^[FROM]	Advisory boards and annual public presentations ^[IN]	Regional guidelines for EMR implementation ^[IN]
Transformational	ICT-driven innovation plan for a regional healthcare system ^[IN]	Public presentations and online community ^[IN]	Regional guidelines for healthcare information system homogenization ^[IN]
Strategic	Regional governance model of the shared health-care services ^[IN]	Advisory boards (and their safety climate) ^[IN]	Maturity model of healthcare information systems ^[IN]

* For each ELM we have emphasised if it has realised its potential through an analysis of the actors/dynamics characterising the innovation ecosystem (learning FROM the ecosystem) or through an interaction with it (learning IN the ecosystem)

Appendix

Table A.1 contains the main innovation initiatives instituted and led by the IHO. Table A.2 outlines the main deliverables that the IHO produced as a result of its orchestrator initiatives since its inception.

Table A.1 – *Overview of the innovation initiatives initiated and led by the IHO*

Year	Id*	Innovation Initiative
2008	CIR ₁	Development of the strategic specifications of an electronic medical record system in a small (200 employees; 80 beds) private hospital
	CIR ₂	Strategic assessment and re-organization of the ICT insourcer of a big (10 million citizens) region (emphasis on the healthcare practice)
	SQR ₁	Nation-wide collaborative reflection of the results of IHP surveys and the case studies
2009	CIR ₃	Assessment and strategic reconfiguration of the ICT department of a large-sized (3,450 employees, 1,200 beds) general hospital
	CIR ₄	Strategic reconfiguration of the ICT department of a medium-sized (170,000 citizens) local authority
	CIR ₅	Development of the guidelines that a big (10 M citizens) region uses to orient and govern the implementation of the EMRs of all the 33 public healthcare organization operating within it

2010	<u>SQR₂</u>	Nation-wide collaborative reflection of the results of IHP surveys and the case studies
	<u>CIR₆</u>	Development of the ICT-driven innovation plan for a big (4.5 M citizens) regional healthcare system
	<u>CIR₇</u>	Strategic reconfiguration of the ICT department of a large-sized (1,100 beds) general hospital
2011	<u>CIR₈</u>	Development of the guidelines that a big (10 M citizens) region uses to homogenize the information systems of all the 33 public healthcare organizations operating within it
	<u>SQR₃</u>	Nation-wide collaborative reflection of the results of IHP surveys and the case studies
	<u>CIR₉</u>	Design of the ICT-based system used by a large-sized (1,000 beds) hospital to interact with patients
2012	<u>CIR₁₀</u>	Strategic analysis of the benefits associated with the development of a computerized drug management system in a large-sized (3,450 employees, 1,200 beds) general hospital
	<u>CIR₁₁</u>	EU project to implement and scale up 7 pilots based on the concept of secure and user-friendly online access by citizens to their health data
	<u>CIR₁₂</u>	Comparison of 3 EE regional healthcare systems to improve the treatments delivered in rural areas
2013	<u>CIR₁₃</u>	Development (and pilot test) of a model that a big (10 million citizens) region uses to assess the maturity of the information systems of all the 33 public healthcare organizations operating within it
	<u>SQR₄</u>	Nation-wide collaborative reflection of the results of IHP surveys and the case studies
	<u>CIR₁₄</u>	Strategic design of an inter-organizational community connecting administrations of 5 hospitals
2014	<u>CIR₁₅</u>	Joint reflections on the role of ICT in the support of fragile/elderly patients, and strategic analysis of the business models of a telemedicine service with a medium-sized (700 employees) ICT provider
	<u>CIR₁₆</u>	Strategic reconfiguration of the ICT department of a large-sized (3,800 employees) general hospital
	<u>CIR₁₇</u>	Preparation of the technical specifications of a tender through which developing the new information system of a medium-sized (1,800 employees; 600 beds) general hospital
2015	<u>CIR₁₈</u>	Pilot (in Italy) of a benchmarking survey that will be run by the JRC of the European Commission to analyse the eHealth deployment of all the EU countries and identify good practices to be shared
	<u>CIR₁₉</u>	Assessment and benchmarking of the maturity of the information systems of all the 33 public healthcare organizations operating within a big (10 millions of citizens) region
	<u>SQR₅</u>	Nation-wide collaborative reflection of the results of IHP surveys and the case studies
2016	<u>CIR₂₀</u>	Development of a model to assess the maturity of healthcare business intelligence systems and tracking of the progress of 5 Italian public hospitals over this model
	<u>CIR₂₁</u>	Development of a plan that a big (10 million citizens) region uses to centralize and govern the ICT-based services that can be shared among the 33 public healthcare organizations operating within it ^{***}
	<u>CIR₂₂</u>	Strategic analysis of the benefits associated with the development of a electronic medical report in a large-sized (3,900 employees, 1,100 beds) general hospital
2017	<u>CIR₂₃</u>	Strategic analysis of the benefits associated with the development of a computerized drug management system in a large-sized (3,500 employees, 1,700 beds) private hospital
	<u>CIR₂₄</u>	Development of a plan that a big (5 million citizens) region in South Italy uses to centralize and govern the ICT-based services that can be shared among its public healthcare organizations
	<u>CIR₂₅</u>	Strategic analysis and improvement plan of the organizational models and the ICT-based solutions characterising the socio-care services delivered by a local health authority to 340,000 citizens
2018	<u>CIR₂₆</u>	Development of an evolutionary plan of the organizational models and the ICT-based solutions characterising the socio-care services delivered by a local health authority to 1,000,000 citizens
	<u>SQR₆</u>	Nation-wide collaborative reflection of the results of IHP surveys and the case studies

^{***} We have underlined the CIR or SQR that have an interorganizational nature

Structured Abstract

Purpose - We aim at investigating knowledge and learning mechanisms in innovation ecosystems as organizations and the surrounding firms' context – including businesses and institutional actors – takes an active role in innovation success. Several studies focus on knowledge as firms' asset and investigate on how knowledge could be transferred, integrated and managed (Blomqvist and Levy, 2006). The practice-based approach gained attention within organizational learning literature (Brown and Duguid 1991, 1999; Gherardi, 2000) to counteract the cognitive-based view of knowledge. We examine how learning perspectives enable collaborative innovation in a multiple context.

Methodology - Action research gave us the opportunity to focus on mechanisms at the base of knowledge and learning processes in an emerging innovation ecosystem (Ramos, 2002). This method is suitable when changes are ongoing. The ecosystem we investigated is linked to a project supported by the Italian Ministry of Research, set up as a mix of different actors to support the management of a smart city. We identified the "generating action" approach (Tacchi et al., 2003) as it fits with both new initiatives and relevant topics of our research, namely resources, knowledge and partners to be managed as a whole.

Originality - The paper contributes to knowledge and learning literature in innovation ecosystem. It identifies ecosystem as an innovation community of practitioners emerging as a form of integrating and organising activities, competences resources and tools lead by (and towards) common and negotiated goals, supporting one another. Collecting, integrating, and generating knowledge are pivotal practices for innovation dynamics and they allow ecosystem to be established. In contexts related to innovations such an approach is necessary to describe how different sources are combined to support projects and how knowledge can be generated, acting as a mean and as an outcome in innovation ecosystems.

Practical implications - The analysis led us to the rise of three different knowledge practices - collecting, integrating, generating - useful to describe the way in which

learning takes place in a networking innovation context, shaped by actors with different backgrounds, like universities, organizations, and government. More into detail collection, integration and generation emerged as the ways in which knowledge shapes the collaboration in ecosystems, before being upgraded, shared, and integrated in order to generate new knowledge to reach the fixed aims.

Keywords –innovation ecosystem, practices, knowledge, learning, collaboration.

Paper type – Academic Research Paper

1 Introduction

This article aims at investigating the mechanisms at the basis of knowledge and learning processes in innovation ecosystem. Ecosystem is emerging as a hot topic in innovation literature (Moore, 1996). It captures the increasing complexity of innovation in a multiple and interrelated context. The idea is that not only organizations but also the surrounding organisations' context, including business, users and institutional actors, take an active role in innovation success (Russells et al., 2011). The ecosystem innovation view implies to consider the different roles played by the wide range of actors moving around the innovation and the way in which entangled systems of subjects, interests and activities are composed. A loosely interconnected network of actors is seen to emerge through interactions. In the ecosystem, the actors simultaneously co-evolve their capabilities and roles, and tend to align themselves with the directions set by one or more central companies in order to better address innovation (Adner, 2006, Carayannis et al 2012).

Similarly others researches focus on the advantage of networking innovation and empirically investigate the mechanisms enabling or constraining collaboration and innovation in network (Nambisan & Sawhney, 2007). Much of these studies focus on knowledge seen as firms' asset and they investigate how knowledge can be transferred, integrated and managed (Ritter and Gemünden, 2003; Blomqvist and Levy 2006). More in to detail the dynamic at the basis of the emerging relationships in innovation network is assumed to be placed on the conscious and explicit creation of new knowledge and activity (Möller and Rajala, 2007) with all different forms of resources, competences and activities flowing through the threads and nodes of the network itself.

The dynamic aspect emerges as a specific feature of both ecosystem (Moore, 1996) and network innovation studies (Ritter et al., 2004; Möller, 2010) and different collaborative mechanisms are seen to be strictly linked to management of knowledge and innovation performance in a networking contexts (Adner and Kapoor 2010). These mechanisms

include the activation of relevant capabilities to manage and coordinate network (Dhanaraj and Parkhe, 2006; Hallikas et al., 2009) as well as the ability of effectively capturing and transforming available knowledge in a more properly form to be transferred and leveraged within and throughout the network. What is stressed is the manageable nature of knowledge and the need for processes, technologies, tools and other resources supporting the organisations in a network to acquire, gather, share and distribute knowledge (Dhanaraj and Parkhe, 2006).

Under different epistemology tradition, the practice-based approach has affirmed in the beginning of this century within organizational learning literature (Gherardi, 2000) to counteract the cognitivist view of knowledge seen as a commodity produced in individual mind and managed by organization. The common idea of practice scholars (Brown and Duguid, 1991, 1999; Nicolini et al., 2003; Gherardi 2000, 2001) is to view knowledge as an activity - that is knowing - situated in the system of ongoing practices the organisational members perform.

The discourse on practice has mainly affirmed as a critic to knowledge management and its managerial ideology (Gherardi, 2009), but it lacks in purposefully supporting the understanding of mechanisms at the basis of knowledge processes in a networking context.

Following this suggestion, in this article we examine how practice- based learning perspective enables to approach collaborative innovation in a multiple and differentiated context. More specifically we are interested in better understanding the mechanisms of knowledge and learning processes in an innovation ecosystem context. Our research aim unfolds under two main question: 1) we want to analyse how actors practices knowledge and learning in innovation ecosystem and 2) contextually by describing both the process and challenges actors are facing when developing knowledge practices to deepen how these practices support the establishment of the innovation ecosystem.

The practice approach contemplates that to understand knowledge and learning processes we need to analyse them in relation to the context in which they are generated. The social interaction and collective learning contribute to create structures designed to manage or influence innovation ecosystem and increase its goal-oriented and strategic activities. In our view the argument of both practical and manageable component of knowledge should be taken into account in the understanding knowledge and learning processes in an innovation ecosystem.

The article progresses as follows. After addressing the learning in multiple context from business and network literature perspective the paper opens up at the contribution of practice based theory on learning. The methodology section introduces our empirical setting and method. By bringing the concepts and ideas from theory and practice we contribute to identify a set of three knowledge practices. Finally we articulate the main conclusion on how knowledge and learning processes take place in an innovation ecosystem and provide some first implications.

2 Theoretical Background

2.1 Network learning perspective

In the recent years, knowledge and learning processes have become one of the hot topics in the agenda of many scholars studying innovation in the networks (Håkansson et al., 1999; Knight, 2002, Möller and Rajala, 2007). Based on the foundation of organisational learning studies, the network learning perspective represents a novelty in learning literature as its focus is on learning by a group of organizations as a group (Hallikas et al., 2009). The emphasis is on the aspect of multiple, emergent and interconnected business and institutional relations that combine knowledge, expertise and technology in the novel ways. The exploration of knowledge through weak connections has been discussed, as well as the essential flexibility of networks (Håkansson et al., 1999; Möller and Svan, 2003; Ford and Håkansson, 2006). Thus in many cases the knowledge and learning processes have been debated in relation to the nodal position held by an actor in the network *because an actor's task in network is to connect multiple actors in the net*"(Möller and Rajala, 2007: p 899). The leading actor is stated has the opportunity to learn new knowledge thanks to the different ties of the network enabling the access to several skills and competencies (Beckman and Haunschild, 2002).

The problem related to relational distance has also been discussed based on cognitive perspective (Argyris and Schon, 1978). The lack of feedback for effective learning processes is seen as very likely when a relatively large number of agents interact with each other in various process steps. So it has been concluded that striving to learn more effectively in network means to enable trust-based mutual communication and continuous feedback as well as that the coordination and co-operation links between the organizations must be strong and kept active (Blomqvist, 2004).

Miles et al. (2000, 2005) have pointed out that the ability to collaborate in the network is a meta-capability for innovation. Similarly, Sivadas and Dwyer (2000) have discussed cooperative competency as “*the ability of the partners to trust, communicate, and coordinate*” (*ibid*, p 40). Moller and Svan (2003) and Ritter et al. (2002) have developed a concept of network competence to understand the capacity of firm to drive innovation success through the effectively management of actors in the network. Many others authors furthered the role of coordination or orchestrator capability (Dhanaraj and Parkhe, 2006; Heikkinen and Tähtinen, 2006, Hallikas et al., 2009) and discussed them in term of: capacity to 1) support absorptive competences among the network actors, 2) foster articulation and codification of tacit knowledge when it is reasonable and possible, 3) develop long-term inter-firm relationships and 4) create a common network vision and identities for members (Hurmelinna-Laukkanen and Natti, 2008).

From different perspective other authors (Peters and Pressey, 2010) have stressed more the collective dimension of collaborative innovation and have discussed how the nature and purpose of the interactions between partners facilitate key learning capabilities, as well as influence what learning is shared and how such learning is utilized by partners.

Despite the fact that collaboration is considered an important source of knowledge and learning for innovation, studies about network learning perspective show some limitations. It is apparent that the social and contextual nature of learning in a network context has received less attention and that innovation emerges by a simply process of translating relationship and knowledge into tangible outcome. Often the focus has been placed mainly on the nature and structure of relationships; similarly the conditions for the effective sharing of knowledge and aims among participants have been reduced to a more general discussion of opportunities and threats instead of considering how interaction and knowledge really occur.

2.2 Practice-based learning perspective

In the last decade, the practice based learning approach has become influential among researchers studying organisation and organizational learning (Gherardi, 2000). Characteristic to practice-based learning studies is that they are multidisciplinary in their search for non-rational-cognitive view of knowledge.

Founding their roots in the long tradition of philosophy and sociology scholars (Bourdieu, 1990) the practice-based learning perspective has start to affirm in contrast

with the knowledge management trend that was in the interest of many of organisational learning scholars in the 1990's. Particularly, the practice-based learning studies deny the mechanistically and instrumentally approach of knowledge management scholars, where knowledge has been seen as something to be possessed. As Gherardi (2000, 2001, 2009) has showed in the practice turn the meaning of knowledge is challenged by the shift from *knowledge*, viewed as an object and a commodity, to *knowing*, which is the activity that people conduct together, collectively and socially (Cook and Brown, 1999).

The social learning perspective of Lave and Wenger (1991) has inspired a large influx on the first studies from practice-based learning authors. These authors have supported a view of learning as situated in communities of practice (Wenger, 2000), something that is located within the social- and material gatherings and that is not separated from doing (Cook and Brown, 1999, Brown and Duguid, 1991). Knowledge is integrated and distributed in the life of the community, and learning is seen as an act of belonging that requires active participation and involvement in a practice (Lave and Wenger, 1991). Within communities of practice, learning is not adequately understood as the transmission/acquisition of information or skill; indeed learning involves the construction of identities' (Lave and Wenger, 1991: 53). Knowledge and learning are about activity and relationship; they are mediated by common artefacts (tools, meanings, etc) and always rooted in interactions within a situated social-cultural context (Brown and Duguid, 2001).

Orlikowski's (2002) perspective of knowing-in-practice has provided an important contribution to the tradition of practice-based studies in organisational knowledge. She has argued that practice is a system of activities in which knowing is not separated from doing that overcomes the traditional distinctions between knowledge that exists "out there" and is encoded in external objects, routines, or systems and knowledge that exists "in here" that is embedded in human brains, bodies, or communities (Orlikowski, 2006). As a consequence, learning is an activity that is situated in social working and organisational practices. This collective knowledgeable doing supports the idea of situated activities and learning within a community that socially sustains it.

Other scholars have advanced the role of knowing in practice by looking at the range of mechanisms through which local practices are constituted and connected within and across organizations (Gherardi and Nicolini 2002, Nicolini et al 2003). In statements of these authors, practices are not simply viewed as routine actions of established group,

community or organization; rather they consist of a collective accomplishment, which depends on a range of spatially and distributed knowledge within a network of relationships (Sole and Edmondson, 2002; Amin and Roberts, 2008) knowledge communities (Lindkvist, 2005), communities of practices (Gherardi, 2009), or nexus of practices (Nicolini et al., 2003).

What becomes apparent is that knowledge and learning processes are not only situated in enclosed groups that pre-exist to activities of practitioners in the group; they are distributed in and between groups as well as involve interaction among human and non-human actors (technologies, objects, discourse carrying knowledge) (Gherardi and Nicolini, 2002, Nicolini et al., 2003). In this sense knowledge and learning involve a complex range of activities also including those of resolving and bridging differences that depend on a range of spatially and distributed knowledge. Carlile (2002, 2004) has referred to the boundary objects as mechanisms acting at the interface of different knowledge domains as an 'integrating device' through which knowledge is transformed and collective learning can be achieved. The bridging activity of boundaries objects provides the communities of practitioners with a venue to communicate coordinate and collaborate and they are both means and products of interaction and of learning in and between communities (Carlile, 2004).

Gherardi (2006, 2009) and Nicolini (2011), have contributed further to debate by emphasizing the dialectical and mediated processes of learning. They have diverted the attention from the practice itself to nexus of interconnected practices in which each practice is immersed and have stressed the idea of practices as socially recognized ways of ordering heterogeneous items into a coherent set (Gherardi, 2006, Nicolini, 2011, Nicolini et al., 2012) that remains attentive to the emerging events. Their understanding of practices underpins their interest in power relations and learning is also being understood as mediated by negotiation on established practices and knowledge, symbols and artifacts and objects.

Any form of learning is stated to be sustained and created in multiple interactions taking place in the nexus shaped context of practices and it is characterized by emergent, dynamic, provisional and unstable nature (Nicolini et al., 2003; Nicolini, 2011). The collective dimension of learning and practicing is emphasized, and it is conceived as the result of reflective activities emerging from a dialogue and questioning between and among practitioners (Gherardi 2006, 2009; Nicolini et al., 2012).

These discussions show that the debate on knowledge and learning in practice is still fervent. Recent view supports the idea of knowledge and learning that are developed from and manifested in activities, expertise and skills at work in interconnected nexus of practices. To investigate in-depth how practices are iteratively sustained by learning mechanisms within social and material interactions is marked as priority in the research agenda of many practice-based learning scholars (Gherardi 2009; Nicolini, 2011).

3 Method

Underpinning the findings presented in this paper is an action research study (Ramos, 2002) of an emerging innovation ecosystem.

We chose an emergent ecosystem as essential point of view in understanding the process by which a multiplicity of actors combine and integrated knowledge and practices and how the social process of learning take place to establish an ecosystem for innovation.

The innovation ecosystem we investigated is OR.C.HE.S.T.R.A. (Organization of Cultural Heritage for Smart Tourism and Real time Accessibility. The investigated ecosystem finds its roots on Italian project within National Operative Program supported by the Ministry of Research and Education started thanks to the contemporary presence of actors from different contexts. This project has been set up as a mix of different actors in order to support the management of cities with a smartization process. More into detail, we identified the “generating action” approach (Tacchi et al., 2003) as it fits with new initiatives, long terms plans and mainly with the focus of our research, namely resources, knowledge and partners to be combined and managed as a whole.

As it regards the research method, our choice to follow an action research study depends on the features of the topic, as this methodology is useful to depict contexts in which relationships among different actors, the system they compose and their perspectives have to be highlighted (Burns, 2006).

To follow action research method we have chosen to conduct a participatory action research study (Greenwood et al., 1993). This specific method has the predominant emphasis on genuinely involving and researching with the participants of a community and presented a number of advantages for investigating phenomena in this case study context (Greenwood et al., 1993).

The steps of our research are aligned with methodological suggestions (Burns, 2006) and they contain both “building and evaluation” in the same process (Jarvinen, 2007).

Empirical data was accumulated over 14 months (from January 2013 to April 2014) through undertaking multiple observations and through participation in plenary project meetings and brainstorming sessions related both to the whole set of partners and to teams resulting from the projects. We augmented data with information from serial semi-structured interviews and feedback sessions with the key actors; working sessions and workshop were organized in this sense too, with the researcher carrying on them; documentations reviews provided additional insights for our data analysis.

It is useful to underline how these steps shape methods linkable both to qualitative research in its classical meaning, like participant observation and interviews, and to other methods more fitting with action research like inquiry groups (Burns, 2006).

The themes of the interview and discussion as well as documented material covered the following issue: how actors experienced collaboration; which relationships of each partners impact on the ecosystem; in which way aims are negotiated and how they change time by time; what actors known and what were learned in terms of knowledge, social structures, and practices; how learning took place collectively and how influenced ecosystem for innovation. Moreover, we analyzed what seemed to be the main contributions of the learning process in social innovation context.

The transcripts of the interviews, working reports and all qualitative data collected were scrutinized for identifying patterns and recurring themes by all researchers involved in this paper.

Then, the approach of Jarvensivu and Tornroos (2010) served to code data. The researchers went through the insights from data by defying three knowledge practices at the basis of collective learning mechanism in an innovation ecosystem. We labelled these practices according to the common language emerging during the cooperative sourcing and analyzing of data research (Jarvensivu and Tornroos, 2010). The authors reviewed categories and discussed them in working session with participants to determine what further data collection was useful to provide a full description of the practices. The iterative process continued until the description of the practices, as well as all the elements related to the practices themselves, were accurate.

4 Context of Investigation

OR.C.HE.S.T.R.A. arises from a nationally funded project aiming to perform some smart interventions in the city of Naples. The project is built around the recent and arising concept of smart city. Nowadays this topic is up to date in public management literature as a lot of cities are carrying on – or still planning – projects to achieve smart improvements. These interventions are conveying a new idea of services to be provided in a different way, namely by taking into account the following features: efficiency, necessity to integrate several services to better provide them, sustainability – both from a socio-economical perspective and with reference to the environment –, and citizens' participation. The set of improved services and features are part of a hi-tech mosaic, known as platform. The platform is usually set up by one of the big corporations acting in this business context and it is useful to provide services, collect data emerging from them and elaborate them in order to improve the services themselves (Anttiroiko et al., 2013). More than 20 firms are acting in the business of smart platforms and this number has grown up recently (Lesgards, 2011), as ICT corporations, mobile operators and hi-tech companies are partnering Local Agencies in favouring this kind of interventions.

The need of a project based on the above cited aims led to some choices, performed by the University of Naples, as the founder actor of the ecosystem under investigation in this research. In detail suitable partners have to be chosen before starting the project, in order to set up an ecosystem aiming to the above cited goals. Thus the University has to be seen as a collector of actors, a resource integrator, and a project leader; first of all it has involved an Institution, due to the necessity of performing an activity on the urban context, related to the provision of services to the local community and to all the actors connected to this context. The choice led to a partnership with the Municipality of Naples, and this was a necessary step due to its unique role in providing services to the wide range of stakeholders of the city more than other local institutions.

5 Findings

5.1 Collecting knowledge

The first 'practice' we depict is the collecting knowledge, with the University as pivotal actor. This practice consists of the collection of knowledge through the involvement of different actors time by time, in order to achieve the designed aims. As it

will be described in the following lines it took place both when the project was firstly shaped and when the different actors involved actors belonging to their organizations.

The role of University had just started with the involvement of Municipality; when defining this relationship this practice went on when planning together the potential configuration of the actors to involve in the project, based on the aims to be achieved. The engagement with the Municipality – or of a similar institutional actor – was unavoidable in all smart city projects, due to the connection to city services and to the role as provider of these services. The ‘collecting’ kept going on to extend the research competences shaping the system of actors, and the need for a different and complementary set of knowledge acting on the same area has led to the involvement of the ‘National Centre for Research’, a public organization engaged in scientific investigation in different domains and transferring the knowledge to private businesses to support scientific, technological, social and economical development of the country. Then the businesses had to be pinpointed in order to complete the set of resources to be integrated to deploy the planned activities; thanks to this choice, two kinds of organizations have been involved: firstly a corporation related to platform has been invited to join the ecosystem in progress; secondly some corporations acting in business areas related to the goals of the projects – mostly tourism and mobility – have been involved. Thus some organizations were involved in order to allow the achievement of two aims: a path towards the platform and the provision of services through it. As it regards the first aim, ‘IBM’ was chosen to drive the path leading to the creation of the hi-tech platform useful to offer services to city stakeholders due to its wide experience in this business. As it concerns the provision of services and even when planning the activities, two relevant organizations were called to join the rising set of actors, namely ‘Lauro SpA’ and ‘Autostrade per l’Italia Spa’. The former is a firm acting in transports over the sea and in services in the harbour area, while the latter is the organization ensuring the building – in the past – and both maintenance and workability of the highways network all over the country, together with the definition of the fares system to be applied.

The set of actors shaping the rising ecosystem we are about to investigate has been created to submit a research proposal to the Ministry of Research and Education within the National Operative Program. The purpose is to receive both an institutional and a financial support to deploy the planned activities among the partners.

Moreover, after the positive evaluation by the above cited Ministry, the partners

started activities to be performed together and they arranged periodically round table and meetings to obtain updates about the results achieved by each partner and to carry on shared activities to deploy the project.

The ‘interacting’ can be seen in a different moment too, since the person-in-charge of each partner set up internal round tables to compose teams to be shaped inside the network of actors. In this way the interactions already existing inside the network was enlarged and enriched thanks to the involvement of new actors from each partner. More in detail the University had chosen a representative from different research areas and each of them brought other researchers in the team. A similar approach was adopted by National Research Centre and its different institutes. The approach was slightly different for firms as internal teams were already built in relation to different domains. The result of interacting can be achieved by sharing the ideas embedded in knowledge and experiences of different partners as already described and towards the aims to be reached, in line with the planned pattern. The participation of a wider number of actors from the same organizations shape the emerging of established ecosystem. It can be considered as an internal widening of the ecosystem itself and it represents a necessity due to the large amount of activities to be performed and of resources to lever on. With particular reference to collecting knowledge practice it is interesting to underline its role in shaping and re-shaping the ecosystem as time goes by and in order to be aligned with the expected aims.

The overall goal of the project can be described as a research activity aiming to both use and develop knowledge and a set of hi-tech solutions addressed to smartly improve value-in-use of cultural heritage in Campania – a region in Southern Italy – for different stakeholders. As the stakeholders are mainly linked to immaterial and material cultural heritage the stakeholders are several and among them it is possible to find Local Agencies, tourists, businesses linked to culture and tourism, citizens and so on. Moreover all the stakeholders are considered both from the city and outside it, and a wider perspective has to be adopted since the above described aims have to be reached in a sustainable and eco-friendly perspective. Tourism and cultural heritage have to be considered as starting points of smart interventions in Naples, due to the vocation of the city, but the way they can be improved is directly linked to other services, like mobility and environment. In a similar and large-scale effort the agenda of the project is composed by a lot of other middle term aims, like the improvement of security, health services,

services to businesses, facilities, and so on.

5.2 Integrating knowledge

The integrating knowledge is a practice describing the way the knowledge held by different actors are put together in order to create a unique set of complementary features to reach the planned aims. First of all this practice acted as a support to propose the project, then it is the way the activities are performed towards the aims defined when the idea had been conceived.

The role of University is crucial in this practice has the engagement in involving partners has to be carried on even to enable the integration of resources. Due to the relevance of this task a specific team was set up. The team consists of a person-in-charge chosen by each partner to act as a governing body for the whole ecosystem. This team has to plan the way in which partners have to cooperate to integrate their own resources in the ecosystem in order to favour the integration towards the creation of a unique set supporting the activities to be performed.

The ‘integrating knowledge ’ was carried on to depict a detailed report on the project to be submitted for evaluation to the Ministry; the partners shaping the upcoming ecosystem act together to compare their resources set and to create a shared set to be used in the project. More in detail the knowledge in service management was carried on by Municipality on a practical perspective and by University of Naples and National Centre of Research on a theoretical side. The three firms act as carriers of different kind of knowledge, linked to hi-tech and to the provision of specific services (especially for tourism and mobility). The experience held by some of the partners was crucial in this phase. More in detail this happen with IBM as this company has led lots of projects based on smartization, both in Italy and abroad. Some of the most important projects carried on around the world by IBM are represented by the smart services provided in Rio de Janeiro, Helsinki, Honolulu, Dubuque, Washington, and Singapore. Some of these cases, namely Helsinki, Singapore, and Dubuque, are considered as best practices in the smart project business. Helsinki is one of the best evidence due to the results achieved, Singapore had a pioneering role in the surrounding area, and Dubuque was one of the first city achieving results in all the smart domains. Among IBM experiences some of them were useful as they were directly brought into the ecosystem; one of them was particularly helpful to show to all participants in a meeting the way the platform can perform its activity in a city, with particular reference to the monitoring of public

transport network. The role of IBM was particularly depicted by this kind of contribution as it can favour the alignment of all partners towards the common aim to be reached.

The comparison among the different knowledge owned by different actors was necessary to describe the potentiality of the upcoming system in relation with the expected activities and aims. Moreover the private partners gave even a financial support to the ecosystem to be joined by the funds provided by the Ministry in case of positive evaluation of the proposal.

After the Ministry accepted the proposal the integration took place again and a focus on resources is a suitable way to describe the 'integrating knowledge' as the actors brought by each partner in the teams shaping the ecosystem are carriers of resources. The leverage on several skills, expertise, and knowledge together with the physical resources of each partner represented an integrated set of resources useful to deploy the project. In order to better contribute to the set of resources to be integrated, the partners defined the actors contributing to this process. More in detail University listed the researchers involved in this project through a selection performed by the actors taking part to the first practice, viz. the collecting knowledge . In order to have a deeper focus on this task and thanks to the financial support provided by the Ministry the University could hire young researchers to support the activities to be performed. The selection of these new contributors was based on the profiling of the knowledge to be integrated, so the issues used as criteria were the skills on service management, cultural heritage management, tourism activities, financial sustainability, and organizational activities.

The activities took place in two ways in the same time: each partner acts as a stand-alone for its research task through the researcher involved from the beginning and the ones hired in a selection. Then time by time meetings and round tables are arranged in order to share the achieved results, to exchange ideas and to define which activities have to be performed together, due to complementary resources brought by different actors. Moreover one important task to be achieved together during meetings was the alignment of different contributions to the common aims. The partners showed the necessity to be coordinated by the governing team, as there were some overlaps among the activities performed, leading to a partial unsatisfying efficiency. In order to solve this problem the governing team during the meetings proposed to create work groups shaped by actors belonging to different partners. The actors planned this new activity to be performed and they better negotiated the sub-aims to be attained, gaining a higher efficiency in the

research process, due to two features: the avoidance of overlapping when doing research and the detailed definition of the interconnections among the sub-aims to favour the internal exchange of knowledge.

5.3 Generating knowledge

The ‘generating knowledge’ took place through the development of the idea thanks to the contribution of all actors and as a consequence of the two previous practices, namely both collecting and integrating. This third practice consists of results held in the phase of definition of the project to be submitted to the Ministry and in the period when the activities were in progress towards the aims shaping the proposal approved and financially supported.

The depicted idea was carefully described to submit the proposal to the Ministry as it was described in the previous parts. The description of this practice was the outcome of the preceding practices, named as ‘collecting’ and ‘integrating’; this linkage takes place as partners planned the activities to be performed to attain the intended aims. Indeed the documents submitted to the Ministry contained the pointing of the resources carried on by different partners, the relationships among them and the way in which they can lever on the common set of resources to perform the activities planned together. Moreover each aim is structured in sub-aims in order to better describe the linkages inside the project and the way the periodic results are connected one another. In the above cited documents two more features emerged, namely the support of each partner in relation to each aim and the time in which each goal is expected due to their feature of being preparatory to favour the achievement of the overall result. As it regards the role, partners are classified on the basis of their participation to each aim and with regards to the location of each activity.

The ‘generating knowledge’ consists of the idea and is an activity in continuous progress as the previous practices described the interaction among partners leading to the definition of new details of the activities to be performed, both as a stand-alone and as a set of actors. The ‘generating knowledge’ kept going on after the approval of the project and it is still in progress as the activities will last until the end of the year. By the way it is already possible to depict which are some of the results generated through the support of different actors shaping the ecosystem. Some smart activities have been planned and some investigation on the territory has been carried on. The Municipality is evaluating together with the other partners which is the best way to provide the new services, especially taking into account the lack of public funding. During the meetings these issues

have been considered, leading to the proposal of some solutions. Meetings showed their usefulness to generate new knowledge and to set up researches to be performed by the partners together on the territory, both as investigation of the context and as testing of the new planned ways of services provision. As it regards financial sustainability the first results are linked to a series of options to be evaluated, even by considering the knowledge acquired through the investigation performed on a wide range of empirical evidences about smart services both in Italy and abroad. This kind of knowledge has been analysed with particular detail thanks to the support of University as the newly hired researchers took part to public meetings related to these issues to discuss about them with person-in-charge of similar projects. This research activity was carried on in some of the most important exhibition on smart projects, as ‘Smart City Exhibition’ the National Meeting carried on every year with the participation of project leader from all over Europe, or ‘Smart Med’, an exhibition consisting of experiences from Southern Italy. According to this kind of investigation, the knowledge acquired was shared inside the ecosystem during the periodical meetings and the partners discussed about the way in which the new information can be fruitful used in the project. The analysis of knowledge generated and of its spread in the ecosystem is particularly interesting as it takes place both during meetings and in an education activity, viz. to a class of about 25 students, selected on the basis of the relation between their background and the issues related to the project. These lectures took place parallel to the research performed by partners and they started with the results of the presentation of the project and the first results of the literature review from University; then they went on thanks to the experiences described by the other partners shaping the ecosystem. Moreover, the upcoming results and the knowledge already owned by different actors were transferred in general meetings to a group of actors interested to these issues. The members of this group were educated and their background was enriched with the knowledge generated through the project, leading to their direct involvement in the ecosystem to support the final part of the projects. The different backgrounds of each member of the group brought in the ecosystem were helpful to complement the existing resources and to favour the achievement of the aims. It is interesting to highlight the mix of knowledge these actors have acquired, due to their direct relation in front lesson with different partners; this can be explicated through the several research proposals presented by each of the member of the class. These contributions act as a support to be mixed with the already defined contributions by actors

shaping the ecosystem. This mix is a sort of bridge between the knowledge already owned by research organizations and firms and the knowledge generated thanks to their participation to the project and the set of knowledge is acting as the engine supporting the achievement of the overall aims.

6 Discussion

The paper aims at understanding the mechanisms of knowledge and learning processes in an innovation ecosystem context.

Drawing from recent practice-based studies we empirically investigated this topic under two interrelated questions: 1) how actors practices knowledge and learning in innovation ecosystem and 2) how these practices support the establishment of the ecosystem relationships for innovation.

Regarding to the first question our findings showed that the three practices of knowledge - we named collecting integrating and generating-are identified at the ground of collaborative working activities involving a multiplicities of actors to address innovation goals. These practices work together in enhancing the alignment among knowledge, aims and working activities in a high and heterogeneous networking context.

As our results show, even if under the process and knowledge leadership of main actor (University), the investigated project (Orchestra) emerges and act as an ecosystem made up and operating as interconnected communities of *knowledgers* (Lindkvist, 2005). In these communities actors interact and experiment new and apply their consolidated knowledge through collaborative working activities. The investigated ecosystem operates on distributed knowledge competences among an articulated set of internal and external partners and its way of enabling integrated collective actions relies on the well-connectedness of practices and knowledge in actions. The actors are held together, especially by knowledge and relations and collective aims. In these contexts what becomes evident is the complex and social activities involving all the actors in the ecosystem in combining, integrating and bridging the different perspectives across boundaries of knowledge domains and practices (Nicolini et al., 2013).

The collaborating, integrating and generating knowledge practices become crucial for innovation dynamics and they allow ecosystem to be established. Innovation dynamics are driven by the potential of collecting integrating and generating knowledge,

competences, tools, goals and all these practices together explain and steer the ecosystem. The learning is seen as emerging by a mixture of knowledge practices that work together and support one each other in the accomplishment of bridging and alignment actions. This view frames the ongoing dimension of learning process as an active and recursive state including multiple knowing process in action. These processes foster innovation and learning by bringing and aligning different knowledge domains and working context.

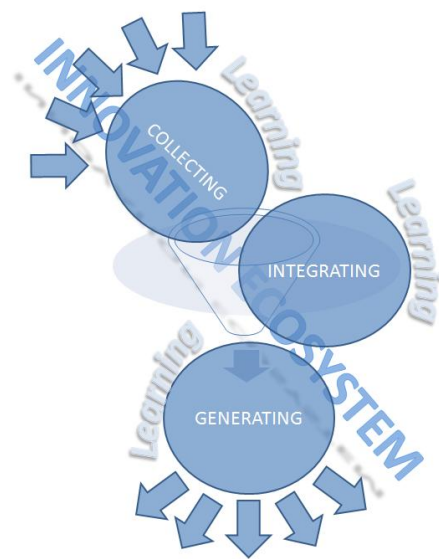

Fig. 1 Knowledge practices and learning in the innovation ecosystem

The practice based view contemplates that to understand knowledge and learning processes we need to analyse them in relation to the context in which it was generated. Innovation in an ecosystem context emerges in a non-linear pathway associated with the development of codified and practical knowledge (Melkas and Harmaakorpi, 2012) embedded and embodied in the ubiquity within and at the boundaries of a collaborative network.

The social interaction and collective learning also contribute to create structures designed to manage or influence the innovation ecosystem and increase its goal-oriented and strategic activities. The issue of establishing ecosystem innovation could be better understood as a question of boundary work (Carlile, 2002, 2004) involving the social dynamic aspect of bridging, translating and making use of the knowledge disseminated among different contexts and domains. This presumes that the focus is both on social

constitutive nature of innovation networking and on managerial decision-making process able to make knowledge and learning at work. In our view the argument of both practical and manageable component of knowledge should be taken into account in understanding knowledge and learning in an innovation ecosystem. The focus needs to be shifted from focal actor's skills to the process of organizing and ordering resources for action (Gherardi 2009) in a collective and reflexivity activity (Nicolini et al 2003; Nicolini 2011) including the idea of consciously and actively pursuing learning at whole..

This view allows to extend the debated question of knowledge transfer only as apparent front of the social driving force that leads and sustains innovations in the ecosystem. The need is to view learning in ecosystem innovation as an intermeshed and continuous ongoing application of collecting, integrating and generating exercise, useful to provide the exploitation that inspires exploration in an endless process as one moves from one context of application to another one.

7 Implications

The analysis leads us to the rise of three different practices useful to describe the way in which learning takes place in a networking innovation context.. More into detail collection, integration and generation emerged as the ways in which knowledge shapes the collaboration in an ecosystem, before being upgraded, shared, and integrated in order to generate new knowledge to reach the fixed aims.

The role of organising and ordering resources in such a complex ecosystem is pivotal in favouring the achievement of the expected goals (Nicolini et al 2013).

Each organization should be ready to think about a shared management of an ecosystem and to change their role when needed, in order to achieve common results. Some actors such as Universities or other research institutions can act as a support to this complex system through their experience in analyzing potential benefits from knowledge and in spreading the processes to fruitfully use it.

The approach to knowledge is a perspective performing positive results if complemented by organisations' experiences, as empirical contexts can be challenging and the definition of services to be provided with high standards is not an easy job. Thus, the integration of knowledge has to take in consideration even the experiences already owned by firms and the ones emerging from the ecosystem.

The results of this mix of knowledge and experiences, together with the resources brought by all different actors, is in the same time as the expression of a great potential to achieve innovation and as something hard to be managed. In order to get the most from the potential and to overtake the difficulties in managing such a complex set a focus on management in ecosystem is necessary, both from practitioners and from scholars.

The need to coordinate the collection of knowledge, the integration and the generation of knowledge towards common aims requires the settlement of a body composed by actors mirroring knowledge, experiences and resources of all partners. A deep focus on how to manage complex systems and on how different actors can do it together is necessary and the empirical context analysed in this research can represent a starting example to define linkages among partners and their activities.

The investigation on complex contexts can be performed through practices, as they are useful to represent actors, activities and results deriving from this mix and to create a model acting as a guideline both for managers and for management scholars (Nicolini et al 2003; Nicolini and Gherardi 2002, Nicolini 2011).

Moreover the knowledge showed a crucial role in activities in general and even more in complex systems as it is the starting point to collect contributions, the core of activities to be carried on, and even the result of the whole process, leading to the improvement of new activities to be performed in an ecosystem.

Structured Abstract

Purpose – To be successful, the innovation and entrepreneurship processes require a systemic and dynamic search, evaluation and matching of purposeful knowledge, expertise and tangible assets. In this vein, the concept of ecosystem has been largely adopted at macro and organizational level to indicate the network of complementary actors needed by one company to succeed in this endeavor. This paper aims to define an individual perspective of innovation ecosystem and propose a model to drive the creation of entrepreneur-centric ecosystems aimed to support a more effective “idea-to-venture” process.

Design/methodology/approach – The review of relevant literature and the analysis of international initiatives has been used to identify the main theoretical constituents of the study. A design science approach has been thus adopted to conceptualize and define the components of the model through the phases of problem identification, objectives definition, artifact development, demonstration, evaluation and research communication. The model has been submitted to a preliminary face-validity test with experts in the areas of entrepreneurship and collective intelligence.

Originality/value – The paper presents an innovative application of the collective intelligence paradigm to design technology entrepreneurship ecosystems which are: a) context-independent, i.e. virtually global; b) specific, i.e. tailored to given technology domains and individual needs; and c) dynamic, i.e. able to gather relevant knowledge needed for the specific phase of the entrepreneurial process. The collective intelligence perspective allows to capitalize distributed ideas, knowledge, and competencies to take better decisions and actions respect to the case in which decisions and actions are taken by individuals alone.

Practical implications – The model can contribute to maximize the incubation, growth and sustainability of entrepreneurial initiatives thanks to a better gathering of critical resources and knowledge which is dispersed in a large network of actors. In particular, the model can support the design and implementation of technology entrepreneurship ecosystems tailored to the real needs of a specific entrepreneur as well as support more effective entrepreneurial processes within corporations and organizations in general.

Keywords – Collective Intelligence, Ecosystem, Knowledge Management, Innovation Ecosystem, Technology Entrepreneurship

Paper type – Academic Research Paper

1 Introduction

Entrepreneurship and innovation have long been recognized as engines of economic growth and societal progress (Wennekers and Thurik, 1999; OECD, 2009). In particular, technology-based entrepreneurship has gained relevance as a driver of economic development and renovation of regions and territories (Phan and Foo, 2004).

However, many good ideas based on technology and scientific research do not survive the “valley of death”, i.e. they are not able to generate successful products/services with appropriate levels of profitability (Auerswald and Branscomb, 2003). These failures have an impact at both individual level (for the entrepreneur, who wastes opportunities and money) and for the society (e.g. missed opportunities for new job creation and territorial development).

The main causes can be found in various areas of the entrepreneurial process, such as mistakes in market analysis, incorrect costs definition, or business models which are not consistent with the technology scenario. In general, the market success of innovation process is not only dependent on the quality of technology and the capability of addressing customer needs, but it also requires the innovator or entrepreneur to establish virtuous interdependencies with many stakeholders which build up a real ecosystem of innovation.

Indeed, to be effective, innovation needs a combination of systematic efforts which involve a much larger number of individuals and organizations that help build the framework conditions and contribute to the diffusion and adoption of innovation results within the market and the society at large.

Innovation ecosystems have been defined as collaborative arrangements through which firms combine their individual offerings into a coherent, customer facing solution, with a crucial role played by the explicit knowledge and formal relations (Adner, 2006). The concept has been largely analyzed at company level (Adner and Kapoor, 2010) whereas few attention has been addressed to examine the conditions to drive the development of entrepreneur ecosystems with a more individual-centric perspective.

Many projects and public initiatives are addressed to promote the creation of entrepreneurial ecosystems worldwide. Among the most successful ones there are those launched by the Babson College, the Kauffman Foundation, the MIT and Stanford University. However, such initiatives mostly attempt to create generically favorable contextual conditions fostering entrepreneurship, mostly geographically bounded and industry-specific. These are mostly static and based on a “pull” logic, where the entrepreneur is asked to identify, access and use available resources based on personal intuition and capabilities.

In this endeavor, this study aims to propose a new model that leverages collective intelligence and enhances networking to create entrepreneurship ecosystems which are *glocal and context-independent, industry-specific, and dynamic*. The model adopts a push logic to build proactively around the potential entrepreneur a system of actors, resources, knowledge assets, services, competencies and relationships needed to better support the idea-to-venture process. The key idea is to develop entrepreneurship ecosystems tailored to the real needs of the entrepreneur and which can be dynamically developed throughout the entire lifecycle of the entrepreneurial initiative.

The article is structured as follows: section 2 presents the literature background with a twofold focus on technology entrepreneurship ecosystems and collective intelligence; section 3 illustrates the model and its components; section 4 discusses the main findings achieved, whereas section 5 concludes the article and draws avenues for further research.

2. Literature Review

Technology is a crucial factor for stimulating and activating the innovation process (Schumpeter, 1934). Especially today, the impressive innovation trends and convergence of major technologies such as ICT, bio and nano-technologies are creating huge opportunities for creating new business ideas and companies, thus driving to a more entrepreneurial society and to a shift from a so-called “managed” economy to an “entrepreneurial” economy (Audretsch and Thurik, 2001).

Technology entrepreneurship enables the transformation of technology-enabled entrepreneurial opportunities into market valuable artifacts and technology applications (Kirzner, 1997; Venkataraman and Sarasvathy, 2001), thus venturing beyond the current state of the art to support new products, services or technological processes (Lumpkin and Dess, 1996).

The concept of technology entrepreneurship combines two main elements: 1) technology, i.e. the knowledge, skills and artifacts that can be used to design and realize new products, services and delivery systems (Burgelman et al., 2004); 2) entrepreneurship, i.e. the process of identifying potential business opportunities and exploiting them through the recombination of existing resources or the creation of new ones in order to develop and commercialize new products and services within existing or new markets (Hitt et al., 2001).

The technology entrepreneurship process includes identification, recognition, discovery, creation and exploitation of entrepreneurial opportunities arising from technology development (Petti, 2009). It can be considered as the bridge between technology development, business creation and market exploitation (Petti and Zhang, 2011), crossing the “*valley of death*” (Auerswald and Branscomb, 2003), that is the blur gap existing between a technological invention and a successful product launched on the market. In this perspective technology entrepreneurship can be conceived as the process by which, leveraging on the technology as enabling success factor, implements technology itself within the market (Byers et al., 2010), delivering new products, services or applications capable to satisfy existing or potential market needs.

Technology entrepreneurship can be characterized as an individual attribute (e.g. Byers et al., 2010), a strategy (e.g. Gans and Stern, 2003), a system (e.g. Abetti, 1992), or a process (e.g. Shane and Venkataraman, 2003; Antoncic and Prodan, 2008; Petti, 2009). At individual level (Byers et al., 2010; Dyer et al., 2008; Hayton, 2005; Suzuki et al., 2002), the behavioral aspects are considered, along with the competencies and the style of business leadership characterizing the profile of an innovative entrepreneur. The organizational level includes the matching of technology-based opportunities with market needs (Gans and Stern, 2003), as well as the organizational structure (Covin and Slevin, 1991), the internationalization attitude (Hitt et al., 1997), the phases to transform a technology development into a new business creation (Shane and Venkataraman, 2003; Antoncic and Prodan, 2008; Petti, 2009), and the components characterizing the entrepreneurial orientation of the firm (Lumpkin and Dess, 1996).

The logic of innovation ecosystem is more in line with the system (and network) level (Abetti, 1992; Kenney and Von Burgh, 1999). In this perspective, it is necessary to consider all the inter-dependent actors (individuals, companies, research centers, universities, financial operators and institutions), resources, relationships, policies,

standards, local conditions and environmental factors, operating as an entrepreneurial ecosystem within a geographic region and able to potentially influence the economy as a whole (Spilling, 1996; Iansiti and Levien, 2004; Cohen, 2006; Isenberg, 2010).

At policy and governmental level, the European Union RIS3 agenda (*Research and Innovation Strategies for Smart Specialization*) promotes the investment in research, innovation and entrepreneurship in every EU member state. In this perspective, the innovation and entrepreneurship process is strongly encouraged by the adoption of a triple-helix model (Etzkowitz, 2004; Etzkowitz, 2011; Etzkowitz and Leydesdorf, 2000), thus involving institutions, companies and research centers/universities working together to identify and develop promising ideas, concepts and proposals, and transform them into successful ventures. The approach is in line with an open approach to innovation (Chesbrough, 2006).

Many projects and initiatives have been launched worldwide to promote the creation of entrepreneurial ecosystems. By observing the different cases, four models can be empirically derived on the basis of the main force which has activated the entire ecosystem:

- *Industry-driven model*, characterized by a leading role played by the company which attracts international talents, protects and exploits the intellectual property (i.e. HP, Google or Apple in Silicon Valley, Infosys or Wipro in Bangalore);
- *University-driven model*, which puts in the center of the ecosystem the university which creates both physical and relational spaces to favor collaboration between students, researchers, companies and investors (i.e. the MIT in Boston, the Carnegie Mellon University in Pittsburgh, the Georgia Institute of Technology in Atlanta);
- *Entrepreneur-driven model*, initiated and activated by successful entrepreneurs who re-invest their incredible profits in new initiatives to promote innovation (i.e. Mike Lazaridis, founder of BlackBerry, who founded in Waterloo the quantum computing technopark, or Tony Hsieh, founder of Zappos, who created in Las Vegas the urban incubator to promote disruptive innovations);
- *Public-driven model*, in which governments invest public funds to create technology-intensive centers and incubators to promote innovation and

entrepreneurship (i.e. Tech City in London, Zhongguancun Science Park in Beijing, Paris-Saclay in France, Skolkovo technology park in Russia, or Israel technology security park).

To these, some projects have been launched to sustain and provide guidelines and support to create entrepreneurial ecosystem, such as the *Babson Entrepreneurship Ecosystem Project – BEEP* (<http://entrepreneurial-revolution.com>), the *Stanford Innovation Ecosystems Network (Stanford IEN)* (www.innovation-ecosystems.org), and the *Sustainable Valley Technology Group* (www.svtg.org).

At Italian level, some interesting cases refer to the *PoliHub* (www.polihub.it), *Area Science Park* (www.area.trieste.it), *H-Farm* (www.h-farmventures.com), *Kilometro Rosso* (www.kilometrorosso.com), and PNI Cube.

These cases are a good example of gathering experiences and resources into a unique ecosystem or complex network aimed to reinforce the potential of individual companies and start-ups, thus giving rise to possible applications of collective intelligence. The concept of collective intelligence emerged at the end of 70s, and it was formalized in the 90s (Lévy, 1994; Pór, 1995; Malone et al., 2008), with an increasing attention towards directing large groups of people towards the solution of relevant problems, such as global warming and earthquakes.

In the last two decades, the spectacular emergence of the ICT and Internet, has enabled unprecedented opportunities for a huge numbers of people dispersed all over the planet to work together and interact within collaborative scenarios. Principles of collective intelligence are today applied in sociology, business management, computer science, communication. The MIT has institutionalized the interest towards collective intelligence as a research field by creating the *Center for Collective Intelligence* - <http://cci.mit.edu>).

In its broad sense, collective intelligence is a shared or group intelligence that emerges from the collaboration and competition of many individuals. It signals groups of individuals doing things collectively that seem intelligent (Malone et al., 2010). It studies how people and computers can be connected each other so that, collectively, they act more intelligently than any individuals, groups, or computers have ever done before (Malone et al., 2010). It has also been defined as “the capacity of a human community to evolve toward higher order complexity thought, problem-solving and integration through collaboration and innovation” (Pór, 2008). In this view, the concept is applied as

approach to solve complex problems such as global warming, earthquakes, traffic management or garbage management. At this purpose, four basic elements have been identified (Boder, 2006) which are represented by the group of competent actors, a set of resources and interaction mechanisms, the results to reach and the evaluation criteria.

Collective intelligence describes a phenomenon where, under conditions of diversity (of the involved people), independence (contributions of one individual are not influenced by the ones of other individuals) and aggregation (mechanisms for pooling and processing individual estimations to a collective estimation), large groups can achieve better results than any single individual in the group since they form a so-called “wisdom of crowds (Surowiecki, 2004).

Generally, collective intelligence systems can be active (e.g. creation of pages in Wikipedia) or passive (e.g. search algorithm improvement in Google). Collective intelligence systems enable *cognition* (to make market judgments and predict the outcome of future events), *coordination* (to coordinate communities, collective actions and organizational processes, and *cooperation* (to enable people to collaborate in virtual and shared environments) (Malone and Crowston, 1994; Ellis et al., 1991; Engelbart and Ruilifson, 1999).

In the entrepreneurship development field, an example of collective intelligence stays in the use of crowdsourcing to support: a) the development of a start-up, with examples such as TopCoder, Innocentive, Elance, oDesk or BootB; b) idea screening and selection, with examples including Spigit, Imaginatik, and VenCorps; and c) crowd-funding, with examples such as Kiva, Kickstarter, GrowVC, Indiegogo, Springboard Ventures, Profounder and StartNext (Laubacher, 2012). Specifically to the crowd-funding, (independently on the type such as equity, donation, lending or reward), it strongly contributes to the diffusion of entrepreneurial culture world-wide, by sustaining innovative ideas and project mainly at the early-stage (Schwienbacher and Larralde, 2012; Lambert and Schwienbacher, 2010).

By considering the entrepreneurial process overall and not a specific phase (i.e. idea evaluation or funding), IStart and IBridgeNetwork powered by the Kauffman Foundation represent two interesting cases. IStart is a hosting competition platform to support networking among aspiring entrepreneurs, mentors and advisors, whereas IBridgeNetwork is an open web-based community for aggregating, searching, and communicating innovations from multiple research institutions. These examples try to

leverage on collaboration, cooperation and connection among all the community members to conceive, refine and develop innovative ideas and transform them into successful ventures.

3. The Entrepreneurship “eGosystem”

3.1 Method

The study was based on a preliminary review of relevant literature and the analysis of international initiatives which helped to identify the main theoretical constituents of the research. Besides, project documentation, technical reports and web portals of entrepreneurship-related initiatives have been analyzed. A design science approach has been adopted to conceptualize and define the components of the model through the phases of problem identification, objectives definition, artifact development, solution demonstration, evaluation and research communication. Design science supports a pragmatic research paradigm that calls for the creation of innovative artifacts to solve real-world problems (Simon, 1996; Hevner, March, Parl and Ram, 2004; Peffers et al., 2006). The model has been submitted to a preliminary face-validity test with experts in the areas of technology entrepreneurship and collective intelligence.

3.2 The Model and its Components

In order to build a new venture, an entrepreneur is required to access to and acquire a set of information, human skills, professional advices, and financial and technical resources which are present within a complex system of actors, institutions, markets, infrastructures, and technology tools. Such complex system represents an entrepreneurial “ecosystem”, a way of making interdependencies more explicit (Moore, 1996; Iansiti and Levien, 2004; Adner, 2006), leveraging on simultaneous cooperation and competition among partners (Brandenburger and Nalebuff, 1997; Afuah, 2000). What normally happens is that such ecosystem is well bounded, both by a territorial and industrial point of view. This has several limitations, but mainly: 1) different entrepreneurial initiatives have different characteristics and needs in terms of knowledge and resources and not all the required assets may be co-localized in one region; 2) entrepreneurial initiatives may be found to be at varying stages of the roadmap and each venture is thus actually involved in one specific activity or phase.

This article introduces a new conceptual approach to creating entrepreneurial ecosystems, i.e. the “eGosystem”, a word which synthesizes two complementary concepts: a) the “ego” of the potential entrepreneur who wants to succeed in his/her own venture; and b) the need to create a “system” of resources required to drive such success. An eGosystem has three distinctive features: a) global and context-independent, through the adoption of ICT and virtuality to expand the “reach” of the entrepreneurial process; b) specific, i.e. tailored to the specific technology domain to enhance the “richness” of available resources; and c) dynamic, it is phase and time-dependent.

In the eGosystem, the entrepreneurial actor does not have to search and put together all the “pieces” of the ecosystem, but it’s rather the system which proactively identifies potential entrepreneurs and put them in the right conditions to start a technology entrepreneurship project (“push” logic). Thus, the eGosystem builds proactively around the entrepreneur a system of information, resources assets, educational experiences, services, competencies and relations needed to successful go and stay on the market.

Five main components build up the model: 1) the Entrepreneurial Actor (EA); 2) the Entrepreneurial Stakeholders (ES); 3) the Innovative Entrepreneurial Project (IEP); 4) the Technology Entrepreneurship Roadmap (TER); and 5) the Technology Entrepreneurship Flows (TEF). The components are described in the following sections.

3.2.1 Entrepreneurial Actor (EA)

The Entrepreneurial Actor (EA) is at the core of the framework. The actor is a “meta-category” including all the different innovators, actual or to-be entrepreneurs who want to pursue the specific goal to bring innovation within their organizations, or in the society at large, through the launch of a new business, a new business unit, a new operating model, a new approach, and so forth. The actor is thus a person or team willing to create socio-economic value by capitalizing a good idea and valuable assets, including potential customers and partners, to accomplish a compelling entrepreneurial project. The distinguishing traits of the entrepreneurial actor which are common to all these categories of people are passion, resilience, self-confidence, flexibility and risk acceptance (Fisher, 2011).

3.2.2 Entrepreneurial Stakeholders (ES)

Around the core actor, several categories of entrepreneurial stakeholders (ES) can be identified which are involved in the definition and development of the entrepreneurial ecosystem. In general terms, a stakeholder is a party that has a peculiar interest in an enterprise or project. The primary stakeholders in a typical corporation are its owners and investors, employees, customers and suppliers. However, modern theory (Allee, 2000) goes beyond this conventional notion to embrace additional stakeholders such as the community, government and trade associations, to create jointly tangible and intangible value. For a generic entrepreneurial initiative, the following stakeholders can be identified (alphabetically):

- Banks and Other Funders (BF)
- Business and Management Consultants (BMC)
- Business Partners (BP)
- Existing Companies (EC)
- Generic Investors (GI)
- IP Offices (IPO)
- Labor Representatives and Trade Unions (LRU)
- Local, National and International Government Bodies (GB)
- Organizations and Associations (OA)
- Researchers and Professors (RP)
- Scientists and Technologists (ST)
- Social Leaders (SL)
- Standardization Entities (SE)
- Universities and Education/Training Institutions (UTI)
- Venture Capitalists and Business Angels (VCA)

Each stakeholder can play a different role, according to the relation that it establishes with the entrepreneur or with another actor. The 15 types of stakeholders can belong to one of different categories of roles involved in the definition and development of an entrepreneurial system, also by a (virtual) community based perspective (e.g. entrepreneurship portal).

In this sense, a relevant category would be that of service/content provider including all the companies, individual, agencies and other organizations which can provide

services (e.g. business, payment, educational, market analysis, knowledge provisioning, etc.) or content (e.g. videos, tutorials, other materials) available for the whole community or for a specific target actor. In the perspective of building community, another key role would be the champions and sponsors which includes testimonials, politicians, famous entrepreneurs, academicians or other public or private personalities able to support or enhance the growth and development of the entrepreneurial initiatives. By following with the possible roles, a project champion can support the community by providing moral, psychological and physical support as well as the needed resources. Besides, he/she advocates the benefits and advantages to all the stakeholders. However, the champion is not the community leader but only a person whose experience, resources, strength and reputation can guarantee the success of the project. Besides formal champions and sponsors, community animators would be crucial to enhance and stimulate the degree of participation and contribution of other actors in the life of an entrepreneurial community. Animators have specific skill in terms of getting people informed and excited about what happens within the community. In order to build an active community, the ecosystem must include also other members such as people which only have the curiosity to be in and participate without having or showing a specific interest towards the entrepreneurial dynamics.

3.2.3 Innovative Entrepreneurial Project (IEP)

The Innovative Entrepreneurial Project (IEP) is the challenging venture undertaken by the Entrepreneurial Actor and it can be of three basic types:

- creation of a new company (start-up or spin-off) which originates from a knowledge-intensive domain such as a university or research center; it valorizes on the market the results of a given research, capitalizes distinctive know-how and competencies, and realizes technology transfer and university-company matching activities (academic entrepreneurship);
- creation of a new company which industrializes/commercializes a new product, process or service (independent entrepreneurship), by starting from an entrepreneurial initiative conducted by an individual who has an idea to pursue deriving from an invention, a market gap or similar opportunity;
- development of a new product, service or process within an organized business context (corporate entrepreneurship) which promotes and supports the initiative

through different strategies and mechanisms (e.g. Google); in such a way, teams within an established company conceive, foster, launch and manage a new business that is distinct from the parent company, but leverages the parent's assets, market position, capabilities or other resources;

All the three types can also have a social impact, and be thus configured as social entrepreneurship initiative. The goal is to create a social venture aimed to achieve a desired social change, measuring performance not (only) in profit and return but also taking into account a positive return to society, furthering broad social, cultural, and environmental goals (commonly associated with the voluntary and not-for-profit sectors), and creating entrepreneurial ecosystems committed to sustainable development in terms of job growth, economic growth, improved environmental conditions, improved health and a reduction of poverty and homelessness. Besides, all of the initiatives can have a local impact or have an international/global scope and scale (international entrepreneurship).

3.2.4 Technology Entrepreneurship Roadmap (TER)

The Technology Entrepreneurship Roadmap (TER) is a complex multi-process roadmap including three main stages, i.e. "desk", "pre-market" and "market" stages, for a total of 12 different activities.

Desk Stage Activities are the preliminary explorative and design tasks which are aimed to prepare the venture creation steps. They include: 1) Scenario Scanning (SS); 2) Opportunity Recognition (OR); 3) Concept Definition and Value Proposition (CV); 4) Revenue Model & Value Capture Definition (RV); 5) Detailed Business Planning (BP).

Pre-Market Stage Activities are the real market preparation steps which precede the access to the market of the new venture. They include: 1) Funding and Capital Raising (FC); 2) Resources Acquisition and Team Organization (RT); 3) IP Analysis and Legal Formation (IL); 4) Product and Service Development (PS).

Market Stage Activities are realized when the venture is fully operating and active on the market. They include: 1) Operations Management (OM); 2) Profit and Harvesting (PH); 3) Venture Expansion & Development (ED).

3.2.5 *Technology Entrepreneurship Flows (TEF)*

The implementation of the eGosystem requires the definition of a shared “environment” where to create a community and cooperation context which can significantly increase the chances that the entrepreneurial venture is successful by avoiding the risk of solutions not adopted by the market (low acceptance), not innovative by socio-technical perspective (old-fashioned) or economically unproductive (un-economical). The environment is addressed to ensure a native and direct involvement of customers and end-users - as “co-designers”, “co-developers” and “co-validators” - of the same knowledge assets, products or services, thus contributing concretely to the creation, by defining specifications, evaluating prototypes and testing solutions gradually identified in the real life.

This purpose, collective intelligence can be assumed as an approach aimed to capitalize distributed ideas, competencies and experiences with the purpose to take decisions and actions which are more efficient and effective than they would be if realized by individuals alone. This is also allowed by the adoption of Future Internet which include innovative tools and technologies such as enterprise social software, augmented reality, semantic interactive research, immersive 3D environments, innovative intelligent agents, recommendation systems, automatic information extraction tools and social network analysis.

It is possible to envision the life of the community as built up from a system of workflows and information flows which are realized between two actors (“1 to 1” flow) ad between one actor and the community (“1 to N”). In this view, the main types of flows could be described in terms of following actions:

- *Conceive*, i.e. a flow involving the production of a primitive and original idea about a new product, service or solution;
- *Create*, i.e. a flow involving the production of an artifact or resource which has to be used or transformed;
- *Decide*, i.e. a flow involving the process of selecting one alternative among different possible solutions;
- *Inspire*, i.e. a flow involving one actor stimulating, also indirectly, another actor in the process of creation or conception;
- *Network*, i.e. a flow involving the enlargement of contacts possessed by an actor;

- *Recommend*, i.e. a flow involving one actor endorse one specific solution, alternative, resource or another actor;
- *Request*, i.e. a flow involving an actor addressing a demand to another actor or group;
- *Share*, i.e. a flow involving the collective availability of something created by a single or smaller group;
- *Suggest*, i.e. a flow involving an advise related;
- *Transfer*, i.e. a flow involving the movement of an informative or monetary resource.

Figure 1 shows the overall technology entrepreneurship model and its five components which are the Entrepreneurial Actor (EA), the Entrepreneurial Stakeholders (ES), the Innovative Entrepreneurial Project (IEP), the Technology Entrepreneurship Roadmap (TER), and the Technology Entrepreneurship Flows (TEF).

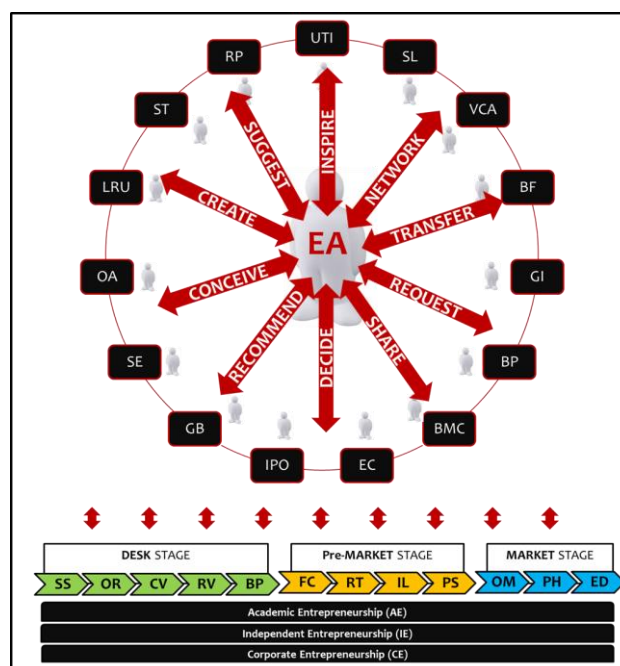

Fig. 1: The eGosystem model

Next section discusses the model and its applicative scenarios in the perspective to build high-performance entrepreneurial ecosystems.

4. Discussion

The eGosystem model can support the formation, incubation and expansion of new entrepreneurial ideas in academic, corporate and independent contexts, and build complementarities and network dynamics among university and industry stakeholders in order to generate a virtuous entrepreneurial context. The model can ensure market follow-up to entrepreneurial ideas, thus providing a relevant contributions to both individual entrepreneurs, companies and public managers. The eGosystem can contribute to the development of innovative entrepreneurial skills and entrepreneurial capital, as a combination of “entrepreneurial competence” and “entrepreneurial commitment” (Erikson, 2002; Elia et al., 2011).

The eGosystem approach combines individual goals with collective intelligence and resources, thus merging the static dimension of the ecosystem with the dynamic of the process and community, as well as with the work/information flows arising among actors and the system itself. In this way, the model transcends the geographical boundaries of where the entrepreneurial actor is physically operating.

Benefitting from a logic of virtual networks rather than agglomeration, the eGosystem may not only compensate for local disadvantages, but also leverages other territories “excess” entrepreneurial capacity or specific entrepreneurial resources, thereby facilitating the flows of entrepreneurial resources from where (and when) they are underutilized to where (and when) they are needed, thus moving from geographical proximity to organizational proximity enabled by the ramification of ICTs.

The model can support two main applicative scenarios: 1) design and implement ecosystems which are tailored to the real peculiarities of the entrepreneur and which can be dynamically integrated, developed and monitored throughout the whole lifecycle of the entrepreneurial initiative; 2) support more effective tech-entrepreneurship processes and innovation-oriented initiatives within corporations and organizations in general (micro or organizational level). The model can support the realization of some success factors which have also been defined as key principles or guidelines, such as (Isenberg, 2010): 1) leverage local conditions while thinking to global exploitation; 2) promote strong public-private collaboration and synergies; 3) focus on ambitious, growth-oriented entrepreneurs who address large potential markets through high-potential initiatives; 4) promote cultural change to support and sponsor entrepreneurial career; and 5) sensitize public decision

makers to renew legal, bureaucratic and regulatory frameworks supporting entrepreneurial activities.

The model can be the basis for supporting the creation of a virtual platform where to build a real entrepreneurial vision, by sharing and promoting the potential of entrepreneurship, and by identifying explicit and latent needs and requirements in terms of innovative products and services. Besides, the platform may support interconnections among actors, roles and mutual relations, and training of entrepreneurial individuals within the industrial world.

The model has also an impact on the entrepreneurship development roadmap. In the desk stage, the eGosystem can facilitate the scanning of scenario in search of opportunities since it involves from the beginning a variety of stakeholders able to extend the perspective, reach and likeliness of success of the entrepreneurial initiative. Besides, concept and value proposition may undergo a preliminary, community-based evaluation which contributes to make them stronger and business planning may become a distributed exercise, which may benefit of state-of-the-art expertise and coaching. In the pre-market stage, funding and capital raising are greatly reinforced by crowd-funding, resource acquisition (e.g. human capital) may benefit from a wide, global audience and product and service development may be done more rapidly and where it is more convenient through a broader network of partners. Finally, in the market stage, operations management and venture development find in the eGosystem a wide array of possibilities and opportunities for collaboration, innovation, efficiency and effectiveness-oriented actions.

The approach can streamline the entrepreneurial action, with the goal to create collaborative technology ecosystems which are *glocal and context-independent, industry-specific and dynamic*. A “push” logic is adopted to propose an eGosystem approach which proactively builds around the entrepreneur a system of information, resources assets, educational experiences, services, competencies and relations needed to successfully go and stay on the market. This differentiates the approach from existing models and initiatives worldwide which typically pursue a pull or “on-demand” accompaniment logic with potential entrepreneurs.

5. Conclusion

The article is mostly a theoretical contribution and it thus needs further development and validation. Nevertheless, the use of preliminary expert feedback framed within a real research project has allowed to introduce a comprehensive and practitioner-oriented framework.

Future research will be addressed to experiment the model in real-life settings. In particular, regional institutions, companies, universities, research centers and potential technological entrepreneurs will be identified with the purpose to design experimental applications of the model through practical use cases and scenarios.

Structured Abstract

Purpose – The paper aims at pointing out how new ventures develop the capabilities they need to compete. In particular the paper focuses on marketing capabilities that, although are usually overlooked in favour of technical capabilities, are important for the survival of the firm. Literature on new ventures has explained the characteristics and dynamics of firm birth, but additional knowledge can be developed in exploring how new ventures can cope with initial capability gaps and the drivers of gap filling, by considering the characteristics of the founders, the structure of the size and scope innovation networks.

Design/methodology/approach – Based on this theoretical perspective, the paper empirically investigates initial capability gaps and focuses on the development of marketing capabilities by new ventures starting with an initial gap, looking for the impact of founding characteristics of new ventures and the structure, the size, and geographical scope of collaborations new ventures are involved in for innovation purposes. The quantitative analysis is based on an original dataset of more than 400 Italian new venture firms specializing in the mechanics and KIBS sectors.

Originality/value – The value of the paper refers to both the theoretical and empirical analysis. From a theoretical point of view, it wants to contribute to the literature of new venture pointing out how firms develop capabilities in the start-up stage, focusing on the overlooked marketing capabilities. Moreover the paper discusses the role the business innovation ecosystem for developing capabilities in the case of new venture. From an empirical point of view, the analysis is focused on new ventures in advanced manufacturing and service industries.

Practical implications – The paper offers an overview of the drivers supporting new venture firms in filling their marketing capability gaps and how the external sources of knowledge can support new ventures in improving their capabilities over time.

Keywords –business innovation ecosystems, knowledge management new ventures, capabilities

Paper type – Academic Research Paper

1. Introduction

As several streams of literature pointed out, capabilities play a crucial role for sustaining firm's competitive advantage (e.g. Teece, 1986). Those capabilities refer to knowledge acquired by the firm in different ways (learning by doing, formal training, entrepreneurs background, external partners, etc.). This process is particularly critical in the formation of a new venture where the firm is fragile because it is in the process of developing and refining its capabilities.

Literature on new ventures explored the processes of formation of a new firm and described how the new venture can start with a certain stock of capabilities at its birth (e.g. Helfat and Lieberman, 2002; Klepper, 2002). However, little attention has been given to describe and explain the following development of new ventures internal capabilities, beyond foundation. Further knowledge has to be provided to explain how a new venture can improve its capabilities and the drivers of such process. Specifically additional research should focus on considering the sources the new venture may rely on in order to cope with perceived capability gaps.

Our paper aims at pointing out how new ventures fill their capabilities gap with a particular attention to marketing capabilities. Even though many studies focused on technical capabilities, in our view even marketing ones are important for the survival of the firm. In order to address this question, we analysed data gathered from an original survey of more than 400 new ventures based in North Italy specializing in high tech industries. The results of our research point out the relevance of the business innovation ecosystems in which the firm is born and evolves.

The paper is organized as follows. Section 2 presents the theoretical framework and the research question related to how new ventures cope with capability gaps they suffer at their birth. Section 3 focuses on how data were gathered and the methodology used to address the research question. In section 4 we present the results of our analysis. Section 5 and 6 refer respectively to discussions of the results and conclusions.

2. Theoretical framework

2.1 The birth of capabilities

As far as the new venture literature is considered, one of the most discussed topics is how they can form the capabilities needed to operate in the market or 'the birth of capabilities', to quote the title of the seminal contribution by Helfat and Lieberman

(2002). In that paper, the authors analyze several types of mechanisms that drive the formation of new firms¹, which they group into two broad categories: i) the parent-company ventures (joint ventures, franchises and parent spin-offs), which born as a decision of the existing company; and ii) the *de novo* ventures, which are not connected with an existing company, nor proprietary nor quasi-proprietary-wise, which can take on different forms including spin-offs founded by employees of existing firms. Helfat and Liebermann define *de novo* spin-offs in a restrictive manner – requesting that the emergent entrepreneur belonged from an incumbent firm in the same industry of the one he is creating – whereas other authors adopted a broader definition including both intra-industry and inter-industry instances (Klepper, 2009).

The most interesting aspect of the typology proposed by Helfat and Liebermann is the link between the birth of capabilities and the resources that they entail. The authors, in fact, highlight that the pre-entry resources and capabilities vary by type of new venture and that such differences have important implications, in particular they affect the likelihood of entry success. For example, the initial resources and capabilities of parent spin-offs depend “on the extent to which the parent firms transfer personnel, organizational systems, physical assets and brand names to the new entities at the time of founding. Even if new ventures receive no assets other than initial financing from the parent companies, the ventures frequently access to parent-firm resources such as infusions of capital, and management advice (e.g. from board members who are executives in the parent firms)” (Helfat and Lieberman, 2002, p. 734). The other types of parent-company venture can count on the fact that the resources are not coming from a sole company but from two or more, so that their initial resource base is likely larger and more diverse. As far as joint ventures are considered, the strategic importance of their “hybrid” nature was highlighted already by seminal study by Kogut (1988): through their establishment, partners may combine resources and capabilities being diverse and complementary.

Moving to *de novo* ventures, they initially hold, on average, lower resources and capabilities of parent-company ventures. However, it is important to highlight that the *de novo* category is a rather heterogeneous one. More precisely, intra-industry spin-offs are favored with respect to the other *de novo* firms that at foundation are facing a market

¹ To be precise, the authors delve in the potential entrants to a market and therefore include in their analysis: a) the birth of new units of existing firms, from which they are still dependent, and b) the acquisition of firms.

situation with which they are less acquainted. Moreover, spin-offs founded by a team of entrepreneurs (coming from the same or different firms) pool different complementary stocks of resources and capabilities (Vyakarnam, Jacobs and Handelberg, 1999; Agarwal *et al.*, 2004) and are therefore favored as respect to spin-offs created by a single entrepreneur.

Among the resources that a firm need at foundation, knowledge necessary to develop the product so as to produce and market it (Teece, 1986) deserves a special attention, considering that this pool of knowledge translates into results useful for the company just if adequate capabilities are present (Amit and Schoemaker, 1993). Beyond the birth of a new company, being it a parent-company venture or a *de novo* one, there is a more or less sizeable stock of knowledge that it inherits. The heritage process has been analyzed mostly in the studies on *de novo* spin-offs (which from now on we will name simply spin-offs), where it gets a precise configuration: within a company, which can be interpreted as a knowledge repository, one or more employees and future entrepreneurs use their absorptive capacity (Cohen and Levinthal, 1990) to learn at least part of the knowledge embedded in the firm; by leaving the parent company such people apply the knowledge absorbed/inherited by creating a new firm (Klepper, 2001; Agarwal *et al.*, 2004; Camuffo and Grandinetti, 2011). Tacit knowledge – which employees acquire largely through processes such as learning by doing and learning by observing (Nonaka and Takeuchi, 1995), and which they keep when they leave to start new ventures (Agarwal *et al.*, 2004) – is of particular importance at this regard. The more the parent firm is rich in terms of knowledge, the larger the potential initial stock of inherited knowledge in the spin-offs that generated from it. For example, studying the new entries in the automotive industry in the United States between 1895 and 1966, Klepper (2002) discovers that the most competitive firms are those founded by people having a long experience within the industry leader firms. Such results support that the generalization suggested by Helfat and Liebermann (2002) has to be considered with caution, as the authors themselves suggests; a spin-off coming from one of the leading company of the industry can enter the same market having an important cognitive advantage as respect to a parent spin-off from an incumbent firm being far beyond the leaders.

The formation of the capabilities of a new venture does not occur just because of a heritage process, irrespectively to its link with a parent firm. Another, relational, factor plays an important role too. As far as *de novo* firms are considered, as suggested by a

wide literature, the interpersonal relations are a key factor. These relations are those the founder or the founding team have managed when developing the new-firm idea (incubation phase) and/or around birth time (resource assembly phase, in the wording by Stuart and Sorenson, 2007). The incubation phase can be considered as a period of learning and preparation for the entrepreneurial activity. The future entrepreneur, through the network of relationships that he develops in the course of time, i.e. his social capital, acquires knowledge that may have an equal relevance than that absorbed within an established firm (Garnsey, 1998; Furlan and Grandinetti, 2014). Even in the phase of resource assembly, interpersonal relationships play a crucial role (Birley, 1985; Starr and MacMillan, 1990; Hansen, 1995; Elfring and Hulsing, 2003). For instance, the new entrepreneur can manage to recruit an expert technician that he knew during his previous professional life, taking him away from an incumbent firm. Considering that the social capital gained by people is, on average, higher within geographical clusters, they have been considered elective places for the birth of new firms (Lechner and Dowling, 2003; Sorenson, 2003).

2.2 Capability gaps and their bridging in the start-up phase

To sum up our literature review on the birth of capabilities it is useful to position it with respect to two precedent theoretical approaches: the theory of liability of newness and the resource-based view.

New firms, at birth and in the subsequent period, suffer a disadvantage with respect to older firms in terms of resources and capabilities. This aspect depends on the so-called liability of newness, a phenomenon discovered by Stinchombe (1965) that depends from factors such as the fact that new firms operate inefficiently as long as organizational routines have not been developed. Stinchombe theory is still valid (Abatecola, Cafferata and Poggesi, 2012) because it explains the high average mortality of new ventures compared to older companies. However, whereas liability affects new venture in general, studies on the birth of capabilities suggests that firms are not all equal as far as resources and capabilities are concerned. Basically, they confirm and complement what the resource-based view discovered for established firms, i.e., that the distribution of resources and capabilities among firms is clearly asymmetrical (Rumelt, 1984; Amit and Schoemaker, 1993). Such an asymmetry at birth can be explained by different factors: the type of enterprise creation mechanism; the differential capability of employees to absorb

knowledge relevant for the future business at firms where they develop their business idea; the personal capabilities of the potential and then emergent entrepreneurs to use their interpersonal relations in the formation of resources and capabilities of the new firm; the relative advantage of entrepreneurial projects rising within firms with abundant knowledge and/or in geographical contexts with a dense web of relationships, i.e. geographical clusters.

The literature reviewed open up an important research question, that has not received adequate answers yet: if the firm suffers, at its foundation, of an important capability gap, how can it fill it in a short time, i.e., within the start-up phase? Such a question can be further specified considering for functional capabilities and more specifically adopting the traditional dichotomy between technological and marketing capabilities (Teece, 1986; Day, 1994). Several studies suggest that such a dichotomy is relevant even in the case of new ventures. For example, in the case of a peculiar category of spin-offs, i.e. academic spin-offs, studies highlight that many of them show a great disproportion in favor of technological ones (Chiesa and Piccaluga, 2000; Lockett *et al.*, 2005). Considering spin-offs founded by former employees of an incumbent firm, the study by Agarwal *et al.* (2004) hypothesizes and tests that organizations with high technological capabilities and low marketing ones, or being in the opposite case, are the ones that generate more spin-offs. The reason behind such evidence is that “asymmetrical” organizations tend “to create frustration among their employees, who perceive their organization as systematically missing out on either value-creating or value-appropriating opportunities” (p. 504). As a consequence, new firms born in the first or the second situation have or, better, inherit a capability gap that the emergent entrepreneurs may try to fill in the more or less short phase that precedes the creation of the new firm or have to do it in the start-up one.

Leveraging on the insight described we propose the matrix reported in Fig. 1. If the new venture has an adequate stock of both types of capabilities its survival probability will be quite high, whereas the opposite situation leads to higher mortality rate. Intermediate situations, when firms lack just one of the two types of capabilities, are the most interesting one. Indeed, the object of our study is to understand how such a gap can be filled in by new ventures in order to increase its probability to continue its activity over time.

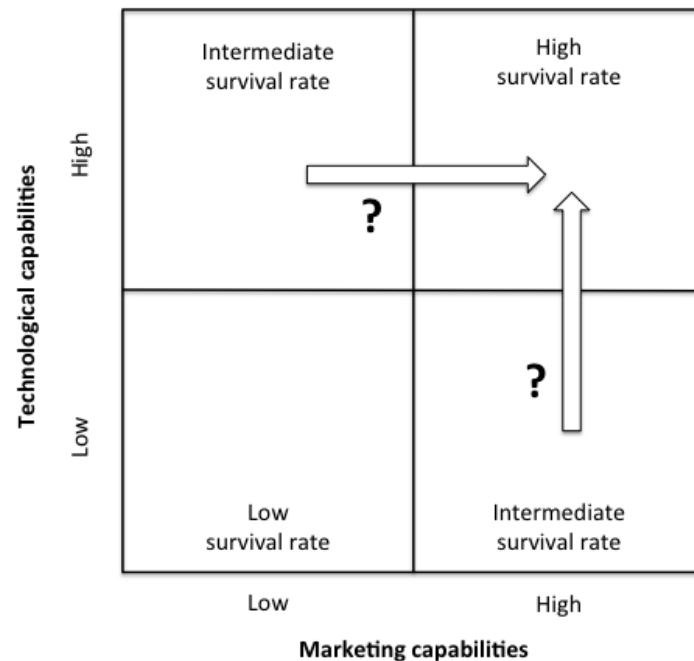

Fig. 1 - Capability gaps at the birth of a firm

3. Empirical analysis

The data for the analysis are drawn from an original survey that addressed specifically new-ventures and was conducted between February and June 2013. The universe considered for the purpose of the analysis consists of all the companies i) with share capital located in North Italy – the most industrialized area of the country; ii) born between 2005 and 2007 – the years preceding the great recession; iii) registered within the business register of the Italian Chambers of Commerce and being still active in 2013. The survey tackled just advanced sectors, in terms of the technology and the knowledge embedded. The sectors included, considered med-high technological industries according to the European classifications of industries, are: i) knowledge intensive business services (KIBS); ii) mechanics and iii) life science and bio-tech. Starting from such a universe, we created a stratified sample based on industry specialization and geographical locations (region). For the purpose of this analysis, the life science sample was disregarded, considering for the high specificity characterizing it. Table 1 reports the specific ATECO 2002 codes (the Italian version of the NACE rev.1 industry codes) used to identify each the sectors mentioned.

Table 1 - The industry considered for the analysis

Industry	ATECO 2002 code	ATECO 2002 description
KIBS	72	Computer and related activities
	73	Research and development
	74.20.1 and 74.20.2	Architectural and engineering activities and related technical consultancy
Mechanics	29	Manufacture of machinery and equipment n.e.c
	31	Manufacture of electrical machinery and apparatus n.e.c.
	34	Manufacture of motor vehicles, trailers and semi-trailers
	35 (excluding 35.1)	Manufacture of other transport equipment

A specialized survey company conducted the interviews with the assistance of the CATI (Computer Assisted Telephone Interview) and CAWI (Computer Assisted Web Interviewing) procedures, targeting firm’s entrepreneurs. The questionnaire was 6 pages long and included questions inquiring on firm’s structural characteristics and market strategies, on the characteristics and motivations of the founders and on the firm’s competences, innovation and networking activities both at foundation and in the following years. In order to be sure that companies were effectively born in the years considered and exclude from the analysis possible cases of older firms being registered in the business register of the Italian Chambers of Commerce with a different year than the true one because of phenomena such as transformations, merge and acquisitions and the like, a specific filter question was administered to firms at the beginning of the interview. Subsequently, we added in the dataset information about the financial performance of the firms, with information coming from the AIDA Bureau Van Dijk dataset and from the Chamber of Commerce databases. From the 2,341 firms initially contacted, we collected 504 valid responses, being 221 KIBS, 209 mechanics and 74 life-science firms.

3.1 Measuring the marketing competence gap

In order to evaluate the level of capability gaps of new ventures we classify interviewed companies based on a variable describing the capabilities the firm has initially and over time. Specifically, such a variable is built on questions asking firms to rate, on a scale from 1 to 5, their endowment both at their founding year and after three years of technological and marketing capabilities. Table 2 reports the average competences hold be the interviewed companies at the founding year and after three years.

Table 2 – Competences hold by companies at the foundation and after 3 years

	Average level of competences				% of firms with low (<3) level of competences			
	Technological		Marketing		Technological		Marketing	
Initial	3.76	(1.05)	2.58	(1.21)	11.2%	(31.6)	51.7%	(0.50)
After 3 years	4.40	(0.77)	3.42	(1.15)	2.6%	(0.16)	21.4%	(0.41)
Var.	17.0%		32.4%		-8.7 p.p		-30.3 p.p.	

S.D. in parenthesis

The average level of technological competences is already high at the founding years, being 3.76, whereas the contrary is true for marketing competences, for which the average level declared is beyond 3 on a scale from 1 (no competence) to 5 (very high). Such a difference in the average endowment of competence at the foundation is evident also when looking at the incidence of firms reporting a low (lower than the medium value, 3) level, being more than half in the case of marketing competences and just 1 out of 10 when it comes to technological ones. After three years of activity the stock of both competences increases, with a greater increment (+32.4% vs. 17.0%) in the realm of the competences for which the companies declared initially lower level, which get to 3.42, above the median value. After such a period of time companies that recognize to have low level of technological capabilities got a true minority (2.6%), but the strongest reduction is again in the realm of marketing competences where they got 21.4% vs. the 51.7% of the initial period.

In order to identify what factors impact on the probability that a firm will fill in the initial gap in terms of marketing capabilities, we use as dependent variable the dummy GROWTH-MKTG. First, we created a dummy variable to identify firms having initially low (lower than 3) level of marketing capabilities but a high (from 3 to 5) level of technological ones, which we named LOWMKTG-INITIAL. The dependent variable used in the main analysis (GROWTH-MKTG) splits the firms for which the variable LOWMKTG-INITIAL values one into two groups: i) it values one in the case of firms having filled in such initial gap, therefore reporting to have an high level of marketing and technological competences after three years from foundation; ii) it values zero in the case of firms that reported to have still a low level of marketing competences after such a period of time.

The data on which our dependent variable is built represent a great advantage for the present analysis, aimed at identifying firms with competences gap, since it allows avoiding possible respondent bias and to overcome possible limitations driven by the fact that it is based on subjective, qualitative responses. Such a question, in fact, asked interviewees a retrospective evaluation of the competences of their firms – reporting at time 3 to rate the competence stock held at time 1 and 2 – ensuring therefore that the same evaluation criteria is used to rate both periods. Having asked the same question at one of the periods under scrutiny (i.e., after three years) may have lead to over-estimated results, because is tougher to have a reliable idea of a phenomena while it is taking place; having asked the same questions at two different periods (i.e., at the founding year and after three years) may have lead to biased results considering for the different conditions affecting the firms and the markets at that specific time. The fact that the questionnaire was filled in just by ‘successful’ start-ups – firms that were still alive after 8-10 years from foundation – further indicated the reliability of the dependent variable we use. The qualitative evaluation of competences, in fact, has been reported by people that proved to be able to be competitive on the market they work in and therefore may have clear(er) ideas of what the level of competences needed are.

3.2 The independent variables used in the analysis

In order to understand the factors relevant to understand how firms have filled in the marketing competence gap, we included in the analysis a number of independent variables. The variable MKTG-EXT is built on a question asking firms to report how both technological and marketing competences were developed distinguishing between three options: just internally, just externally (both by acquiring external services or through collaboration with external partners) or both. The dummy MKTG-EXT takes on value 1 in the cases firms declared to have increased marketing competences in the second or third mode, therefore at least partially through the interaction with external partners. The questionnaire further investigated how firms learn about their market asking to rate, on a scale from 1 to 5 the intensity in which they use each of the following as source of information: i) participation to trade shows or conferences; ii) public research reports or database; iii) internally, ad-hoc developed reports or database; iv) suppliers or other industrial partners; v) KIBS; vi) industry associations; vii) universities or public research centers; viii) industry journals; ix) blog, newsletter, websites, social networks; x) other

sources. SOURCEDEPTH is a count variable that reports the average intensity through which the firms uses the ten sources just listed to improve the knowledge of its market. The variable COOPBREADTH, instead, is a proxy for the relational attitude of the firm and is built on questions asking firms to report the intensity of collaboration with external partners for innovation, among the following: i) suppliers; ii) clients; iii) other industrial partners; iv) KIBS; v) universities or public research centers; vi) other. COOPBREADTH counts the number of partner typologies among the six listed for which the cooperation intensity was rated high (higher than 2 on a scale from 1 to 5).

We included also the dummies SECTOR-FOUND and EDUCATION, in order to proxy for characteristics of the founders. In particular, the first variable measures if the founders of the start-up (being them firms or individuals) belongs to the same industry or not, which we use as a proxy for differences in the firm's initial competences endowment, considering that, having worked in different industries, the founders may bring different competences too. The second, instead, aims at evaluating the initial level of competences of the single founders: it values 1 if any of the founders (in case of individuals) has a tertiary education (holds a undergraduate, graduate or post-graduate degree) and 0 otherwise. Furthermore we included a number of control variables to control for possible industry effects (the dummy INDUSTRY values 1 if the firms belong to the KIBS sector, 0 if to the mechanics); size effects (including the natural logarithm of the number of employees at the founding year, SIZE); or geographical effects (the dummy LOCATION values 1 if the firm is based in the North-East of Italy). Table 3 summarizes the variables used in the analysis and reports their descriptive statistics.

Table 3 – Description and descriptive statistics of the variables used in the analysis

Variable	Description	Obs	Mean	S.D.	Min	Max
LOWMKTG-INITIAL	Firms having initially good technological competences but not marketing ones (d)	427	0,44	0,50	0	1
GROWTH-MKTG	Firms having initially low marketing competences having increased it (d)	187	0,57	0,50	0	1
MKTG-EXT	Marketing competences has been developed at least partly externally (d)	427	0,37	0,48	0	1
SOURCEDEPTH	Importance of external sources as source of info for competences development	430	2,33	0,61	1	4,1
COOPBREADTH	N. of external partners with which it cooperate deeply	428	1,83	1,55	0	5
SECTOR-FOUND	Founders (being firms of individuals) from different sectors (d)	430	0,12	0,32	0	1

EDUCATION	Founders with tertiary education (d)	430	0,57	0,50	0	1
INDUSTRY	Sector (KIBS vs. Mechanics) (d)	430	0,51	0,50	0	1
SIZE	Initial size (employees) (ln)	414	1,33	1,06	-2	6
LOCATION	Location (North-East vs. North-West) (d)	430	0,51	0,50	0	1
FINANCING	Incidence of initial funds by external sources	415	21,30	34,88	0	100
ONE-FOUNDER	Having just one founder (d)	420	0,22	0,42	0	1

4. Results

Considering that the dependent variable of the analysis (GROWTH-MKTG) is a dummy and that it focus just on a sub-group of the sample, we employed a binary outcome model that controls for possible selection bias arising from the exclusion from the analysis of the firms that had not a competence gap at the initial period (those for which the variable LOWMKTG-INITIAL values 0). The model chose is a two-part logit model (Cameron and Trivedi, 2005; De Marchi, 2012), which has proved to be appropriate for estimating actual outcomes and more suitable than a Heckman selection model since the dependent variable is not continuous (Haas and Hansen, 2005). Such a method consists in performing two, subsequent analyses. In the first stage, the probability for a firm to have a marketing competence gap (PR-GAP) is calculated by regressing exogenous variables available for all the observations of the sample on LOWMKTG-INITIAL. Variables included are SIZE, INDUSTRY and LOCATION – used as control variables also on the second stage – plus INIT-MARKET, FINANCING and ONE-FOUNDER and the dummies reporting the year when the firm was founded. INIT-MARKET values one if, at foundation, the company served an existing market producing products or services just marginally improved. FINANCING allows to capture the impact of initial source of financing, being the incidence of initial funding coming from external sources (namely banking and private or public venture/seed capital or business angels). Last, ONE-FOUNDER is a dummy valuing 1 if the firm was founded just by one firm or one entrepreneur.

In the second stage, the main model, just firm having initial low level of marketing competences but not of technological ones are considered (i.e., just firms for which LOWMKTG-INITIAL=1), so to verify what is the impact of the independent variables considered on the probability that the firms have been able to fill in that gap or not (GROWTH-MKTG). The inclusion of the variable PR-GAP on the second stage controls

for possible selection bias by including the effects of firms that did not have the initial gap. A logit specification is used for both stages, which passed tests for multicollinearity, goodness of fit and model mis-specification. Table 6 in the Appendix lists the correlation among the variables used for the main analysis.

Table 4 – First stage logit regression, explaining the propensity to have low marketing competences at foundation

LOWMKTG-INITIAL		
	Coef.	S.E.
INIT-MARKET	0.494**	(0.225)
ONE-FOUNDER	-0.580**	(0.272)
FINANCING	0.007**	(0.003)
SIZE	-0.244**	(0.116)
INDUSTRY	0.485**	(0.227)

Chi-squared	24.33	

Robust standard error. * p<0.1. ** p < 0.05. *** p < 0.01.

Table 4 reports the results of the first stage analysis, evaluating what factors impact on the probability that the firms have a gap in terms of marketing competences at foundation. Interestingly, the innovative attitude of the firms is negatively correlated with the probability to show a marketing competences lack. The coefficient of the variable INIT-MARKET, in fact, is positive and significant, suggesting that the more the firm has been founded to serve a traditional market, the higher the probability that it does not know its market well. Other interesting and counter-intuitive results regard the variables ONE-FOUNDER and FINANCING, being respectively negatively and positively related with LOWMKTG-INITIAL. The first supports that firms founded just by one entrepreneur (or firm) have larger probability to have already a high level of marketing competences. We interpret this result with the fact that, considering the higher risk entailed by such option, just entrepreneurs having a sufficient level of both technological and marketing competences go this way. Also the evidence of a significantly positive correlation of the

variable measuring the incidence of external financing on the overall funds raised by the firms to start up is rather intriguing, despite the level of the coefficient is very low. The interpretation of this result is twofold: on the one hand, it may signal a bad capacity of funding actors to identify which start-up has the highest and most complete competence stock to face successfully its market; on the other hand, it may be interpreted with the fact that firms having access to external funds may be less prone to equip with knowledge that may improve the probability to get successfully to the market.

Unsurprisingly, larger firms have lower probability to have an initial gap, as suggested by the negative sign of the coefficient *SIZE*: smaller firms may be endowed with good technological resources but rather lack marketing ones. Also industry plays a role, suggesting that *KIBS* firms are less likely to have marketing competences than mechanics firms. Geographical factors, instead, are just weakly significant in explaining marketing competence gaps, with firms based in North-East Italy having greater probability to be weaker. Year dummy have been included but are not significant.

Table 5 – Second stage logit regression, explaining the propensity to increase marketing competences if started from a low level

GROWTH-MKTG

Robust standard error. * p<0.1. ** p < 0.05. *** p < 0.01.

Table 5 reports the second stage logit regression, explaining the propensity to fill in the initial competence gap in the subsequent three years three years. Results point to the

importance of combining diverse knowledge bases, being either internal or external to the firms. The variables impacting the most are SECTOR-FOUND and MKTG-EXT, having both the largest coefficient and significance level. Our analysis supports that firms being founded by entrepreneurs or firms belonging to different sectors (SECTOR-FOUND) have a higher probability to fill in the marketing gap in the subsequent years. On the contrary, the education level of entrepreneurs (EDUCATION) has no impact, suggesting that technical, learning-by-doing type of knowledge is still more relevant than more advanced competences.

Whenever an initial gap is identified, filling it in by engaging with external partners - both by acquiring specific services or by cooperation - is a most effective practice than trying to do it internally (MKTG-EXT). The relevance of knowledge and competences from external partners is underscored also by the positive and significant coefficient of the variable SOURCEDEPTH and COOPBREADTH, even if the second one is significant just at the 10% level and has a much lower coefficient. The higher the relevance of external sources to develop market knowledge and the larger the number of partners cooperating for innovation, the higher the probability to fill in the gap in a relatively short amount of time. Finally, control variables are not relevant, nor in terms of industry specialization (INDUSTRY) nor of the initial size (SIZE).

5. Discussions

Our analysis shows interesting results in terms of networking behaviour of new ventures and consequences on their improved set of capabilities marketing-wise.

As it emerges from the data, there is a non-negligible number of new ventures with low levels of marketing capabilities, compared to technology ones. The technology-driven process of company creation can explain this initial gap, where Italian companies show to focus more on competences useful for the development of the business offering than on competences valuable to reach and manage the market. In particular, a result that should be further investigated is the role of external financial sources and its negative link with the level of new venture's marketing competences. In fact, the research of external support should usually require a certain level of marketing competences to present the value proposition and convince external investors. From this point of view, new ventures may be pushed to improve their marketing competences properly due their experience in

interacting with supporters, such as through the management of innovation projects with external (non-financial) partners.

It specifically emerges the positive implications for new ventures that have a proactive approach toward the development of external relations, where the new firm strategically invest in collaboration with other players. This openness is crucial both in terms of quantity and quality of the partners involved and it couples with the internal variety the new venture has at its birth – through the different industry origin of the founding team. Investing in outsourcing activities – that is selecting right knowledge suppliers or source - and collaborations for innovation are important paths that sustain the new ventures. The new venture is able to internally improve if it has the absorptive capacity (Cohen, Levintal, 1990) to acquire external knowledge about marketing practices and this may be explained by the role played by the variety in the profiles of founders.

At the same time, however, this process requires the new ventures to be inserted in a context that facilitate this process of competence enlargement. According to our result the industry of new venture specialization - KIBS, mechanics – is not relevant in order to explain the differences in the process of competences improvement. On the contrary, we may refer to other approaches that can support the explanation of our results (Teece, 2007). Studies on business innovation ecosystems can help us in understanding the dynamics we observed in Italian new ventures. As described by Moore (1993) and others (i.e. Adner, 2006; Adner and Kapoor, 2010), an innovation ecosystem is a loosely connected network of companies that are mutually related and collaborate toward a shared (innovation) goal, in a framework of common knowledge and skills.

On the one hand, those ecosystems are characterized by the leading role of one or few firms that act hubs or orchestrators of the relationships and influence the innovation process (hub-based business ecosystems). Nambisan and Baron (2013) emphasize the opportunities that new ventures can have in acting within hub-based business ecosystems. “Ecosystem entrepreneurs” (Nambisan and Baron, 2013, p. 1072) have to cope with pressing forces of the hub firm as well as find out their own opportunity to develop with the business ecosystem. Through a self-regulatory process the new venture can recognize promising growth and innovation opportunities both within and outside the (hub-based) business ecosystems. On the other hand, according to Teece (2007) firms are able to shape the ecosystems in which they act in a dynamic way, specifically through innovation and through the collaboration with other firms or institutions and these processes are

intertwined with the firm's capabilities. In this perspective, as other firms, also new ventures can develop the process of "sensing" described by Teece (2007, p. 1324), in order to identify new opportunities and also new sources of knowledge that they can exploit on a collaborative basis. This process of searching has to be addressed to both the core and the periphery of the business ecosystem.

Our results show that neither the industry specialization nor the initial new venture size is relevant in explaining the process of gap filling concerning marketing competences. Hence, we may argue that the range of alternative opportunities of collaboration a new venture can have access to in relation to the business ecosystem the firm acts can positively influence this "upgrading". At the same time, the new venture over time develops and exploits dynamic capabilities of networking – i.e. partner selection and management – that sustain innovation activities (intense collaboration with external partners for innovation purposes) as well as the acquisition of marketing competences. Internal differences in the founding team in terms of past experience allow the new venture to be more ready to start the networking process – such as through previous relationships of the founders – as well as to combine inputs coming from different partners – also as far as marketing-related knowledge is concerned – and to internalize those contributions.

North Italy is characterized by a dense presence of medium and small firms, often strongly interconnected in a nested set of business relationships, where also agglomerative effects play a role in innovation processes (i.e. clusters). In this contest the new venture phenomenon has been related to spin-off dynamics within clusters as well as connected to strong entrepreneurial attitudes. From this point of view we can consider the environment of the observed Italian new ventures as a business ecosystem not necessarily hub-centred – that is led by a large enterprise – but an ecosystem as described by Teece: "the community of organizations, institutions, and individuals that impact the enterprise and the enterprise's customers and supplies" (Teece, 2007, p. 1325), where the new venture, with its strategy and its dynamic capabilities, is able to identify opportunities for growth and innovation through appropriate collaborations.

6. Conclusions

The paper explores the process through which new ventures can enhance their internal competences by relying on external partners, beyond the starting time of birth. Through

an original empirical quantitative analysis our study shows that through a proactive networking approach new ventures can fill their gap concerning marketing competences, in addition to the positive role of variety in the founding team.

According to our study, the role of industry specialization or size in explaining the evolutionary process of new ventures has to be carefully taken into account. On the contrary, the business ecosystem in which a new venture is acting – and the potentialities it could offer in terms of collaboration – can explain in more general terms the process of competence acquisition carried out by the new venture. The characteristics of the founders are important, but they are not the only determinant in new venture development. In addition is crucial to also consider the perception of the relevance of external sources of knowledge for the firm.

This is a first attempt to enrich literature on new ventures by exploring the dynamics of those companies beyond their birth through the analysis of the improvement of new venture's competences, the drivers of such process and firm implications. From a theoretical point of view our study proposes to integrate in the analysis of new venture dynamics also contributions from business ecosystems in terms of framework for innovation relationships and business-to-business ties. From a managerial point of view, our study suggests that new ventures have to invest in external forms of collaboration – through both breadth and variety of partners – in order to enrich their internal competences and overcome their gaps at the early stage.

A limitation of this study regards the lack of information concerning the reasons for networking and the detailed characteristics of the business ecosystems (hub-centred or not). An additional limitation concerns the specialization selected that consider only high-tech firms. Further research should be developed in order explore more deeply how new ventures are able to convert external inputs into marketing competences in terms of knowledge management processes and partners involved. Additional research should also analyse different firm specializations beyond high-tech as well as the geographic dimension. Finally, further attention should be given to describe the business ecosystems the new ventures are in to evaluate their capabilities to develop and retain knowledge produced outside the firm.

Structured Abstract

In our study, we scrutinized multidisciplinary and multisectoral cooperation to learn about the factors which influence idea generation and coupled open innovation in cooperation. We specialized on multidisciplinary and multisectoral cooperation because those collaborations seem to have a high potential of developing disruptive technologies and innovation. Our study is a pre-test to set up a research model and to prepare further investigations.

Purpose - The goal of this study has been the investigation of coupled open innovation processes and the mutual idea generation in multidisciplinary and multisectoral cooperation. We have scrutinized how idea creation and creativity processes work, and how the factors: partner's perspective (motivation, perceived risk, etc.) and cooperation background (rules, cooperation culture etc.) influence the performance of coupled open innovation processes in multidisciplinary and multisectoral consortiums.

Originality/value - Our study will give suggestions about the composition of collaborative relationships to create trusting environments to foster idea creation and knowledge/know-how exchange between the participating partners. Thus, coupled outside in and inside out open innovation processes can enable the development of products and services with the potential for disruptive innovations initiated by the input of multidisciplinary technology and multisectoral application knowledge and experience.

Key words - Coupled Open Innovation, Mutual Idea Generation, Creativity, Co-Creation, Knowledge Management, Multidisciplinary Cooperation, Multisectoral Cooperation

Paper type – Academic research paper

1 Introduction

An organization's capacity for idea creation is a vital source of new technologies, services, processes, and business models in today's competitive international environment and offers competitive edges (Gay, 2014). An organization can improve its idea creation capacity by working together with other organizations (outside-in and inside-out open innovation approach) (Chesbrough, 2007). Cooperation usually does not work when it is confined only to the outside-in approach. Ideas have to be exchanged and commonly evaluated and further developed (coupled open innovation approach). Many well-known companies, such as 3M, constantly improve their research and development abilities by even collaborating with competitors (Nonaka, 1994).

Enkel et al. (2009) stated that one of the most important sources of ideas for an organization has been organizations from other industries (multidisciplinary cooperation approach) and the combination of different industry-specific knowledge leads to new ideas. Consequently, many innovations are based on already existing inventions, technologies, concepts, etc. derived from other industries.

Ideas can also come from different application sectors such as information and communication technologies, environmental technologies, production technologies (multisectoral cooperation approach), and even biology. Cooperation with organizations from these sectors can boost the creation of new ideas.

Multidisciplinary and multisectoral cooperation are good foundations for industry-specific knowledge spillover and the development of common new patents, products, services, and processes. The intellectual interactions in that cooperation based on complementary partners provide a better framework for creativity and innovation when compared with homogeneous collaborations (Alves et al., 2007).

Nevertheless, the market success of new ideas, which become inventions is not sure. There are many influence factors such as regulations, customer preferences, country culture, and environmental matters that can influence the production or realization of new products and services. To improve the realization probability, organizations can include as much stakeholders in the cooperation e.g., federal regulatory bodies, technical standardisation agencies, environment of organizations, unions, and even psychoanalysts and cognition experts. Furthermore, the participation of all value creation chain members are helpful to create valuable ideas which could evolve to new innovations.

In earlier stages of research and development taking place mostly in research organizations, multidisciplinary mutual research might include fields such as physics, chemistry, engineering, as well as, economics and social sciences. In later stages of the development process, multisectoral cooperation approaches become important, which include knowledge and experience from different application areas and markets.

2 Coupled Open Innovation Processes and Collective Idea Creation

The benefits of cooperation are rising since more and more organizations have decided to implement open innovation in their organizational culture. (Enkel et al., 2009) “Not all the smart people work for us. We need to work with smart people inside and outside our company” (Chesbrough, 2003). Saint-Paul, (2003) stated that every company will suffer competitive disadvantages if it does not participate in interorganizational cooperation when it hits the industry. Even, “firms that do not cooperate and which refuse to exchange their knowledge decrease their knowledge base on a long-term basis and lose the ability to enter into exchange relations with other firms and organizations”. (Koschatzky, 2006, p.6) Enkel et al., 2009, argue that cooperation with externals is core to increase innovativeness and reduce time to market. The **coupled open innovation processes** (joined innovation and exploitation) is a mixture of the outside-in-process and the inside-out-process: internalization of external knowledge in combination with externalization of internal knowledge. Thus, other organizations and stakeholders should be actively involved in the development of innovations and at the same time innovations should be externalized to form a market. (Gassmann and Enkel, 2004). Consequently, forming a cooperation with complementary partners is a good opportunity to use the coupled open innovation effects to improve the own idea creation capability, to exchange and exploit knowledge. The unwanted exploitation or uncontrolled exchange of the organization’s know-how by partners and external companies etc. has been always problematic in cooperation. There are two ways to protect know-how - secrecy and legal exclusion rights (Henkel J., 2013), which are often necessary for a successful cooperation. (Arora et al., 2001; Chesbrough, 2003, 2006) In our case study, all partners signed a non-disclosure agreement and possess their own patents.

The **collective idea generation** depends heavily on the participants’ creativity. The concept of creativity can be defined as the generation of new and useful/valuable ideas for

products, services, processes and procedures by individuals or groups in a specific organizational context. (Martins and Terblanche, 2003)

In our study, we wanted to scrutinize multidisciplinary and multisectoral cooperation to learn how idea generation and knowledge management in cooperation work and which conditions and pre-settings the participating partners have regarding their goals and assumptions in cooperation.

We set up a **research model** about factors, which influence idea generation and creativity in multidisciplinary and multisectoral cooperation. As influence factors on the mutual knowledge management, we investigate the partner's perspective and the background of the cooperation. Furthermore, we observed if the mutual idea generation and the knowledge/know-how exchange leads to the development of new products, services and technologies, and a mutual technology exploitation.

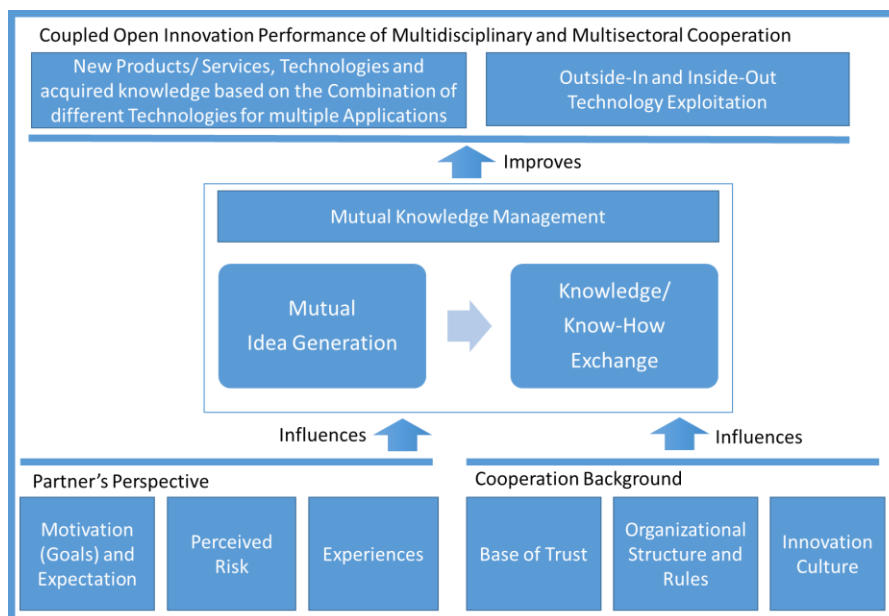

Figure 1: Research model of influence factors on the success of multidisciplinary and multisectoral collaborations based on coupled open innovation processes

3 A Case Study of a Multidisciplinary and Multisectoral Cooperation

3.1 *The Consortium*

Our investigation is based on a long-term highly-multidisciplinary and multisectoral conglomerate that wants to improve human-machine interactions by means of 3D-measurement technology.

Human-machine interactions have been a hot topic for many organizations and even governments for many years. The interface between computers/machines and their users is almost confined to keyboard and mouse. Voice recognition is an important technology that has already improved human-machine interaction. Visual interactions are another possibility to connect humans with machines. It offers a wide area of application possibilities. Machines try to recognise people and interpret their gestures and mimics. It is being used for analyzing human presents and reaction, important for example in security and production. Furthermore, by using visual interactions, humans can control machines and robots by the intentional movement of body parts etc. In that regard, the interpretation of movements that depend on intention and cultural background of humans play an important role for human-machine interaction. To investigate this area, the cooperation has needed a partner who focuses on the human factor by including the knowledge of psychological behaviour into the development of new human-machine interfaces.

In 2013, a research institute started building up the conglomerate with the idea to further develop human-machine interactions scientifically and transfer that knowledge into applications that lead to improvements in healthcare, production, security, and mobility. A goal of the consortium has been for example the recognition of humans in an automated production environment to improve people's safety and to enable those workers can interact with robots and can be present in a robot driven manufacturing environment. The research institute searched for company and research partners for the development of innovations most relevant to society such as autonomous mobility, efficient production, reliable security, and cost-efficient healthcare.

A governmental funding organization has been co-sponsoring research and development projects in the consortium due to their high potential of solving big social challenges. The consortium started in 2014 consisting of 70 organizations containing 20 research institutes and universities, as well as, 50 companies from all over Germany. 30

of them have been SME's. The organizations want to develop and commercialize technologies, services and products for the following application areas: information, production, health, and security. These areas offer the largest market opportunities and, thus, promise the best results for the alliance.

Since 2013, many of the partners have known each other or even had known each other before. The technology is about 3D measurement and visualization for a variety of applications. Image capturing and image visualisation are at the beginning of a revolutionary change. Two hundred years after the discovery of photography, the first devices for picture capturing and visualization of three-dimensional objects are available. The consortium targets the multidisciplinary combination of expertise in optics/photonics, IT/software engineering, and electronics with expertise in design, neuroscience, cognitive science, and ergonomics. Furthermore, social, creativity, medicine, legislative and engineering knowledge is included in the consortium. The target of the consortium is the discovery of new holistic human-machine interaction to bring new technologies to applications. The consortium hopes that the technology will find a rapid acceptance in industry and society. Beside of technical challenges, there are economic and society challenges to solve. Thus, the consortium includes not only the entire value creation chain but also all stakeholders, which the technology bundle pertains. The consortium hopes that the new technologies would penetrate markets quickly. Figure 2 shows the multidisciplinary and multisectoral approach of the consortium.

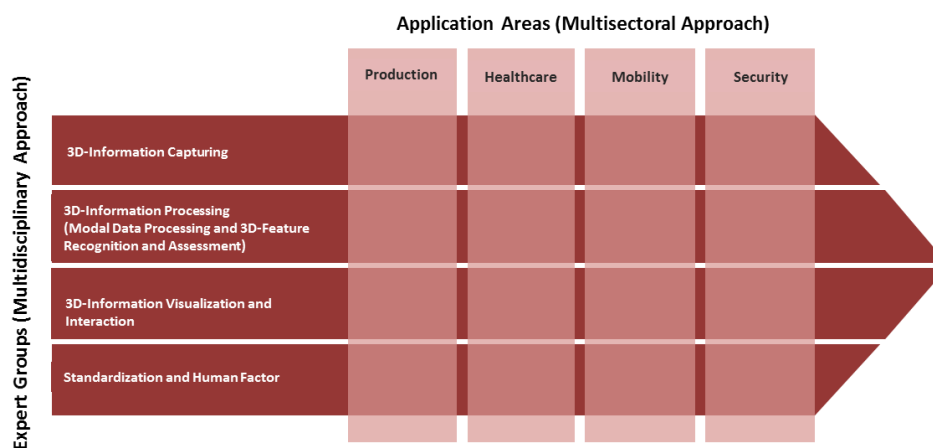

Figure 2: Multidisciplinary and Multisectoral Approach of the Consortium

The multidisciplinary approach is represented by four expert groups: 3D-information capturing, 3D-information processing, 3D-visualization and interaction, and standardization and the human factor. The multisectoral approach is represented by four application fields (production, health, mobility, and security). The combination of different scientific disciplines and application areas leads to cross-border idea creation effects and hopefully to a high potential of disruptive innovation development. Moreover, the technology usage for many applications leads to synergy effects such as lower research costs.

3.2 Establishing the Consortium - Consortium Start Phase

After had convinced the funding agency that the consortium is able to provide solutions in human-machine interaction, a strategy phase started. The goals have been: set up of a roadmap and strategy development, elaboration of an organizational and managerial concept, and development of a communication concept. For the roadmap and the strategy, a market and application analysis was needed. Furthermore, the coordination, project steering, quality control had to be ensured in the four expert groups. For the elaboration of an organizational and managerial concept, the definition of the organizational structure and the organizational processes in the consortium, the installation of a financial and organizational controlling system, and a concept for knowledge management in the alliance had to be developed. The development of a communication concept, the evaluation and analysis of the communication requirements, the creation of a communication strategy, and the implementation of the communication strategy were necessary. To be in line with all partners, the consortium organized several workshops.

The organization of the consortium were split up in seven areas: internal information and communication policy, external communication, information acquisition, project funding processes, consortium agency, contract/law, and conflict management. Figure 3 and 4 depict the sub-topics of the organization strategy. All these topics had to be addressed in workshops to form an effective administration and regulatory body of the consortium.

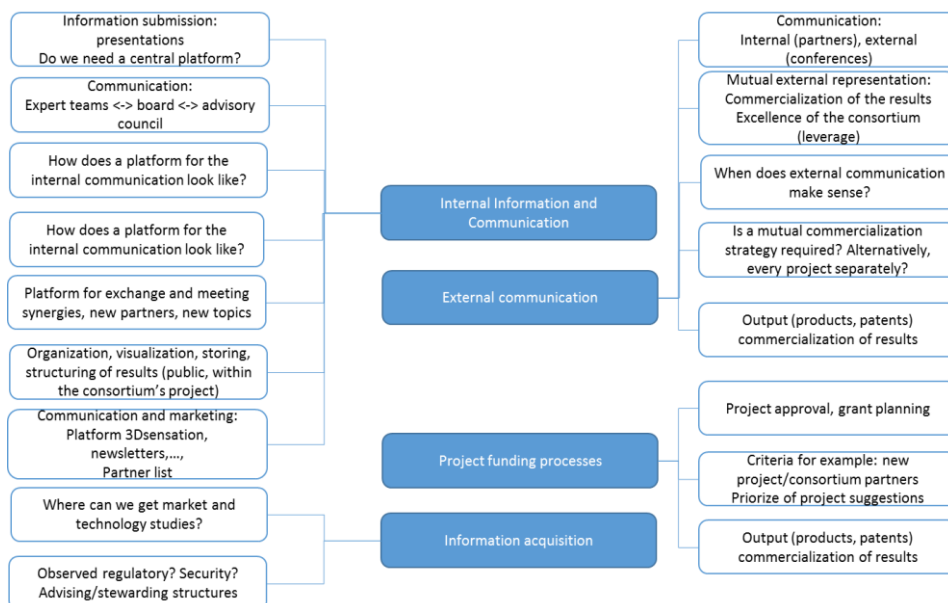

Figure 3: Important organizational areas of the consortium – I

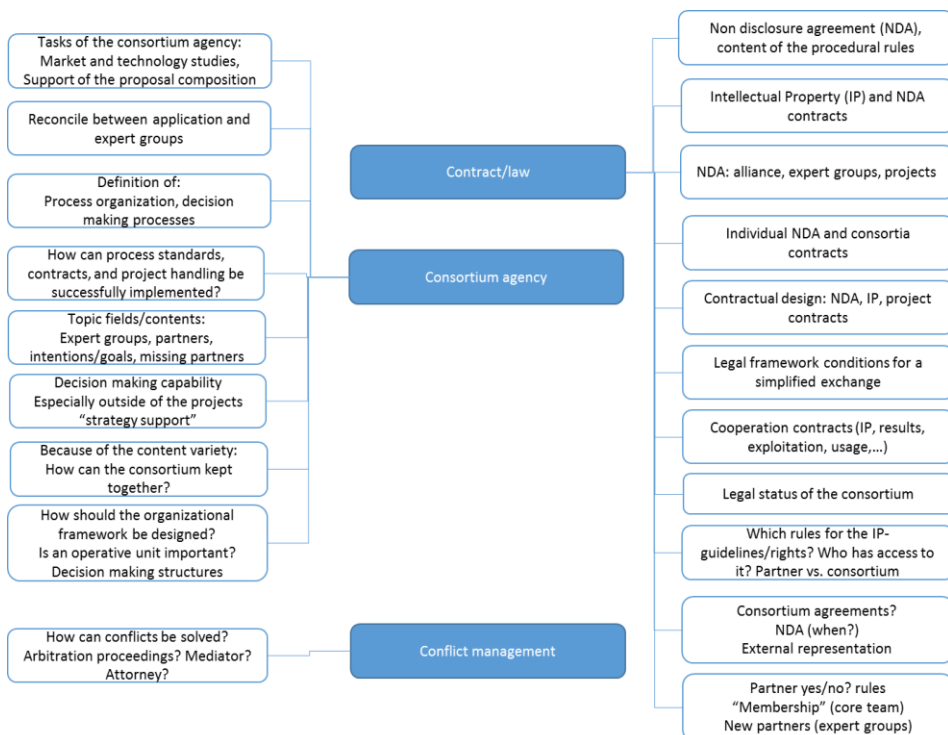

Figure 4: Important organizational areas of the consortium -II

3.3 Organization and Management of the Consortium

Multidisciplinary and multisectoral cooperation need an appropriate organization and management structure. The goal is to work together and maintain the economic independence of the partners. An efficient decision making process and work will be ensured by establishing a transparent organization structure, clear responsibilities and communication tools. Especially important was that the organization structure has allowed for and supported the extension of the consortium by new partners and new technological and social themes.

The ideas that have been invented in the consortium have been evaluated by the board and the expanded board. Those high potential ideas were partially funded from the funding organization. The funding is necessary for the companies and the research institutes because the high potential ideas are very risky and they will not realized otherwise. The financial loss would have been too much for most of the participating organizations if the ideas do not generate results. Furthermore, the funding pushes the development of technologies in which the government has a large interest in. The funded ideas in the consortium become projects and are done by several partners. However, all partners in the consortium will be informed about the funded projects and can participate in them if they have the necessary expertise. The intellectual property that is created in those funded projects is the property only of the participating organizations in the project.

3.3.1 Organisational Structure of the Consortium

The alliance has a board, an expanded board, an advisory council, a consortium agency, four expert groups, and a pool of partners (figure 5). The board and the expanded board are the most important managerial units in the consortium. The advisory council is the most important supervision unit of the consortium. The partners of the consortium participate in the decision making process by an annual general meeting.

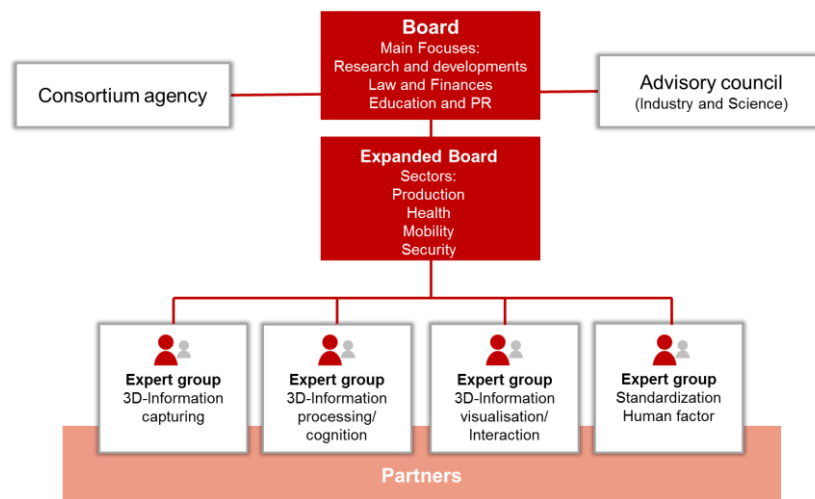

Figure 5: Organizational structure of the consortium

The **board** is responsible for the strategy in the following matters: research and development, law and finances, and education and public relation. The board determines the technical content, technology direction, and the funded projects of the consortium in coordination with the expanded board. The board must decide together with the expanded board which research and development projects, suggested by the expert groups, will be supported. Furthermore, the board decides about including new partners and technological and social themes. The extension of the consortium is possible in regard to current tasks and challenges. The board is also responsible for the financial and legal controlling of the consortium and must decide which dissemination and marketing strategy is appropriate. The board functions as the official spokesperson to the funding organization and the advisory council. Furthermore, the board calls up general meetings. The board members come from all sectors of the consortium. The board is supported by the expanded board, the advisory council and the consortium agency.

The members of the **expanded board** are subdivided in the four application sectors: production, health, mobility, and security. Each application sector is represented by one industry representative and each expert group by one scientific representative which ensures the representation of the different interests. The expanded board suggests ideas of high potential to the board. Furthermore, it sets up a roadmap and a long-term strategy of the consortium. Furthermore, the expanded board conducts target-performance comparisons of the funded projects and their results. Decisions should be made by mutual

agreement between the board and the expanded board. The general meeting elects the representatives for the expanded board every two years. Moreover, the expanded board suggests new members to the board and is responsible for conflict management in the consortium.

The representatives from the **advisory board** are experts who originate from industry, science, and society. The tasks are supervision and control of the consortium. The board gives advises about upcoming challenges in science, economy, politics, and society. Furthermore, it evaluates the consortium regarding its strategy and achievements in the light of the consortium targets. These measures make sure that the decisions of the board are in line with the interests of the partners and the funding organization.

There are four **expert groups**: 3D-information capturing, 3D-information processing, 3D-information visualization/interaction, and standardization and the human factor. The partners of the consortium are members of these expert groups and work closely with each other to solve the technical and social challenges. The workshop leaders and the expert group leaders are responsible for protocols and information as well as the dissemination on the prepared internet platform.

The responsibilities of the **consortium agency** are coordination and the support of the consortium such as diverse operative tasks and support of the strategic decision making processes by providing financial controlling figures. Operative tasks are for example the support of the board, expanded board, and advisory council, controlling and supervision of projects, communication, marketing and public relations, reporting, preparation of workshops and meetings. The consortium agency informs regularly about news. Important information/protocols/dates will be stored at a secured area on the prepared internet platform.

The **pool of partners** includes 70 organizations. They meet every year at a general meeting. The partners can always introduce ideas to the expert groups. The general meeting elects the board and the expanded board every year. Every partner is advised to be active in the consortium. Consequently, thematic workshops organized by the expert groups take place regularly and every partner is eligible to participate in those to bring in ideas, influence the expert groups, and partially determine the research direction of the whole consortium. A partner constitution defines the rights and duties of every participant. The consortium is based on open communication behaviour, trust, transparency and cooperation between its members. New members are accepted after

specific decision criteria for admission and resignation are met. When votes take place, a simple majority of the members decides.

3.3.2 Rules of Participation

The dissemination of internal information such as fact files, project ideas to externals is prohibit. As of the signing of a cooperation contract and memorandum/procedure rules, all ideas for products, services and processes have been the common property of the involved partners. It is prohibit to use an idea from the idea stock and no idea can be used exclusively by just one partner.

3.3.3 Project Creation Process in the Consortium

The ideas, as already explained, come from the partners or are created at the expert group workshops which take place regularly. The board and the expanded board evaluate and decide which proposed ideas should be funded.

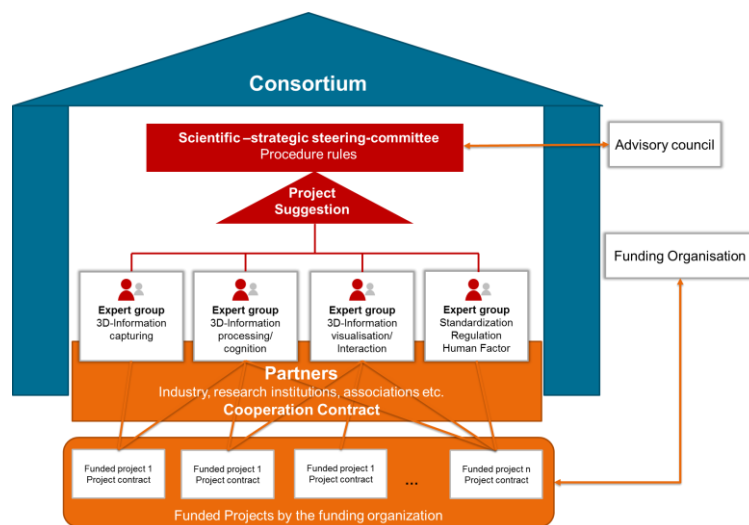

Figure 6: Project creation procedure in the consortium

The consortium uses a four step idea creation process adapted from Amabile (1983).

1. Identifying, structuring of central problems and challenges by the board and the expanded board (problem formulation)

2. Development of ideas in the technology and social science area by the expert groups and their members (Preparation and idea generation)
3. Evaluation/prioritization of ideas by the board and the expanded board (idea evaluation and idea selection)
4. Combination of the necessary expertise by the board and the expanded board (forming the project team)

The successfully evaluated ideas become funded projects and the project participating partners can start their common development. The outcome of these projects are evaluated regularly and have to fit in the overall research and development strategy to achieve the common goal of human-machine interaction and their successful adaption in applications in production, mobility, security, and healthcare.

4 Research Approach

The study is based on the consortium described in chapter 3. This publication is a pre-study to test our research model. For that reason, we tested our questionnaire by interviewing a research partner of the consortium. This research institute is the coordinator of the cooperation and has organized most of the events and moreover is responsible for the knowledge management, idea creation techniques, and organization of the strategy phase. The interview were audiotaped and transliterated. The results from that interview and further analyses will be the basis for advanced studies. At first, we plan to strengthen the research model by interviewing more partners of the same consortium. Afterwards, we plan to conduct a large survey covering multiple multidisciplinary and multisectoral cooperation. The interview was conducted with a partner that does research in 3D measurement systems.

5 Results

5.1 Motivation (Goals) and Expectation

Each partner has a specific motivation to participate in the cooperation. Reasons (goals) for participation can be for example obtaining funding, transferring technology, generating ideas, finding new employees, attracting new customers, using others infrastructure and resources, gathering complementary expertise, finding new partners for

further projects, gaining knowledge about technologies and markets, discovering new application fields of own products and services, etc. The partner of the case study consortium answered: *“The first reason for participation in a cooperation is of course the funding for the coming years. This is a totally banal expectation. [...] The next point is finding new applications for our technology. [...] Another expectation is that the industry partner will implement the technology in a product. A technology shift to application is important. [...] A further issue is that the project unveils new interesting research themes for further developments. [...] Actually, we are experts in specific technology areas... but we want to know where we can apply our technologies and which technology modifications are needed to create new applications [...] sometimes we get good application ideas from companies. [...] it is not only about finding new applications, we also want to get contact to new customers [...] usage of resources of other participating partners: I say that this is an issue at very interdisciplinary projects. At the standard technology projects, we have the necessary infrastructure and expertise [...] Maybe sometimes our partners provide a specific technical component [...] at very interdisciplinary projects for example in the biology area, we must provide a biochip for biomaterial analysing. That is more as we can offer and then we do need external resources.*

The expectations of the partners signify to which extend the cooperation goals can be achieved. Small expectations mean the partner does not believe that the goals of the cooperation can be accomplished and high expectations mean the opposite.

Each partner has a specific expectation and a specific motivation about the output of the cooperation. We wanted to know if the extend of the expectations influence the success of the cooperation and what influence the different motivations will have on the success of the cooperation.

5.2 Perceived Risks

Partners often perceive risks when they participate in cooperation. These risks might be for example draining of knowledge to competitors, poaching of labour, wasting time and resources, usage of own ideas by others, sneaking out of the organizational strategy by others. The test questioning resulted in the following statements: *“[...] I know other people think differently but in my opinion there is no risk. Indeed, I want to work together with the partner. [...] cooperation always mean that partner companies are interested in*

employees and know how [...] it is a matter of coping with those issues [...] of course, I won't unveil every detail to the partners [...] I believe it is critical if you see risks in a partnership, by doing so you will be restrained towards your partners [...] I know colleagues who do so but that is not a good way. A company understands if you do not want to give away everything [technology], but if you do so with such restrains such as I go my own way and I do not want to tell you something. The partner will notice. One might think, does they want to cooperate or not?"

5.3 Experiences

Experiences made in other cooperation might influence the partner's behaviour in the present consortium. Good or bad experience can be made in regard to know-how protection, fulfill the obligations and tasks that are agreed on (work, funding, etc.).

The case study interview revealed: *"There were cooperation with much trust and with less trust, but I think companies have to be more aware of being trustful regarding of their know-how protection. Research institutes do not need to be so."*

5.4 Base of Trust

Trust is one of the most important requirements of forming a consortium because without trust the partners hesitate to share ideas. Questions were for example: Do you trust the participating partners? What is the base of trust and is an open idea exchange within the consortium possible?

The research partner in our case study mentioned: *"[...] I think it is very important to tell your partners about your goals, what you are planning to do, about the chances and about the risks. [...] It is not good to tell your partners something out of the blue. It is better to tell them there are chances to have an outcome of the project. However, there are also some risks."* Furthermore, we wanted to know if the length of the partnership and knowing the partner for a long time play a role in the base of trust. Our case study partner answered no.

5.5 Organizational Structure and Rules

The case study consortium uses non-disclosure agreements, a constitution, cooperation agreements, and intellectual property regulations to provide a structural framework and to rule the consortium. Every partner has to sign a non-disclosure

agreement before being accepted in the consortium. The constitution rules the decision procedure and defines the organizational structure (see figure 5). Cooperation agreements rule the mutual work during the funded projects and the intellectual property regulations determine how to protect the ideas that have been developed during the expert group sessions. Issues to be ruled in these agreements and regulations are for example who makes decisions if controversy opinions occur, what is the procedure for problem solving, to which extend should be rules determined at the beginning of the project? Has it disadvantages if to many details are ruled by agreements and contracts? Alternatively, a consensus finding approach in the consortium could be a fruitful problem solving. Our case study interview resulted regarding these points: *“It should be determined in the consortium. Otherwise, it ought to be arranged in the contract.”* The interviewee said that it was mainly a matter of contracts and it was not about who had more power. Non-disclosure agreements are common in such consortiums. A matter of discussion is how detailed a cooperation agreement should be. If it is too detailed the partners will either discussing about minor point and this takes too long or the trust in the consortiums drops because a too detailed agreement signifies distrust. Our interviewee was that a cooperation agreement should not be too detailed. *“The best way is to provide a framework and be trustfully and the willingness to compromise when facing problems.”*

An appropriate organizational structure of the consortium is also a decisive factor for the success of a cooperation. Important questions are for example: can there be too much or too less organization? What can be improved regarding organizational structures and the consortium lead? Our case study interviewee mentioned to this subject: *“Every cooperation should have a structure. Who is going to be the coordinator depends on the funding. If the funding organization wants to have a strong applied and industry focus, it is be required that the coordinator is a company. Usually, the research institute is the coordinator or at least the hidden coordinator, because the administration effort is high and companies will not do it. [...] usually, there is too little coordination effort in cooperation. The people sometimes fall behind their goals and then try to cope with their duties when a report has to be composed. Project meetings are scheduled and the partners have to prepare their outcome presentations. This is always a good occasion to motivate the collaboration partners to keep up with the work. A problem is that sometimes there is no continuous work on the project. A project controlling would be a useful measure to improve the outcome and foster the project development. But it is not easy to*

implement if there are people who you cannot oblige to work further on the project. There should be some viable measures to force the project partners to keep on track with the project plan.”

5.6 Innovation Culture

The Innovation culture in a consortium is very important. Important factors play a role for example: openness to criticism, possibility to admit errors (failure tolerance), openness for idea exchange. We have wanted to know if a good innovation culture fosters idea generation and innovation culture. The interview partner from our case study example argued: *“Some partners give detailed hints regarding things to notice and things we have to scrutinize to have success. Furthermore, constructive criticism will be expressed.”*

5.7 Mutual Idea Generation

The research question for us has been: how can mutual idea generation work in cooperation and specifically how can it be fostered. There are many idea creation tools and techniques available. The question is if they are used? Our interviewee from our case study cooperation admitted: *“There are no tools that we have used to foster idea creation. There should but there was nothing.”*

Holding idea creation workshops is an effective possibility to develop mutually new ideas. We wanted to know from our case study interviewee if it had been used in his past cooperation. The interviewee answered: *“Most of the time, a project meeting is being used to exchange ideas and to present the latest developments. At the beginning of the project, there are sometimes workshops in which the problem is being defined and a fundamental solution is being searched. During the project until the end of the project, the idea search is getting gradually smaller. [...] An idea creation workshop might make sense at the beginning and in the middle of a project.”* Information technologies has given us many new ways to communicate and to exchange ideas. Are these technical possibilities used especially in research institutes as cooperation partners? Our interviewee from a research institute answered: *“Meetings are the best way to exchange ideas.”* That mean that face time is still the best way to exchange ideas regarding to our interviewee. Nevertheless, virtual meetings are a new way to connect and hold meetings face to face. We wanted to know if those virtual meetings are as effective

as regular meetings. Our interviewee's opinion was: *"There is a trend to hold virtual meetings. However, physical meetings are more effective."*

5.8 Knowledge/Know-How Exchange

For gathering and exchange knowledge (documents, studies, data, etc.) for example, tools can be used such as Intranet webpage, Dropbox, and Googledocs. The answer of our interviewee were: *"There has been no preferred way. There was one occasion in which one partner wanted to have a separate data exchange transfer with the research institute and did not want that other partners know."* Consequently, we asked if more knowledge management and tools for idea creation used should be used and if it is useful for the cooperation. Our interviewee stated: *"Yes I think. A project server as knowledge management tools is a useful tool. There is often a moment when you think about a presentation at a former project meeting and you want to see the slides. Then, if there is a well maintained project server one can download the presentation one needs."* The interviewee thinks a project server is the most efficient tool to exchange knowledge: *"A project server is a very practical tool and the implementation is easy."* Another tool to exchange knowledge are social networks such as Xing and LinkedIn but our interviewee thought it is not useful.

Is there a methodical approach? *"There is no methodical approach. It is just common sense. When a project starts one will know what we have to do, is there any problem, and how can we solve it. That is not a sophisticated method. It would be a good idea if there we use a method."*

There are many possibilities available how a consortium a mutual creation and development can design. Within the last years, many software and cloud services appeared and offer the possibility to share data, form work teams, and talk to each other. Those digital platforms are for example Live Link, Moodle, etc., data exchange platforms such as Googledocs, etc., information exchange platforms such as wikis, blogs, forums, social media platforms such as Facebook, Xing, Research Gate, etc.

5.9 New Products/Services, Technologies and acquired knowledge based on the Combination of different Technologies for multiple Applications

There are many ways to measure the success of cooperation and the opinions what a success is differ. Individual success depends on the goals of each participant. We measure

the success of the mutual idea generation and the knowledge/know-how exchange by the amount and the quality of new ideas. Moreover, it is even rated as success when knowledge has been learned in a common project and there has been no further outcome. Our case study interviewee replied that many interdisciplinary cooperation result in learning effects and knowledge which cannot instantly used for new products especially when research institutes are involved. This knowledge might be useful in the future at later projects.

5.10 Outside-In and Inside-Out Technology Exploitation

Furthermore, we screen the outside-in and inside-out knowledge exploitation. If the partners of the cooperation origin from different application and technology fields, it gives the larger opportunity of a better market coverage and a mutual exploitation strategy than partners from the same technology area. For example, an option is that different partners cover different stages of the value chain and built up a supply, distribution, and sales chain. That enables benefits for all participating organizations and is rated as success of the cooperation.

6 Conclusion

The study has shown that the factors partner perspective and cooperation background influence the idea creation and the mutual knowledge management in multidisciplinary and multisectoral cooperation. We tested our research model with a research partner of a large cooperation in the 3D measurement area. The following table provides a summary of the results of the case study.

Factors	First Results from the Case Study
Partner's Perspective	
Motivation (Goals) and Expectation	Important reasons for the participation in the case study cooperation were the idea generation about new applications of the existing technology and learning of multidisciplinary knowledge about technologies and their applications. Partners should have appropriate expectations towards the cooperation. Too low expectations signify bias and may hinder idea creation by an engagement.
Perceived Risks	Risk awareness can influence the behaviour of the participating partners regarding their idea generation potential in a cooperation. The interviewed partner has not seen risks, such as knowledge drain, and if there are risks it is a matter of coping with them. So,

	potential risks should not prevent partners from exchanging ideas. Otherwise, the cooperation will fail. Tools such as non-disclosure and cooperation agreements reduce those knowledge related risks.
Experiences	Prior made experiences influence the level of trust in cooperation. Research institutes in comparison to companies sometimes do not need to be so concerned about their know-how protection.
Cooperation Background	
Base of Trust	Goals of the partners should not be a secret in the cooperation. This rises distrust and hinders idea creation and knowledge exchange.
Organizational Structure and Rules	Rules especially regarding to ideas and knowledge exchange should be determined by contracts. Non-disclosure agreements are usually used. The cooperation agreement and the organizational structure should provide a framework for trust and improve idea creation and knowledge exchange. Over detailed agreements raise distrust and hinder idea generation. The coordinator of the cooperation also influences the success of the idea generation in the cooperation. Partners call fall behind their goals and stay inactive for a long time. A strong coordinator takes care of the idea generation and thus advances the knowledge output of the cooperation.
Innovation Culture	Getting feedback about ideas is important in a cooperation but the feedback must be constructive. Otherwise it will hinder idea generation.
Mutual Knowledge Management	
Mutual Idea Generation	There are many idea creation tools available but they are not used often. Project meetings are being used to exchange ideas and present latest developments. At the start of the cooperation, workshops are used for problem defining and searching for fundamental solutions. While the project is running, idea generation lowers. Despite of many new digital possibilities of meeting people, face to face meetings are always the most effective way to create and exchange ideas.
Knowledge Exchange	Regarding to our interviewee, a well maintained project server is the best way to exchange data and ideas, and keep a knowledge record of the project.
Coupled Open Innovation Performance of Multidisciplinary and Multisectoral Cooperation	
New Products/ Services, Technologies and acquired knowledge based on the Combination of different Technologies for multiple Applications	The transition of research and development ideas into products is always the top goal. If it is sometimes not possible, a learning process of multidisciplinary technology knowledge and multidisciplinary application knowledge and thus the extension of the knowledge base is a successful outcome.
Outside In and Inside Out Technology Exploitation	A mutual exploitation for example for organizations along the value creation chain is profitable. Furthermore, the access to diverse markets with new applications by using the help of partners is a success for the cooperation.

Structured Abstract

Purpose – In an ever-changing business environment, organizations have begun to recognize the importance of behaviors that emphasize employee initiative, such as making constructive suggestions for change and innovation (LePine and Van Dyne, 2001). Different initiatives have been taken by private and public organizations to leverage arts as potential drivers and motivational factors spurring people to act in a certain way and create value. However, we still lack research that builds on behavioral studies to investigate the relationship between arts-based initiatives and individual and group performance. This paper recognizes such limitations, shows the centrality of understanding human behavior to optimize performance-oriented actions, provides a theoretical framework that emphasizes behavior's antecedents and consequences, and addresses the value of arts from both theoretical and practical perspectives in cultivating the right attitudes that have the potential to drive consequently people actions and performance.

Design/methodology/approach – This research is based on a thorough literature review including five major fields: human resource development, applied psychology, the knowledge-based view of the firm, performance management, and arts-based management. The purpose is to review the theoretical assumptions of each field and develop a theoretical framework that draws connections between arts-based initiatives, behavioral drivers, contextual factors, and human performance. This research will also draw on a few cases to provide empirical evidence on how arts-based initiatives affect human performance through behavioral alignment and outcomes.

Originality/value – This research provides a theoretical framework and empirical evidence on how arts-based initiatives drive behavior and human performance. This will help organizations to better understand the behavioral consequences of arts-based initiatives and how they translate into performance outcomes.

Practical implications – This research suggests new assumptions and perspectives that show the centrality of human behavior in organizations and lays the foundations of a behavior-based performance management model. Such an understanding will help both scholars and practitioners develop theories and tools linking arts-based investments to individual and organizational performance outcomes.

Keywords – behavior-based performance, arts-based initiatives, behavior antecedents, behavior consequences, performance management

Paper type – Academic Research Paper

1 Introduction

In the current era, characterized by dynamic societal, technological, and economic changes as well as an increasing diversity in the workforce, previous approaches to job performance are being challenged. We can identify at least two distinct perspectives to job performance: behavioral and outcome (Campbell et al., 1993; Sonnentag and Frese, 2002). Performance in effect encompasses different dimensions and there is a need to focus on specific behaviors that contribute to organizational effectiveness in particular jobs, work groups, and organizations (LePine and Van Dyne, 2001).

For over 50 years, scholars have recognized the importance of behavior that is not strictly role prescribed but contributes to organizational effectiveness indirectly through the development and maintenance of the organization's social and psychological context (e.g. Barnard, 1938; Katz and Kahn, 1978; LePine and Van Dyne, 2001). Borman and Motowidlo (1997) distinguished between two types of performance: Task performance that focuses on valuable behaviors that contribute to the core technical activities and contextual performance which includes behaviors that maintain or improve the organizational, social or psychological environment of work (Motowidlo et al., 1997). This view is also consistently reflected in team process research (e.g. Stewart and Barrick, 2000) where team effectiveness or success has been shown to depend on two

mechanisms: behaviors related to the task itself (technical) and behaviors that promote the socio-emotional context of the group (social).

Job performance in organizations is greatly influenced by organizational constraints (Evans, 1986). Individual behavior is also a primary determinant of two categories of organizational outcomes: the level of organizational performance and the level of organization members' individual development (Robertson et al., 1993). Researchers in the field of organizational behavior focus on the study and understanding of individual and group behavior and patterns of structure in order to improve organizational performance and effectiveness (Mullins, 2005; Robbins, 2005).

Investments have also been made in different organizational systems to direct individual and group behavior and enhance their motivation, commitment and engagement. Different initiatives have been taken by private and public organizations to leverage arts as potential drivers and motivational factors spurring people to act in a certain way and create value. However, we still lack research that builds on behavioral studies to investigate the relationship between arts-based initiatives and individual and group performance. This paper recognizes such limitations, shows the centrality of understanding human behavior to optimize performance-oriented actions, provides a theoretical framework that emphasizes behavior' antecedents and consequences, and addresses the value of arts from both theoretical and practical perspectives in cultivating the right attitudes that have the potential to drive consequently people actions and performance. This research sheds also light on the interplay between arts-based initiatives, contextual factors, and various behavioral drivers. The objective is to gain a better understanding of behavior dynamics in organizations and their effect on people performance through the lens of arts-based initiatives. Such an understanding will help to lay the foundations for a behavior-based performance management model linking arts-based initiatives to individual and organizational performance.

For this purpose, this research draws on the following guiding principles: (1) organizations are contexts within which people behave (Robertson et al., 1993), (2) effective behavior of individuals in organizations is multifaceted (Evans, 1986), and (3) any behavior is always a function of person and situation (Lewin, 1936; Rosenstiel, 2011).

This research is based on a literature review encompassing published scholarly articles in applied psychology, organizational behavior, organization development,

performance management, human resource development, and arts-based management. Specific keywords in relation to behavior and performance constructs were used to search two journal databases: EBSCO and JSTOR. The articles were then reviewed, and selected based on their relevance for the study. The retained articles were summarized and stored in a Procite database and the main findings are presented in this paper.

The aim of this paper is to show the importance of integrating the construct of behavior in performance management research and practice and provide guidelines on how performance management can learn from both research in organizational behavior and human resource development and practice in arts-based management to develop more appropriate tools that can help organizations enhance their effectiveness.

The remainder of this paper is organized as follows: first, we define behavior from both psychological and organizational perspectives. Then, we identify the major antecedents and drivers of individual behavior in organizations, emphasizing those factors that can influence and direct people behaviors in work settings, and we discuss the behavior consequences and their effects on individual and group performance and organizational effectiveness. Next, we investigate how arts-based initiatives represent behavioral and performance drivers. Finally, we provide guidelines showing the centrality of human behavior in performance management research and practice, and we present empirical evidence based on case studies to demonstrate the value of arts to human performance.

2 Explicating behavior

The study of behavior can be viewed in terms of three main disciplines – psychology, sociology, and anthropology (Chaneta, 2010). Effective behavior of individuals in organizations is multifaceted. Human behavior is both a function of person and context and a function of their interrelationships (e.g. Edwards, 1996: person-environment fit; Conrad and Haynes, 2001: actor-structure dualism). Weiner (1986) and other researchers have demonstrated the usefulness of distinguishing between internal and external as well as stable and unstable factors, which have distinct emotional and motivational consequences.

A central concept to understanding human behavior is the notion of attitude. An attitude is a learned predisposition to respond in a consistently favorable or unfavorable

manner with respect to a given object (Fishbein and Ajzan, 1975). When specific attitudes are organized into a hierarchical structure, they comprise value systems (Katz, 1964). Attitudes can be examined through the use of a model that treats the concept from the arousal process (Guerin, 1970): (1) a cognitive factor acts as a stimulus, (2) it is interpreted through the needs and value system of the individual, (3) then the attitude is aroused. Following this process, attitudes act as behavioral triggers based on a stimulus-response consistency (Katz, 1964).

The stimulus-response consistency refers also to our perception or the process whereby individuals organize and interpret their sensory impressions in order to give meaning to their environment and construct what they call reality (Robbins and DeCenzo, 2008). Different factors shape and sometimes distort perception and consequently our intention to engage or not in a certain behavior. These factors can reside in the perceiver (i.e. personality, motives, interests, past experiences etc.), in the object being perceived, or in the context in which perception is made. Hayek (1952) asserts that stimuli cannot be perceived by an individual in their original and pure shape, they are only perceived when connected with other stimuli. Also, perceiving is not a passive act; it entails an act of interpretation (Rizzello, 1999). Such an interpretation refers to individuals' genetic background and individual experience, but also to primary dispositions that developed over time in society. An example of such dispositions is habit whereby individuals engage in previously adopted or acquired behavior or thoughts, triggered by an appropriate stimulus or context (Hodgson, 2006).

Philosophy, psychology and sociology suggest that people explain intentional behavior differently from unintentional behavior, and these different explanations have typically been called respectively reason explanations (Kalish, 1998) and causal explanations (Heider, 1958). Most authors describe reasons as mental states like beliefs or desires that both motivate and rationally support intentional action (e.g. Anscombe, 1957; Davidson, 1963; Goldman, 1970), and they describe intentions as mediating between reasons and action (Brand, 1984; Bratman, 1987; Mele, 1992; Searle, 1993). Intentionality consists hence in a self-reflective control which we exercise over our current behavior (Joas, 1996).

Attribution theory has been the predominant psychological account of people's behavior explanations, focusing on the various causes that people assign to behavior (e.g. Heider, 1958; Jones and Davis, 1965; Kelly, 1967, 1973; Weiner, 1986). Through

processes of perception and attribution, individuals form beliefs regarding their organizational environment (Robertson et al., 1993). These beliefs, energize, direct, and regulate behavior (Bernstein and Burke, 1989). Actors tend to attribute their own behavior to situational causes whereas observers tend to attribute the same behaviors to stable dispositions (Jones and Nisbett, 1972). Cognitive dissonance theory asserts that individuals will behave in a manner that supports their attitudes and beliefs to avoid the dissonance (negative stimulation) that is caused by an inconsistency between opposed beliefs and behavior (Festinger, 1957).

It is largely recognized that people perception, attitudes, intentions and behaviors are driven by their personality. An individual's personality is the combination of the psychological traits that characterize that person (Robbins and DeCenzo, 2008). Nearly all personality traits that can be diagnosed in adults – whether cognitive or motivational – are genetically based to a certain extent and therefore largely stable (Rosenstiel, 2011). A widely used model to view personality is the Big Five Model (Digman, 1990) that delineates five factors of personality including extroversion, agreeableness, conscientiousness, emotional stability, and openness to experience. Research has shown that important relationships exist between these personality dimensions and job performance (e.g. Vittorio et al., 2001; Hurtz and Donovan, 2000; Hochwarter et al., 2000).

There is also a growing recognition that individual values play an important role in shaping employees' work behaviors (Higgs and Lichtenstein, 2010; Meglino and Ravlin, 1998; Cha and Edmonson, 2006). Hayek (1952) views individuals as driven by moral sentiments that can never be explained following a fully rational concept (Gick, 2003). Allport (1955) also emphasized that individual's value priorities influence their perception of reality and in turn their behavior. Caprara et al. (2006) found that values were more powerful in explaining behavioral variation than personality traits. Personality traits are largely endogenous characteristics whilst personal values are learned adaptations strongly influenced by the environment (Oliver and Mooradian, 2003).

While people respond to the way they perceive their environment this facilitates their learning. Learning theorists typically segment learning into three different distinct stages that represent the different learning processes occurring over time (Mone and Shalley, 1995; Kanfer and Ackerman, 1989): declarative stage, knowledge compilation stage, and procedural stage of learning. Social learning theory (Bandura, 1977) recognizes that

individuals learn through both observation and direct experience. In fact, learning is defined as any relatively permanent change in behavior that occurs as a result of experience (Robbins and DeCenzo, 2008). Motives, personal preferences and attitudes change and develop over time, and these changes have an impact on work behavior (Schalk et al., 2011).

Learning behavior is a process forming and storing a connection between a stimulating signal and a specifically resulting signal (Whitlock et al., 2006). Operant conditioning (Skinner, 1971) argues that behavior is a function of its consequences. Operant behavior is voluntary or learned rather than reflexive or unlearned behavior. When consequences are pleasant, people tend to repeat and reinforce their behaviors. Manz and Sims (1980) define reinforcement contingencies as environmental cues that precede employee behavior (i.e., discriminative stimuli), and to the rewards that subsequently reinforce employee behavior.

When learning occurs, new knowledge is acquired. Knowledge is memorized in rules of perception and in rules of conduct (Hayek, 1978). Rules include norms of behavior and social conventions as well as legal rules (Hodgson, 2006). Knowledge can also be regarded as mental model or belief (North and Denzau, 1994). Knowledge is a stable connection between one signal (event) and another signal (event) owned by an individual. New knowledge is from new signals. Accumulation of knowledge is the storage of the stable connections (Zhu and Zhao, 2008). Such stable connections are mainly synaptic connections in human brain transmitting, receiving and processing electrical-chemical signals from neurotransmitters within a synapse. Cognitive theory indicates that knowledge serves as the medium for the formation and maintenance of schemes (Gagnon et al., 2008). Schemes are cognitive structures that individuals create and use to make order of the world.

When receiving a signal or feedback signal from outside, an individual processes it, compares it with stable and unstable preferences and knowledge, then maintains the original preferences, knowledge and behavioral pattern, or adjusts them and forms the new ones (Zhu and Zhao, 1998). When a new signal just causes the unstable knowledge to change, an individual behavior pattern may be changed. Such complex dynamics make both rationality and bounded rationality very limitative in explaining human behavior in its entirety (Cosmides et al., 1994).

This discussion leads us to the following proposition:

Proposition 1: Behavior is a consequence of a perceptual process involving external stimuli and the individual value system. Individual personality plays a moderating role between perception, attitudes, intentions, and behaviors. Learning is a consequence to individual behavior and it occurs through shaping up the unstable patterns of personality.

Figure 1: Explicating behavior

3.1 Behavior antecedents

Whilst the social psychology literature suggests that social norms and personal attitudes predict human behavior (Fishbein and Ajzan, 1975; Trafimow, 2000) the social cognitive theory explains human functioning in terms of a triadic model of dynamic interplay between the environment, individual cognitive state and attitudes (Bandura, 1977). Behavior is also affected by patterns of organizational structure, technology, styles of leadership and systems of management (Chaneta, 2010). An organizational work setting comprises four major interrelated subsystems: organizing arrangements, social factors, technology, and physical setting (Porrás, 1987; Porrás and Robertson, 1992). Rosenstiel (2011) states that “the behavior of people in organizations is not only dependent on the characteristics of the person but also on the general conditions, the rules, regulations, job descriptions and other explicit guidelines, but also on informal norms inside the group and the corporate culture, but also on hard conducive or obstructive conditions (i.e. resources and barriers).”

The variables affecting behavior fall into three major classes: (1) ability to do the job, (2) motivation to do the job, and (3) external factors that facilitate or constrain doing the job (Evans, 1986). Thorndike (1920), as well as contemporary scholars of intelligence (e.g., Gardner, 1983; Sternberg et al., 2000), recognized that a model of intelligence based only on intellectual capacity and abilities is insufficient to explain human capabilities and behavior in real life (Ashkanasy and Daus, 2005). Emotions should also be considered as

part of human intelligence. Some scholars have characterized this type of intelligence as emotional intelligence defined as an individual's ability to perceive emotion in self and others, to understand emotion, and then to manage emotion in self and others (Barsade et al., 2003; Salovey and Mayer 1990; Mayer and Salovey, 1997; Ashkanasy and Daus, 2005; Sala, 2002).

Motivation variables include the intrapersonal concepts of intention, cognition (sense of efficacy and performance-reward expectancies), and values (Evans, 1986). We can identify three major theories of motivation: expectancy theory (Vroom, 1964), goal setting theory (Locke et al., 1981), and achievement theory (e.g. Weiner, 1972). The rapprochement among these theories has been based on a large extent on the social learning theory developed by Bandura (1977) and articulated by Weiner (1985). Motivation is different from satisfaction. While motivation is generally defined as the energy spurring people to act in a certain way, job satisfaction is mostly viewed as an attitude to different facets of the work situation (Neuberger and Allerbeck, 1978). Satisfaction or the emotional states resulting from the positive evaluation of work experiences influence organizational climate. Motivation is also related to commitment defined as an individual's attachment and willingness to support his or her organization (Mowday et al., 1982).

The job characteristics model (Hackman and Oldham, 1980) posits that job characteristics (comprising skill variety, task identity, task significance, autonomy and feedback) should enhance work performance through three psychological states (experienced meaningfulness, experienced responsibility and knowledge of results). The job characteristics affect performance and satisfaction through motivation (Evans, 1986). For instance, feedback as a determinant of behavior receives much attention in the management literature (Balcazar et al., 1985; Locke and Latham, 1990). By feedback we mean objective data about performance against goals. Individual behavior is influenced by the goals that a person chooses or accepts. Although people have been shown to use search-reduction heuristics in past research (e.g. Payne, 1976), Mone and Shalley (1995) found that individuals with specific difficult goals on complex tasks actually engaged in greater change in strategy. Role conflict, role ambiguity, and experienced stress would also affect the extent to which goals and intentions can be translated into accomplishment.

Goal setting and acceptance as well as feedback-seeking behavior are influenced by individual and organizational cultural orientation (De Luque and Sommer, 2000). An

organization, too, has personality which we call its culture (Chaneta, 2010). Organizational culture is a system of shared meaning within an organization that determines, in large degree, how employees act (Robbins and Coulter, 1996). In every organization there are systems or patterns of values, symbols, rituals, myths, and practices that have evolved over time (Chaneta, 2010). Hofstede (1980) developed four value dimensions along which culture may vary: (1) individualism-collectivism; (2) uncertainty avoidance; (3) quantity-quality; and (4) power distance. Such dimensions direct individual behavior.

Individual work behavior is driven by personal goals and organizational factors as well as social networks (Robertson et al., 1993). For instance, group pressures and dynamics including groupthink and social loafing can have a major influence over the behavior and performance of individual members (Albanese and Van Fleet, 1985; Chaneta, 2010). In a social system, the behavior among the members is ensured by altruism, solidarity, sympathy and group decisions and is considered the morality of the small group (Hayek, 1979). Multilevel analysis showed that collective efficacy, or the shared perception of team capability, influences the extent to which an individual engage in a certain behavior (Bandura, 1977; Tasa et al., 2011).

Other organizational factors including leadership and empowerment can influence individual behavior. Leadership can be described as a process through which the supervisor structures reinforcement contingencies that modify the behavior of subordinates (Sims, 1977). Leadership has implications for developing commitment and increasing compliance in task behavior, influencing group maintenance and identification, and influencing the culture and climate of an organization (Guzzo and Salas, 1995; Bass, 1990). Similarly, Empowerment climate and psychological empowerment play complementary roles in engendering individual and team performance behaviors (Tuuli and Rowlinson, 2009).

This discussion leads us to the following proposition:

Proposition 2: Different individual and organizational factors influence the perceptual process and affect consequently individual attitudes, intentions, and behavior. Such factors include for instance individual cognition and intelligence, motivational characteristics, job characteristics, the management system, and the organizational culture.

3.2 Behavior consequences

Job performance behaviors are defined as the measurable behaviors that are relevant to the achievement of organizational goals (Campbell et al., 1993). A study conducted by Choi (2004) determined that both organizational context and individual characteristics influence employees' innovation-use behavior. In a similar vein, Dorenbosch et al. (2005) found a strong positive relationship, indicating that a proactive attitude as ownership promotes the generation and implementation of ideas within the work context. Motowidlo et al. (1997) also specify a stronger link between personality characteristics and contextual performance. Similarly, individual psychological characteristics including perceived self-efficacy, personality, and commitment were identified as determinants for knowledge sharing as an individual behavior (O'Reilly and Chatman, 1986; Bock and Kim, 2002; Cabrera et al., 2006; Wang, 2004).

Contextual performance research has focused primarily on conformistic or cooperative behaviors and not on change-oriented behaviors such as voice (Speier and Frese, 1997). Scholars have begun to recognize the importance of behaviors that emphasize employee initiative, such as making constructive suggestions for change (e.g., LePine and Van Dyne, 1998; Nemeth and Staw, 1989; Scott and Bruce, 1994).

Organizational qualities such as decentralization, job enlargement and participative management can also promote behaviors that result in beneficial experiences for organization members (e.g. Likert, 1967; McGregor, 1960). In contrast, organizational characteristics designed to control members' behavior can generate behavioral reactions such as aggression, withdrawal, apathy, and minimization of the amount of work performed (Strauss, 1963). An increased body of evidence suggests also that strong cultures are associated with high organizational performance through their effect on individual behavior (Chaneta, 2010).

Organizational researchers have been investigating the relationship between job satisfaction, job performance and productivity for decades. However, they have been unsuccessful in finding strong or consistent correlations between these constructs (Brayfield and Crockett, 1955; Vroom, 1964; Johnston, 1976). For instance, Waters et al., (1974) found no relationship between the climate dimensions and the effort and performance variables. Similarly, Fisher (1980) asserts that neither organizational climate nor leadership style has been unambiguously and consistently related to individual performance.

Early empirical research in psychology indicated that motivation and performance are significantly influenced by feedback (Ammons, 1956). Those in the field of organizational behavior continue to promote feedback as a cue for motivation, performance, and learning (Castellan and Swaine, 1977; Earley, 1988; Koestner et al., 1987; Lee and Yates, 1992; Vroom, 1964). The motivation of employees to engage in proactive or extra-role behavior is the focus of research on concepts such as ‘organizational citizenship behavior’ (Organ, 1988), ‘personal initiative’ (Frese et al., 1996), ‘employee creativity’ (Oldham and Cummings, 1996) or ‘critical reflective behavior’ (Van Woerkom, 2003).

Team effectiveness has also been shown to depend on two mechanisms: behaviors related to the task itself (technical) and behaviors that promote the socio-emotional context of the group (social) (Stewart and Barrick, 2000). Teamwork behavior is described as activities that are devoted to enhancing the quality of the interactions, interdependencies, cooperation, and coordination of teams (Morgan et al., 1993). Collective efficacy influences the relations between individual traits and behaviors in teams (Tasa et al., 2011). Collective efficacy has been shown to relate to group cohesion (Lee et al., 2002; Lent et al., 2006) and group cooperation and communication (Lester et al., 2002). In contrast, negative group behaviors such as ego-defensiveness resulting from the dissonance created by pressure of threat or inducement may lead to hostility, rationalization, and withdrawal may be the consequence (Guerin, 1970).

This discussion leads us to the following proposition:

Proposition 3: Individual behavior affects team and organizational performance. Such performance translates into cooperative and/or change-oriented behavior, positive working atmosphere, an organizational climate conducive to learning and productivity, and increased individual motivation and commitment.

4 Implications for performance management

The analysis of the interplay between individual characteristics and organizational elements, their influence on both intentional and unintentional behavior, and the subsequent effects in terms of satisfaction, motivation and performance will help us address specific principles that can guide the development of behavior-based performance management systems in organizations.

First, there is a clear need to distinguish between measuring behavioral antecedents and triggers, employee behavior at work, motivation and performance. Referring to job satisfaction and the difficulty to establish a relationship between this construct and employee productivity, Fisher (1980) suggests that attitude measures should be related to specific job behaviors, while general satisfaction measures should be related to the favorableness or unfavorableness of an individual's total set of work-related behavior.

Second, there is a need to integrate human behavior as a variable in existing performance management and measurement systems and tools. Most of the existing systems try to establish a cause-effect relationship between organizational investments in human capital, processes, and performance consequences taking for granted that these investments will help people achieve their goals and without a clear understanding of how such investments can push people to act in a certain way. Behavioral dynamics in relation to such organizational initiatives remains a missing area of research in performance management.

Third, there is a need for more qualitative measures to understand employee behavior and to link it to desirable organizational objectives. The majority of existing goal-setting studies that measure performance have a primarily focus on quantity rather than quality measures (Austin and Bobko, 1985). An alternative venue would be to integrate the four measurement criteria suggested by Kirkpatrick (1987) including subjective reactions, improvement of knowledge, change of behavior, and then 'hard' performance improvements.

Fourth, we should rethink the way individual and team performance are managed in organizations and adopt a holistic perspective that encompasses different organizational and managerial characteristics and considers the interplay between such elements and individual characteristics. Structural variables, culture, communication, job and process design, management functions and leadership styles all influence people attitudes through perceptual mechanisms that draw on stable personality traits, mental states and learned behavioral patterns. Efforts should be made to relate organizational, structural and managerial characteristics to desired behavioral patterns for a better alignment between strategic and operational objectives and behavior expectations and changes.

Fifth, to build a performance management system conducive to learning, motivation, and performance, we can open up the field's boundaries to integrate frameworks, models and applications from other fields like human resource management and development

(Swanson and Holton III, 2001), organizational behavior (Robbins, 2005), organization development (McLean, 2006) and applied psychology (DuBrin, 2004). Over the past years, large body of knowledge was consolidated in such fields to disentangle the complexities revolving around human and group dynamics in organizations and develop planned interventions using behavioral-science knowledge to increase organizational effectiveness. For instance, in human resource management different applications proved to be successful in boosting individual and organizational performance including behavioral interviewing techniques to ensure a better person-organization fit, employee orientation processes, training and development, performance and potential appraisal, talent management and succession planning, and total compensation and rewards systems to align between organizational goals and individual objectives.

Finally, while pursuing such a behavioral orientation, research in the field of performance management should also use more ethnographic methodologies, obtrusive and unobtrusive observations to grasp the soft attitudinal determinants of performance. As correctly stated by Thomas (1984), the survey still dominates in the analysis of employee behavior in organizations. Experiments and action research which could provide clearer statement regarding causality are rarely carried out (Rosenstiel, 2011). We pay much more attention to validity and reliability but sometime at the expense of data and finding accuracy.

This discussion leads us to the following proposition:

Proposition 4. Performance management must target individual and team behaviors while considering their respective antecedents and consequences. Investments to enhance performance should emphasize behavioral and contextual factors and must rely on soft and qualitative indicators to measure learning and performance outcomes.

In the next section, we will explore how arts-based initiatives used as performance management triggers can influence people behavior and help an organization generate value.

5 Arts-based Initiatives as behavioral and performance drivers

In today's socio-economic scenario, organizations have to become agile, intuitive, imaginative, flexible to change and innovative to meet the complexity and turbulence of the new business age. They have to shift their focus from efficiency to adaptability and

transformation to cope with emergent business challenges. Following such a view an emergent employee's challenge to be faced is how to engage, energize and inspire people so that they can exercise their feelings in everyday working activities and operate as innovation and transformational agents.

The arts can represent a powerful instrument that organizations can deploy to develop people's emotional and energetic dynamics and support the enhancement of organizational value creation capacity. Especially the planned managerial use of art forms (i.e. Arts-based Initiatives - ABIs) can sustain organizations in their efforts to face today's competitive challenges and improve their value creation capability.

An ABI can be defined as any organizational and management intervention using one or more art forms to enable people to undergo an art experience within an organizational context, as well as to embed the arts as a business asset. It is primarily and fundamentally an experience-based process involving and engaging people both rationally and emotionally through either active or passive participation (Schiuma, 2011).

The focus of an ABI is not the work of art in itself, but the arts experience instead. An ABI is intended to use works of art and arts as media to trigger, catalyze, drive, harness and govern the emotional and energetic dimensions of an organization which can have an impact on people and/or on the organizational infrastructure of tangible and intangible assets. Through ABIs new strategic organizational value drivers, such as passion, emotions, hope, moral, imagination, aspirations, and creativity (Boyatzis et al., 2002; Bruch and Ghoshal, 2003; Cross et al., 2003; Gratton, 2007; Steers et al., 2004) can be fruitfully developed, generally first at the individual level, engaging a person emotionally and intellectually, and then at group and organization levels.

Undoubtedly, the value generated from arts experiences is extremely difficult to quantify using money as unit of measurement. Regardless of artworks that can also represent investments and that their value can be measured through the price, assessing the outcomes of ABIs is challenging. This is because any arts experience tends to meet different needs which are subjective, idiosyncratic, context- and time-related. Moreover, their effects on individual and organizational change are basically intangible in nature, elusive and hard to quantify, especially in economic terms.

Despite this, the analysis of the adoption of ABIs within organizations has led to the definition of two fundamental implications which represent two essential assumptions for the assessment of the organizational value of ABIs.

The first assumption is that ABIs do not have a clear and direct link to the bottom line. Except those cases in which ABIs either correspond to specific business activities in the cultural sector aimed to generate cash flow, or equal to real estate investments, it is extremely difficult if not impossible to draw a direct link between arts initiatives and economic returns.

The second assumption is that the benefits of ABIs will be fundamentally found within the positive impacts that they have on individual and organizational behavior and on developing business value drivers. These mainly refer to intangible and knowledge-based assets, grounding business competencies and affecting the efficiency and effectiveness of business processes. In particular, an ABI can have an impact on two fundamental dimensions of a business: (1) the organization's human resources, and potentially any other organizational stakeholders; and (2) the infrastructure, or overall tangible and intangible structural assets grounding the working mechanisms of the business model. Therefore, the assessment as well as the planning of an ABI have to take account of both dimensions of a business: the change of people behaviors and the organizational infrastructure development.

In his book "The Value of Arts for Business", Schiuma (2011) proposes a framework, the "Arts Value Map", to support management in the understanding of how ABIs drive the improvement of business performance. The framework provides a mapping-based assessment methodology to grasp how ABIs can be converted into business performance improvements. In particular, the "Arts Value Map" elucidates the pathways through which the adoption of ABIs affects the development of the knowledge-based, competence-based and process-based dimensions of an organization and improves business performance (Figure 2).

The fundamental assumption at the basis of the Arts Value Map is that the growth of knowledge assets operates as a key driver to activate value creation dynamics (Carlucci et al., 2004; Carlucci and Schiuma, 2007). The development of organizational knowledge domains improves organizational capabilities enabling a better execution of business processes that in turn allows an improvement of organizational performance and, more generally, the achievement of business and strategic objectives.

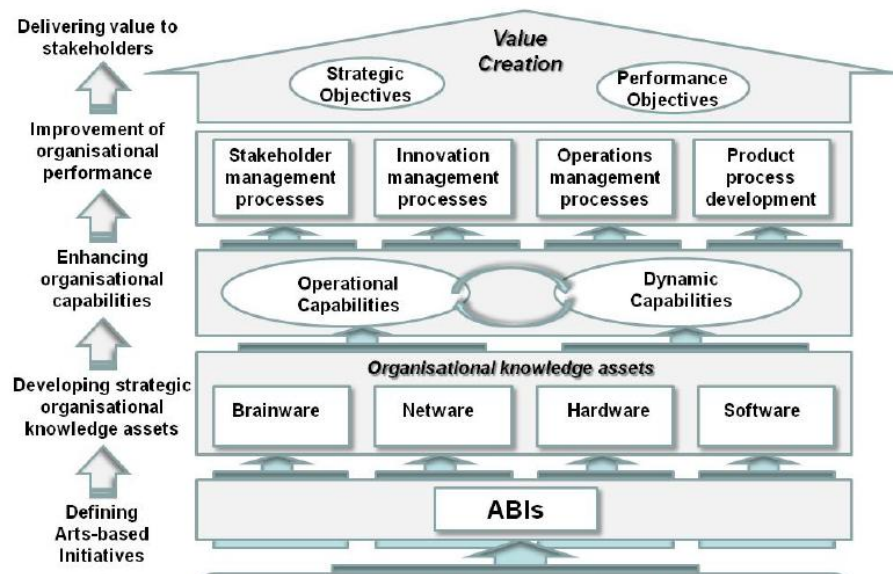

Figure 2: The Arts Value Map (Schiuma, 2011)

6 The value of arts to human performance: empirical evidence

When approaching the use of art forms in organizations, it is important to be aware that the benefits of ABIs can be understood at different levels of analysis. A pivotal role is generally played by individuals. Indeed, individuals are those that finally capture the benefits of using the arts in business.

ABIs are able to communicate and/or create aesthetic experiential processes that can affect people's emotional states and behavior. Undoubtedly, the intensity of people change and development produced by ABIs can be different. ABIs can have 'transient impact' on people and their emotional and energetic states. In this case people that experience an ABI feel engaged, emotionally and energetically aroused, but the ABI's effects fundamentally disappear after the arts-based experience has finished. Sometimes ABIs can affect people's way of seeing and approaching the reality around them for a longer period of time. This energy results in a short-term behavioral change that can be properly channelled for action. Finally, ABIs can lead people to analyze and eventually challenge their beliefs and values, deeply affecting their attitudes that in turn can drive change with the emergence of new personal behaviors.

In order to shed more light on the value of ABIs as drivers of people behavior and performance, we analyze hereafter some relevant case studies stemming from real-life applications of arts-based initiatives (source: Schiuma, 2011). The overall purpose of the case evidence is to highlight relevant insights on how the implementation of ABIs intervenes in behavioral change and development. Following the assumptions underpinning our theoretical framework, the analysis focuses on how ABIs can mould people's behavioral intentions and affect, somewhat, individual organizational performance outcomes.

Case study 1: instilling collaborative behavior

Nestlè has been pioneer in the integration of arts in its management system. Among the many ABIs, Nestlè has developed an initiative based on a mixture of the BBC TV shows *Dragons Den* and *The Apprentice with tradesecrets*. The aim of the artistic intervention was to enhance creativity as well as to develop communication skills and collaboration in terms of sharing ideas and expertise of team marketing.

Employees were taken to the venue where the original TV series was filmed and spurred on to develop ideas to generate new products with a combination of industry outsiders and brand specialists acting as facilitators. Participants were coached on their presentation style and then had to pitch to a panel of five 'dragons' made up of entrepreneurs and actors. The teams were allowed to view each other's presentation on monitors in a specially designed studio in the basement in order to learn from each other's successes and failures.

From a behavioral viewpoint, the initiative has galvanized people, arousing their emotions and energy and has increased employees' intention to adopt a more collaboratively behavior and perform generation and analysis of new ideas as a team.

Case study 2: reflecting on one's own behavior

ABI can be used to raise awareness of behaviors by tracking people's moods. In this regard, an interesting case example is represented by the arts-based project implemented at Unilever UK named 'Stimulating Reflection'. People were asked to choose between statements related to their daily business behaviors (such as: having fun; you have let a colleague down; this is the place to be; you have taken a risk; bureaucracy got in your way; you have passion for winning) by landing on mats, that had the statements written

on them. These mats incorporated sensors that made it possible to record the number of landings.

From a behavioral viewpoint, the artistic intervention provided an assessment of the organizational atmosphere and supported a self-reflection and self-awareness among employees about the individual behaviors that affect organizational climate.

Case study 3: changing people's attitudes in managing relationships with customers

Hall and Partners, a successful advertising research agency has developed a theatre-based program called 'Creative pitching', aimed at enabling employees to handle unexpected and strenuous situations. The agency was expanding rapidly in America, and needed their key personnel to develop the strength and confidence to win and keep clients and businesses such as Microsoft. As an extremely successful and rapidly growing company, people at Hall and Partners were asked to learn fast and particularly to understand how to deal with client relationships. Especially employees' behavior determinants, such as self-confidence, self-expression and communication skills needed to be developed.

To address this issue a theatre-based program was implemented. The premise underneath the initiative was that handling an encounter, a presentation and/or a relationship with a client is like a creative pitch. Just as in the theatre, where a performer must engage the audience both emotionally and intellectually to have an impact, relationship managers have to be able to engage client's hearts and minds. A theatre-based approach using improvisation skills was used. Theatre was used to rehearse meetings with senior clients, played both by actors and trainers. Many different live situations were tried out, with diverse things happening, involving improvisation and experimental approaches, tools and behaviors to improve employee competencies.

The initiative has contributed to increase the employees' intention not to be intimidated by senior figures; to get the best out of situations; and develop a self-management orientation and the ability to improvise. According to the CEO of the company, the theatre-based initiative, challenging and stretching people, made a real difference to employees' day-to-day performance, particularly in terms of changing people's attitudes in managing relationships with customers. Hall and Partners was voted as one of the top small businesses to work for by the Sunday Times. This can be

considered as a consequence, amongst other factors, of the adoption of innovative training approaches for employee development, such as the theatre-based program.

Case study 4: overcoming cultural barriers

Undergoing a takeover process from the French group Lafarge, Blue Circle Industries adopted percussion workshops as a team-building exercise and as a means of getting ready for the merger with a company of a very different culture. A percussion symphony was used as a metaphor for how different parts of the organization could work together. All the participants needed to learn to play in time together, working up to a grand finale.

The ABI was facilitated by the arts-based organization tradesecrets. The director of tradesecrets, played the role of a fictitious symphony orchestra conductor Gregor Timeriovich, who had an enormous ego and was obsessed with individuals. This subverted the whole procedure and he was eventually thrown out of the room.

The percussion workshop helped to look at the individual's role in the whole and what part they played for the ongoing success of the group.

The initiative has developed the employees' intention to overcome cultural barriers and establish fruitful relationships with employees of the merged company.

Case study 5: identifying "negative attitudes and behaviors" to look for better relationships

Television¹ had recently grown considerably in size as the result of a merger of a number of different companies, each with their own cultures and different ways of doing things. As a result, Television was looking to build a new corporate culture and establish new shared values and behaviors. For this purpose a set of questionnaires and focus groups at all levels of the organization were implemented to investigate perceived organizational values. However, Television recognized that simply talking about the new organizational values would be quite meaningless to people on a day-to-day basis and that they should make sure that the new values affected the way people actually behaved. The technical skills of Television's staff were second-to-none, but a culture had developed where staff relied on that alone and hid behind their technical expertise. This culture increased the employees' intentions to ignore the need for good relationships among colleagues.

¹ The real name has been changed for confidential reasons.

The training and development manager liaised with heads of departments and their staff, asking them to write short reports containing examples of 'bad behavior' between employees and between managers and staff. A great deal of material was produced, with examples of 'bad behavior' ranging from mild to very serious.

Thus, it was decided to use the approach of the forum theatre workshops to force people to reflect on the organizations' behaviors and to absorb and apply on day-to-day activities the new set of values. Ci: Creative intelligence was brought in with the task of designing and implementing the Values Roadshow, a program of forum theatre workshops to be run throughout the organization.

Starting from Television's reports on values and behaviors, Ci: Creative intelligence conducted an investigation to better understand the organizational context, interviewing staff, witnessing them at work, and viewing their finished products. They then wrote a play, with three scenes, incorporating many of the behaviors which had come out of the investigation. The play was rehearsed using actors which had an understanding of the corporate sector and the cultural and behavioral issues companies faced. The scenes illustrated familiar situations and issues with which people could relate. During the forum theatre workshops the audience was asked to correct the behaviors played in the scenes. The workshops were interactive with the actors responding to suggestions from the participants and re-performing the scene. By representing all of the behaviors found in the investigation into three short scenes as well as slightly exaggerating behaviors, they avoided stigmatizing participants as perpetrators of bad behavior and instead allowed them to discuss behavior through proxies, without individuals having to confront each other. The play was first presented to senior management at two levels prior to the running of 21 further workshops around the country, and ultimately being rolled out to the whole organization.

The ABI forced people to reflect on their personal and inter-personal behaviors. In addition, they also provided learning insights on how to modify and handle communication and feedback style in order to enhance the quality of the relationships with colleagues. Employees through the forum theatre workshops had the opportunity to identify and analyze the 'negative attitudes and behaviors' and experiment with how to improve them. This generated great benefits in terms of changing employees' behavioral intentions to create good relationships with colleagues.

As a result of the Value Roadshow, as reported by the evaluation feedback gathered after the program, employee behaviors within the organization changed and relationships between colleagues improved. It was also reported that some quite dramatic changes had occurred. Once behavioral norms were established, the senior management felt legitimate in reacting strongly to inappropriate behavior.

These short case studies show that ABIs create organizational energy and a tension for action by challenging people's way of seeing and feeling reality, stimulating reflection and observation on personal and business issues, enlarging and changing their perspectives, enhancing emotional responses, and changing behavioral intentions.

Artistic interventions can enhance people's skills and attitudes; can modify and improve people's behaviors; can develop relationships and networking approaches; can allow to recognize, absorb and share organization's new values and ethics.

From a strategic viewpoint, the case studies show that frequently ABIs are adopted as tools on the basis of specific needs related to management challenges or business problems to deal with. However, arts-based practices can be fully incorporated into the business model of the organization. The former considers ABIs as strategic management actions to be brought into organizations every time it is necessary. The latter assumes that ABIs can become part of the everyday organizational life.

7 Conclusion

In this paper, we defined behavior as a complex phenomenon driven by different individual characteristics and organizational factors. From an individual perspective, our intentional and unintentional behaviors depend mostly on our perceptions and reactions to stimuli. The perception processes are affected by our personality traits and the inner and outer hierarchy of knowledge, preferences, dispositions, mental states, and values. Such stable/unstable and learned/unlearned behavioral patterns affect our attitudes and determine the way we interpret the world and we attribute our judgments, the way we act and the way we interact with others and with our environments. Structural, organizational, and managerial characteristics present different stimuli, direct our perception, condition our motivation and hence trigger our behavior and action.

Since most of behavioral patterns are stable, they are difficult to change even with the use of positive and negative reinforcers. The objective of performance-driven investments

including arts-based initiatives becomes then to seek a better alignment between organizational goals and individual objectives. Besides meeting personal needs which may enhance satisfaction and organizational climate without any effect in terms of productivity, planned performance interventions and arts-based investments should spur people to act and put the necessary efforts to achieve both personal and organizational objectives.

Following a thorough analysis of behavior antecedents and consequences we addressed specific implications for performance management in general. Drawing on this analysis and its implications, we suggested then different guiding principles on how we can integrate such soft behavioral dynamics into performance management research and practice through the lens of arts-based interventions. We believe such principles have the potential to lay the foundations and constitute the building blocks of a behavior-based performance management system that can help organizations allocate their resources where it really matters and develop the right measures to capture the real value of performance outcomes.

Knowledge Management: Assessing a Dynamic Capability.

Stephen McLaughlin

Innovation Value Institute
National University of Ireland, Maynooth
Maynooth, Co Kildare, Ireland.

Structured Abstract

Purpose – Over the last 24 months the Innovation Value Institute (IVI) has been working with a consortium of industry, academia, and government (Triple Helix) based organizations to develop a capability view of how organizations can effectively manage their knowledge. This has the potential to be a broad and complex endeavour, so the research workgroup (made up of triple helix members) focused on the IT influencing / influenced capability that drives an organization's ability to effectively manage their knowledge asset. The outcome of this research has resulted in an industry-tested assessment for organizations interested in driving knowledge asset management (KAM) as a competitive capability. This KAM assessment looks at 3 key areas: Governance, facilities & processes, and the knowledge life cycle. These are then broken down further into thirteen sub-capabilities, or capability building blocks. This paper will present in detail how the KAM assessment was developed, validated, and what value the assessment output can bring to those organizations using it.

Design/methodology/approach – This paper will present its findings in a case study format (Yin, 2002). However, the manner in which the IVI engages and conducts its research will be examined, as this is fundamental to encouraging a triple helix (academia, industry, and government) collaborative open innovation approach. IVI is mainly engaged in mode 2 research that follows an 'engaged scholarship' (Van de Ven, 2007) approach, with particular emphasis on a 'design science' (Hevner, et al, 2004) perspective. Through design science the desire to look for and encourage the development of artefacts as part of the research process is important as it provides an added incentive to industry and government partners to engage in research and any follow-on development projects.

Originality/value – This paper will outline the first capability maturity approach to assessing knowledge asset management from an organizational perspective. There are many frameworks and models that describe how organizations shape, and engage with knowledge management activities. Many of these frameworks (over 23) have been used to inform and shape the research thinking around this KAM assessment but this, the author believes, is the first framework that will help define an organizations knowledge capability – this is vital for organizations that view the understanding of capability in any form as critical to developing sustainable competitive advantage (Davenport et al, 2001).

Practical implications – This approach to developing a capability view of knowledge management is helping a number of organizations (both public and private) operating complex organizational structures drive clarity around defining the scope of their 'knowledge' activates, with particular focus on tacit-explicit-tacit knowledge transfer

activities. By assessing their capability against specific aspects of knowledge management organizations are given a relative scale against which they can assess their progress. The KAM assessment also provides the organization with a list of potential improvements to be made that will positively influence knowledge capability maturity. This means that the assessment not only 'quantifies' the organizations current capability, but it also provides a set of industry-validated practices, metrics and expected outcomes. This enables the participating organization the ability to build an improvement roadmap to move the capability up the maturity curve to the desired level of performance.

Keywords – Knowledge management, dynamic, capability maturity

Paper type – Practical Paper

Introduction

A significant body of literature has been written concerning the resource-based theory of the firm. Penrose (1995) defined the internal resources of the firm as the “*productive services available to a firm from its own resources, particularly the productive services available from management with experience within the firm*”. This view of the organization as a collection of resources has prevailed driving the view that the final output (products or services) at any given time merely represents one of several ways in which the firm is using its resources (Teece, 2013). What organizations looking to compete in today’s hyper-competitive markets must do is identify those resources that they can develop into unique capabilities that are hard to replicate (Boisot, 1999). In terms of ‘knowledge intensive service’ (KIS) industries, organizations still find the most difficult resource to accumulate, and manage is knowledge (Teece, 2013). This problem is being compounded by the global, and virtual nature of the way organizations operates. How can an organization begin to develop an organization-wide capability that helps manage its knowledge resources in a way that drives value for the organization? However, before this happens organizations first need to understand the current maturity of their knowledge management capability. This was the challenge the Innovation Value Institute (IVI) was tasked to do by its industry, academic and government based research partners.

The IVI has been developing the IT Capability Maturity Framework (IT-CMF) since 2006. This framework has been designed to help organizations view their IT resources from a capability-centric, as opposed to a process-centric perspective. The framework encompasses 35 critical capabilities, all of which are focused on a particular IT influencing, or influenced, capability. One of these capabilities refers to the capability of managing knowledge, or as it is titled in the framework: Knowledge and Asset

Management (KAM). The framework provides a detailed description of the capability, with capability maturity profiles ranging from level 1 (Initial) to level 5 (optimising). In the case of KAM, each maturity level is assessed against 3 category areas of capability: Governance of KAM, Facilities and Processes, and internal Knowledge Life Cycle.

Table 1 lists the three category areas, and the sub-capabilities (capability building blocks) that make up these areas.

Category	Capability building Blocks	Description
Governance of KAM	Knowledge Strategy and KAM Programme	<i>Defines a knowledge strategy, which may include a KAM roadmap and knowledge goals, to position KAM within the organisation. Prepares the KAM programme, outlining high-level action plans for the current period to translate the knowledge strategy.</i>
	Knowledge policy	<i>Establishes the set of principles to govern the role and contribution of knowledge activities and knowledge assets within the organisation.</i>
	KAM Roles and Skills	<i>Assigns roles with accountability for KAM. Defines and agrees requisite employee skills.</i>
	Impact Measurement Plan	<i>Develops a master plan to guide the measurement of knowledge activities and knowledge assets.</i>
Facilities & Processes	Knowledge Environment	<i>Creates an environment for the management of knowledge activities and knowledge. Includes features such as learning and knowledge workspaces, processes to guide knowledge work and, technologies to organise and streamline knowledge efforts. Promotes best practices in knowledge activities to enable collective learning in the creation, use, reuse and sharing of knowledge assets.</i>
	Knowledge Asset Repository	<i>Designs, develops and adopts a virtual repository that is based on agreed criteria of, for example: structure and content representation in order to facilitate access to the organisation's knowledge assets. Distributes information about the location of available knowledge assets.</i>
	Collaboration and Culture	<i>Promotes approaches that allow employees to communicate, coordinate and work together. Motivates and reinforces behaviour-shaping activities to build a culture of adopting knowledge across the enterprise.</i>
	Enhancement and Lessons Learned	<i>Establishes target elements of the KAM environment, the knowledge life cycle and knowledge assets that are to be enhanced. Collects, captures and maintains success stories of experiences with knowledge activities and knowledge assets. Defines recommendations to support the knowledge strategy, and to meet current and future work objectives.</i>

Knowledge Life Cycle	Register of Knowledge Domain Experts	<i>Captures information about knowledge domain experts to establish their areas of expertise and experience.</i>
	Identification, Collection and Capture	<i>Identifies records of knowledge within the organisation. Collects such records in order to conduct structured analysis, interviews of ownership and selection. Advises on the capture of defined knowledge assets and tacit knowledge, and ensures their availability for use.</i>
	Profiling and Classification	<i>Uses a procedure to develop definitions of individual knowledge assets (such as the basic types of their identity, domain reference and structure), and relationships between them. Applies classification schemes.</i>
	Storage, Maintenance and Protection	<i>Preserves the content of the virtual knowledge asset repository. Maintains the repository using evaluation criteria of, for example: accuracy, quality and relevance. Applies protection principles. Performs a discretionary advisory role on contractual and legal issues of knowledge assets.</i>
	Definition of Business Impacts, Analysis and Reporting	<i>Categorises knowledge asset use by type and impact. Applies analytics (such as descriptive/text and quantitative) to measure value contributions for business reporting. Develops an asset plan for the management of one or more categories of knowledge assets. Communicates regular reports (such as number and types of requests for knowledge, satisfaction of the knowledge assets' users, and business value of knowledge assets use) across the enterprise.</i>

Table 1. KAM Categories and Capability Building Blocks

By assessing the maturity of the KAM critical capability, organizations can determine the effectiveness of their knowledge management capability against each of the capability building blocks. The framework will also provide a set of industry-recognised, and validated practices, outcomes and metrics for each critical building block at each maturity level. This in turn helps an organization to identify and implement practices that will improve their current maturity.

2. Methodology

Although the author is employed by the IVI the findings outlined in this paper are being used to form the basis for on-going research and the building and managing current and future collaborative engagements. This in turn is part of an inter-disciplinary, and multi-sectoral research initiative coordinated by IVI. As there is little academic research on knowledge-resource capability management the author relied on his pre-understanding

(Gummesson, 1991, McLaughlin & Paton, 2008) of the process and organization as a valid starting point for conducting this research. Objectivity and academic professionalism was maintained by the need to conform to the requirement to engage with on going research initiatives.

Ultimately the aim of IVI's research initiative is to develop an underpinning theory and associated models relating to improving organizational performance through effective capability management. The research is exploratory in nature and a Case Study (Yin, 2002) methodology is being used to support this line of inductive theory building. The research and analysis outlined in this paper has been conducted using qualitative methods with all data gathering complying with validation criteria as outlined by Yin (2002).

How the KAM capability and critical capability building blocks manifest themselves as part of the IVI's research process will form the base case on which the author will look to develop an inductive emergent theory. In order to capture the data concerning knowledge capabilities and how those capabilities can be effectively assessed the author engaged with twelve lead researchers who in turn were responsible for 35 workgroups. As said earlier the research outlined in this paper only covers part of the overall research project. The author will validate the findings from the IVI case with other complex organizations, drawn from across both the public/private sectors. This will help validate and develop the theory underpinning the development of the KAM capability.

2.1 Conducting Our Research

The IVI engages in collaborative research with Multi-National Enterprises (MNE), and SME's on an on-going and continuous basis. The nature of the research is centred on the use of IT as a business enabler for organizations. The collaborative partners in this research cover multiple industry sectors (Utilities, IT, Health Care, Finance, Consulting, Local Government, Education etc.). This has provided the IVI with a wealth of understanding and knowledge around the many complex issues organizations are facing in aligning their ICT capability to the increasing requirement to develop and support sustainable innovative business practices.

In order to help organizations understand and manage their ICT capabilities the IVI use the IT-Capability Maturity Framework (IT-CMF) as the basis on which to help define and understand current operating practices. The IVI have been developing the framework since 2006, using a design-science methodology to support an academic / practitioner lead research agenda (Hevner, 2004). This collaborative endeavour has resulted in the

development and testing of 33 critical processes, which in turn have resulted in case studies concerning Sustainability of ICT, ICT Organization Design and Planning etc.,

The IT-CMF model helps put into perspective the IT resource in terms of four key aspects of business related IT management.

Through the process of engagement with organizations from differing backgrounds, in terms of business objectives, target sectors, organizational structure, service / product offering, culture, and nationality, the IVI has developed a mechanism that allows it to develop a consistent and thorough understanding of complex ICT issues. This approach has been refined to ensure research is conducted in a way that not only develops an understanding of how ICT is being employed across multiple industry sectors, but also informs those participating in the research how to improve and develop their ICT capability.

IVI obtains the level of detail required to understand an organization's ICT alignment issues through the use of 35 critical capabilities (Figure 2) that make up the four macro-capabilities.

Figure 1. Critical Capabilities

These capabilities have been developed, tested and refined through collaborative research with IVI's global network of research partners (i.e. BCG, Intel, Chevron, Ernst & Young, BP, SAP, Microsoft, and SME's including Sumerian, CSE, and Clarion Consulting. etc.,). The process by which IVI has engaged with its research partners demonstrates IVI's ability to conduct research at a global level, across complex business environments, whilst managing the expectations of all the participants in terms of what has to be delivered, and the time lines for delivery.

The diagram in Figure 2 identifies the process steps used by IVI in developing an understanding of the core-processes impacting ICT capability. This staged approach was used to ensure the IVI developed a clear understanding of how the core-processes manifest within the different organizations, and how these processes can be expected to mature. The development of these processes is rigorous and dependent on a continuous peer-review in order to ensure validity and relevance.

Intellectual property development for a critical capability divided into four phases separated by stage reviews

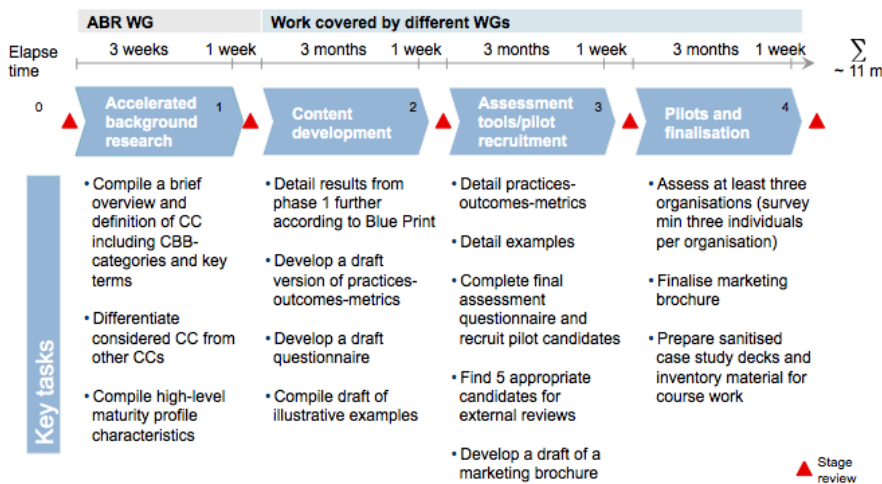

Figure 2. Research validation process

Once the capability has been developed to stage 3 the process is further tested for validity and relevance through a number of pilot assessments, and validation workshops. Although the validation process strives to ensure a balanced and objective view is maintained throughout the duration of the research engagement, the success, relevance,

and objective approach is based on the dynamics of the workgroups that are formed to drive and shape the research projects.

3. Capability Overview

As stated the KAM capability is just one of 35 critical capabilities an organization might have in terms of IT influenced or IT influencing capabilities. Because of this each capability needs to be developed in harmony with the other capabilities. The framework also takes into consideration that capabilities do not work or exist in isolation of each other, and will demonstrate varying levels of influence on each other depending on their maturity levels. To that end, when developing the capability three things needed to be considered: the definition of KAM, what's 'in scope' in terms of the capability, and what's 'out of scope'. In terms of what's in and out of scope this will be dependant on what's already covered in other capabilities.

For KAM the definition is as follows:

Knowledge Asset Management (KAM) is the systematic development of a unified and holistic way of addressing needs for knowledge and of exploiting knowledge assets in order to attain specific business outcomes.

Knowledge assets comprise a collection of organised, explicit and tacit knowledge that is captured from employees, processes, practices, products, services and stakeholders; and the outcomes of actions such as research, innovation and learnt experiences.

The categories of capabilities of KAM are:

- **Governance** ensures accountability of the KAM programme and long-term viability of the knowledge assets supported by knowledge strategy, knowledge policy, roles and skills and impact measurement plan.
- **Facilities and Processes** optimise the knowledge environment and repositories for the continued availability of quality knowledge assets; and include collaboration, culture, enhancement, and lessons learned.
- **Knowledge Life Cycle** constantly enhances information about knowledge assets; and, measures their business impacts and value contributions.

For what is defined as being covered and not covered by the KAM capability (in scope and out of scope respectively) are defined in Table 2 below.

In Scope	Out of Scope
<ul style="list-style-type: none"> ▪ Governance of directed accountability of KAM, knowledge assets including responsibility for behaviour-shaping activities and culture reinforcement. ▪ KAM programme supported by knowledge strategy, knowledge policy and direction of change management. ▪ Knowledge environment to support facilities, people, processes, technology and collective learning. ▪ Discretionary advisory role on contractual and legal issues about knowledge assets. ▪ Management of the following knowledge life cycle activities: <ul style="list-style-type: none"> ▪ Register of Knowledge Domain Experts ▪ Identification, Collection and Capture ▪ Profiling and Classification ▪ Storage, Maintenance and Protection ▪ Definition of Business Impacts, Analytics and Reporting 	<ul style="list-style-type: none"> ▪ Creation of knowledge as part of on-going organisation-wide activities. ▪ Recruitment of employees, expertise/skills, and rewards for existing skill sets for KAM functions (see People Asset Management). ▪ Education and training of employees for KAM effort (see People Asset Management). ▪ Training of employees on use of IT and business applications (see User Training Management). ▪ Assessment, management and resolution of change related to KAM projects (see Program and Project Management CBB – “Change and Risk Management”). ▪ Integration of KAM environment into the organisation’s technical infrastructure (see Technical Infrastructure Management). ▪ Development of organisation policy for contractual and legal protection of knowledge assets.

Table 2. In scope and out of scope

In the out of scope column there is reference to other capabilities, from the IT-CMF, that cover these abilities. These include People Asset Management, User Training Management, Project and Programme Management, Risk Management, and Technical Infrastructure Management. As one can see these cover a wide array of abilities, which highlights the pervasiveness of knowledge management activities. However, it is not the purpose of this paper to cover these additional capabilities.

3.1 Capability Maturity

The KAM capability provides organizations with a way of assessing their current maturity for each category, and even down to a capability building block level. Table 3 shows a high level view of the maturity descriptions at a categorical level.

Maturity Level	Governance of KAM	Facilities & Processes	Knowledge Life Cycle
5 (Optimising)	<ul style="list-style-type: none"> ▪ Knowledge strategy is aligned with overall business strategy and KAM programme continuously improved based on results. ▪ Knowledge strategy aligned with knowledge policy and 	<ul style="list-style-type: none"> ▪ Integrated knowledge environment adopted, customised and aligned with knowledge strategy and business strategy. ▪ Virtual repository with complete directories is adopted enterprise-wide, regularly 	<ul style="list-style-type: none"> ▪ Automated register of knowledge domain experts is adopted enterprise-wide and regularly optimised. ▪ Identification, collection, and capture automated and continuously improved. ▪ Classification schemes

	<p>regularly optimised.</p> <ul style="list-style-type: none"> ▪ KAM taxonomy of skills continually improved and matched to job fulfilments. ▪ Senior management assigned governance and revision of impact measurement master plan. 	<p>improved.</p> <ul style="list-style-type: none"> ▪ Employees manage collaboration tools and positive behaviours continuously reinforced towards desired culture. ▪ Enhancement plan is continuously improved; Lessons learned repositories adopted and recommended actions applied in work practices. 	<p>continuously improved and matched to business needs.</p> <ul style="list-style-type: none"> ▪ Storage, maintenance and protection continuously improved, and aligned with evolving business needs. ▪ Analytics and reporting extended to enterprise business intelligence: asset management plan enhanced with value principles and business value of knowledge assets.
4 (Advanced)	<ul style="list-style-type: none"> ▪ Knowledge goals aligned at enterprise level; KAM programme action plans developed. ▪ Governance processes for aligning knowledge policy with knowledge strategy established. ▪ KAM taxonomy of skills approved at enterprise level. ▪ Impact measurement master plan applied across most of the enterprise. 	<ul style="list-style-type: none"> ▪ Knowledge environment designs are evaluated , approved implemented with change programs. ▪ Repositories evaluated and codified directories defined. ▪ Work structures and practices to foster collaboration and use of IT tools; behaviour shaping projects across organisation. ▪ Enhanced features integrated into existing IT. 	<ul style="list-style-type: none"> ▪ Register of knowledge domain experts is evaluated. ▪ KPIs improve identification, collection and capture. ▪ Results of profiling pilot evaluated: classification schemes aligned and automated. ▪ Storage methods aligned with access service: and maintenance and protection guidelines adopted. ▪ Pilot analytics and reporting project is implemented: asset management plan for impact categories is in place.
3 (Intermediate)	<ul style="list-style-type: none"> ▪ Draft knowledge strategy developed and deployed ▪ KAM programme defined, designed and deployed. ▪ Knowledge policy framed with approved principles and stakeholder inputs. ▪ Some roles assigned; taxonomy of skills defined. ▪ Impact measurement process defined. 	<ul style="list-style-type: none"> ▪ Knowledge environment developed from approved blue prints. ▪ Knowledge asset repository developed and applied in pilot projects. ▪ Behaviour shaping, collaboration and IT tools workshops in place. ▪ Enterprise enhancement plan defined and project is sponsored. 	<ul style="list-style-type: none"> ▪ Register of knowledge domain experts is created. ▪ Knowledge assets identified, collected and captured on IT systems. ▪ Classification schemes defined and applied: profiling project defined, sponsored and piloted. ▪ Detailed guidelines for storage, maintenance and protection defined. ▪ Analytics and reporting function is established.
2 (Basic)	<ul style="list-style-type: none"> ▪ Basic goals and objectives for the 	<ul style="list-style-type: none"> ▪ Knowledge environment blueprints 	<ul style="list-style-type: none"> ▪ Basic guidelines to define work areas, topics

	<p>knowledge strategy and basic list of issues to be addressed in KAM programme are established.</p> <ul style="list-style-type: none"> ▪ Basic knowledge policy principles are defined. ▪ Roles and skills requirements are identified. ▪ Relevant impact measurement approaches and metrics identified. 	<p>designed.</p> <ul style="list-style-type: none"> ▪ Knowledge asset repository project is defined and sponsored. ▪ Collaboration on tasks and projects: behaviour shaping and cooperation introduced at department level. ▪ Enhancement actions identified: lessons learned collected at department level. 	<p>and experts.</p> <ul style="list-style-type: none"> ▪ Design of procedures to guide identification, collection and capture activities. ▪ Classification schemes identified at department level: business case for profiling defined and communicated. ▪ Storage methods identified: basic guidelines for maintenance and protection established. ▪ Scope of KAM analytics and reporting defined: basic process for measuring impact of knowledge assets.
1 (Initial)	<ul style="list-style-type: none"> ▪ Limited efforts to define knowledge strategy or KAM programme ▪ Knowledge policy not defined. ▪ Limited understanding of KAM roles and skills. ▪ Limited measurement of some knowledge activities. 	<ul style="list-style-type: none"> ▪ Knowledge environment confined to local IT tools. ▪ Silos of knowledge assets across organisation. ▪ Informal collaboration: no behaviour shaping for culture in place. ▪ Limited capture of lessons learned. 	<ul style="list-style-type: none"> ▪ Limited access to knowledge domain experts. ▪ Ad hoc knowledge identification, collection and capture. ▪ Ad hoc storage, maintenance and protection. ▪ Ad hoc analytics and reporting. ▪ Limited direct evidence of the impact of knowledge assets on business activities.

Table 3. Maturity Levels for KAM

Maturity level 3 is deemed to be the ‘Breakthrough’ level for the capability. This is the level at which this capability can demonstrate significant value add for the organization. Once an organization can objectively evaluate its current capability maturity, the next stage is to identify what, if anything, needs to be done to improve that capability.

3.2 Practices Outcomes and Metrics

As with all capabilities within the IT-CMF, KAM provides a detailed set of industry validated practices, outcomes and metrics (POMs). Once the maturity level is defined senior management can use the POMs to identify the practices most appropriate to their needs in order to improve the maturity of their KAM capability. The POMs are broken

down and aligned to each of the critical building blocks (as identified in Table 1). Figure 3 gives an example of what POMs look like at a high level (category level).

The POMs are expressed in generic form, to allow the capability to be applied across multiple industry sectors.

Knowledge Asset Management (KAM) Summary of key practices, outcomes, and key metrics

Maturity	Key practices	Outcomes	Key metrics
High	5 Optimising <ul style="list-style-type: none"> Alignment process for knowledge strategy, knowledge policy and business strategy. Integrated knowledge environment is adopted across the enterprise. Virtual knowledge asset repository is adopted with complete directories. 	<ul style="list-style-type: none"> Alignment for business value delivery. Integrated knowledge environment with "learning by doing" culture. Virtual repository provides timely availability of knowledge assets. 	<ul style="list-style-type: none"> Yes/No indicators for alignment. % knowledge assets accessed from repository – per time period. % achievement of knowledge strategy against measured results.
	4 Advanced <ul style="list-style-type: none"> Evaluation of results of KAM pilot projects. Knowledge asset repository is evaluated. Skill requirements identified. Positive behaviours and collaboration mechanisms reinforced. Impact of knowledge assets categorised in detail. Analytics and reporting function established. Asset management plan is developed. 	<ul style="list-style-type: none"> Virtual knowledge asset repository is fully defined with complete directories. Work processes defined to foster collaboration and culture. KAM taxonomy of skills. Managed categories of knowledge assets with defined business impacts and value contributions. Recommended actions from lessons learned are applied. 	<ul style="list-style-type: none"> % knowledge assets migrated to repository. % work processes with defined collaboration mechanisms in use. % of roles and skills fulfilment with KAM capabilities. % of impact categories available for use. % of knowledge assets with known business impacts and value contributions. % effective recommended actions.
	3 Intermediate <ul style="list-style-type: none"> Knowledge environment blueprints; knowledge asset & lessons learned repository prototypes are developed. Knowledge policy principles defined. Impact measurement approaches defined. Behaviour-shaping activities and collaboration, role and skills training. Knowledge domain experts register created. 	<ul style="list-style-type: none"> Approved designs of knowledge environment, knowledge asset and lessons learned repositories. Draft knowledge strategy and knowledge policy. Impact measurement master plan. Some assigned roles and domain experts are trained. 	<ul style="list-style-type: none"> % of blueprints approved for use. # of repository prototypes approved. # of successful training programs completed. % employees cooperating and applying positive behaviours. # of experts available for lead roles in defined key areas and topics.
	2 Basic <ul style="list-style-type: none"> Basic goals and objectives defined as input to knowledge strategy. Basic list of issues to be addressed are defined. Basic principles for knowledge policy are identified. Basic list of KAM roles and skill requirements are defined. KAM measurement goals are defined. Guidelines to knowledge activities defined. 	<ul style="list-style-type: none"> Basic alignment of department level goals and objectives. Checklist of issues of be addressed. Basic checklist of principles of knowledge policy. List of roles and skill requirements. Behaviours and measurement goals. Guidelines to knowledge activities. 	<ul style="list-style-type: none"> % of approved priority time-based goals that are matched to knowledge strategy. # issues to be addressed in KAM programme. # of basic principles. # of KAM role requirements. # of required KAM skills. # of measurement goals recommended. # of guidelines for knowledge activities.
	1 Initial <ul style="list-style-type: none"> Knowledge strategy, knowledge policy, roles, skills, and knowledge environment are not enforced. KAM programme is not defined. 	<ul style="list-style-type: none"> Knowledge activities are random. Identification of roles, skills and issues to be addressed in KAM programme. 	<ul style="list-style-type: none"> # of KAM programme issues approved in decision process.

Figure 3. Summary of POMs for KAM

4. Assessing An Organization’s Knowledge Capability

During the second half of 2013 an KAM capability assessment was carried out by a multi-national US bank. An internal team of 8 bank employees handled the assessment, with the assessment being carried out across 125 participants. The assessment was conducted over a period of 23 weeks, in order to fit in with the operational requirements of the Bank. Figure 4 shows an output report for the KAM assessment. The figure shows the current (actual) capability maturity against the desired maturity. The desired maturity is determined by the organization and is based on the strategic and operational requirements they may have for certain capabilities. Figure 4 also calls out some performance practices that are driving capability performance, and also some actions necessary to reach the desired performance targets.

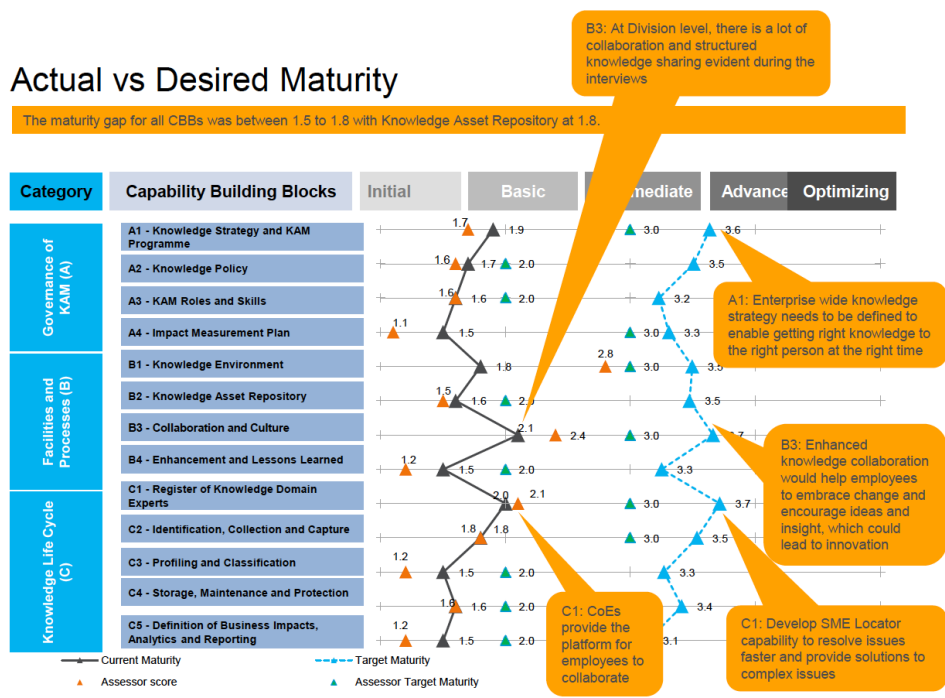

Figure 4. Assessment output for KAM

As an outcome of this assessment some existing strengths were identified, and some performance improvements recommended. These are outlined in Table 4 below.

Strengths	Opportunities for Improvement
The management is focused on enabling a knowledge management environment	Knowledge needs across the enterprise are not being identified
Capability owners have been identified to focus on improving KAM capabilities	A document policy and strategy that promotes the adoption of a knowledge management discipline and culture does not exist.
Communities of excellence act as a significant enabler for knowledge dissemination and collaboration	Definition of the roles and responsibilities for KAM initiatives have not been mapped out at an enterprise level.
At a divisional level there exists a strong drive to use collaborative technology based repositories.	An enterprise infrastructure for managing life cycle of knowledge assets does not exist.
There is a centralised knowledge based portal to enable employees to search and access relevant information from various repositories across the enterprise.	Subject Matter Experts from the business are not being fully utilised.
A digital workplace initiative has been launched to provide a seamless digital experience for employees	Communication between business and the IT providers in not formalised.
Business knowledge repositories are beginning to develop and connect across the enterprise.	Impact of existing KAM initiatives on service delivery is not measured.
	Rewards and recognition programme to encourage employee participation in KAM not implemented.

Table 4. Strengths and Opportunities for KAM

Because the KAM assessment can help identify clear areas for improvement, this allows for strategic targeting of specific improvement initiatives. Although the improvement roadmap developed for the Bank is confidential, many of the senior management team expressed very positive views of the capability assessment process and what it had to offer the organization. This comment sums up the overarching feeling concerning KAM.

“We need to have KAM in peoples goals and objectives – specific goals. The value of KAM is accepted, by prioritisation on KAM is lacking”.

5. Conclusion

By taking a capability-centric view of knowledge management, the IVI have been able to better link the notion of knowledge as a strategic resource to organizational performance. It is accepted that knowledge, as a capability, can be viewed from many perspectives, and that the one presented in this paper forms just one of them. However, the KAM capability, although developed from a codified knowledge perspective, has allowed a complex organization to identify where it is under performing in terms of its capability to manage its growing and complex knowledge landscape.

This capability view of KAM fits within the definition of a dynamic capability as defined by Helfat *et al* (2008). The definition of a dynamic capability ‘...*is the capability of an organization to purposefully create, extend or modify its resource base*’. Through the application of the KAM capability an organization is able to objectively understand how knowledge influenced, and influencing, resources are aligned across their organization. They can then best assess how to develop, or create, and modify these resources in a way that drive performance improvement. The notion of a dynamic capability is dependant on the ‘purposeful’ nature of how the organization views the capability. This word indicates some degree of intent. Helfat *et al* (2009) distinguish dynamic capabilities from organizational routines, which in turn consist of organizational routines that lack intent (Dosi *et al*, 2000). This also fits very well with the view of knowledge as a critical capability for developing organizational competitive advantage.

From the perspective of dynamic capabilities one of the most important questions is ‘How can organizations build or acquire new capabilities’. In an ever increasingly competitive marketplace, organizations have to address this question on an ever more frequent basis. Although the KAM capability will not provide the necessary resources to build knowledge management capability, it will provide a road map showing

organizations how to align, and develop their existing resources in a way that will develop strategically aligned capabilities. In effect the KAM capability provides organizations with a lens in which to view knowledge management. IVI believe that this version of the KAM capability is not necessarily the final word in what constitutes a knowledge management capability, but it does believe that by taking a capability-centric view on knowledge management it identifies a more explicit link between knowledge management, strategic capability, and competitive positioning.

6. Research limitations

Although the KAM capability was developed with input from individuals representing over 20 academic and industry based organizations, the case study findings presented in this paper only relates to one organization. Although the Bank that took part in the assessment was very positive with the findings from the assessment exercise, more assessments need to be carried out in order to further validate the structure of the KAM capability, and assess its relevance and importance for organizations looking to improve their knowledge management capability.

From intellectual capital to company's competitiveness

Ramona – Diana Leon

Department of Management, Marketing and Business Administration
Alexandru Ioan Cuza University of Iasi
Carol I, no. 22, 700505, Iasi, Romania

Structured Abstract

Purpose – Researches made in the last 25 years presented knowledge as a dynamic and fluid resource, critical for company's success. Although there are some remarkable attempts of measuring knowledge assets and intellectual capital of a firm, their analysis tend to be static. They are either reflecting the current stage of development or they are highlighting an average performance. Besides, they overlook the fact that company's competitiveness depends on competitors' characteristics and actions. Starting from these, we aim to develop a benchmarking tool capable of capturing company's competitive position and future evolution, based on its efficiency of using intellectual capital.

Design/methodology/approach – Developing an exploratory research, we combine the qualitative with the quantitative analysis. We create a composite index, entitled Competitiveness Intellectual Capital Index (CICI), for 20 Romanian companies listed on the Bucharest Stock Exchange (BSE). Our longitudinal study has three phases. First, we establish CICI's value during 2009 – 2012, for each company. Then, we determine the average annual growth rate registered during 2009 – 2012. In the third stage, we develop a strategic knowledge map, using CICI's value and the average annual growth rate. Based on these coordinates, we split the companies in four categories: leaders, chasing stars, followers and traditionalists.

Originality/value – This methodology brings forward the relative character of intellectual capital and its long term relationship with company's competitiveness. First of all, it reflects that intellectual capital means more than money; it's about creating, disseminating and using knowledge; it's about valuing company's human resources and its relationships with all the stakeholders. Secondly, it highlights that a company is competitive only when it manages its knowledge assets more efficiently than its competitors. Taking this into account, CICI is the first instrument that evaluates a company's intellectual capital by comparing its performance with the one registered by the direct and indirect competitors.

Practical implications – The outcomes of developing and using this instrument focus on strategic issues. First of all, by using CICI, managers can have a complete image on what's happening in the environment in which they operate. Secondly, they can notice where do they stand (compared with their competitors and companies from different fields of activity); they can identify potential threats and opportunities, they can monitor

change and they can develop future strategies. In other words, it may serve as a managerial early warning system.

Keywords – Intellectual capital, Competitiveness, Human capital, Turnover rate, Stock price.

Paper type – Academic Research Paper.

1 Introduction

Evolving from the post-industrial economy to the knowledge based one brought to forefront the importance of knowledge as an organizational resource. On a broad sense, this exists in any company and is related to employees' skills, abilities and competences. But, although their role in the process of knowledge creation, dissemination and use is fundamental, they are not the only source of knowledge that a company may access. This can also be brought from other companies under the form of licences, patents, equipments etc. Taken these into account, for more than 25 years, knowledge has been described as a fluid and dynamic resource (Lilleoere and Hansen, 2011; Nonaka and Takeuchi, 1995); it comes from different sources (employees' skills and competences; firm's relationships with its stakeholders; other companies products and services etc.), it can be transformed inside company's boundaries and it can be incorporated in firm's processes, products and services. This unique character captured managers' interest and emphasized its capacity to generate competitive advantages (Amiri et al., 2010; Drucker, 1993; Grant, 1991; Kamukama et al., 2011; Sveiby, 1997).

Since the mid-1980s when Karl Erik Sveiby analyzed the "know-how" companies (Sveiby and Riebling, 1986), the value of knowledge assets created and used by a company was labelled as "intellectual capital". The development of this concept has, so far, two phases. The first one began in 1990s and focused on analyzing case studies, concepts' operationalization and establishing definitions (Edvinsson and Malone, 1997; Roos and Roos, 1997; Stewart, 1998; Sveiby, 1997) while the second one started in 2000 and concentrated on measuring, modelling and extending its levels of analysis (Bontis, 2002; Bueno et al., 2011; Chen et al., 2004; Marr et al., 2004; Molodchik et al., 2012; Tóth and Jónás, 2012).

In almost 15 years of research, some remarkable attempts of measuring the intellectual capital of a firm had been made. Some models reflect the current stage of development (Bueno et al., 2011; Pulic, 2000; Sveiby, 1997) while others highlight the

average performance recorded during two or three years (Lev, 2001; Stewart, 1997). In other words, they tend to forget that knowledge is dynamic and the current level of development does not guarantee a similar performance in the future. Besides, they do not take into consideration that intellectual capital competitiveness depends on the characteristics and actions of the direct and indirect competitors and business partners. As a consequence, although plenty of models had been developed, there is no general accepted method and evaluating the performance of intellectual capital remains a challenge for managers (Tai and Chen, 2009).

Starting from these, we aim to develop a benchmarking tool capable of capturing the competitive position and future potential evolution of a company, based on its efficiency of using intellectual capital. In the next section of this article, we will review some of the models developed for measuring the intellectual capital of a company. Then, we will present our research methodology and the principles we followed in order to develop a benchmarking tool, entitled Competitiveness Intellectual Capital Index (CICI), for the Romanian companies listed on the Bucharest Stock Exchange. In the fourth part of this article, we will discuss the performance of intellectual capital in Romanian companies, in 2012. We will analyze their progress during 2009 – 2012 and will include them in a specific category (leaders, followers, chasing stars or traditionalists). Based on the elements that characterize these categories, we will estimate their potential future evolution. We will close this paper highlighting the utility of CICI and indicating some further research directions.

2 Intellectual capital – an embryonic research field

Since the early 1990s, a large number of studies analyzing various aspects of intellectual capital were undertaken (Bontis, 2002; Bueno et al., 2011; Edvinsson and Malone, 1997; Marr et al., 2004; Stewart, 1998; Sveiby, 1997), but the field is still embryonic. New dimensions of the intellectual capital are highlighted and new measurements are developed.

If Sveiby (1997) identified 3 dimensions of the intellectual capital, namely: employee competence, internal structure and external structure, Liebowitz and Weight (1999) emphasized 4 components, entitled: human capital, customer capital, process capital and innovation capital. A couple of years later, Bueno et al. (2011) described the intellectual capital using 6 dimensions: human capital, organisational capital, technological capital,

business capital, social capital and entrepreneurship and innovation capital. Despite the fact that most of the previous studies concentrate on classifying intellectual capital in human capital, structural capital and relational (customer) capital, this continuous development proves that the intellectual capital research field has still a lot to offer; not all the variables of intellectual capital were brought to forefront.

This may be one of the reasons that stimulate the appearance of new instruments for intellectual capital measurement. Since there is no general accepted framework, developing a valid measurement of intellectual capital performance becomes a challenge. Some researchers focused on the financial statements and tried to bring forward what lies behind the numbers while others developed complex instruments in order to offer a holistic perspective on company's intellectual capital (Table 1).

Table 1. Models usually used for measuring the intellectual capital performance

Model	Characteristics	Limits
Market to net book value	<ul style="list-style-type: none"> • it defines intellectual capital as the difference between market value and book value. • it offers information regarding the value of intellectual capital of a firm at a given moment. • it is easy to use. • it is the most widely known and used indicator. 	<ul style="list-style-type: none"> • according to this, intellectual capital includes all the elements that increase company's value and are not registered in accounting. Therefore, it depends on the national and international accounting rules. • it highlights the lack of vision; an increase in company's market value may be the result of external factors and not necessary a consequence of using intellectual capital. • it perceives firm as an independent entity and not as part of a system; it neglects the influence that competitors and business partners may have on intellectual capital performance.
Calculated intangible value (Stewart, 1997)	<ul style="list-style-type: none"> • it reflects the value of intellectual capital based on an average performance. • it focuses on a three-years period. • it facilitates comparison within industry and between industries. • it is easy to use. • it allows trend analysis. 	<ul style="list-style-type: none"> • it is based on financial information when the value of intellectual capital goes beyond the monetary expression. This reflects a set of skills and abilities which are incorporated in firm's procedures and business methods and cannot be resumed to a monetary unit. • it does not emphasize the elements that define intellectual capital. It

		presents the results but not what lies behind it.
Value added intellectual capital (Pulic, 2000)	<ul style="list-style-type: none"> • it defines the intellectual capital performance as the sum of the value added by human capital and physical capital. • it brings to forefront the importance of human capital. • it facilitates comparison between companies. • it is easy to use. 	<ul style="list-style-type: none"> • it evaluates human capital based on its cost and not its abilities, skills and competences (its real value). • it is based on financial information.
Intellectus Model (Bueno et al., 2011)	<ul style="list-style-type: none"> • it measures the intellectual capital performance using 342 indicators which are organized based on a “relevance tree” approach (more indicators are defining a variable; more variables are defining an element; more elements are defining a specific type of capital). • it uses a “multiplying factor” in order to determine the future value of intellectual capital. 	<ul style="list-style-type: none"> • some indicators included in the model are redundant. • indicators distribution among variables and capitals is unequal (in example, for Business Capital 71 indicators are taken into account while Social Capital is measured using 41 indicators). This increases their influence on the general result. • it is difficult to use.

We may notice that the models which are usually used for measuring the intellectual capital performance focus on obtaining a value, on labelling the results gained (or assumed to be gained) by using knowledge assets. None of them takes into account the relative character of competitiveness; this mainly depends on the actions of direct and indirect competitors and business partners. Although the Value added intellectual capital method facilitates comparison within industry and between industries, this is presented as an option and not as a “must”, like it should be.

When it comes to intellectual capital, monitoring its evolution is not sufficient; this should be compared not only with competitors’ results but also with the ones obtained by companies which are operating in other industries. Intellectual capital is like a metal; it changes its shape under different condition (from one domain of activity to another) and it generates complex reactions (along the supply chain and not only). For example, if you put a metal in an acid solution, it will produce a salt and a gas; if you put it in a bases solution, it will not react unless it is strong enough to precipitate a metal hydroxide. The same happens with intellectual capital performance. One way or another it exists in any company in a more latent or active form. If the environment in which the company operates is “acid” (highly competitive, based on innovation and quality), then the internal

mechanism will be adapted (a “salt” will be created by developing an organizational culture and structure that encourages creativity, initiative and thinking outside the box) and innovative products and services will be delivered to the market (the “gas” that will affect company’s customers, competitors, partners and other related domains of activity). On the other hand, if the environment in which the firm activates is a “bases solution” (customers demand is predictable, the market is split between a reduced number of players, prices are the only ones that make the difference between competitors), then the intellectual capital will remain in a latent state until some coordinates of the internal or external environment will change.

Synthesizing, the models developed so far are internally oriented and lack of strategic orientation. They focus on measuring firm’s performance without taken into account the influence of the external environment. They neglect the fact that knowledge becomes a source of competitive advantage only if a company uses it more efficiently than others. We will fill this gap by developing a benchmarking tool, entitled Competitiveness Intellectual Capital Index (CICI).

3 Research methodology

3.1 Research purpose and objectives

We aim to develop a benchmarking tool capable of capturing the competitive position and future evolution of a company in the Romanian business environment, based on its efficiency of using intellectual capital. Therefore, we focus on:

- analyzing the intellectual capital of the Romanian companies;
- determining the aspects on which the Romanian companies tend to concentrate on when it comes to intellectual capital;
- identifying the most competitive Romanian companies, based on their efficiency of using intellectual capital.

In order to achieve our goal, we employ an ethic approach and develop an exploratory, holistically, interdisciplinary and diachronic research. The exploratory character of this research drove its essence from the fact that there is no other benchmarking tool that analyzes companies’ performance in terms intellectual capital valuation. As we could have noticed most of the previous models adopt an internal approach; they focus on what are firms doing in order to increase their value without

taken into account competitors' performance. We aim to address this issue by developing a benchmarking tool that highlights the position that a company occupies compared with other economic agents.

The holistic approach is the result of using objective data and quantitative methods while the diachronic approach is reflected by the fact that our analysis is based on the time evolution of the main components of intellectual capital. Interdisciplinary appeared as a consequence of combining knowledge management with strategic management, statistics and informational technology.

3.2 Sample

In order to achieve our goal, we concentrate on the 106 Romanian companies listed on the Bucharest Stock Exchange (BSE). Our decision is based on the fact that in order to be listed, firms must develop their social responsibility and they have to make their information publicly available. The first aspect not only reflects company's responsibility to the environment in which it operates (Anderson, 1998; Dodd, 1932; Schwartz and Carroll, 2008; van Marrewijk and Were, 2003), but it also facilitates firm's access to stakeholders' knowledge (Mura et al., 2013). Therefore, it is interested in being competitive in the knowledge economy era. The second issue assures our access to data describing the organizational environment.

After excluding the financial institutions and the tradable but unlisted companies, 62 firms remain. From these, we select 47 enterprises with export activity. We used the presence of export activity as a selection criterion because it reflects company's capacity of penetrating international markets. In other words, it highlights its ability of using efficiently its intellectual capital and its capacity of disseminating knowledge on an international level.

Only 20 enterprises were profitable during the economic crisis and in the years after (2009 - 2012). Their profitability in time of crisis proves they are capable of reacting in a faster pace to market challenges and they are aware of their knowledge assets value (Economist Intelligence Unit, 2009; Fodor and Poór, 2009). Therefore, these 20 firms that are activating on both internal and external market and managed to be profitable during 2009 – 2012, represented the research sample.

3.3 Research instrument

Our longitudinal study has three phases. *The first one* focuses on establishing the value of the Competitiveness Intellectual Capital Index (CICI) during 2009 – 2012, for each company. This offers a unique opportunity to analyze the intellectual capital landscape in Romanian companies.

For each year and each firm, CICI is determined as a weighted mean of its pillars scores: human capital, structural capital and relational capital. The weights are distributed following the same principles as the ones used by World Economic Forum (2013) for evaluating the global competitiveness. Therefore, the elements that constitutes basic requirement, namely the organizational capital, receives 20%, the efficiency enhancers (human capital) – 50% and the innovation and sophistication factors (relational capital) – 30%.

Structural capital represents the basic requirements since it reflects the internal structure. Company's routines, processes, information and technology are the ones that support decision-making and knowledge creation, dissemination and use (McKenzie et al., 2011; Stewart, 1997). If these stimulate and encourage creativity and innovation, then human capital may become an efficiency enhancer.

Human capital defines employees' knowledge, abilities, skills and competences (Edvinson, 1997). It is the only one capable of transforming all the other organizational resources and generating innovation and strategic renovation (Bontis, 1998; Curado, 2008). Its unique character makes it the most important source of firm's sustainable competitive advantage (Cabrita and Bontis, 2008).

Relational capital includes the relationships that a firm has with its stakeholders (Nahapiet and Ghoshal, 1998; Saint-Onge, 1996; Subramaniam and Youndt, 2005). It emphasizes company's capacity to make its present visible on the market and to access stakeholders' knowledge.

Table 2. Variables included in CICI's structure

Pillars	Weight	Variables
Human capital	50%	<ul style="list-style-type: none">• proportion of professionals in the company;• share of expenses with human resources in total expenses;• average length of employment;• value added per employee;• turnover rate.

Structural capital	20%	<ul style="list-style-type: none"> • number of hierarchical levels; • age of organization; • intangible assets; • share of expenses with research, development and innovation in total production expenses; • share of executives in total staff.
Relational capital	30%	<ul style="list-style-type: none"> • stock prices; • number of social responsibility activities; • share of sales to international customers in total sales; • number of economic sectors in which the company's activities are carried out; • share of expenses with external parts in production expenses.

Each pillar includes 5 monetary and non-monetary variables (Table 2). Variables were selected based on a documentary study and information regarding their evolution was collected from company's annual reports using content analysis as a research method.

The pillars scores represent the arithmetic mean of its variables. In order to make variables aggregation possible and to provide a comparative assessment of the intellectual capital performance of the Romanian companies, data are normalized on a 1 to 10 scale (Lin and Edvinsson, 2008; WEF, 2013), based on the following relation:

$$y_{ic}^* = 9 \times \frac{\text{company score} - \text{sample minimum}}{\text{sample maximum} - \text{sample minimum}} + 1,$$

where, y_{ic}^* is the normalized value of variable i for company C ;

sample minimum is the lowest value recorded by a company, for variable i ;

sample maximum is the highest value recorded by a company, for variable i .

For those variables for which a higher value indicates a worse outcome (like, turnover rate, number of hierarchical levels etc.), the normalization formula takes the following form:

$$y_{ic}^* = -9 \times \frac{\text{company score} - \text{sample minimum}}{\text{sample maximum} - \text{sample minimum}} + 10$$

By applying a min-max transformation, we manage to maintain company's position in the business environment.

Since the sample size was too small we could not use the principal component analysis (Gorsuch, 1983; Hatcher, 1994; MacCallum et. al, 2001) or the partial least square modelling technique (Bontis, 1998; Bontis et al., 2002; Hulland, 1999) for assessing the consistency of the CICI framework in terms of number of pillars and

adequacy of indicators in describing each pillar. Still, CICI's validity is tested using univariate and multivariate statistical analyses. The univariate analysis is carried out indicator by indicator and focuses on the presence of missing data, outliers, and the impact of asymmetric distributions (skewness) on CICI.

The reliability of the measurements is evaluated using Cronbach's alpha test. As suggested by Nunnally (1978) and Churchill (1979), this should be the first measure taken in order to ensure the quality of metrics. After performing this test and obtaining a Cronbach alpha score higher than 0.7 for each pillar (human capital – 0.872; structural capital – 0.895; relational capital – 0.728), we claim that the measures used for developing the Competitiveness Intellectual Capital Index are reliable.

The second phase concentrates on determining, for each company, the average annual growth rate registered during 2009 – 2012. At the beginning, we define growth for each company C per variable i (r_{ic}^t) as the ratio between the non-normalised values for year t (y_{ic}^t) and year $t-1$ (y_{ic}^{t-1}).

$$r_{ic}^t = \frac{y_{ic}^t}{y_{ic}^{t-1}}$$

Then, we determine the average yearly growth rate (\bar{r}_{ic}^t) which indicates variables' progress from one year to another. In order to do so, we use the geometric average of these variables growth rates:

$$1 + \bar{r}_{ic}^t = \prod (r_{ic}^t)^{w_i}$$

where all variables receive the same weight w_i (since CICI includes 15 variables, w_i is equal with 1/15).

Next, for each company C, we calculate the average annual growth rate (R_C) as the geometric average of all yearly growth rates:

$$1 + R_C = \prod (1 + \bar{r}_{ic}^t)^{w_t}, \text{ where } w_t = \frac{1}{\text{no. of years}-1}$$

In the third stage, we develop a strategic knowledge map, using the value of CICI for 2012 and the average annual growth rate for 2009 – 2012. This reflects company's position in the national business environment, based on its efficiency of using intellectual capital. Taking into account these two coordinates, we split the Romanian companies in four categories (Table 3):

- *leaders* – the value of CICI and the average annual growth rate are above the average;

- *chasing stars* – the value of CICI is below the average and the average annual growth rate is above the average;
- *followers* – the value of CICI is above the average and the average annual growth rate is below the average;
- *traditionalists* – the value of CICI and the average annual growth rate are below the average.

Table 3. Companies typology based on CICI's value and the average annual growth rate

		CICI value	
		Below the average	Above the average
Average annual growth rate	Below the average	<p><i>Traditionalists</i></p> <ul style="list-style-type: none"> • remain faithful to the traditional business models and procedures; • focus on maintaining the status-quo; • progress appears as an accident. 	<p><i>Followers</i></p> <ul style="list-style-type: none"> • develop new business models and procedures for specific problems; • focus on generating changes in the internal environment; • progress is the result of internal and external factors.
	Above the average	<p><i>Chasing stars</i></p> <ul style="list-style-type: none"> • improve their business models and procedures only if they have to; • focus on adapting to market challenges; • progress is generated by external factors. 	<p><i>Leaders</i></p> <ul style="list-style-type: none"> • their activity is based on new, innovative business models and procedures; • focus on generating changes in the external environment; • progress is generated by internal factors.

4 Competitiveness Intellectual Capital Index of the Romanian companies

Intellectual capital becomes a source of competitive advantage if a firm use it more efficiently than its competitors. Starting from this assumption, we developed a benchmarking tool, entitled Competitiveness Intellectual Capital Index (CICI). Based on a comparative assessment, this tracks the progress in intellectual capital performance in Romanian companies.

According to data presented in Figure 1, the intellectual capital performance of the Romanian companies is modest; on a scale of 1 to 10, the highest score achieved was 6.29 points. Besides, we must remark that there are no significant differences between the analyzed firms. Despite the fact that they are operating in distinct domains of activity, CICI's value for the analyzed companies varies in a range of 0.01 to 3.04 points. In other

words, there is an interest in using intellectual capital as a source of competitive advantage among the Romanian firms but managers' efforts are still underdeveloped.

Figure 1. CICI's value for the Romanian companies, in 2012

The best performers belong to four different domains of activity which are present among the same supply chain. On the first position, we have UZC (with 6.29 points on a scale of 1 to 10) which is a company that manufactures motor vehicles, trailers and semi-trailers. On the second place, on a difference of 0.15 points, we have COTE which is uncharged with land transport and transport via pipelines. On the third position, with 5.83 points, we find SNP which is responsible with extraction of crude petroleum and natural gas while the fourth place is occupied by OIL (5.35 points), a firm that activates in the domain of warehousing and support activities for transportation. Since these four companies do not have business agreements with one another, this distribution highlights that a firm's interest in developing and using its intellectual capital has a domino effect among the companies from the domains with which it interferes.

But these results are nearly the tip of the iceberg. They reflect companies' performance on general basis and not the ones obtained in the specific area of human capital, structural capital and relational capital.

The relationship between domains is also described by the Human Capital Index (Figure 2). OIL (7.55 points on a scale of 1 to 10), COTE (7.14 points), SNP (6.80 points) and UZC (6.19 points) remain the best performers, although their position in the top is changed. OIL occupies the first position while UZC is placed on the fifth position (on a difference of 1.36 points). Besides, there is a new entry on the top 5, namely PTR (with 6.80 points). This operates in the area of mining support service activities.

Figure 2. Distribution of the Romanian companies based on the value of the Human Capital Index in 2012

Since the highest score achieved was 7.55 (on a scale of 1 to 10 points) and 60% of the analyzed companies obtained more than 5 points on the Human Capital Index, in 2012, we argue that the Romanian managers became aware of the human resources

impact on company's success. Still, their performance tends to be diffuse if we take into account that the differences between companies scores varies from 0 to 4.31 points.

Although human capital represents the “piece of resistance” in the process of developing company's intellectual capital, its performance depends on the development of structural and relational capital. This should not be neglected since they ensure knowledge dissemination and use inside and outside firm's boundaries. Some Romanian enterprises seem to overlook this detail (Figure 3). Firms like ELMA, CMF, ELGS and PTR concentrate on developing their relational capital and ignore the importance of structural capital. As a result, they are among the best performers when it comes to relational capital and the worst ones when their structural capital is analyzed. They focus on the outside, on improving their image on the market. These results will be ephemeral if they are not supported by proper organizational structure, procedures and routines (elements that characterize the structural capital).

Figure 3. Distribution of the Romanian companies based on the values of the Structural Capital Index and Relational Capital Index, in 2012

The situation is reverse in the case of ATB. Its competitiveness is higher at the structural capital level compared with the one achieved at the relational capital level. This

describes a firm that realized the importance of intellectual capital and tries to adapt its business models and procedures. Besides, the results obtained by these companies on the Structural Capital Index and Relational Capital Index are below 5, on a scale of 1 to 10 points which highlights a very modest performance.

If we analyze the general performance of the Romanian firms at the structural and relational capital level, we observe that the last one is the one that manages to make a remarkable difference. The Relational Capital Index for 2012 varies from 1.66 to 6.35; the difference between the best performer (UZC which gained 6.35 points on a scale of 1 to 10) and its challenger (COTE which obtained 4.61 points) is equal with 1.74 points. These results emphasize firm's capacity of coping with its stakeholders and disseminating their knowledge.

Last but not least, we have to remark that the most competitive companies, according to CICI's value, are the ones that managed to maintain a balance between their human capital, structural capital and relational capital.

CICI not only highlights the intellectual capital performance of the Romanian companies but it also tracks its evolution over the time. As we can notice from Figure 4, during 2009 – 2012, some firms focused on increasing their intellectual capital performance while others decreased their efforts. Based on this dynamic, the Romanian companies may be split in four categories: leaders, followers, chasing stars and traditionalists.

The "leaders" category includes those firms that registered a high value for CICI in 2012 and a positive average annual growth rate during 2009 – 2012. Almost 30% of the analyzed companies belong to this category, namely: UZC, CMP, OIL, ELMA, STIB and ARTE. These are the type of firms that aim to develop themselves continuously and to generate changes in the external environment. They don't just wait for things to happen; they challenge the status-quo and go beyond the limits. Their knowledge assets and the relationships with their stakeholders assure their position as best performers in their domain of activity. These enterprises serve as a model for their competitors and business partners.

Figure 4. Growth of intellectual capital performance in Romanian companies, 2009 - 2012

The “followers” category reunites those companies that obtained a high value for CICI in 2012 and a negative average annual growth rate during 2009 – 2012. These firms are in a “transition” period. They realized the importance of intellectual capital but they are still learning how to manage it effectively. This position is temporary; if they learn how to manage their knowledge assets in a more productive manner, they may become leaders. But, if they experience difficulties and they do not find the “power” or the motivation to move on, they may become traditionalists; they may go back to the safety of the traditional business models and procedures. Only 15% of the analyzed firms are included in this category, namely: COTE, SNP and PTR.

The “chasing stars” category includes those enterprises that are guided by the “here and now” principle. They will do what they have to do in order to achieve their goal. Their motivation for changing is induced by external forces (like, market challenges, competitors behaviour etc.) and that is why they obtained a low level for CICI in 2012 and a positive average annual growth rate during 2009 – 2012. They realized that knowledge is a potential source of competitive advantage and they try to exploit if they have to. As a consequence, they improve their business models and procedures so they

can adapt faster to market demands. In this category are included 25% of the research sample represented by, ELGS, ARS, ALT, PREH and BIO. They may become “leaders” if they realize the global utility of intellectual capital or they return to the “traditionalists” stage once their objectives are achieved.

The “traditionalists” category describes those companies that maintain the status-quo; CICI’s value for 2012 is below the average and the average annual growth rate during 2009 – 2012 is negative. They developed once a “success recipe” and since this is still working (providing an income) then there is no need to change anything. They remain faithful to the traditional business models and procedures until they become obsolete. 30% of the research sample belong to this category, namely: VNC, CMF, ATB, UAM, CBC and ALU.

Last but not least, we should take into consideration that more than half of the research sample (65%) oscillates around the average. In other words, the managers of the Romanian companies recognize the importance of knowledge in the current business environment and are interested in developing the intellectual capital of their firms. But, their attempts are still modest.

5 Conclusions and further research

In the current unpredictable economic environment, intellectual capital represents a significant and unlimited source of competitive advantage. As a result, it captured researchers’ and managers’ interest. They tried to analyze it and to determine its value but the works created so far are on an embryonic stage of development. They don’t seem to agree on the dimensions and variables of intellectual capital (each model has a different set of indicators, variables and dimension) and they neglect the fact that competitiveness is reflected by comparison.

The models that focus on measuring intellectual capital performance tend to be internally oriented and lack of strategic orientation. They focus on measuring firm’s performance without taken into account the influence of the external environment. They neglect the fact that knowledge becomes a source of competitive advantage only if a company uses it more efficiently than its competitors.

We filled this gap by developing a benchmarking tool, entitled Competitiveness Intellectual Capital Index (CICI), for the Romanian companies listed on the Bucharest Stock Exchange. This brings forward the relative character of intellectual capital and its

long term relationship with company's competitiveness. First of all, it reflects that intellectual capital means more than money; it's about creating, disseminating and using knowledge; it's about valuing company's human resources and its relationships with all the stakeholders. Secondly, it highlights that a company is competitive only when it manages its knowledge assets more efficiently than its direct and indirect competitors and business partners. As we could have noticed, the best performers, according to CICI's value for 2012, were belonging to four different domains of activity that were part of the same supply chain, namely: manufacture of motor vehicles, trailers and semi-trailers; land transport and transport via pipelines; extraction of crude petroleum and natural gas and warehousing and support activities for transportation

Although the results of this research are representative only for the exporting Romanian companies listed on the Bucharest Stock Exchange, CICI is the first instrument that evaluates a company's intellectual capital by comparing its performance with the one registered by the direct and indirect competitors and business partners.

The outcomes of developing and using this instrument focus on strategic issues. First of all, by using CICI, managers can have a complete image on what's happening in the environment in which they operate (who are the best performers when it comes to using efficiently company's intellectual capital; which lessons could be learned and from whom; what changes should be done etc.). Secondly, they can notice where do they stand (compared with their competitors and business partners); they can identify some potential threats and opportunities, they can monitor change and they can develop future strategies. Therefore, it may serve as a managerial early warning system.

Starting from these, in a future research we aim to:

- analyze the influence of the exporting activity on companies' intellectual capital performance;
- determine the impact of national intellectual capital on organizational intellectual capital.

Structured Abstract

Purpose –The purpose of our paper is to develop a *IC Maturity Model (ICMM)* for Universities which is a flexible model of implementing Intellectual Capital (IC) approaches within Universities. The ICMM provides a theoretical continuum along which the process of maturity can be developed incrementally from one level to the next one moving from IC Data Collection, Awareness of IC, Adjustment of IC specific indicators, Measurement of IC, Reporting of IC, Interpretation and decision making, Strategy and Planning.

Design/methodology/approach – The Maturity Model has been developed in the course of three Mutual Learning Workshops (MLW) organised in Romania in the period October 2012 – May 2013. 15 international experts and practitioners have worked together aiming to develop a Model for IC Management in universities. The MLWs have been developed in the frame of the Project "*Quality Assurance in Higher Education through Habilitation*

¹ *The views expressed are purely those of the author and may not in any circumstances be regarded as stating an official position of the European Commission*

and Auditing" initiated by the Executive Agency for Higher Education and Research Funding of Romania (EUFISCDI).

Originality/value – Although several methods for IC measurement and management exist, most of these are not able to affording the trade-off between the comparability aims and the efforts to capture the institution's uniqueness when designing an IC model or framework. Pathways for adoption of IC management and reporting model strongly depend on the characteristics of the university, its previous experience with management tools and its managerial orientation. The *IC Maturity Model for Universities (ICMM)* explicitly allow to take in consideration these aspects hence enlarging the wide spectrum of Strategic Management approach inside the different University settings.

Practical implications – The IC maturity model provides a staged framework to initiate a step-by-step change within a University based upon its current level of IC management maturity. It allows Universities to follow different paths not necessarily the linear sequence; while some universities may start with the formulation of a strategy and a consecutive operationalization by using some IC indicators, others may gain experience in using some basic indicators and get aware about the necessity to use more specific IC indicators.. The ICMM can be used as a controlling and monitoring instrument in times of radical transformations and reforms.

Keywords – Intellectual capital, University, Maturity Model, IC Management, IC reporting

Paper type –Academic Research paper

1 Introduction

Universities are considered critical players in the knowledge-based society and are at the core of the policy agenda at national and EU level. The 'Europe 2020' Strategy recognized explicitly their central role to help Europe to become a smarter, greener and more inclusive economy (European Commission, 2010). Moreover, they have a pivotal role in regional development and a great potential in the development and implementation of Smart Specialisation Strategies (S3), which are key in the new Cohesion Policy framework (Kempton et al., 2013). During the last decades European universities have been immersed in important transformation processes aiming to make them more autonomous, transparent, economically efficient, more competitive world-wide and financially sustainable (Elena and Sanchez, 2013; De Dominicis et al., 2011; European University Association 2005, 2007; EUA, 2006; Estermann and Nokkala, 2009). Despite the general policy recommendations towards the implementation of new management tools and governance modes (European Commission, 2011), in the realm of practice, most European universities are trying to cope with the increasing social and policy demands

without significant changes in the way they manage their internal affairs (Elena and Sanchez, 2013; Ramirez Corcoles et al., 2011).

Management of universities has become, at the same time, the main solution and barrier to tackle the emerging challenges. Moreover, increasing stakeholders' demands for greater transparency, competition between universities and greater institutional autonomy push universities towards organisational innovations in designing management and performance systems. The key issue at stake is represented by the effective management of intangible assets and Intellectual Capital (IC) that constitute the largest proportion of universities' assets (Secundo et al., 2010; Sánchez et al., 2009). In this context IC approaches seem to be of prime importance for institutions of higher education and research since knowledge is their main input and output.

During the last two decades, some attempts have been done to apply IC models in universities and research centers especially in European Countries (Leitner et al., 2014; Ramirez and Gordillo, 2014; Wu et al., 2012; Veltri et al., 2012; Nava and Mercado, 2011; Secundo et al., 2010; Ramírez, 2010; Bratianu, 2009; Sanchez et al., 2009; Ramirez, et al., 2007; Leitner, 2005; Observatory of the European University, 2006; Sanchez and Elena, 2006; Leitner, 2004; Leitner and Warden, 2004). Despite the proliferation of IC models - mainly designed by individual institutions and implemented on voluntary basis (Sanchez et al., 2009) - only Austria universities use a homogeneous model and are obliged by Law to publish an IC Report.

Framed in the above premises, our concern is focused on the design of an IC model suitable for affording the trade-off between the comparability aims and the efforts to capture the institution's uniqueness. Our analysis points out that the pathways for adoption of IC management and reporting strongly depend on the characteristics of the university, its previous experience with management tools and its managerial orientation. Thus, in our view, what is needed is a more general, flexible and comprehensive model that could be used by universities with different profiles and development stages as higher education organisations, regardless of its voluntary or obligatory nature. Framed in the above premises, the purpose of our paper is to propose an "*IC Maturity Model*" for *Universities (ICMM)* which aims to be a flexible framework for defining and implementing IC approaches within universities. The ICMM provides a theoretical continuum along which the process of maturity of the University that allow to be developed incrementally from one level to the next one moving from: Data collection, IC

Awareness, Adjustments, Measurement, Reporting, Interpretation and Decision making, and Strategy and Planning. Thus, the ICMM proposes a staged framework to initiate a step-by-step change within a University based upon its current level of IC management maturity. Moreover, the different steps of maturity might be an answer to cope with the huge diversity of European universities, some of which have strong managerial orientation, while others follow collegial form of governance.

The paper is structured as follow. Section 2 provides the rationale to understand why IC is relevant in the context of higher education and research institutions. Section 3 presents the research approach and methodology. Section 4 proposes the maturity model for universities, its components, the different stages and the full cycle of IC management. Finally, Section 5, the discussion and conclusion, emphasises the added value and advantages of the model proposed and also its limitations and ways of improvement and moving forward.

2 Rationale for IC approaches in universities

Intangible assets and Intellectual Capital (IC) are seen as elements essential to value creation in companies (Moustaghfir and Schiuma, 2013) and for nations' economic wealth (Martín-de-Castro et al., 2011; Lev, 2001; Cañibano et al. 2000). Although the IC concept was first developed as a framework to analyze the contributions of intellectual resources in for-profit enterprises, it was soon extended to public and non-profit organizations due to its importance (Mouritsen et al., 2004; Kong and Prior, 2008). This section briefly describes the general background to understand what IC is in the context of universities and the rationale for proposing IC approaches for these institutions.

2.1 *What Intellectual Capital means in the context of universities?*

In practical terms, IC strategic management focuses on the ways to visualize and make use of individual and organizational resources and capacities in a holistic manner, with a focus on intangible assets, and on how to develop in a sustainable manner such resources and activities. From an organizational point of view, the term 'Intellectual Capital' refers to the resources on which the organization relies in the broadest sense, including not only human capital resources, but those of the organization itself (structural capital) and its relations with its external stakeholders and its general environment (relational capital) (MERITUM, 2002). IC has been also defined as the combination of intangible resources

and activities that “allows an organization to transform a bundle of material, financial and human resources in a system capable of creating stakeholder value and organizational innovation (European Commission, 2006, p. 4). Moreover, it could be described as intellectual material that has been formalized, captured and leveraged to produce a higher valued asset (Schiuma, 2009). Without doubt, the tripartite classification is the one that has the widest recognition in the specialized literature, structuring IC in three blocks: Human Capital (HC), Structural capital or Organisational Capital (SC) and Relational Capital (RC).

In the context of universities, the tripartite classification is as follows:

- *Human Capital (HC)* refers to the intangible value that resides in the individual competencies; this includes the expertise, knowledge and experiences of researchers, professors, technical staff, PhD students and administrative staff.
- *Structural Capital (SC)* comprises the intangibles resources that are found in the organisation itself, i.e. what remains when academic staff and students leaves. This includes, among others, the databases, the intellectual property, the research projects, the research infrastructure, the research and education processes and routines, the university culture and the governance principles.
- *Relational capital (RC)* is related to the intangible resources and capabilities able of generating value linked to the university’s internal and external relations. This includes its relations with public and private partners, position and image in networks, its academic prestigious, its brand, partnerships with the business sector and regional governments, its links with non-profit organisation and civil society in general, collaborations with national and international research centres, networks and alliances, attractiveness as a place to study and to work, etc.

As with private organisations, the weigh, role and internal meaning of each of the components of the IC concept differs depending of the university’s profile, mission and vision.

Accordingly, those Universities defined as *research-intensive* will emphasise the critical role of consolidated researchers (HC), publication records of the research personnel (SC), and networks with prestigious universities (SC); while *entrepreneurial universities* will focus on personnel with an entrepreneurial mind-set and involved in business oriented activities (HC), creation of spin-off (SC) and partnership agreements with the private sector (RC); and *teaching universities* will concentrate its attention in

attracting the best professors and students (HC), develop competitive graduate and post-graduate programme (SC) and partnerships agreements with prestigious university for student mobility (RC).

Beyond the different types of universities, each university (even being classified under the same typology) has a different managerial approach and maturity level in terms of management of intangibles and IC depending on the national law and regulations procedures where the University is located. A series of researches have dealt with the development of methods to measure IC and to support IC management and reporting in Universities (Silvestri and Veltri, 2011; Siboni et al., 2013). These initiatives have been developed or promoted by the European Union (Cañibano et al., 2000; European Commission, 2006), by national governments (e.g. Danish Trade Industry Development Council (DMSTI), 2003; Federal Ministry of Economics and Labour (FMEL), 2004; Austrian Research Centers (ARC), 2005), and by groups of experts (Observatory of the European University (OEU), 2006). In the wide range of public organisations several studies have highlighted a lack of research with reference to state universities (Hellstrom and Husted, 2004; Sanchez and Elena, 2006; Bezhani, 2010), and several calls for research have been published to improve the managing of IC in those organisations (e.g. Castellanos and Rodriguez, 2004; Leitner, 2004; Sanchez et al., 2009; Secundo et al, 2010).

Probably the most comprehensive effort done so far to provide a comprehensive and homogenous IC Model for managing and reporting IC in universities (the so-called ICU Report) was developed by the Observatory of the European University (2006). As proposed by the ICU Report (OEU, 2006; Sanchez et al., 2009), a proper IC management and reporting tool has to take into consideration three elements: (a) the vision of the institution, which includes the main general objectives, the strategy and the key drivers to reach them, (b) the intangible resources and activities that the institution can mobilize and the different activities undertaken or planned to improve them, and (c) the system of indicators defined to allow the internal and external bodies to assess the performance and estimate the future of the institution correctly.

Despite the efforts for developing a comprehensive framework for IC management and disclosure, the attempts to make the ICU Report a reality show several shortcomings in the implementation process mainly related to internal characteristics of the institutions, such as the definition of the university's boundaries and profile; the level of involvement

of managers and their experience with similar tool or the exiting of conflicting objectives within the institution (Sanchez et al., 2009). In other words, IC management approaches were not able to provide a solution for the huge diversity of universities in Europe. Sanchez et al. (2009, p.320) argued that some of these shortcomings have led to the idea that “it would be better to build specific models for each organisation, which could only be done with voluntary initiatives”.

Other advanced models (Chiucchi, 2004) adopted the evolved notion of IC as a dynamic system on intangibles resources based on knowledge (Veltri et al, 2012). In these kinds of model, that overcome the limitation of the pioneering IC measurement models, attention is focused on the interactions between the IC components and on intangible activities which are essential in the production, maintenance and development of intangible resources (Silvestri and Veltri, 2011). The assumption behind these models is that measurement of IC is necessary for the management of knowledge, and their main aim is to identify the paths of an organization’s value creation based on knowledge (Veltri et al, 2012). Some features are considered relevant when analysing and defining an integrated IC management and reporting model: *the potential value of IC and its dynamic* and the *organization-specific nature*. Understanding these factors in the context of Universities means that as regard the first feature, in order to create value, IC components have to interact with each other and with tangible factors. Furthermore, the dynamic nature of IC implies that it is a concept in evolution, which undergoes changes over time and which must be constantly understood and interpreted (Kianto, 2007). The implications for researchers and practitioners are that an exhaustive list of IC components does not exist, due to these constant changes of classification (Grojer, 2001). The organization-specific nature of IC also implies that IC indicators are specific for each single organization, sector, industry, typology, size of organization, etc. Even the more accredited guidelines for drawing up an IC report do not propose an exhaustive list but include only some organisations specific examples.

2.2 Why intellectual capital approaches are relevant for universities?

The need for universities to have a greater involvement with their wider community and the general concern to ensure comparisons and benchmarking among them makes advisable to manage and disclose information on IC (Ramirez Corcoles et al, 2011). General methods for identifying, evaluating, managing and reporting on intangibles

within universities finds its justification on the one hand in the political and managerial challenges that universities are facing (Harayama, 2007; Johnes et al., 2009; Parker, 2011; Veltri et. al., 2012), and, on the other hand, in the fact that their most valuable resources are its researchers, students and their relations and organisational routine, and their most important output is knowledge, that is basically intangibles (Siboni et al., 2013; Canibano and Sanchez, 2009, Leitner, 2004).

In general terms, the benefits of implementing an IC management model fall into two categories (Marr and Chatzkel, 2004, European Commission, 2006): (a) Its potential to function as a management tool to help develop and allocate resources, create strategy, monitor the development of the organisation's results, and facilitate decision making and (b) Its potential to function as a communication and reporting tool linking the institution to the stakeholders and as a way to attract resources – financial, human and technological.

In the context of HE institutions, the challenge is to combine flexibility and adaptation to the fast-changing environment which necessarily implies the introduction of management tools. Additionally other reasons why IC management tools are of great potential for universities (Elena and Warden, 2011) are as follows:

- Universities are being provided with more autonomy to manage their own affairs, not only academic but also financial, to redefine their own internal structures, which necessarily requires new management and reporting systems.
- Universities have to be more transparent and, thus, to disseminate more information to stakeholders (researchers and teaching, students, funding bodies, governmental agencies, labour market, and society as a whole).
- The increasing cooperation between universities and firms has resulted in the demand for similar processes of evaluation for both players. Accordingly, universities would have to implement new management and reporting systems, which necessarily incorporate intangibles.
- IC management can help to shift strategic focus of universities towards intellectual resources and enhance their capability to adapt to the challenges posed by the non-profit environment they are operating in.
- Finally, IC should play a key role in human resource management (HRM) within organisations, thereby also addressing the organisational factors (structural capital) that are important that employees and students can enfold their creativity.

Despite the benefits and potential of IC approaches, in the realm of practice, universities face serious difficulties when trying to implement a “business” thinking to steer the organization towards a successful future. They are complex organizations dealing with a multi-mission approach, task complexity, professionalism and administrative values (Sporn, 1999). Furthermore, the governing modes of European universities, often based on collegial models, hinder the implementation of new managerial decision making processes and tools (Elena and Warden, 2011). There are also important external constraints, such as the changing role of the state, public budget pressures and new societal demands.

Framed in the above premises and based on the idea that “one solution does not fit all”, the research aims of this article is to conjugate the IC measurement and management perspectives within Universities, by developing a flexible framework able to adapt to individual characteristics of different institutions and different stages of managerial development. This provides an opportunity for IC approaches to reinvent itself and to facilitate a more balanced approach among management, measurement and reporting.

3 Research approach

The research approach followed is based on what has been called the “third stage” of IC research (Marzo, 2014), which focused on the praxis of IC approaches and models rather than on its theoretical conceptualisation. When dealing with IC in non-for profit organisations, as it is the case of universities, the gap between theory and practice is very broad. The benefits of IC approaches advocated by the specialised literature and policy recommendations are clear but crash with the daily life and the reality of these organisations. Hence, our research approach was practice-oriented and has been produced in the frame of the Project “Quality Assurance in Higher Education through Habilitation and Auditing”¹ run by the Executive Agency for Higher Education and Research Funding of Romania (EUFISCDI) and co-funded by the European Social Funds (Sectoral Operation Programme Human Resources Development 2007-2013).

As argued by Dumay (2009; 2012) neither practitioners nor the academic community support the universal implementation of any of the proposed frameworks because none

¹ Project co-funded by UEFISDI and European Social Funds (Sectoral Operation Programme Human Resources Development 2007-2013).

of them seems to offer a robust solution to visualise, manage and report the IC. For the case of universities is even more clear since the wide range of individuals experiences of managing and reporting on IC have been, in most cases, one stand-alone practice and there is no continuity over time.

To this purpose and with the aim to cover the highlighted research gap, three Mutual Learning Workshops (MLWs) were organised as a mean to bring together international experts and practitioners to share their views and experience on IC Reporting and setting up task forces to draft the Blueprints for IC Reporting for universities. The MLW took place in Bucharest (Romania) from October 2012 to May 2013 involving 15 experts from across Europe.

The mutual learning methodology is a valid tool to provide a common space, a “platform”, for experts, practitioners, managers and policy-makers to reflect upon, share, consolidate and transfer experiences and lessons. This methodology has been proved to be highly effective in other areas of high relevance and policy impact such as the definition and implementation of Smart Specialisation Strategies (S3)¹.

The expert team conducted the work along four stages:

- Stage 1. Mutual learning from the IC management in European Universities. In this phase the existing approaches and lessons with IC management at universities across Europe have been discussed and synthesised. Analysis included experience from Spain, Austria, Greece, Italy, Romania, Lithuania, Poland and Latvia.
- Stage 2. Identification of the main shortcomings of the existing models and instruments for IC reporting and management. A common discussion and analysis of existing approaches allowed to define the requirements for a new model to be developed.
- Stage 3. Development of the model. The IC model was defined taking into account the features of universities and the operational requirements to draft a model which can be applied for very different universities concerning their management development and organisational culture.

¹ For more information see the Smart Specialisation Platform peer reviews activities based on the principles of mutual learning workshops: <http://s3platform.jrc.ec.europa.eu/peer-review>

- Stage 4. First validation of the Model with experts in IC management and colleagues of the project, team which in parallel developed a model for IC management in Regions

The lessons learnt can be organised around the following four key issues: (i) critical review of functions and purposes of IC management and reporting models from the university perspective; (ii) IC models and frameworks should be reoriented and adapted to individual institutions; (iii) the definition of indicators should consider the trade-off between comparability purposes and usefulness for managers, and (iv) shortcomings of the implementation process.

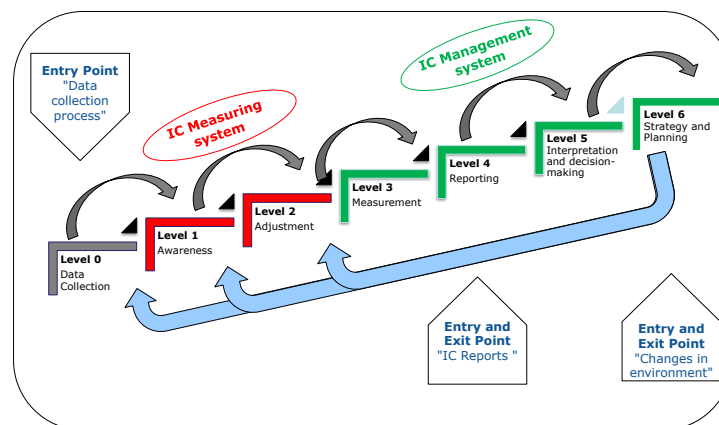

The final result of the Project is a set of guidelines for IC management implementation in European universities (Leitner et al., 2014).

4 Towards an IC Maturity Model for Universities

As mentioned in previous sections, European HE landscape is very diverse in terms of missions, forms of governance, level of autonomy, capacities and existing processes for management of tangible and intangible assets. This suggests that there are no ‘one-size-fits-all’ solutions and thus the adoption of IC management systems should be flexible and tailored to individual needs and capabilities. To this end we suggest an approach for IC management based on the concept of maturity models.

Maturity models were initially developed in computer programming with the view of ensuring systematic development of software and ensuring inter-operability of programmes (Van Looy et al., 2010). Subsequently such models were applied to monitor and manage the introduction of a broad range of organisational innovations: from new product developments to e-learning or open source. Maturity models provide a flexible framework for the introduction and management of innovations along a continuum of maturity levels: from *ad hoc* activities carried out by ‘heroic individuals’ to systematic implementation and subsequent continuous improvements. Depending on capabilities and individual characteristics, organisations typically start at different levels and proceed to the next stages at varying speed. Hence, maturity models serve several functions: a) initial appraisal of *status quo* (i.e. identification of maturity level before introduction of innovations); b) step-by-step roadmaps on how to proceed; c) instruments for monitoring the progress.

The proposed *IC Maturity Model (ICMM) for Universities* and has been constructed in line with three guiding principles (see Figure 1). First, IC management system should be introduced considering the mission, objectives and unique features of the university. Hence, there are multiple ‘entry points’. In other words, universities are likely to start the definition and implementation of an IC management approach from different levels (e.g for the data collection process or from the reporting of IC information or even just from a change in the environment). Second, fully functioning IC management system is an iterative rather than a linear process. IC measurements should be systematically integrated into decision-making processes and periodically reviewed in line with shifting strategic and operational objectives. Third, IC management is not ‘yet another management tool’: a fully mature system should be at the heart of strategic and operational decisions taken by university.

Source: Own elaboration

Figure 1. ICMM for Universities: paths for IC definition and implementation

As Figure 1 illustrates the full cycle of maturity model includes seven levels, so provides targets on improving maturity, three “entry points” (data collection process, IC reports and Strategy and Planning) and two “exit points” (IC reports and Changes environment). As mentioned above, the “entry point” implies that the institution can start with the model at different levels, and not necessarily from level 0, given the different degrees of its management maturity. Those universities not familiar with the IC approach and still with a need to homogenise data bases and gather further data will most likely start from level 0, while for instance universities already reporting on IC (such as could be the case of Austrian universities) can start from Level 4. On the contrary, “exit points”

means that the institution could stop the process and not finalise the full maturity cycle for different reasons. It could be the case than the institution would like to stop the process when the target of reporting has been accomplished or when changes in the environment impose reorientation of managerial priorities.

The seven levels of maturity are as follows:

- **Level 0: Data collection.** All European universities collect, to greater or lesser degree, some data for accounting, management and/or external accountability purposes (e.g. number of students, degrees awarded, number of research projects, number of staff, etc.). Some of these indicators could be related to intellectual capital, but are neither conceptualised as such, nor used in the management process. Such data collection process (either for management or reporting purposes) represents a typical ‘entry point’ for of IC measurement and management.
- **Level 1: Awareness of IC.** Universities are producing knowledge, but a rather small proportion of them can clearly identify unique intangibles that differentiate them from other universities or alike institutions. Hence the first level of implementation of IC management systems involves the definition of key intellectual assets unique to a University. This process is typically guided by strategic objectives and the available information on current strengths and weaknesses. Awareness of IC may be the result of long-term strategic orientation and, over time, could lead to the next level: adjustment of data collection and monitoring system.
- **Level 2: Adjustment of monitoring systems.** Once the objectives and scope of IC monitoring is defined, indicators and routines for data collection are reviewed so as to explicitly incorporate relevant dimensions of organisational IC. This includes systemic review of all the data collected by university, relinquishing of irrelevant indicators and introduction of new ones to reflect the strengths and weaknesses of IC of a university. While consensus building on unique IC dimensions (awareness level) is likely to involve broad participation from academic community, optimisation of monitoring systems is usually performed by the management.
- **Level 3: Measurement of IC.** Measurement involves systemic collection of data in line with *ex ante* defined indicators. This process involves considerable costs

to university administrators and academic community who have to provide additional information. Well-functioning measurement systems are based on a limited set of indicators and a shared vision regarding the rationale behind data collection. If levels 1 (awareness) and 2 (optimisation) are immature, measurement process is likely to be problematic. On the one hand, if there is lack of consensus on the objectives of IC management, academic community may decline to provide additional information. On the other hand, definition of the right indicators and measurement process can create incentives for academic community to align their individual agendas with that of the university.

- **Level 4: Reporting of IC.** Publication of IC reports could be an indication that university has reached the fourth level of the ICMM. Importantly, the reports should serve two functions: a) accountability of external stakeholders as well as tax-payers at large and b) provide vital information for managerial decisions (EQU, 2006). All too often information on IC is used only for external accountability purposes. This stage could also represent an 'exit' point, i.e. IC measurement system is not used as an integral part of IC management.
- **Level 5: Interpretation and decision-making.** The sixth maturity level involves use of information on IC in everyday decision making. It should constitute an integral part of human resource policies, investment decisions as well as set the framework for deliberations on curriculum and research agenda.
- **Level 6: Strategy and planning.** Fully functioning IC management system involves periodic reassessment and reinvention of universities' unique strengths, long- and short-term objectives and means to achieve them. Hence, the last maturity level involves use of information on intellectual assets to review universities' internal processes, redefine mission, values, objectives and strategic plan. These decisions should be reflected in the next planning cycle: what are the core assets, how they should be monitored and managed to improve mission and performance?

Strategy and planning phase could also reflect an 'entry point' to IC management. Radical shifts in strategic orientation of university (typically caused by factors such as economic crisis, change in regulatory framework or appointment of new Rector) could create a need to introduce IC management as an instrument to flesh-out universities' mission or reallocate resources.

5 Discussion, Conclusions and ways forward

Universities are moving from a traditional academic organization to new forms of Entrepreneurial Universities where the processes of education, research and innovation are strictly integrated to support cooperative activities and relationships with external stakeholders and funders (Hunt, 2003; Gibb and Hannon, 2006). The increasing emphasis on integration – such as university-industry-government cooperation – calls for new forms of academic and administrative management (Weber, 2006). At this purpose Universities need to take into account new IC management strategies for identifying, measuring and valuing intangibles as part of an overall management perspective.

“At present, the numerous initiatives on IC reporting provide many interesting and challenging ideas, but arguably have little prospect of widespread adoption. Perhaps, the lack of agreement among academics and practitioners on most aspects of IC reporting including what to report (or what is IC) and how to report, can be blamed for the current moribund status of IC reporting” (Abhayawansa, 2014, p. 119). Nevertheless, the situation is likely to change, because the increasing autonomy and competition among universities and research organizations will oblige universities to position themselves strategically, raise new financial resources and find new ways of accounting for their investments and expenditures. In response to these challenges, universities and research organizations are already implementing new management and reporting systems, which must incorporate intangibles.

However, the design of an IC model suitable for affording the trade-off between the comparability aims and the efforts to capture the institution’s uniqueness when designing an IC model or framework is still open. With the aim to cover this gap, our analysis pointed out that the pathways for adoption of IC management and reporting strongly depend on the characteristics of the university, its previous experience with management tools and its managerial orientation. An *“IC Maturity Model” for Universities (ICMM)* has been presented as a flexible framework for defining and implementing IC approaches within universities. The ICMM provides a theoretical continuum along which the process of maturity of the University allows to be developed incrementally from one level to the next one.

Transitions from lower to higher maturity levels are neither predetermined, nor effortless. Climbing the ‘maturity ladder’ requires at least three preconditions. First, strategic leadership is essential to tackle at least three challenges: a) inertia in decision-

making routines and managerial practices; b) countering a rather widespread belief that knowledge creation is not susceptible to management, but rather relies on individual efforts of ‘super-star academics’ and autonomy from managerial or bureaucratic ‘red-tape’; c) taking tough decisions in reallocating resources in line with the strategic and operational objectives that emerge from interpretations of IC measurement system. Second, transition between maturity levels requires continuous efforts from academic community. Hence, it relies on broad consensus on the benefits of exercise to justify the costs. Lastly, transitions to higher levels are to necessitate introduction of additional analytical, managerial and similar systems. For instance, measurement requires definition of indicators, careful analysis of the costs and benefits of collecting each additional data point, review of other monitoring systems to facilitate benchmarking, etc. Development and maintenance of these systems will consume scarce human and financial resources. Hence, as Cohen, March and Olsen (1972) argued, it is likely that organisational innovations are likely to emerge in universities with large institutional ‘slack’, i.e. availability of additional resources that are not essential for other vital organisational functions. This suggest that universities continuously operating under large financial stress are not likely to introduce (or increase the maturity of) IC management systems.

Maturity models seem to be useful because they allow organizations to self- assess the maturity of various aspects of their processes against benchmarks. Specification of a University’s IC maturity helps in determining the current attitude towards intangible assets, the state-of-knowledge in the University about the IC and finally the University’s-specific strategy for implementing IC related activities in order to improve performance.

The ICMM also provides a staged framework to initiate a step-by-step change within an University based upon its current level of IC management maturity. The application of the model would be a healthy exercise in transparency for these institutions to facilitate access for their stakeholders to a variety of information which is relevant to their decision making. So, the ICMM could facilitate universities on the path to presenting information useful to their stakeholders, contributing to a greater transparency and comparability in the higher education sector, to help decision-making processes, improve the articulation of public policies and increase transparency in the whole system. The originality of the ICMM Model lies in its adaptation to cope with the huge diversity of European universities, some of which have strong managerial orientation, while others follow collegial form of governance.

Future research will include the identification and validation of IC indicators according the features of the University where to apply the model. To this end, a questionnaire will be sent to members of the governing board of a set of identified Universities to identify their opinion on the necessity of disclosing these IC indicators; analysis of the different perceptions of each group of stakeholders regarding the importance of disclosing information about IC.

Structured Abstract

Purpose – The aim of this paper is to provide a comprehensive research review on knowledge management in small and medium enterprises in order to identify gaps in the body of literature. By connecting these gaps to business future trends we identify several future research avenues for each research area.

Design/methodology/approach – The main objective of this literature review is to analyse the state-of-the-art of knowledge management in small and medium sized firms from the management perspective in order to identify relevant research gaps. The review has been carried out using Scopus and Web of Science Academic databases, and it has been conducted using the keyword “knowledge management” in combination with “SMEs” or “small firms” or “small business”. Seventy papers in total were selected and studied in detail; they are all relevant scientific papers covering the topic of KM in SMEs from 2003 to 2013.

Originality/value – This methodology puts in evidence the current situation in knowledge management in SMEs’ research field.

Practical implications – The outcomes of the application provide a valuable understanding of both knowledge management’s best researched topic, which concerns the factors affecting knowledge management in SMEs and the knowledge management topics which are poorly investigated which concern KMSs adoption in SMEs, the barriers hindering their dissemination and the impact of KM on firm performance. From a practical perspective, the review concludes that the barriers connecting to KMSs implementation seem to belong more to cultural area rather than technological one and need to be exploited more in depth.

Keywords – knowledge management, enabler factors, barriers, SMEs.

Paper type – Academic Research Paper

1 Introduction

A vast literature underlines that in modern industrial environment SMEs are playing a crucial role for large companies competitiveness (Al-Mutawah et al., 2009; Dyer, Hatch, 2006; Esper et al. 2010; Esposito, Passaro 1997; Esposito, Raffa, 1994; Esposito, Raffa, 2007; Gunasekaran, Ngai, 2007; Lakshman, Parente, 2008; Lee et al, 2010; Samuel, 2011; Iandoli et al. 2012). Nevertheless, although there is an abundance of studies describing how large companies are successfully practising KM, the reasons why small firms show poor usage of KM tools are still unclear and benefits of KM adoption are not fully exploited by these firms (Alavi, Dorothy, 2001; Durst, Edvardsson, 2012; Marra, Ho, Edwards, 2012; Thorpe et al., 2005). Several researches highlight that the issues relating to KM in SMEs are different from large firm. In KM practices issues faced by small businesses cannot simply be a scaled-down replica of large-company experiences (Pillania, 2006, 2008a; 2008b; Sparrow, 2001). As asserted by Frey (2001), although major corporations have led the way in introducing and implementing KM, for SMEs is increasingly important manage their collective intellectual assets. In line with this perspective, Desouza and Awazu (2006) identify five key peculiarities that differentiate practices of knowledge management in SMEs than large companies: the dominance of socialization in the knowledge creating cycle; common knowledge, that is knowledge known to all members of the organization; the way to avoid lost of knowledge (the close social ties among members of the SME act as a deterrence against employees leaving the business and avoid pitfalls of knowledge loss); exploitation of external sources of knowledge; people centred knowledge management (technology is never used as a means to manage knowledge). Similarly, McAdam and Reid (2001) using a modified version of Demarest's Socially Constructed model for the KM that in turn is an adaptation of Clark and Staunton's model describes the key dimensions of KM process (knowledge construction, knowledge embodiment, knowledge dissemination and knowledge use/benefits) and for each dimension conducts a comparison between large firms and SMEs. Sparrow (2001) identified four components of KM in small firms: the appreciation of personal and shared understanding; knowledge bases and knowledge systems; the integrated and contextualized action needed for knowledge projects in SMEs; the knowledge and organizational learning processes in SMEs. Egbu et al. (2005) highlight

that knowledge generated in SMEs is tacit in nature due to various reasons. In the context of SMEs some elements of KM are practiced but in an 'ad hoc' fashion. Indeed, any technological infrastructure that is put in place to support KM must be adapted to the organisation's needs and not the other way round. Wong (2005) underlines that most of research concerning factors that may influence the success of KM implementation is heavily focused on large companies as early adopters and superior performers of KM were large and multinational corporations. As such, existing factors are mainly large companies oriented, thereby reflecting their situations and needs. Directly applying these factors into the SMEs environment may not be sufficient without an understanding of their very own and specific conditions. In this context, Wong (2005) and Wong and Aspinwall (2005), proposed a more comprehensive model for implementing KM in SMEs based on eleven critical success factors: management leadership and support, culture, information technology, strategy and purpose, measurement, organisational infrastructure, processes and activities, motivational aids, resources, training and education and human resources management.

From the other point of view there are several works which stressed how firm's performance can be enhanced by knowledge management processes Daud (2011); Bagnoli (2012).

The above literature highlights that there are profound differences in the process of KM between SMEs and large companies. Directly or indirectly these differences turn around the following aspects:

- In SMEs the nature of knowledge is mainly human embedded;
- In SMEs there is a sort of common knowledge, that is a knowledge known to all members of the organization;
- The scarcity of resources pushes SMEs towards the exploitation of external resources of knowledge.

Although these aspects seem reasonable, the Information and Communication Technologies (ICTs) are more and more reducing their weight by offering new tools for KM that are (Antonelli, et al., 2000; Esposito, Mastroianni, 2001; Garrigos-Simon, et al., 2012; Matlay, Westhead, 2005):

- *Low cost*. This means that new KMSs do not require relevant financial resources and are compatible with budget of SMEs;

- *Ease to use* (friendly). That is, ICTs are offering KMSs that to be used do not need high skills;
- *More effective*. Compared with traditional tools, new ones are able to support the processes of socialization among members of a group.

In synthesis, new technologies are reducing the human and financial barriers that hinder the adoption of KMSs, are facilitating the process of socialization of the knowledge that is crucial for SMES, and are offering new opportunities and new benefits that push SMEs toward practices of KM.

The reality is constantly changing and although the number of papers is increasing in the last few years, the body of knowledge regarding knowledge management in SMEs is still limited (Durst, Edvardsson, 2011).

Assuming that SMEs are the drivers of most nations all over the world, this situation is to be improved.

According to the literature review written by Durst (2012), there are three areas of KM, which seem to be relatively well researched in SMEs.

These are KM implementation, KM perception and knowledge transfer while the body of knowledge regarding the topics of knowledge identification, knowledge storage/retention and knowledge utilisation is rather poor.

Therefore in order to meet both market changing in IT field and taking inspiration from some evidences retrieved in literature, the aim of this paper is to review research on KM within smaller firms in order to identify gaps in the literature which justify further research avenues as well as to clarify what are the well researched areas.

The paper is organized into three sections. Following this introduction, the second section describes the methodology used to carry out a systematic literature review on KM in small firms and provides the main results achieved. Conclusions and implications are outlined in the third section.

2 Methodology

The review has been carried out using Scopus and Web of Science Academic databases, which ensure a comprehensive coverage of scientific output as they contain more than 8,000 scientific journals, including the most important high-ranking journals. Adapting the approach suggested by Kolbe and Burnett (1991) and Li and Cavusgil

(1995), the systematic study of existing body of knowledge on the above topic has been done through the three following main phases: 1) sampling, 2) classification and 3) analysis.

2.1 Sampling

The sampling phase is aimed at identifying all relevant papers that covers the topic of knowledge management in SMEs.

The search was conducted using the combination of the following keywords: “knowledge management”, “SMEs”, “small business”, “small firms”, “small enterprises”.

Journal articles, which appeared in the period from 2003 to 2013, were collected. These articles were sourced from ISI Web of Knowledge and Scopus database.

This allows us to identify 269 documents from Scopus database and 74 documents from Web of Science Academic database. It is important to stress that about the 90% of the latter are included in the former database.

The further step in this phase was to achieve a high level of rigorousness of scientific products retrieved and control over quality of the search process. This was achieved by limiting the search to peer-reviewed journals (including papers already presented in international conference proceedings and published on peer-reviewed journals after the conference). As a result, prefaces, editorial notes, review and other editorial materials, in addition to any articles from magazines or industry publications, were excluded. We adopted the selection criteria of title, abstracts, keywords and making reference only to the subject areas of social sciences the final sample obtained at the end of this stage consists in 70 journal articles.

2.2 Classification

For the retained 70 articles we conducted a descriptive analysis before studying their contents in more depth.

The descriptive analysis covers the articles distribution over time (Fig. 1) and journal research area (Table 1).

Concerning the 70 retained articles distribution over time, it mirrors the timing trend of the all 269 articles which have been yielded in Scopus database.

To classify the articles identified in the previous phase the functionalities, provided by the Web of Science Academic database, have been used. These allow to identify the

distribution of 70 articles retrieved by 19 subject areas of the database. The subject areas have been grouped into the following four macro areas (Table 1): a) Engineering (7 article), b) Information systems and computer science (7 articles), c) Operations research and management science (46 articles) and, d) Multidisciplinary (10).

The articles were obtained from the e-journal search engines available in the University of Napoli Federico II electronic library. These include access to journals published by several publishers such as Elsevier, Taylor & Francis and others.

Fig. 1 - Articles distribution over time

Table 1 - Sample articles by macro areas

Macro areas	Papers
Operations Research & Business Science	46
Engineering	7
Computer Science & Information Systems	7
Multidisciplinary	10
Total	70

Full bibliographic details of the 70 articles selected for the analysis are shown in the reference section in order to make our research processes transparent.

The 70 articles were studied in detail and the results of the analysis are described in the following section.

2.3 Content analysis: characterisation of research areas

Content analysis of the 70 articles gives us a detailed overview of the aspects covered by research on knowledge management in SMEs; the articles have been clustered according to macro topic areas which in turn have been split, as possible, in classes of influence or otherwise in subgroups in order to get a fully overview of the problem.

2.3.1 The first macro topic area: factors affecting the knowledge management in small and medium enterprises

The articles belonging to this topic deal with the factors that can influence the success of KM implementation; taking inspiration from Wong (2005)'s study, at first, three classes of influences can be proposed to classify these factors: managerial, resource and environmental influences.

The managerial area involves four main aspects: coordination, control, measurement and leadership; resource area consists of knowledge, human, material and financial resources with human resources in turn involves human capital: education, experience, social skills and motivation (Jones, 2010), whereas environmental influences includes: competition, markets, time pressure, governmental and economic climates.

At the end, another important class of influence to KM implementation can be identified, it is the firm's infrastructure (Lee, 2011), which involves: technology, organizational structure and organizational culture.

According to the first class of influence there are several studies in literature (Wong, 2005; Valmohammadi, 2010) which argue that top management behaviour and its full support is able to motivate employees to take part in successful implementation of knowledge management, so it is a point to stress.

Concerning human resource area, training and education is another important field for successful KM, in fact if employees are trained and educated in using the KM system and other technological tools for managing knowledge they can utilise the full potential and capabilities offered by these tools as argued by Wong (2005).

From the other side the motivation of employees is another critical human factors to take into account and to support because if individuals are not motivated to practise KM, no amount of investment, infrastructure and technological intervention will make it effective.

Concerning firm's infrastructure influence it involves at first organizational structure which makes reference to the degree of centralization and formalization (Ghoulipour, 2010), a too formalized structure can inhibit dynamic interaction that is critical to knowledge creation.

Another factor that belong to infrastructure dimension is the firm' culture. Concerning the cultural issue, Wong (2005) argues that culture is a wide concept, which comprises many aspects. One cultural aspect, which is crucial for Knowledge Management, is collaboration. In fact a collaborative culture requires individuals to keep in touch each other, to exchange ideas therefore it is an important enabler for both knowledge transfer and knowledge creation. Trust is also another fundamental aspect of a knowledge friendly culture (Wong, 2005). In fact the building of a trust atmosphere between individuals and groups inside the firm is able to get down the knowledge barriers about intellectual property and the fear of exploitation and therefore can improve the knowledge sharing process.

So the culture is an important point to stress because if it has not been fully exploited it can become the largest obstacle faced by organisations in creating a successful knowledge-based enterprise as the survey, conducted by Chase (1997) and reported by Wong (2005), suggests.

Another factor which belongs to infrastructure is information technology (Lee, 2011), it is an indisputable key enabler for implementing KM in SMEs (Wong, 2005) but its development and utilisation have to meet the particular firm's need with reference to the knowledge content, organizational structure, suitability to users' needs in order to develop systems which evolve from merely being a static archive of information to being connector of a human to information and of one human to another (Wong, 2005).

The identified classes of influence can be clustered into two macro-areas: internal factors area and contingency factors area.

1. Internal factors cluster. The first cluster involves the articles belonging to managerial, resources and infrastructure classes of influence, these classes have a peculiarity in common, in fact they deal with factors inside the firm, which affect knowledge management and which are directly controllable by an organization (Valmohammadi, 2010); the most part of articles retrieved in literature belongs to this area.

2. *Contingency factors cluster*. This sub-topic research area covers only 6 articles. The articles belonging to this area deal with both factors outside the firm, affecting the enrichment of company's own knowledge base such as environmental influences, as earlier explained, and contextual factors (organizational size and age firm). In literature many questions have been arisen concerning the relation between KM and organizational size (Moffett and McAdam, 2006), and in particular whether KM programmes can be applied across all organizations equally. Concerning this topic we have to also make reference to background variables like: location, turnover, gender, and age of managers (Edvardsson, 2009).

The explored factors can influence the success of KM implementation whether they are well employed and combined otherwise they become barriers to knowledge management.

In fact as Nunes (2006) argues, there are several issues related to KM implementation.

The first is associated with the already discussed syndrome that "long term investments" are always lower priority than "short term investment" Nunes (2006). The second reason is related with the difficulties in obtaining a "believable Return on Investment case" (Nunes, 2006).

These issues make reference to organizational cultural influences and top management behaviour, which have been earlier explored.

Others barriers connecting to knowledge spread are intellectual property and, sometimes, organizational structure (Milosz, 2010).

As shown in the survey conducted by Wong and Aspinwall (2005), in SMEs sector in UK, there are several reasons for not practising knowledge management.

These reasons point to the lack of a sound conceptual foundation in KM and in its potential benefits. This is consistent with the findings of other studies related to SMEs (McAdam and Reid, 2001).

However only 4 articles adopt this viewpoint to face knowledge management topic.

The classification of articles, belonging to the first topic area, can be summed up as shown in Fig. 2.

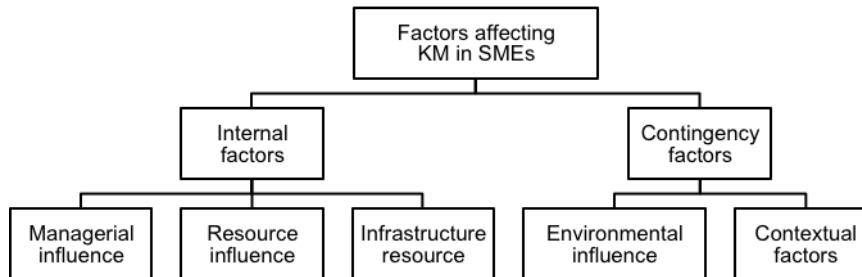

Fig. 2. The articles' topic areas

2.3.2 The second research topic: KM in small and medium enterprises and firm performance

Concerning the second topic it deals with the relationship between Knowledge management process implementation and improvement of firm performance.

There are various perspectives in literature to evaluate KM performance; adapting Chen and Chen (2006)' approach we can identify the following categories: quantitative analysis and qualitative analysis.

Concerning the quantitative analysis it makes references both to financial measures (profit, return on assets, payback periods, Tobin'q indicator, sales growth, shareholder equity) and to non financial measures.

About non financial measures, they involve market performance indicators (increasing market share, increasing level of customer satisfaction, market flexibility, competitiveness) and operational and technical performance measures (decreasing operation costs, decreasing product cycle time, increasing productivity, flexibility in resources utilization and process efficiency, quality).

About qualitative analysis it concerns measures, which involve human resource management perspective (improving employees' skills, developing customer and suppliers relationships, work relationship, creativity and staff performance, employee retention), strategy perspective (improving quality strategy, improving core business processes) and technological perspective (innovation).

Gholami (2013) deals with the relationship between Knowledge management process, which involves knowledge acquisition, knowledge storage, knowledge creation, knowledge sharing and the improvement of organizational performance, which includes

critical components such as productivity, financial performance, staff performance, innovation, work relationships, and customer satisfaction.

Bagnoli (2012) evaluates the relationship between SMEs innovation and organizational performance through a quantitative analysis carried out on a sample of 60 manufacturing SMEs in northeast Italy.

Salojärvi (2005) shedlights the positive relationship among the employment of knowledge management practices, policies in small and medium-sized enterprises and sustainable sales growth of those enterprises through a survey of 108 Finnish SMEs.

Delen (2013)'s research findings instead reveal that knowledge utilization appears to be the most important factor of KM in terms of its effects on both financial and non-financial firm performance. It is due to the fact that knowledge is valuable if only it is utilized. Hence, one of the most challenging dimensions of KM is how to leverage and utilize knowledge in accordance with organizational objectives and convert it into a valuable form in order to gain a competitive advantage.

Durst (2012) stresses the need for the SMEs' succession planning to develop control mechanisms of knowledge retention and therefore to implement measures to face the problem of undocumented knowledge and the dominance of tacit knowledge in order to avoid the danger of knowledge attrition caused by organizational turnover or large term absenteeism of critical staff members.

Soon and Zaino (2011) argue how knowledge enablers like learning, IT support can affect organizational creativity as "the creation of a valuable, useful new product, service, idea, procedure, or process by individuals working together in a complex social systems" and thus organizational performance.

All this seems to shedlighth that KM contributes to an overall growth of SMEs by enhancing simultaneously both quantitative and qualitative performance indicators but it is required in literature to develop a further empirical evidence which stresses the relationship between performance's elements and their importance.

The variables influencing knowledge management performance analysis can be summed up as reported in Fig. 3.

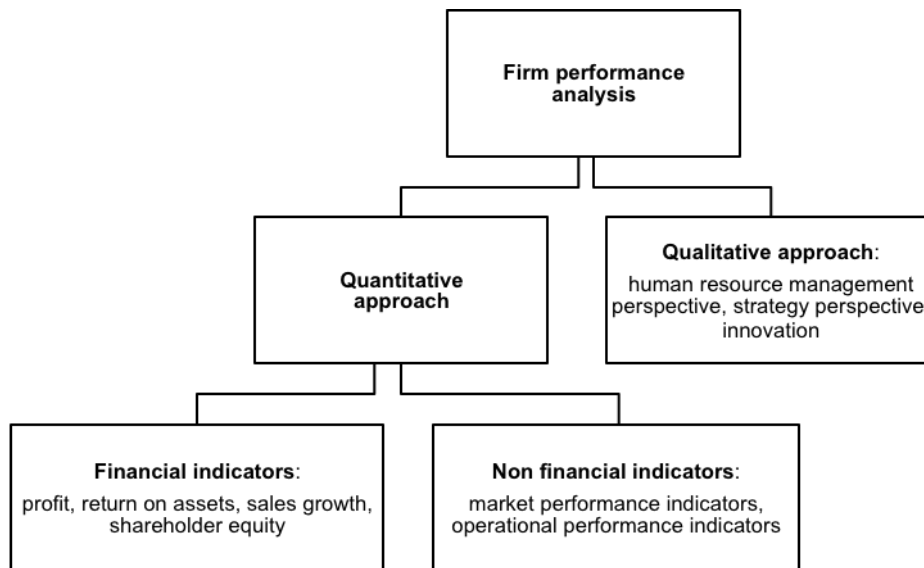

Fig. 3. Firm performance' analysis

2.3.3 The third research topic: KM practices

This topic covers 25 articles, which can be addressed to two subtopics according to the classification suggested by Turner et al. (2010):

1. *human oriented practices*, including such methods as communities of practice, job rotation, coaching, mentoring, after action review, storytelling, status meeting.
2. *technology oriented practices*, including collaboration platforms, document management, yellow pages, skills inventories, expert systems, blogs, information portals and wikis.

Concerning the first category as Desouza (2006) argues SMEs manage knowledge mainly by humanistic way, these include the use of face-to-face meetings, observations, apprenticeship training methods; and technology is not fully understood as a means to manage knowledge; it was due to the fact that several times SMEs do not exploit the potential benefits of IT for KM (Egbu, 2005).

According to the survey conducted by Edvardsson (2009), the Icelandic SMEs which funded in ICT adopted Internet and Intranet, data warehousing and groupware, but few got advanced KM technology like document management systems and decision support.

Boden (2012) carries out two case studies to show how knowledge exchange is performed by analyzing four knowledge sharing practices: status meetings and

maintaining awareness, the collaborative use of shared artefacts and repositories, and human ‘bridges’ that mediate between people and cultures.

In respect to the human oriented knowledge practices a great importance in literature is given to communities of practice.

As duPlessis (2008) argues, the communities of practice are groups of people, which work together to achieve objectives and start building relationships.

Each of the members in the community of practice brings a unique skills set to the community of practice, which is then shared to create a greater body of knowledge and skills among the members of the community. This assists in innovation and knowledge creation across boundaries in the organisation.

According to Wenger et al. (2002), communities of practice vary from work groups and other work entities. Communities of practice share an area of competence and are willing to share the experience of their practice in that particular area. It differs from a work team or project team, however, as it has no specific time bound work objective but exists indefinitely for the issues based on which the community of practice was formed.

Many times these practices replace informal processes as: discussion groups, mentoring program, brainstorming, compiling knowledge directories, firm visit (Hutchinson, 2008).

These practises can support one or more knowledge management processes as shown in Fink (2009)’ study however the practices retrieved in literature are developed to support particularly the area of knowledge creation/acquisition and transfer (Spraggon, 2007; Pillania, 2008; Yao, 2011) while the area of knowledge identification and storage are less supported by ad hoc practices. It is in accordance with Durst review’s findings.

Concerning the technologies oriented practices, mainly adopted by SMEs, a great attention in literature is given to wikis.

According to Leuf and Cunningham (2001) wiki is a freely expandable collection of interlinked webpages, a hypertext system for modifying and storing information database, where each page is easily editable by users. It is a collaborative space due to its total freedom, ease of use and access, simple and uniform navigational conventions and is also a way to organize and cross-linked knowledge.

Grace (2009) in his case studies also finds that some benefits which move the small and medium enterprises towards the usage of wikis include “its ease of use, ability to track and edit, its influence on the building of a trusting culture and as a central repository

of information, one significant and tangible benefit from the use of wikis is its ability to save time and therefore, money”.

From the other point of view Razmerita (2011) argues that “social media tools like wikis, blogs or social networks are the new way to knowledge sharing for SMEs because they are open source and free of charge and therefore can be adopted by companies without high costs”.

The use of information technology, especially Web sites, is recognized as a critical success factor for knowledge management initiatives in the SME sector also by Wong & Aspinwall (2005). Wong (2005) sees information technologies as a key enabler for the implementation of knowledge management, and considers in the development of a knowledge management system factors such as the simplicity of technology, ease of use, suitability of users’ needs, relevancy of knowledge content, and standardization of a knowledge structure as key factors for knowledge diffusion.

However there are few articles focus on technology oriented practices (tools) in SMEs and the barriers connecting to their adoption, while the most literature work focuses on practices, which are human oriented or more generally speaking on knowledge management processes.

The distribution of articles by macro-topic areas has been reported more in details in Tables 2 and 3.

Table 2. Sample articles by macro-topic areas

Macro Topic Area	Papers
Factors affecting KM in SMEs	33
KM and performance	12
KM practices	25
Total	70

3 Conclusions

According to our classification we can identify some gaps in the literature.

The articles belonging to the first cluster focus particularly on the enabler factors which influence the knowledge diffusion in SMEs it is in accordance with Durst’ viewpoint who argued that knowledge transfer and, in a roundabout way its enablers, is a well researched topic in literature.

Otherwise very little attention has given to the barriers connecting to knowledge management systems implementation; these barriers however seem to belong more to cultural area rather than technological one and need to be exploited more in depth.

From the other side very little attention is given to the importance of knowledge spread across SME's networks in fact only an article (Cappellin, 2003) stresses this topic.

As Cappellin argues, the evolution of knowledge in SMEs is the result of interactive learning processes, which involve not only individuals inside the firm but also the SMEs' networks stakeholders.

Therefore there is the need to exploit the knowledge flow between SMEs rather than to limit the research to only a single SME' boundaries.

The articles belonging to the second cluster deal with the improvement for SMEs owing to the adoption of KM, in terms of different elements as competitiveness, organizational performance, sales growth but a further empirical work which classify the variety of firm' performance and evaluate its elements' interaction is needed.

From the other point of view only one article deals with the need for succession planning in SMEs to storage knowledge, it is in accordance with Durst' outcomes who argued that the topic of knowledge retention seems to be avoided in the field of KM in SMEs so the topics of knowledge retention and techniques to measure the level of gained knowledge in SMEs need to a better investigation.

Table 3. Articles' topic areas

Factors affecting KM in SMEs	KM and performance	KM practices
Contextual Davenport (2005) Hsu et al. (2007) Moffett and McAdam (2006)	Alegre et al. (2011) Bagnoli and Vedovato (2012) Daud and Yusoff (2011) Delen et al. (2013) Egbu et al.(2005)	Technology oriented practices Beylier et al. (2009) Choudhary (2013) Dotsika (2013) Grace (2009)
External Cappellin (2003) Edwards (2007) Roy and Therin (2008)	Filippini et al. (2012) Gholami et al. (2013) Liu and Abdalla (2013) Salojärvi et al. (2004) Soon and Zaino (2011)	Gresty (2013) Lopez-Nicolas, Soto-A. (2010) Razmerita and Kirchner (2011) Rosu et al. (2009)
Internal Bocquet and Mothe (2010) Boden et al. (2012) Cantù et al (2009) Chen et al. (2012)	Talebi and Tajeddin (2011) Wei et al. (2011)	KM processes and human oriented practices Ambrosini and Bowman (2008) Corso et al. (2003) Desouza and Awazu (2006)

Chen et al. (2013) Costa and Jimenez (2009) De Saa-Perez (2012) Deng (2008) Eze (2013) Gholipour et al. (2010) Hussain et al. (2011) Jones et al. (2010) Lee and Lan (2011) Migdadi (2008) Montequin et al (2006) Patalas-Maliszewska and Hochmeister (2011) Pillania (2008 b) Tan and Hung. (2006) Tseng et al. (2012) Valmohammadi (2010) Wee (2013) Wong (2005) Wong and Aspinwall (2005)		Du Pessis (2008) Durst (2011) Durst (2012 b) Edvardsson (2009) Fink and Ploder (2009) Hutchinson and Quintas (2008) Levy et al. (2003) Lin (2012) Massa and Testa (2011) Navarro et al. (2010) Pillania (2008 a) Spraggon and Bodolica (2007) Whyte (2012) Yao et al. (2011)
Barrier hindering KMS adoption Anand (2013) Joshi (2012) Milosz (2010) Nunes et al (2006)		

The articles belonging to the third cluster deal with the knowledge management practices, these are based mostly on direct or mediated communication between people, that are human oriented practices and less on the adoption of ICT tools, that are technology oriented practices.

It is in accordance with Durst literature review, which shows how the knowledge identification area, which involves the utilisation of KM tools and practices to acquire existing knowledge, is still poor.

Nowadays firms have to face globalization, mature markets, high levels of customer service and a continuous need for cost reduction, so there is the need for enterprises of integration and knowledge sharing with the other business partner by technology infrastructure so the attention towards the development of KM tools grows up.

Nevertheless as shown in literature review there is a poor and not methodical usage of km tools in SMEs, although the relative importance is stressed and the IT tools' price is getting down, a strong cultural barrier concerning their adoption goes on.

From the other side ICT adoption should rather be analysed in the frame of the wider Knowledge Management Systems that also includes organizational tools and management practices.

In fact in many occasions organisations have made the mistake of introducing high quality technology before employees were sensitised and motivated for the use of the new system's capabilities; so it would be preferable to start with the human oriented approach because it represents a precondition for taking a system oriented approach and it is more promising in achieving short-term success in KM (Turner, 2010).

The research directions should moves towards to fill the above mentioned gaps and in particular towards the study concerning the development of technology oriented practices which are suitable for the particular needs of the enterprise according to an integrative approach, that is the most important challenge for SMEs.

Structured Abstract

Purpose – Network collaborations continue to be a central focus in a firm’s success and businesses are regularly striving to harness the collective capabilities of the networks to which they belong through the use of effective collaborative strategies. It is therefore vital for the firms to ensure sound and effective knowledge sharing strategies in their network practices. Previous literature has extensively investigated the impact of these network strategies on the performance of firms, but little empirical research has been conducted to examine the process of knowledge sharing through network collaborations. Moreover, the context of small and medium-sized enterprises (SMEs) is substantially unexplored in reference to these problems. Hence, the main purpose of this article is to examine the mechanisms at the base of knowledge sharing in SME business networks.

Design/methodology/approach – Data were collected from SMEs through an extensive survey covering 116 SMEs based in the UK that manifested different modes of collaboration with their business partners and different knowledge sharing mechanisms. Empirical data was used to determine the factors that contribute to knowledge creation and important hurdles in sharing the knowledge between various network partners. A chi-square test, ANOVA test, a post-hoc analysis and a factorial analysis were conducted to analyse the dataset and verify robustness of findings.

Originality/value – Key findings of this research include understanding of formal and informal mechanisms used by SMEs to share knowledge in business networks, as well as key barriers associated to implementation. Moreover, results are discussed on the light of theory and in reference to different industries.

Practical implications – The paper contributes to the literature by providing empirical evidence on different mechanisms of knowledge sharing in SME business networks. Findings are relevant to academics for further development of theory and to practitioners for the formalisation of knowledge sharing strategies in a SME environment.

Keywords – Small and Medium Enterprises (SMEs), Business Networks, Knowledge Sharing, Empirical Research.

Paper type – Empirical Research

1 Introduction

Small and medium-sized enterprises (SMEs) play an important and vital role in a country's growth by providing employment, promoting innovation, inciting competition, and building economic wealth. Governments have realised that the SME sector can support in generating more employment, and help to indigenise technology in order to create a competitive advantage and foster growth (Quayle, 2003; Vaaland T and Heide M, 2007). Generally, SMEs have a comparative disadvantage in terms of management practices: organisational resources such as manpower, finance, marketing, R&D and IT, dynamic and informal strategies; and business volume (Bhagwat and Sharma 2006).

In today business environment, competitiveness is not only driven by the performance of single companies or industry, but it is dependent on the combined performance of networks of agents that collaborate together to co-create value (Gadde *et al.*, 2003). In a business network, different sorts of collaboration can be established between the different actors (Poler *et al.*, 2008) so as to create an environment of interconnected business relationships. Horvath (2001) has contributed to characterize the benefits correlated to cooperation between companies. Taticchi *et al.* (2012) in a recent work have reviewed the possible configurations of business networks and investigated the managerial issues that arise in in the context of SMEs. In fact, networking of companies causes new organizational problems, such as the decentralization of decision-making, the horizontal coordination between different business functions Ghoshal (1990) as well as the problem of knowledge management (Taticchi *et al.*, 2009). Both theoretical literature and empirical research supports the belief that Knowledge Management (KM) can play a key role in managing businesses effectively and drive success (Maier, 2007; Patriotta, 2004).

In this paper we focus our attention on knowledge sharing mechanisms activated in business networks of SMEs in the UK, with the goal of contributing to the body of knowledge by providing relevant findings from empirical research. Moreover we considered that supply chain collaboration and various collaborative strategies such as joint ventures, co-design, co-development, co-logistics, co-manufacturing, aggregated purchasing, joint problem solving, shared resources and collaborative planning, forecasting and replenishment are important in sharing the knowledge in business network. This paper primarily focuses on these collaborative strategies as knowledge sharing mechanism in the SMEs. This works limits to present partial findings of a larger study the authors are developing in reference to several countries and industries.

This paper is organised as follows: section 2 introduces relevant literature, the research methodology is explained in section 3; the analysis and results are explained in section 4 followed by discussion and conclusion in section 5.

2 Review of Relevant Literature

Today, it is possible to assert that the ability to learn, acquire, foster and integrate relevant knowledge within an organization and its extended environment is one of the most vital competences to achieve strategic success and competitive advantage (Collison and Parcell, 2001). Buckler (1998) argues that the poor performance of companies, often, is partly due to a poor and fragmented understanding of organizational learning processes, that are critical for the enablement of business excellence and innovation.

Van Baalen (2005) claims that knowledge transfer within and between organisations is not a one-way activity, but a process of trial and error, feedback, and mutual adjustment of both the source and the recipient of knowledge and that for this reason the terms “knowledge sharing” better reflects the social processes that are involved. In agreement with this definition, we have used this term in our work.

In KM literature, the implementation of knowledge sharing practices in business networks has been defined with different terms based on the approach used. Brown and Doguid (2000) have introduced the popular terms of “Networks of Practice” where knowledge is shared between different actors in an indirect way (e.g. with the use of reports, newsletters, shared portals); and “Communities of Practice” where different actors work together collaboratively with the purpose of sharing knowledge, processes and practice. In recognition of this evidence, in our work we identified supply chains as a starting point for our analysis and identified companies presenting explicit and proactive mechanisms of knowledge sharing fitting therefore in the definition of “Communities of Practice”.

In literature there is evidence that different mechanisms can be activated inside business networks with the purpose of knowledge sharing. A popular category of mechanisms concerns the use of ICT-based Knowledge Management Systems (KMSs) that are enabling technologies to effectively support knowledge management aspects and related learning processes (Maier, 2002). Early ICT-based KMSs have substantially failed to address the KM needs of companies, and this has encouraged the application of KM

soft approaches that are focused on learning through direct social communication and interaction at different levels (Senge, 1990). A number of empirical works demonstrate that a combined approach based on ICT and soft KM sharing mechanisms proves well in terms of facilitating organizational activities, promoting continuous knowledge creation and improvement, and supporting growth through innovation (Magnusson, 2004).

In the peculiar context of manufacturing SMEs, knowledge sharing mechanisms have proved successful to help companies in continuous improvement and total quality management initiatives (Bessant, 1995), in the diffusion of wide variety of technologies, and in increasing the knowledge base and business capabilities (Fuller-Love and Thomas, 2004).

3 Research Methodology

3.1 The Survey Approach

A survey research approach was adopted for investigating the knowledge sharing practices employed by SMEs located in the UK (the definition of SME provided by the UK HM Revenue & Customs was considered: Turnover \leq €100 million and \leq 250 employees). The survey method gave access to a larger number of respondent SMEs which in turn increased the scope of the study. It offered a holistic view of the issues under investigation by providing detailed insight into the knowledge sharing practices. The use of a survey approach is advocated by researchers such as Flynn 1990, Forza 2002 and Bryman and Bell 2007. Specifically, the use of a survey study is appropriate given that the study involved an exploratory investigation of the current knowledge sharing environment in the SMEs.

3.2 The Sample

An ideal sample for this work would have been drawn from the total population of the SMEs in the UK. Drawing such a random sample from the sampling frame was not easy and feasible. We used 'manufacturing' and 'number of employees' as the criteria to identify the SMEs in the UK. Additionally, we employed 'contact details' of the SMEs including name, position, email addresses and telephone numbers of higher level persons (managerial level and above) as the inclusion criteria. This level was chosen because of the extensive knowledge of their organisations, network structures and knowledge sharing strategies. This way it was ensured that the research questionnaire was responded by the

key persons in the company. On the basis of these criteria, a sample frame consisting of 720 SMEs was derived.

3.3 Data Collection

The survey questionnaire was used for collecting the primary data. It was used to effectively gather information on the relevant variables covered in the study. The survey relied on the total design method of Dilman (1978) for design and administration of the questionnaire. As the respondents were higher-level staff in the companies, Dilman's suggestions such as the covering letter, return envelope in the questionnaire pack, follow-ups were implemented. This resulted into more responses from the sample.

3.4 Respondents

The survey covered as many manufacturing companies to be included therefore respondents were selected from a wide range of industries such as: pharmaceutical, food, construction, furniture, electrical components, construction, heavy manufacturing, auto components, plastic, engineering, paper, garments and general products. A sample profile is provided in Figure 3.1.

Figure 3.1. Sample Profile: Number of respondents

The questionnaire pack was sent to nearly 50 (360) percent of the sampling frame. 142 packs of questionnaires were returned undelivered, 65 packs were returned because the respondents were not interested in the survey and 27 packs were returned because of the company's policy not to participate in any survey. Out of 126 completed and returned responses (35.5 % response rate) 10 responses were eliminated for two reasons: completed by lower-level staff and missing information in the responses. This resulted in 116 valid responses with a usable response rate of 32.7 percent.

4 Analysis and Results

4.1 External collaboration and knowledge sharing in SMEs

The respondents were asked to respond to the question: Does your organisation share knowledge with other network partners? The results indicate that network collaboration and sharing of knowledge are very common in SMEs and more than 73% of SMEs do have some form of network collaborations with external organisations. Table 4.1 provides more details.

External collaboration and knowledge sharing	Yes (%)	No (%)
	73.7	26.3

Figure 4.1: External collaboration and knowledge sharing

The external collaborations and knowledge sharing were analyzed by considering a range of independent variables such as type of ownership and network structure. On the basis of ownership type, it was found that 75.4% of local SMEs collaborate externally with other companies 74.1 % of foreign SMEs and 33.3 % of joint venture SMEs collaborate with other external organisations. The test for association between ownership and external collaboration was conducted and it was found that these two variables are associated (chi square value $\chi: 9.74, p = 0.03$). Table 4.2 shows the details pertaining to type of ownership and the external collaboration in the SMEs.

Table 4.2: Ownership and Collaboration

Ownership and External Collaboration	%
Local SMEs	75.4
Foreign SMEs	74.1
Joint Venture SMEs	33.3

On the basis of network structure, it was found that 100 percent of SMEs with S-M-W-R structures collaborated externally, around 80 percent of the SMEs with S-M-D-R and S-M-W-D-R structures collaborated externally. Chi square value ($\chi: 14.03, p = 0.01$) suggested that there is an association between Network structure and external collaboration. Table 4.3 shows more details of network structure and external collaboration.

Table 4.3: Network Structure and external collaboration

Network structure and external collaboration	%
S-M-R	68.3
S-M-W-R	100
S-M-D-R	80.0
S-M-W-D-R	80.8

4.3 Knowledge Sharing Strategies in SMEs

The result of different forms of knowledge strategies employed by the SMEs considering independent variable such as ownership type and network structures are provided in Tables 4.4 and 4.5. A chi-square test was conducted to find out any association between different the knowledge sharing initiatives and the independent variables. On the basis of the chi-square values, it can be established that almost all collaborative initiatives are associated with the respective independent variables.

4.3.1 Knowledge Sharing Strategies and Ownership

Based on the chi-square values, it was found that 27 knowledge sharing strategies were associated and 18 knowledge sharing strategies were not found to be associated with the ownership type. The major ones were: joint ventures with supplier and customer; co-manufacturing with supplier, customer and competitors; co-logistics with supplier, customer and other organisation. The results in table 4.4 show that knowledge sharing strategies are popular in each of the three ownership types.

Local SMEs are more focussed towards joint problem solving, CPFR, co-design and aggregated purchasing initiatives, whereas co-manufacturing, joint ventures and co-developments are also popular knowledge sharing strategies, however, co-logistics and

shared resources are the knowledge sharing strategies which were found to be difficult and less common knowledge sharing initiatives in the local SMEs.

Foreign SMEs, on the other hand, were more focussed towards joint ventures, co-developments and co-designs., However, such SMEs were less inclined towards co-manufacturing, aggregated purchasing and shared resources for knowledge sharing with their network partners.

Local-foreign SMEs were found to be more focused on joint-ventures, joint problem solving, CPFR, aggregated purchasing and co-design strategies. These SMEs were also found to be involved in co-manufacturing, co-logistics and shared resources with their network partners.

Table 4.4: Knowledge Sharing initiatives and ownership

Knowledge Sharing Initiatives		Local	Foreign	Joint Venture	Chi-square Test
		%	%	%	
Joint Ventures	Supplier	20.0	26.3	12.3	3.57, $p = .068$
	Customer	14.3	17.5	8.8	1.91, $p = .384$

4.3.2 Knowledge sharing Strategies and Network Structure

A chi-square test was conducted in order to establish association between different knowledge sharing strategies and it was found that only 14 knowledge sharing strategies were associated with the type of network structure as shown in the table 4.5.

Table 4.5: Knowledge sharing initiatives and network structure

Knowledge sharing Initiatives		S-M-R	S-M-W-	S-M-D-R	S-M-W-D-R	Chi-square Test

	Other	4.1	2.0	0.0	1.8	15.23, $p = .004$

4.3.3 Knowledge Sharing Strategies and ANOVA and Post Hoc Test

For further analysis, one-way between groups analysis of variance (ANOVA) and a post-hoc test were conducted to explore the impact of ownership type and supply chain structure on different knowledge sharing strategies. Based on the results, it was found that there were statistical differences at the $p < 0.05$ level in the different knowledge sharing initiatives for the groups of respondents. Eta squared values were also used to determine the effect size of the results. Eta squared is calculated as: sum of squares between groups divided by the total sum of squares. Statisticians classify 0.01 as a small effect, 0.06 as a medium effect and 0.14 as a large effect. With respect to ownership, responses were divided into three groups: local, foreign and local-foreign joint venture and in terms of supply chain structure the responses were grouped into four as S-M-R, S-M-W-R, S-M-D-R and S-M-W-D-R. The results indicated significant differences between the different supply chain strategies in terms of ownership. However, supply chain strategies were not found statistically different in terms of supply chain structure.

5. Discussion and Conclusion

This work has analysed knowledge sharing mechanisms of manufacturing SMEs operating in business network environments through a large survey carried out in the UK. Findings show that SMEs operate in “communities of practice” as defined Brown and Doguid (2000) where formal mechanisms for knowledge sharing are activated. In fact, our results confirm that formal network and knowledge sharing initiatives are very common in SMEs. Joint problem solving emerged as the most popular knowledge sharing initiative, while CPFR, joint ventures, co-design and aggregated purchasing are also popular initiatives that include knowledge sharing goals. However, initiatives such as co-logistics and shared resources were found to be difficult strategies for the knowledge sharing goals. The results suggest that SMEs understand the need and importance of network collaborations and actively seek opportunities to collaborate with strategically

important partners for specific knowledge sharing initiatives, whenever it is required. These findings are in line with the views of other researchers (Barratt, 2004; Mentzer et al., 2000). This study did not include and examine other important factors such as length of network relations, outcome of these relations on the knowledge sharing strategies and other relevant experience/s with individual network partners. This could be further area of research work in the future and will to be included in our future work

The results also indicated that knowledge sharing strategies are not restricted to only vertical relations with suppliers and customers but also extend to horizontal supply chain relations. SMEs are actively collaborating with their competitors and other organisations in joint ventures, co-manufacturing, aggregated purchasing and shared resources. This suggests that competitors and other organisations are important partners in these knowledge sharing initiatives compared to their direct supply chain partners (suppliers and customers). The results also identified that SMEs are more active in collaborating with vertical supply chain partners for co-development, co-design, co-logistics, joint problem solving and CPFR initiatives.

The study identified two major limitations, one the sample consisted of 116 SMEs from the UK While the basic nature of manufacturing and operations may not differ in the SMEs but other aspects of manufacturing and operations may differ across different industries in the UK, therefore covering and including more industries will improve the generalising of the findings of this study. Another limitation was cross sectional analysis using only ownership and network structure as independent variables, future works can include age size and nature of SMEs, and other variables to further examine the robustness of our findings. The authors already expanded the research by looking at the practices of Indian SMEs for a cross-country comparative study and are currently in the process of analysing the findings.

Knowledge management in the international marketing channel – the case of two SMEs

Olavi Uusitalo *

Department of Industrial Management
Tampere University of Technology
PO Box. 547
33101 Tampere, Finland

Structured Abstract

Purpose – It is widely agreed that the know-ledge management (KM) lay beyond the success of companies. In case of small and medium sized enterprises (SMEs) the value of KM is indisputable; some research has even shown that the majority of SMEs' competitive advantages refer to knowledge management and intangible assets. However, KM has been studied extensively especially in large organisations, but not in SMEs. The purpose of this study is to find out the utilization of KM in brand creation and R&D within an international marketing channel (marketing channel replaces supply chain, because of the marketing nature of the case) of SMEs.

Design/methodology/approach – We propose an approach of a case study methodology as our aim is at theory building rather than theory testing. Case studies may be used as illustration in the context of making a conceptual contribution and to sharpen existing theory. The focus is on KM in international marketing channel between two SMEs. The case companies, one in Finland and the other one in the United States, are analysed during their first seven years of cooperation (1959-1965).

Originality/value –This methodology puts in evidence that KM utilization within an international marketing channel of two SMEs can include brand creation and R&D. Successful operation requires knowledge sharing, trust, commitment and learning.

Practical implications – The outcomes of the application suggest for managers knowledge sharing, commitment and trust for successful cooperation in marketing channel. on the one hand the Finnish manufacturer recognised the potential of its U.S. partner and granted the right to its brand, but on the other hand the partner realized a tremendous opportunity, together with a major responsibility, in creating a strong brand. This reflects consortium in licensing models.

Keywords – knowledge management, marketing channel, SMEs, brand, R&D

Paper type – Academic Research Paper

1 Introduction

Human resources can be argued to be the most important asset of companies. This is true especially in the case of small and medium-sized enterprises (SMEs), where the success of the company is based on the proficiency and motivation of the personnel (VTT, 2000). Both practitioners and researchers have widely agreed that knowledge management (KM) and other elements of the intellectual capital lay beyond the success of companies (see e.g. Edvinsson and Malone, 1997; Kujansivu and Lönnqvist, 2007; Sveiby, 1997). Most particularly human capital, which Edvinsson and Malone (1997) defined as the individual's knowledge, experiences, capabilities, skills, creativity and innovativeness, has long been argued to be a critical resource in most firms (Pfeffer, 1994).

Knowledge management has been studied extensively especially in large organisations, but not in SMEs (Durst and Edvardsson, 2012; Marra et al., 2012; Wong and Aspinwall, 2004). Durst and Edvardsson's (2012) literature review of KM within SMEs revealed that the body of knowledge regarding of KM, although it is highly important for SMEs, is limited. According Edvardsson and Oskarsson (2011) there is lack of understanding of how firms create knowledge and of how this is translated into competitive advantage and enhanced customer relations. Moreover, studies in corporate branding dedicated to SMEs are almost nonexistent (Ahonen, 2008; Inskip, 2004). Trust, shared values, commitment and participation positively relates with learning capacity for combined knowledge strategy (Cheng et al., 2009) and for building a learning chain between two companies (Maqsood et al., 2007). Choi et al. (2004) described five models of licensing relationships in supply chain to extract value from intellectual capital assets. This research answers partly the quest posed by Marra et al. (2012) who regard the knowledge accumulation process, within the supply chain, as an interesting topic to understand more deeply and ask for research with new insights in improving supply chain performance.

The aim of this paper is to find out the utilization of knowledge management in brand creation and R&D within an international marketing channel or marketing channel of two SMEs. We study a Finnish lure manufacture, Rapala and its partner in America, Normark. This research is limited to small and medium sized enterprises (SMEs, employees less

than 250 and turnover less than 50 million euros, European Commission, 2005). SMEs constitute a large group of firms within the Finnish economy (In 2013 99,8 per cent of all Finnish enterprises were SMEs; Statistics Finland, 2013).

The remaining part of the paper is organized in the following way. First, we explain the pertinent literature underlying our research. Second, we describe the research methodology. Third, we report the start of the co-operation of Rapala and Normark within their marketing channel in the early 1960s. Finally, we analyze our marketing channel case to KM and its impact on positioning and new product development (NPD), draw conclusions and discuss implications.

2 Literature

2.1 Knowledge management in SMEs

Knowledge management studies have focus mainly large organisations (Durst and Edvardsson, 2012; Marra et al., 2012; Wong and Aspinwall, 2004). “Durst and Edvardsson (2012) showed in their literature review that amongst other KM areas, particularly the issues of knowledge utilisation, or knowledge outcome, respectively, represent a neglected field of study, at least in the context of small and medium-sized enterprises (SME).” (Edvardsson and Durst, 2013:52).

Durst and Edvardsson (2012:899) divided in their literature review empirical studies of KM in SMEs in eight areas: KM perception & KM implementation, knowledge identification, knowledge creation, knowledge retention/storage, knowledge transfer, knowledge utilisation, scope & context of KM research, and perspective used in research. KM perception & KM implementation, knowledge transfer and scope & context of KM research have received attention while knowledge identification, knowledge retention/storage and knowledge utilization are under-researched areas. There seemed not to be any studies of a marketing channel / supply chain of SMEs.

External knowledge is of prime importance to SMEs (Chen et al. 2006) and knowledge sharing is important for internationalising SMEs (Flecher and Prashatham, 2011).

2.2 Knowledge management in international marketing channel

Marra et al. (2012) divide the literature in the continuum from knowledge exploitation to knowledge sharing or transferring. Cheng et al.'s (2008) suggested that shared values,

participation, communication and learning capacity are positively related with trust and knowledge sharing. Next these concepts are looked in more detail. Shared values are important for the development of interorganizational relationships and they create trust between channel members, since they enable one member to understand other's behaviors and objectives better (Anderson and Weitz, 1989; Dwyer et al., 1987; Sahay, 2003). Participation refers to the level to which a shared commercial goal to be accomplished is included in decision making of including the idea generation, participating in decisions, and goals setting (Dwyer and Oh, 1988). A shared decision making process would improve the performance of marketing channels (Kim and Oh, 2005). Both informal and formal co-operation enables sharing of relevant and timely information (Anderson and Narus, 1990; Håkansson and Johanson, 1988). Maqsood et al. (2007) emphasised the building of a learning chain for handling the complexity of markets and organizations. The learning chains could be created through a culture of knowledge sharing across the marketing channel.

Trust can reduce the uncertainty embedded in decision-making, because the trusting channel member has confidence that the trustworthy party can be relied on (Morgan and Hunt, 1994). As such, the success of specific relationships lies in the presence of relationship commitment and trust, not coercive power and the ability to condition others (Morgan and Hunt, 1994). Establishment and development of an international relationship is a result of bilateral or even multilateral interaction. Thus development of in a foreign market is a complex, uncertain and time-consuming process requiring considerable commitment (Johanson and Vahlne, 2003). Trust and power between partners in a relationship are interlinked and they co-evolve over time, in which the existence of trust may make the need for using power useless in certain activities (Inkpen and Currall, 2004). The significance of close, mutual and lasting relationship between autonomous partners and the control their co-operation has that way reduces the importance of power coming from ownership control (Johanson and Vahlne, 2003). Trust refers to a company's belief to have confidence in its partner's reliability and integrity that will lead to positive outcomes (Anderson and Narus, 1990; Morgan and Hunt, 1994). In the context of supply chains as well as marketing channels, trust is a phenomenon, which increases to the strength of interorganizational relationships (Sahay, 2003; Wu et al., 2004). Trust is an important precondition in marketing channel management (Halldorsson et al., 2007) and information sharing is a prerequisite for trust in marketing channels (Henriott, 1999;

Kwon and Suh, 2005). As such trust facilitates interorganizational knowledge sharing (Mentzer et al., 2000).

When companies do business abroad and learn they get something which may be of value in the future. By doing business in foreign the company creates market specific assets, but the value of these assets is connected to and dependent on specific context. At the same time the company increase its commitment to these markets, as well (Johanson and Vahlne, 2003).

2.3 Brand creation in SMEs

Branding is usually considered the province of big business operating in consumer market (Merrilees, 2007; Mudambi, 2002; Webster and Keller, 2004). Strong consumer brands are built to differentiate one seller from another (Aaker, 1996; Kapferer, 1997). According to Kapferer (1997) branding is more than just giving a brand name to a product or products: “brands are a direct consequence of the strategy of market segmentation and product differentiation. Thus the role of branding and brand management is primarily to create differentiation and preference in the minds of customers. According to Webster and Keller (2004) the fundamentals of a brand strategy are market segmentation, targeting and positioning. The development of product brands has been built around the core role maintaining differentiation in a certain market (Knox and Bickerton, 2003). There is little brand research within SMEs (Abimbola et al., 2007; Berthon et al., 2008; Merrilees et al., 2011).

Differentiation from competitors is one of the major benefits of branding. Criteria for choosing brand elements can be divided in two groups: to build the brand and to defend the brand from competitors. The brand building criteria are memorability (how easily the brand is remembered), meaning (what product qualities the brand suggests), and likeability (how it appeals to the customer). The brand defending criteria transferability (how easily the brand can expand e.g. to new markets), adaptability (how easily it can be updated) and protectability (e.g. is it legally protected from competitors). Kotler and Keller (2009). Corporate branding builds on the product branding, seeking to create differentiation and preference. However, corporate branding is conducted at the level of the firm instead of the product or service, and it targets not only customers but stakeholders such as employees, customers, investors, suppliers, partners, media, authorities etc. (Hatch and Schultz, 2001).

2.3 Knowledge management in international marketing channel or SMEs

Based on branding literature customers should be segmented into segments which have different type of customers in each of them but similar within each segment (see also Uusitalo, forthcoming). More over segments should be large enough and to be communicated with different ways. Products should be differentiated from those of competitors. Based on the company resources best segment(s) and best product(s) are selected. This is market/product fit or targeting. Positioning follows after this selection. This framework for differentiation, segmentation, targeting and positioning is illustrated in Figure 1.

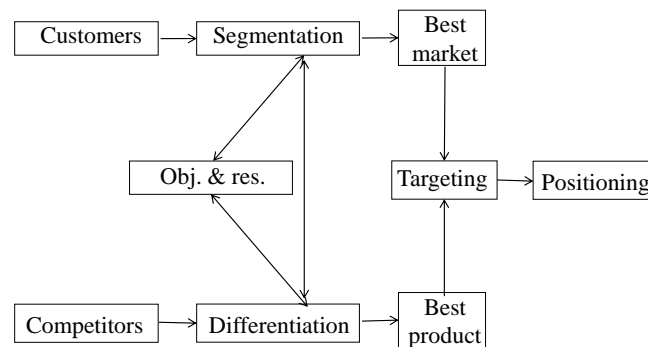

Figure 1. Segmentation, differentiation, targeting and positioning based on branding literature

Based on knowledge management literature within SMEs and supply change and KM has been integrated in the framework. The most important features in international supply chain or marketing channel from KM's point of view are shared values, participation, commitment, communication and learning, the good shape which of which increase trust and enhance knowledge sharing. The research base of two individual SMEs forming an international marketing channel can be increased by well managed KM. KM brings synergy to the channel; the sum of 1+1 is more than 2. In Figure 2 this is the enlarge objectives and resources (the dotted line). Enlarge resources provided by KM also has impact on both segmentation (via market and institutional experience; Johanson and Vahlne, 2003) and differentiation and thus also on targeting and positioning, that is the whole framework. KM management also I particularly look the impact of KM on branding and NPD.

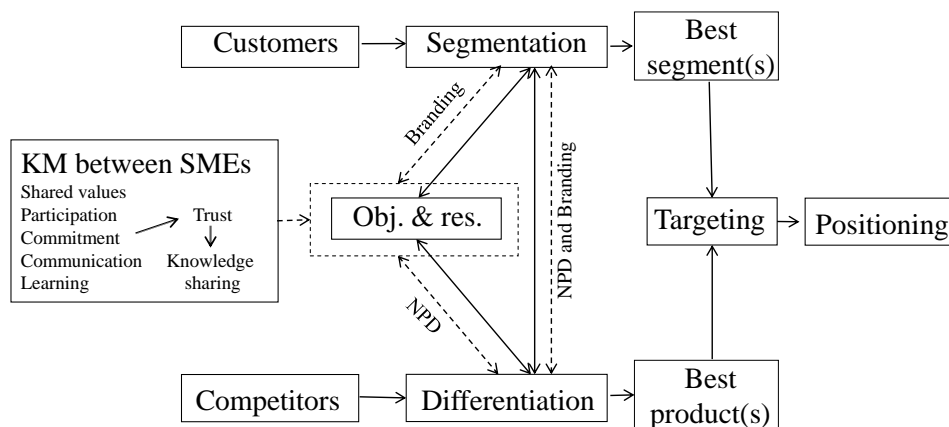

Figure 2. Knowledge management in an international marketing channel of two SMEs

3 Research methodology

The new status of the combination of brand creation and R&D within an international marketing channel of two SMEs as well as my aim at theory building rather than theory testing requires a qualitative, longitudinal and historical case study (Yin, 2009). According to Siggelkow (2007) case studies may be used as illustration in the context of making a conceptual contribution and to sharpen existing theory by pointing to gaps and starting to fill them.

Abductive (with induction and deduction) research process assumes that the gained theoretical insights during the research can modify data collection and theoretical framework, and the matters rising up from the data can lead to new questions and theoretical views (Eisenhardt, 1989; Dubois and Gadde 2002). Triangulation (Jick, 1979; Pettigrew, 1990) was applied with data sources which include interviews, histories of the companies, datasheets, promotion material, articles in magazines, trade journals, newspapers and Internet pages.

This study focused specifically on brand factors unique to a manufacturing SME on global industrial markets. The case of the company Rapala was randomly selected. The company has been studied for a decade. In 2002 a case study with analysis was written (Uusitalo, 2003). The findings of the later research are reported in conference papers (Uusitalo, 2013; Uusitalo and Grønhaug, 2013). Detailed histories have been written on Rapala (Hahl-Harjakorpi, 1986; Mitchell, 2005; Olkkonen and Sirpa Glad-Staf, 2013;

Rapala-yhtiöt,1990; Rapala, 2003) and its U.S. Partner (Dupont, 1998). The case study is based on a thorough analysis based on in-depth interviews with both closed and open-ended questions and an extensive research on archives.

4 International marketing channel of SMEs

In the 1930s Finland had an economic depression when Lauri Rapala earned a living for his family by working as a lumberjack in the winter and a fisherman in the summer. He designed his own lure to get better fish. He already knew that in schools of minnows, the wounded ones, those which wobbled when they swam, were the most attractive for larger fish. In the 1950s, the Rapala lures found their way to North America by participants of the 1952 Helsinki Summer Olympic games, Finnish immigrants and visitors (Hahl-Harjakorpi, 1986, Dupont, 1998 and Mitchell, 2005). In 1953 Lauri Rapala installed a testing tank in his workshop. In 1948 and 1954, Lauri won prizes for his craftsmanship at local agricultural fairs. In 20 years (1936–1955) Rapala, a family company, made about 51,500 lures. Lauri Rapala's four sons helped in production while his wife took care of packaging and accounting. In 1955 Rapala exported the first lures to Sweden and in 1959 it had 17 employees.

Ron Weber started as a tyre sales engineer. However, his love for fishing made him switch to the fishing tackle distributorship. In 1958 he formed his own fishing tackle sales company in Minneapolis close to the premier fishing areas in the US. (Dupont, 1998 and Mitchell, 2005). In a trip in August 1959 Weber learned about Rapala lures and saw them catching fish after fish. Soon he bought them and tested them for two weeks. The more Weber thought about the Rapala lure, the more convinced he became that the product could revolutionise fishing in America. (Dupont, 1998, Mitchell, 2005 and Sivonen, 1986). Weber told about the Rapala lures to his friend Ray Ostrom, who had a store called Ostrom's Marine and Sporting Goods. Also Ostrom found them excellent.

In September 1959 they wrote a letter to Rapala and ordered first 3000 lures in the early 1960. Rapala granted exclusive right for Weber and Ostrom to sales in North America. Normark was founded. In January 1961, it received Lauri Rapala's written permission to register Rapala as a trademark in the US. Weber and Ostrom realised the value of developing a strong brand (Dupont, 1998 and Mitchell, 2005). The timing for Rapala plugs was perfect (Dupont, 1998). The industry needed lighter lures. The double price of the Rapala lures compared to established American plugs was not a big

challenge. In 1960 Rapala sales was 3,040 lures and in 1961 sales soared to 31,135 lures. In the same years sales to Scandinavia and Finland were 25,000 and 17,500 lures, respectively (Mitchell, 2005:74)

Early on, Ostrom understood the importance of media in the marketing and sales. He had solid connections with local radio and TV stations, newspapers and magazines. Ostrom regularly appeared on local TV fishing programmes. Long time he had organised fishing trips and tournaments for stakeholders. Ostrom switched from promoting his own business to that of Rapala. Since then Ostrom used Normark's boat called the Lord of Rapala for social functions to entertain stakeholders. In 1961, a reporter from Life magazine visited Minneapolis. Ostrom was invited to dine with the reporter. Ostrom brought Rapala lures to the dinner and told the story of Lauri Rapala. The reporter sent the lures with a short report to his boss. In spring 1962, the boss caught fish well with the Rapala lures and decided to write a story. A Life reporter interviewed Lauri Rapala in Finland. The Rapala story appeared named as "A Lure Fish Can't Pass Up" on the August issue. In August Marilyn Monroe, the U.S. number one actress, died. The very Life Magazine issue had her picture on the front cover and the life story in its pages. This issue surpassed all circulation records. Millions of people bought the magazine. This was Rapala's and Normark's greatest exposure. Normark received three million orders, of which it could fill only a fraction. The demand was further fuelled by enterprising resort owners and tackle stores that limited the sale of lures. In the black market the price was \$25 or even more. Some resorts rented Rapala lures at a daily rate of \$5, with a \$20 deposit (Durant, 1998:11). Now Weber and Ostrom made a full-time commitment to the Rapala business. They sold their earlier businesses and formed a company in Canada (Mitchell, 2005)

In July 1962, during Weber's first visit to Finland, a contract was signed between Rapala and Normark to establish a long-term relationship. Normark agreed to purchase Rapala's production up to 300,000 pieces in the next year. The lures were paid in advance. If Normark purchased 100,000 lures each year, it had sole rights in North America until 1970. Normark would finance the new factory. Weber also explained to Lauri Rapala the need to expand the range of lures. The Original lure was of high quality, but it was too light to cast in the wind. Lauri understood the need. In 1961 the Jigging Minnow was design and over 7,500 jigging lures were exported to the US that year. In 1964-1965 the Countdown (7, 9 and 11 cm models) lure was developed on a trial-and-

error basis. An 18-cm version of the Original lure was introduced, as well. (Mitchell, 2005:77).

By the mid-1960s, America had over 40 copies of the Rapala lures. Rapala refused to lower its standards to increase production. Rapala tank-tested each lure to ensure their better quality than the lower-priced copies. The number of available lures in 1964 grew from 6 to 13 in 1965. Moreover, each lure was available in three colours, making a total range of 39 lures. Rapala grew steadily and quickly. Its staff and sales statistics in the 1960s are shown in Table 1 (Mitchell, 2005:93).

Table 1. Rapala's staff and sales figures in the 1960s (Mitchell, 2005:93).

Year	Staff	Sales of lures to US	Total sales of lures
1963	18	225,348	272,482
1964	46	783,582	934,009
1965	77	1,334,916	1,579,556
1966	84	1,531,042	1,713,083

By the mid-1960s, Normark won Importer of the Year award and Rapala lure was named twice "The Hottest Selling Lure in the Country". At that time, Normark started importing the Finnish Martini knives to the US to enlarge the Rapala brand to "Rapala Fish'n and Fillet". In 1970-1982 the joint R&D brought several lures on the market. (in 1970 the Magnum for saltwater predators; in 1972 the Deep Diver and all-metal lure, Vertical Jigging Pilkki; in 1974 the jointed lure with attractive vibrations for cold or cloudy waters; in 1982 the very successful Shad Rap). (Mitchell, 2005).

In 1974, Weber and Ostrom were awarded by the Finnish Central Chamber of Commerce to commemorate Normark's contribution to Finnish international trade. They in turn praised Lauri Rapala's immense contribution to their success. In 1984 Ostrom sold his part of Normark to Weber while in 1990 Weber sold Normark (the U.S., Canadian, the UK firms and the brand) to Rapala. That time Rapala's turnover was €75 million and it had 650 employees (Rapala-yhtiöt, 1990). Next year Rapala bought Normark Scandinavia (from Mats Olofsson, Weber and Ostrom) and the French Ragot. In 1991 Rapala owned 30 companies in 12 countries and manufactured its 150 millionth lure. (Mitchell, 2005).

5 Conclusions

In Appendix 1 there are shown the KM and marketing channel aspect of both companies. According to Marra et al. (2012) areas where knowledge management has been used in supply chain are outsourcing (the most common), the construction industry, decision support, NPD, risk management, build to order, procurement and organizational performance. In this study outsourcing from the U.S partner point of view was important as well as NPD. One new item not listed in the Marra et al.'s list is brand building. This case demonstrates how knowledge management created first trust, which enabled the good relationship, exclusive sales agreement, granting the right to the Rapala brand and committed brand building within the marketing channel.

For managers this paper suggests knowledge sharing, commitment and trust for successful cooperation in marketing channel. Thus, Rapala recognized the potential of Normark and granted the right to the Rapala brand. Normark saw a tremendous opportunity, together with a major responsibility, in creating a strong brand. This reflects consortium in Choi et al.'s (2004) licensing model.

According to Maqsood et al. (2007) for an organisation to maintain its competitive edge and continually innovate it has to facilitate learning throughout the whole marketing channel to become a learning chain. Trust and commitment are pre-requisite to achieve the aim of learning chain. In the case above this was what took place. In the early phases trust was created between Lauri Rapala and Ron Weber and between Lauri Rapala and Ray Ostrom. All of them were committed to the mutual business and shared information. Rapala granted exclusive right, gave the brand and made production commitment. Weber and Ostrom tested the product, did brand building effectively, financed the new plant, gave market information for new products. Since the beginning the hand shake was the guarantee for the commitment.

The relationship between Lauri Rapala with Weber and Ostrom was unique as Ostrom's quote tells: "Every time Ron and I met Lauri he had tears in his eyes, and every time we said goodbye to him he had tears in his eyes. Lauri took us to his family. We were not just business associates, we were almost like adopted sons. If the relationship had not developed this way our business would not have been a success." (Mitchel, 2005:107)

Within this case, we have demonstrated the concrete customer value (the lure caught fish far better than its competitors did) created for the marketing channel and consumers.

The trust between the business partners was immense. When the co-operation started, both parties respected each other. Ostrom and Weber used Ostrom's Marine and Sporting Goods company letterhead to make the letter to Rapala more official. Trust was maintained between Weber and Ostrom and the Rapala family across three generations, which paid off when Weber wanted to withdraw from the business. He was willing to wait until Rapala had arranged financing for the acquisition by loans and funds from the sales of the consumer durable businesses. Weber also accepted part of the purchase price in the form of Rapala stocks. For some reasons, these family firms had realised the importance of trust, as Rotter (1967:651) puts it:

“One of the most salient factors in the effectiveness of our present complex social organization is the willingness of one or more individuals in a social unit to trust [each] other. The efficiency, adjustment, and even survival of any social group depend upon the presence or absence of such trust.”

Structured Abstract

Purpose – The purpose of this paper is to increase understanding of the reciprocal nature of the client-consultant relationship in management consulting. Although different aspects of the client-consultant relationship have been addressed – including interaction between client and consultant (Fincham, 1999; Pellegrinelli, 2002; Werr and Styhre, 2002), the multitude of roles of both the client and the consultant during the consulting process (Hislop, 2002; Kaarst-Brown, 1999; Schein, 1987; Williams, 2001) and the knowledge transfer or creation during a consultancy process. (Todorova, 2004, Handley et al., 2007; Ko et al., 2005) – the research still lacks proper descriptions of the process of interaction in management consulting projects. In this paper we show with the aid of case study analysis how the client affects the final outcomes of a management consultancy process and how external processes and events have an impact on the outcome of the consultation process. The study describes a changing event path, during which an IT outsourcing project was affected by decisions by the client company's management, its board, and the suggestions from an external consultant. In addition, the paper discusses the consulting project success criteria.

Design/methodology/approach – In this paper we build on a single case study of an internationalizing Finnish SME technology company. The case provides a design enabling us to examine longitudinally and in rich detail the changing goals and directions of a consulting project, affected both by the consultant's and the client's input in knowledge creation. In the case study we relied on multiple sources of data: of in-house

memos, emails, interviews, project reports, meeting notes, consulting evaluations, and field observations. The collected data in this study was analyzed according to case study protocol (Yin, 1989) with a connection to the explorative and grounded theory approaches, in which data collection, analysis, and theory stand in reciprocal relationship with each other. (Straus & Corbin 1990, p. 23)

Originality/value –This paper adds to the existing research by showing how the client and the consultant interact and how the external unexpected and not-controllable factors affect the whole consulting project. Secondly, the case shows that the client problem can change during the project and the consultant has to adapt to the changing client's problem and criteria. Thirdly, the case shows how different types of clients in the consulting projects actually have different goals and unclear or hidden agendas. This widens the view on client-consultant relationship in existing theory on knowledge intensive client work (cf. Sturdy et al., 2009; Ciampi, 2007; Todorova, 2004; Pellegrinelli, 2002; Bitner et al., 1997) and especially in the reciprocal client-consultant processes. (cf. Nikolova & Devinney, 2012)

Practical implications – The proposed results of the analysis provides a framework, which allows the clients of management consultants better design, brief and guide the consultancy processes. From the consultant's perspective, the results of this study contribute to a view which encourages to design facilitation methods, which strengthen the need for understanding the multiplicity of client's goals.

Keywords – Management consulting, knowledge creation, innovation, internationalization, client-consultant relationship.

1 Introduction

The special dimensions of consulting services are intangibility, uniqueness of the service provided to each client's needs and the inseparability derived from the relational exchange between buyer and seller during the main stages of the process (Bennett & Smith 2004, p. 438). The client-consultant relationship is based on bilateral communication, in which the development in the client organization is a result of both the client's and the consultant's efforts. (Kakabadse et al., 2006; Mohe & Seidl, 2011; Werr & Styhre, 2002) Different aspects of the client-consultant relationship have been addressed; these include the interaction between client and consultant (Fincham, 1999; Pellegrinelli, 2002; Werr and Styhre, 2002), the multitude of roles of both the client and the consultant during the consulting process (Hislop, 2002; Kaarst-Brown, 1999; Schein, 1987; Williams, 2001) and the knowledge transfer or creation during a consultancy process. (Todorova, 2004, Handley et al., 2007; Ko et al., 2005). As Fincham (1999, p. 349) noted, an improved interpretation of the relationship between the consultant and the client would be such, which conceives the relation as open-ended and structurally symmetrical. Hence, management consultancy is a collaborative and processual interaction, where

relationships, roles, knowledge processes, and political and other outcomes are co-produced. (Sturdy et al. 2009, p. 249)

The knowledge created during a consultancy project is part of the delivered service, and thus, "the active managing of the process of consultancy can impact on the content of such interactions, that is, the production of management knowledge and associated organizational changes." (Sturdy & Wright, 2011, p. 490) In this process of co-production, the quality of service is dependent on the nature of the interaction between the consultant and client. (Den Hertog, 2000)

Pemer & Werr (2005) have shown how consultants and clients form their relationship and how consultants are utilized dependent on the managers' perceptions of their role as purchasers and users of consultancy services. Schwarz and Clark investigated how clients respond to consultant's activity, "managing" the relationship and ultimately affecting also the outcome of the consultancy process. (Schwarz & Clark, 2009) Schein (2000) noted that the consultant's role shifts over time along the relationship with the client. However, as Alvesson et al. (2009) noted, the positioning of both the consultant and the client is a complex procedure, which affects many dimensions of the consulting process. The position and role the consultant takes or is given (Alvesson et al., 2009) influences among others the content and relevance of the consulting process (Nikolova et al., 2009) and perceiving who is "the client". (Schein, 1987) These in turn are in connection to what is or will be the outcome of the consultancy process.

Knowledge inflow from consultant to client is influenced by the consultant's openness to knowledge flow from the client, both of which ultimately influence the creation of useful knowledge. (Todorova, 2004) Management consulting is knowledge intensive action, in which the customer has a central role in generating knowledge. The client's output is used as an intermediate input in the production processes of the consulting firms. (Nachum, 1999 The transferring of knowledge to the individual, group, or organization "...is expected to affect attitudes, subsequent individual behavior and finally the performance of organization." (Kubr 1985, p. 18)

However, this is only an ideal model, omitting a lot of challenges visible in the real life. The majority of previous research has discussed the consultancy process solely from an unidirectional perspective, stressing the consultant's effect on the client. Despite of the growing interest towards client-consulting reciprocity (Cf. Schwarz & Clark, 2009; Nikolova & Devinney, 2012; Pozzebon & Pinsonneault, 2012), there is still a lack of

proper understanding of client's role in the two-way relationship and how it affects the advancement of consulting projects by reconfiguring the client's expectations for wished outcomes. In this paper we contribute to this need by describing empirically by a case study specific event paths, during which the client affected the consultant, by resteeering the started consulting project and driving it to emergent directions and alternative solutions.

The purpose of this study is to increase understanding of client influence on management consulting processes as a reciprocal interplay between the client and the consultant. The research goal has been formulated as two important a research questions: (1) Alongside of the consultant having an influence on the client, how does the client influence the consultant? (2) How does this affect the evaluation of the success of the consulting project in question? This builds of wider views on management consulting evaluations, as the dominant view on the impact of management consulting argues that consulting has a direct impact on the client.

In the rest of this paper, with the aid of case study analysis, we show how the client activity influences the consultant during the consulting process. Then, in the conclusion sector, we summarize based on the first part's findings and existing literature, in order to understand the findings of the case study.

2 Implementation of the Study

This research has adopted the case study design. A case study examines and interprets the reasons for the occurrence and significance of a phenomenon. The material is taken as a whole, it is thought to shed some light on "singularly understood structure of an internal logic". (Alasuutari, 1995, p. 28-29) Case study is a research strategy, which is concentrated on understanding the dynamism within single, even unique settings. (Eisenhardt, 1989, p. 534). A case study is an empirical inquiry that investigates a contemporary phenomenon within its real-life context; when the boundaries between phenomenon and context are not clearly evident and in which multiple sources of evidence are used (Yin, 1989, p. 22).

The analysis utilizes the principles of historical inquiry is a cyclical process of inference and tracing evidence from the past. Multiple and even complex pieces of evidence – newspapers, stories, interim reports, market analysis, legends - can serve as

sources in order to draw credible inferences and claims about events in the past. The sources provide useful information after thorough critical and systematic consideration. The outcome of the analysis is a construction of credible claims about what happened. Events, incidents and phenomena have many explanations. The historical researcher constructs a path of development, adds a bulk of causes and creates order in it, and arranges the explaining causes in some ranking order. (Carr 1963, p. 94-95)

The collected data in this study was analyzed according to case study protocol (Yin, 1989) with a connection to the explorative and grounded theory approaches, in which data collection, analysis, and theory stand in reciprocal relationship with each other. (Straus & Corbin 1990, p. 23) We began with an chronological event case, and the expanded it by identifying challenges and turning points in the management consulting project. This was followed by a categorization of the main events, during which the consulting was affected by the client.

The goal of this research is to explain a phenomenon, to increase understanding about it. Thus, this research is committed in creating substantive theory – "the formulation of concepts and their interrelation into a set of hypotheses for a given substantive area". (Glaser and Strauss, 1965) This paper relates to a management consultancy assignment and experiences acquired by the consultant, the Finnish Trade Commission which is an independent revenue based business consultancy agency. The Client Company is a Finnish internationalizing SME technology company from the field of IT services and outsourcing.

There are several reasons for selecting the company as a study case; first of all the consultancy assignment consisted of three consecutive and directly interrelated client cases which were completed. This provides an opportunity to study consultancy work in retrospect, including the case flow, the phase transitions, and team interaction. The total case value translated into a considerable but not exceptionally large case and one of the authors of this paper acted as the primary project manager. The named consulting project spanned one year and progressed in terms of pragmatic responsibilities. In other words, client-consultant cooperation was fairly typical, occasionally intensive and the level of interactivity was high.

The chosen case study is a revealing case because the client-consultant relationship was intensive and lasted for a comparatively long time. The case therefore provides a design enabling us to examine longitudinally and in rich detail the reciprocity in the

consultant-client relationship in securing the needed knowledge for internationalization efforts. In this longitudinal case study we relied on multiple sources of data: of in-house memos, emails, interviews, project reports meeting notes, consulting evaluations, and field observations.

We use a pseudonym of the case company, as well as of the actors involved, due to confidentiality of the consulting assignment.

3 The Case

The Client Company in this research was an IT service provider, operating in Finland and Sweden. The Client Company had more than 45 years of experience in the development of IT services. The company offered wide variety of different services, including electronic invoicing and printing, consultancy and solution deliveries. One of the Client Company's focus areas was outsourcing services for mid-size companies. The Client Company defined its client segment as companies with 200 to 2000 IT-users. In this customer segment the Client Company is among the leading service providers in Finland with more than 200 clients. The Client Company's core services include continuous services: Service desk and user support, Application management, Workstation management, Server management, Data communication. The Company employed approximately 700 IT experts and its annual turnover was over €140 million.

The Client Company growth was determined by acquisitions. According to Client Company figures, in 2010 approximately 25% of turnover came from international operations. Internationalization provided the Client Company with the opportunity for stronger growth. The company had three strategic objectives: (1) Excellent profitability requiring improved efficiency of processes and outsourcing of tasks with a lower processing value to the Eastern European countries and India, (2) Well-considered expansion in the Baltic region, (3) Utilizing Superior Nordic expertise by allocating its personnel resources to demanding expert tasks and subcontracting a significant part of services to the countries with lower cost levels.

3.1 The Beginning

In the beginning of October 2010, Finpro consultant learned from a Finpro business developer that the Client Company was interested in Poland. The business developer was the one that had the initial face-to-face meetings with the Client, whereas consultant received the quotation for the approval. The Board of the Client Company planned to expand to new markets in the Baltic region and the management was given the task to study the Polish IT-market as a source of lower cost IT-expertise and as a target market for the company's expansion. The Client Company wanted to present the report to the Board already before Christmas 2010, as became evident during a telephone discussions with the Finpro business developer and his quotation.

The Client Company was in need of general business environment information about Poland in comparison to the Central and East European Region, information about the foreign direct investments in Poland as well as information about Polish IT sector (locations, workforce, salaries, education etc.). The general view on the Client Company's business potential should have been drafted based on this information. The quotation was prepared by Finpro business developer, Finpro sales person and Finpro Project manager. A draft of the Client's problem with the Finpro solution proposal were based on face-to-face discussions between business developer and Client Company Director.

The first solution offered to the Client by Finpro business developer was a market analysis. The project scope was broken down into three phases with regards to required information type and ways of collecting it. The first phase was basic data collection and tailoring it to the Client Company's needs was identified during a workshop. The second phase comprised of specified data collection and interviewing local players. The third phase consisted of field visits in order to get first impressions on market. In fact, the market analysis phase was not typical for Finpro and not in line with Finpro service offering templates and tools. The quotation was adapted to Client's needs and time schedule, which was considered as tight.

3.2. The visits to Poland

In the beginning of October the Finpro consultant started to work on market analysis, and also Finpro's business developer worked on some parts of the report. Simultaneously the consultant prepared a program for the visits to Poland for Client Company's Director. He visited Poland on November 23 and had a few meetings in Warsaw during his stay.

Finpro Consultant accompanied him and this was the beginning of deeper direct discussions between the two. So far Finpro had worked directly with the Client via other persons. It became clear, that the Client Company's Director wanted to grow the IT services business of his company through an acquisition of a Polish company. In order to achieve the goal he had to convince the Client Company Board that Poland was a good, potential market and that there existed an interesting company for acquisition, a company which provided helpdesk services and was focused on IT outsourcing.

The first phase of the consulting project, the market analysis, was aimed to provide general information about Poland including a comparison of the market with the Central and Eastern European region. The consultant collected data on Poland and Polish IT sector, whereas Finpro Project Manager collected data on other countries located in the region. Simultaneously to data collection and report writing, the consultant was organizing several visits of Client Director to Warsaw. The aim of the visits was to provide him with impressions about the market, its maturity, companies' perception of services outsourcing in Poland. The consultant was also assisting the client during the meetings in Poland.

From the very beginning, from the first meeting, the Client Director took a leading role during the visits to the Polish companies. He was asking questions and leading conversations when the consultant was making notes and rising additional issues if appeared. During the visits the consultant was learning from the Client what kind of topics were of his interest and how to ask difficult questions, for example how to check in a polite and delicate way whether the company is for sale. On the other hand, the consultant was explaining to the Client how the Polish business culture and hierarchy in Polish organisations looked like.

When searching for acquisition targets the characteristics of companies was changing according to the Client Director ideas and suggestions. First, the consultant was searching for big companies (in terms of employment) which offered offering IT outsourcing, helpdesk and network administration services. Next, when the companies appeared too big the consultant focused on searching for medium-size companies and, also, for data centres, which initially were not taken into account as primary targets.

The Client Company Director had a lot of information needs and open questions like: was there any demand for Client Company -type of services in Poland? Who could be their clients, were they public or private companies, big or small companies? Was

outsourcing in general preferred in Poland? What was the approach to IT outsourcing in companies? What is the maturity of the Polish market in buying outsourced services? What IT activities companies outsource in Poland? The Client Director needed to learn and understand the Polish customers, their needs and behaviour.

The normal procedure would have continued after the general analysis of the Polish IT market with the planning of market entry that would have included an Entry Mode analysis and market entry strategy development. However, the Client had already an established idea of how to enter the market through a merger and acquisition type of transaction. When the consultant discussed the acquisition with the Client Director, she mentioned that the alternative would be the establishing an own company in Poland, in case of not finding an appropriate acquisition target. The Client did not take this alternative into consideration as he remained in the belief that an acquisition of a Polish company enabled a faster market entry and provided immediate customer base for the operations.

The Client Director had already an idea what kind of company he was searching for. He specified the range of services the potential acquisition target should provide, as well as the size and location of the acquisition target. Firstly, the target company under search should have been a provider of helpdesk and network administration services with focus on IT outsourcing. Secondly it should have employed 50-100 people, and thirdly, it should have had an office in a large city and production sites in low-cost area.

3.3. The First Iteration

As a result of discussions between the Client and the consultant as well as the lack of market entry planning option the consultant drafted the following objectives for the next consulting project: (1) To increase understanding of the outsourcing market development in Poland, (2) To develop further understanding of customer behaviour in Poland, (3) To create a long list of acquisition targets. These objectives were the basis for potential next quotation for the Client Company. The decision concerning further interest in the Polish market and further co-operation with Finpro depended on the results of the market analysis and on the decisions of the Client Company's Board.

During his first visit the Client Director met a few Polish IT companies, potential acquisition targets. It appeared that the term "IT outsourcing" had different meanings in Polish companies and the consultant was unaware of the variety of services were offered under this title. The consultant gained detailed information what kind of companies the

Client Company looked for and thanks thus it was easier to search for the acquisition targets during the second phase of the project. At this phase the consultant was creating the list of potential acquisition targets with short descriptions of the companies, and later profiles of the companies selected by the Client Director. The list was continuously updated and reviewed by the Client. Profiles of candidates were based on telephone and face-to-face interviews. The main challenge was the necessity to adapt to the changing criteria of acquisition targets. That is why the list was constantly changing, some companies were deleted and some new included.

The whole project was focused on information gathering (through desk study, face-to-face and telephone interviews), analysing it and considering what the most relevant findings for the Client were. Throughout the whole project the Client was counselled on his ideas and questions that were appearing. The consultant and the Client exchanged opinions about each meeting and each company, considered different criteria for acquisition targets, and reassessed approaches to establishing business in Poland.

The market analysis was finalized in the beginning of December 2010. The Client Director presented the general market analysis on Poland to the Company's Board. Both the Board and Director agreed that Poland seemed to be an interesting market. As the result of this conclusion the next quotation was prepared by Finpro Project Manager. Before that the consultant sent him the objectives drafted during Client Director's visit to Poland. During teleconference the consultant and project manager agreed a proposal for a solution to the Client. The project scope was broken down into four phases: 1) Definitions for the study and pre-work, 2) Acquisition target identification, 3) Demand side analysis and 4) Competition analysis. The criteria for acquisition targets were drafted in the quotation. The Client influenced the size criterion (preferably company with EUR 5-10 million turnover, at least over EUR 2 million turnover, employing more than 50 employees) and location criterion (company with office in large city but with production in low-cost areas). The acquisition target identification was scoped by the consultant and project manager according to standard Finpro process. For the demand side analysis and competition analysis the project manager suggested interviews as method of information gathering.

The quotation was scoped according to issues discussed earlier with the Client Company's Director. The project was aimed at helping the Client to understand Polish customers and find candidate companies for acquisition. The order was signed and the

consultant started to work on the new project for the Client Company on December 21, 2010. During the execution phase it appeared to be difficult to find a company that would meet client expectations in terms of size and service scope. The screened acquisition targets were either too small or too big in terms of employment and structure.

Simultaneously, next three visits of the Client Director were organized. Together the Client and the consultant we were meeting Scandinavian companies located in Poland in order to learn their perception on Polish market and outsourcing of services, as well as potential acquisition targets in order to learn their business, size and approach to Merger & Acquisition type of transaction. Polish IT companies were met to learn their opinion about the Polish IT market, its development and maturity.

It is worth mentioning here, that Client's and consultant's perception of the size of the acquisition target company was different. For the consultant, the company employing 40 people was of medium size, for the Client – small size. In general, the market appeared to be full of companies employing 5-10-people, and on the other side, companies around 200 people. The consultant suggested a purchase of a medium-sized company (small according to The Client Company's Director) and to develop and grow it in line with the market growth. The Client was interested in bigger companies as he believed that only with volume the Client Company could reach a better profitability. He was thinking about targets employing around 100 people.

In the meantime the Client Company's Director met a new Finpro project manager and raised a number of issues. Poland was an interesting market but there was not enough understanding how to approach it. The challenge was that there were no active players on the market and there was not enough similar offering to the Client Company's offering on the market and the clients were not experienced in and used to buy this kind of services. A short list of acquisition targets was seen good but maybe there were still some other companies on the market that were not identified.

Regarding acquisition targets the consulting company project manager suggested a few alternatives. The Client Company could purchase a bigger company with different businesses and sell out those which were not interesting. They could purchase an optimal company in terms of employment and client base that had a different service offering and could change the company focus. An option would also be to purchase a company that fit the needs but was too small at the moment. So it must have been grown into a larger size.

3.4. The Second Iteration and the End

It was obvious from the exchange of ideas and opinions between the Client and the consultant that the Client was not happy with the acquisition targets listed by the consultant. None of the companies was meeting his initial criteria. The option of obtaining a business unit from a big company appeared during consultant's meeting with one company, which focused on hardware but also had a helpdesk services unit. During the meeting the Board Member of the company was considering to sell off all non-core business.

Additionally, The Client Company's Director was wondering how the companies' valuation process looked like in Poland and what were the motives behind companies' sale. Since the consultant knew at least two owners of the companies that had been sold in Poland and could arrange meetings with them, she suggested a new project that could provide understanding of mergers & acquisition transactions in Poland, as well as a list of additional acquisition targets.

In June 2011 a new quotation was prepared by Finpro project manager. It had two major objectives: to identify additional potential acquisition targets including business units from large companies and to provide initial understanding of the merger and acquisition transactions valuation in Poland. The proposed solution was tailor-made and did not remind any standard Finpro solution. The proposed solution had four phases: Phase 1: Identifying alternative acquisition targets in Poland, Phase 2: Screening the old and newly listed companies, Phase 3: Identifying deals and interviewing specialists and entrepreneurs that had sold their businesses, and finally Phase 4: Meeting the most prospective candidates.

Again, The Client Company's Director signed the order and the co-operation with the Client could continue as planned. All three subsequent consulting projects mentioned above were signed by the same Client Director. However, all phases of the project and all offers were to be accepted by the Board, which remained at this stage as an underlying client. The consultant did not have any chance to meet them or talk with them. Thus, the whole consulting process was affected heavily the Client Director.

In August 2011 Finpro project manager and consultant received suddenly the information that The Client Company had changed plans. Due to on-going investment projects at the Client Company and economic slowdown, the Client Company did not have a possibility to proceed as fast as planned in the Polis investment case. The company

was still positive about investing in Poland, but not at that particular moment. At this point the decision was not to open any discussions with the owners of potential acquisition targets in Poland. However, the consultant was expected to continue the project and prepare a “final” short list, even though she knew that the Client Company would not undertake any concrete actions in the nearest future. In practice, the project was paused at that moment, there was no reason to interview the companies or organise any meetings.

Next, the consultant and the project manager learned that the Client Company’s Director had to leave the company and he was not working any more in the Client Company. As a result, the consultant and project manager had one more meeting with the Client Company in autumn 2011 and the consultant’s live engagement with the Client Company ended. During this meeting the consultant met the Senior Vice President of the Client Company, who was not involved in the consulting engagement, but he was influencing her work indirectly by assessing the performance of the Client Director. He was one of the Board members that had influence on contract termination with the Client Company’s Director. During the meeting with consultant, he mentioned that the Board had not wanted to acquire a big company in Poland. Finally, there was one manager less in the company and the final decision of not entering Poland had been taken.

4 Conclusions and Discussion

The consulting project started normally as an incremental step-by step advancement true navigation gates in a planned and established service route. The Client’s involvement increased in every step. However, contrary to the standards, the client kept his own mind during the course of events and acted against the consultant’s suggestions. The small deviations made the consultant’s service delivery closer to tailored services. The consultant had an open and good relationship with the representative of the Client, the Client Director. Consequently the consultant based her aspirations about the final outcomes of the project on the guidance of the Client Director, considering him to present the Company’s vision about the investment in Poland. The aim was both in securing high quality service delivery and also a continuity in the Client relationship.

During the project, all previous Client’s decisions showed that the project was on a good track towards its final target, which meant the establishing of the Client Company operations in Poland. There were no elements or decisions that would have signalled the

opposite. The Client Company's Director was assigned by the Management Board to research the Polish market and he was a professional who was given the complete responsibility for execution of the potential merger & acquisition in Poland. The consultant believed that there had been real commitment from the Management Board to invest in Poland and she was not able to predict sudden change of the Client Company's strategy.

However, external factor that unexpectedly affected the consulting projects stemmed from a change in the strategy, initiated and supervised by the Management Board. The changes in focus related to among other in the decision of not to enter the Polish markets. The consultant did not have any influence on this decision since her recommendation was the opposite.

The table below lists the main events in consultant's relation with the client company with the aim to clarify the flow of the consulting project.

Table 1. Main decisions during the consulting assignment, which had an impact on the direction of the service delivery.

What	Who	Results	Decision	When	Did the decisions bring the project closer to establishing operations in Poland
Meeting in Warsaw, joint visiting companies	Consultant, the Client Director	Beginning of close co-operation		X 2010	
Delivery of the project's phase 1, the market analysis for the Client Company's Director	Consultant			XII 2010	
Presentation of the market analysis to the Board	The Client Director	Poland appeared to be an interesting market for The Client	Board decides to continue in Poland	XII 2010	The decision of the Board shows that the project is on the good track towards the target
Delivery of the project's phase 2, acquisition targets to the Client Company's Director	Consultant	Polish companies did not meet the criteria	The Client Director decides to continue in Poland and search for more candidate companies	IV 2011	Decision of the Client Director brings the project closer to the final outcome

The Client Company changes plans regarding Poland	Board	The Client Director leaves the company	Board decides to cease co-operation with The Client Director	VIII 2011	Both, the change of plans and Board's decision suddenly moves the project away from the target and final outcome
Presentation of the project's phase 3 Meeting with the Board Member of the Client Company	Consultant, Project Manager	Final delivery of the project	Board decides to close the project in Poland	X 2011	

In delivering the consulting project, there were three occasions, in which the client influenced heavily the course of events and the final outcome of the consulting project. The content of the events was related to 1) affecting the consultant's suggestions by widening the scope of possible acquisition targets, 2) continuous interactive learning about the client's expectations with a reciprocal observation-commenting-learning-revisioning loop, 3) redefinition of the terms of reference and the mandate for the consulting assignment.

The client affected the consultant's suggestion by either accepting or disapproving the proposals. In the case, the consultant and client had different views on the size of the acquisition targets, as well as should it be a greenfield investment, a merger, or scaling up and growth of an existing nonrelated business.

The client was involved in modifying the consultant's perceptions about what the client wanted by giving information, showing example, sharing insights, and focusing on certain topics of discussion. The consultant in her turn used this as an input to make her probe suggestions and for learning from the client's feedback and comments. This in turn contributed to the revisioning the content and focus of the consulting assignment.

Lastly, in the final phase of the project, the client terminated the whole cooperation. This meant a large-scale redefinition of the consulting project framework. This underlined the questions about the usability of the knowledge created during the whole project. As the generation of new applicable knowledge is one of the main reasons in purchasing management consulting services, we could ask, what kind of knowledge was created during the consulting project? Naturally, as the end result of the project the Client obtained information about the potential of Polish IT market and Polish companies. During the project the Client Company representative met numerous local IT companies, established contacts with many managers and potential customers. Consultant's

recommendation was to enter Polish market and purchase a medium-size company. This information was used by the Client Company's Board in order to decide whether to enter Polish market and acquire local company.

However, the final result of the whole consulting project was a decision not to enter the Polish market and not to purchase any Polish company. The consultant together with two project managers provided the background information and supported this decision-making process. The consequence of the "not-to-enter" decision was that the real Client, The Client Company's Director left the company. The relations with the Management Board representative remained good.

The question arises whether the consulting project was a success or failure. The answer depends on the point of view and perspective. The Consultant perceived the whole project as a failure. From her point of view the project would have been a success if the Client Company would have followed her recommendation to enter the Polish market and to acquire a company in Poland. If the outcome of the project would have been the establishing of Client Company's new business in Poland it would be a success. Finally, even though the relations with The Client Company's Board and The Client Company's Director remained good, Finpro did not manage to maintain the long-term relations with the Client. As a result, from the consultant's perspective the definition of success in this particular case would have included the following criteria: Firstly the Client follows recommendations; Secondly, the Client establishing successful operations in Poland; Thirdly, creation of growth in the Client's business; and fourthly, establishing long-term relations with a Client company. However, if at the very beginning of the project the consultant would have defined success merely as "a satisfied client" her evaluation of the engagement would be totally different.

Nonetheless, the project can be perceived also as a success. The long-term project for the Client Company has been a good reference case for the consulting company. The Client – here meaning the Board - was satisfied, i.e. it had no contrasting views on the proceeding of the project nor to the quality of the services delivered, and the Client remained in good relations with the consultants. For example, the Client Director – who left the Client Company – continued cooperation with Finpro and the same consultant on another, completely new consulting assignment. The Client Company's Director, most probably, would consider the project as a failure. He did not manage to convince the Board to invest in Poland and lost his job. The Client Company's Board, on the other

hand, might consider the information provided by Finpro as an enabler in their risk-avoiding decision.

The case showed that the client problem can change during the project and the consultant has to adapt to the changing client's problem and criteria, and find the opportunity for on-sell based on this. Finally, the case presented that different types of clients can actually have different goals and unclear or hidden agendas. That is why it is important to meet both the real and the underlying client, learn their needs and build good relation with them.

The Client Company case is an example of how the external (unexpected and not-controllable) factors can affect the whole consulting project and turn it into success or failure. It also shows how differently the project's success/failure can be perceived. As a learning, it is very important to define the project's deliverables, impact and, separately, success at the very beginning of any consulting engagement.

For practitioner, the case shows that it is important it is to establish relations with the underlying clients and understand the wider picture in every consulting assignment. The real or even hidden needs, considerations and plans must be comprehended. In order to establish such relationships, the consultant meeting the clients should always look for a possibility of meeting with the top management. The aim of such a meeting would be learning the needs of the client and evaluating their commitment in the project, but also establishing a communication channel during the whole project. It should be important for consultants to meet the Client company Board members, establish relations with them and involve them into the project or, at least, to correspondence; and encourage them to be assertive and provide their opinion in formal way at the moment they feel it is important.

Structured Abstract

Purpose - The knowledge and competencies of the individual employees are valuable asset for a knowledge-intensive organization. A continuous education and training system enables an organization to build new knowledge and competencies among its members. To have an efficient and effective education and training plan that not only meet the need of individual employees but also improve organizational competencies is an important task for human resource management. Data mining has been used to discover the hidden patterns of data from a large-scale data warehouse. After further analyses, these data patterns may be transformed into intelligent knowledge as to support various decision makings. By using data mining, this study is aimed to explore the competency gap of the individual employees, and build the training needs predicting models. These models can assist human resource department to have an education and training plan that reduce the competency gap of the individual employees and also raise organizational knowledge asset and competencies as a whole.

Design / Methodology / Approach - The total amount of 638 example collected from Taiwan municipalities government 360-degree competency appraisal were used. These data were analyzed by SPSS to obtain statistic results. Data mining was used to explore the relationship among these data. Based on these results, the training needs predicting models were constructed.

Originality / Value - The results show that (1) the 360-degree competency appraisal model can be used to find out the competency gap and competency status. (2) the results of SPSS and data mining can be used to construct the training needs predicting models with accuracy above 70%. (3) the staff education and training plan can be obtained based on the training needs predicting models.

Practical Implications - The paper provided the reference of using data mining on the knowledge and competency management. The results could also provide the reference for planning the staff education and training plan, in order to achieve the purpose of improving individual and organizational knowledge and competencies.

Keywords: data mining, knowledge and competency management, 360-degree competency appraisal, staff education and training plan

Paper type – Academic Research Paper

1 Introduction

Previous studies have indicated that education training is considered the most efficient way to improve employee competency, training is also a key component in order to develop employee problem solving skills, attitudes and job knowledge. Taiwanese government spends a significant budget in employee training every year; therefore, the training strategy, planning, requirement and performance evaluation have become very important.

Desimone and Harris (1998) claimed that human resource development and training should start from education training evaluation, because it is a strategic planning tool. To plan education training should focus on their demands of different employee level to fit what they need. When making educational training decisions, one should also consider dimensional assessments in addition to employee needs; so that could distinguish the gap between self-evaluation and evaluation from others.

Now, the private corporations and/or government departments have become interest in increasing employee productivity and efficiency. Central government and local governments have relative employee competency execution plans to ensure the development of their employees. Hamidah et al. (2010) considered the data derived from the human resource field can increase employee training knowledge. For instance, applying employee performance records, learning ability and competency data mining to analyze the relative of data and make organizational decision rules.

With the new demand and increased visibility, human resource management seeks a more strategic role by turning to data mining methods(Ranjan,2008).In addition to the aforementioned, other scholars determined data mining technology can be used to build demand classification which will increase organizational education training efficiency.

Thus, developing appropriate competency management is an important strategic issue for HR managers or decision-makers to determine who should be trained, and what training programs should trainees participated. However, most competency management studies have explored the construction of competency models or have involved competency assessments conducted through self-evaluation to present descriptive statistical results. Consequently, competency data are rarely used to obtain accurate or valuable information.

The purposes of this study were to assess the gap for discovering the competencies which employees require training, and develop the training-needs prediction model to

identify crucial trainees by using data mining. This further facilitate in making more accurate and inexpensive decision , plan training activities, and choose appropriate trainees, that leaves little mismatch between training needed and training provided.

2 Literature review

2.1 Competency

Competency is a combination of knowledge, skills, motivation, attitude and personal characteristics which are demonstrated in behavior and influence employee's superior performance. Competency approach focus on how an employee creates value and what is actually accomplished (Spencer & Spencer,1993). The assessment of competency, as well as the development of competency-based management frameworks to support processes such as gap analysis, learning and other key human resource activities. Anitha, Anirudha (2010) believed that the most important aspect of competency evaluation is to identify employee ability gaps, which can be mitigated through training.

This paper used the personnel officer competency model in Taiwan's public sector to do assessment and analysis, as shown in Table 1.

Table 1. The Competency Model of Personnel Officer

	Job level below seven	Job level above eight
Management Competency	1. Communication Ability	1. Goal and Performance Management
	2. Team Motivation	2. Innovation Service and Procedure Management
	3. Emotional Management	3. Problem Tracking and Solving Ability

	3. Performance Management	3. Performance Management
	4. Information Technology	4. Information Technology

2.2 360-Degree Competency Assessment

Multiple-source multiple-rater feedback (MSMR) which includes many members to perform the personal assessment. Milliman et al.(1994) believes that 360 degree assessment can stimulate organizational communications and interactions. The group members who participate in the assessment should have full observation opportunities to understand the subject's working performance and personality. The evaluating members could be managers, colleagues, subordinates, customers and/or the individual (Tornow, 1993; Van & Nijhof, 2004) , as shown in Figure 1.

Figure 1. 360-Degree Assessment

Civil Servants Protection and Training Commission (2010) reported that 360-degree competency assessment could obtain the competency status of personal or organizations.(e.g. strong competency, weak competency, self-others consistency) and set the goal to conduct the individual development plan or planning education training.

This paper is using the 360-degree competency assessment model of personnel officer in Taiwan's public sector to do competency gap analysis and determine the order of educational-training demands, as shown in Figure 2.

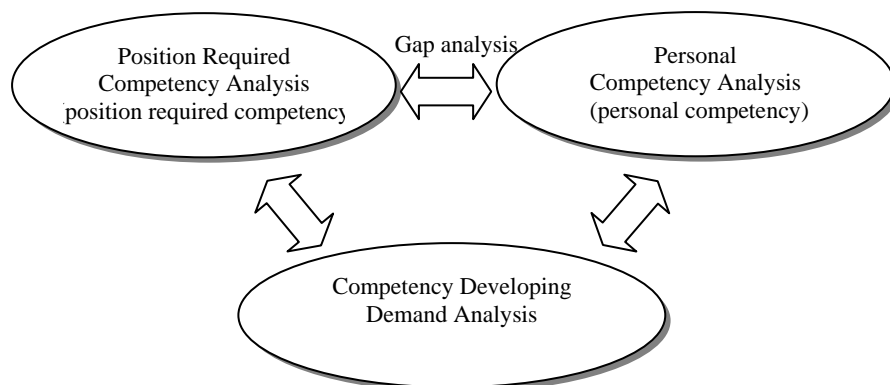

Figure 2. The 360-Degree Competency Assessment Model of Personnel Officer

2.3 Competency Based Training in Public Sector

In recent years, the private corporations and/or government departments have become interest in increasing employee productivity and efficiency. Central government and local governments have relative employee competency execution plans to ensure the development of their employees (Directorate-General of Personnel Administration,2007; Civil Servants Protection and Training Commission,2010; The Examination Yuan,2012; Civil Service Development Institute,2012).

Civil Service Development Institute (2012) collected the competency data of government officer to develop the core competency model, and conducted“Take Off Program for Senior Civil Service(TOP)”to train the competencies for senior officers. Therefore, competency based training has been conducted in public sector, no matter trainees selection, or training programs planning, all focus on the competency-based approach to training.

2.4 Data Mining for Human Resource Management

Presently, data mining is a part of process in knowledge discovery in database, which receives great attention and is recognized as a newly emerging analysis tool. Many areas have conducted data mining techniques, such as in marketing, manufacturing, customer relationship and health care. However, the used of classification techniques in data mining approach does not attract much attention among people in human resource field (Ranjan,2008). Today’s organizations have to struggle effectively in terms of cost, quality. The success of these tasks involves much managerial decisions to decide the right person for the right job at the right time.

Classification and prediction is the common task for knowledge discovery and future plan in data mining. Decision tree is the powerful classification algorithms as stated in some studies, it has many advantages, for example it can produce a model which may represent interpretable rules or logic statement; it is more suitable for analyzing categorical outcomes; easy to interpret; computationally inexpensive; it’s prediction model is explainable to the user. Due to the reasons, this study is aimed to use the C5.0 classification algorithms to handle issue on the competency developing demand of 360-degree competency assessment for building a prediction model.

3 Methodology

In this study, we attempt to assess competency gap and competency status to determine the order of educational-training demands from the 360-degree competency assessment model. Moreover, developing the training-needs prediction model by using data mining to identify appropriate trainees, the research structure of this study as shown in Figure 3.

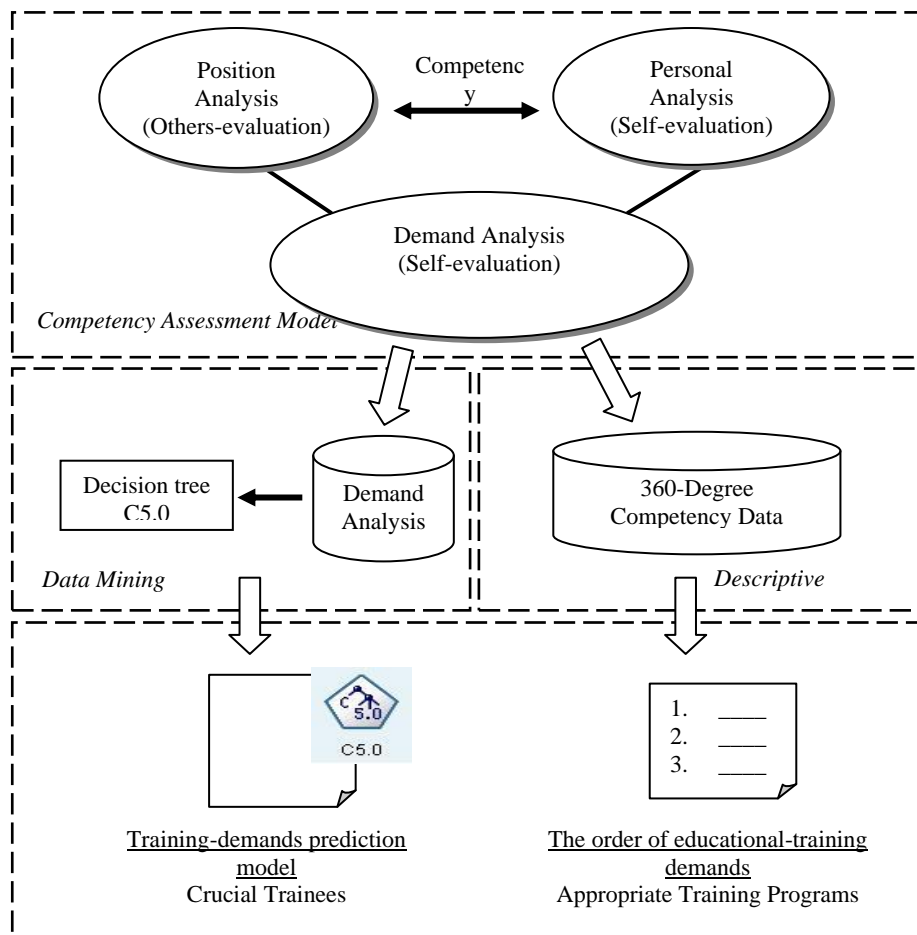

Figure 3. Research Structure

3.1 Data Resource

The data collected from the personnel officer in public sector of Taiwan by using a 360-degree competency assessment, which could be divided into three groups of 360 degree questionnaires. The content can be separated into three parts: basic information,

professional core ability, and management core ability. The questionnaire of professional core ability and management core ability is a five scale evaluation. This paper investigated 664 personnel officers and has a sample of 638 matched samples, each sample collected with its 360-degree evaluating data. The return rate is 96%.

This paper is using the data of 360-degree competency assessment to assess the competency gap and identify the training demands, the following are:

Table 2. Effective Response Sample

		Job level below seven		Job level above eight	Total
		Non supervisor	supervisor		
Self-evaluation	Questionnaire code 【investigated sample】	A 【267】	B2 【203】	B1 【168】	638
	Total of sample	267	203	168	
Third Party-evaluation (360 degree evaluation)	Direct superior Questionnaire code 【investigated sample】	A(c) 【252】	B2(c) 【196】	B1(c) 【167】	1365
	colleague Questionnaire code 【investigated sample】	A(a) 【257】	B2(a) 【189】	B1(a) 【156】	
	Subordinate Questionnaire code 【investigated sample】		B2(b) 【20】	B1(b) 【128】	
	Total of sample	509	405	451	

Total Population:2003

(1) Competency Gap-Consistency

Atwater and Yammarino (1992) mentioned that when distinguishing the consistency between self-evaluation and third-party evaluation, one must collect the grade from self-evaluation and third-party evaluation; and calculate the grade of self-evaluation and grade of third-party evaluation. Through standardization procedure, translate two distribution curves into a Z-score distribution (mean=0 ; standard deviation=1). Z-score can present the individual relative position in a group; therefore, the research uses “grade of self-evaluation(Zs)” and “grade of third-party

evaluation(Z_o)” to analyze the result of consistency between self-evaluation and third-party evaluation.

The consistency results could be divided into three categories (Jihn, 2006) , then calculating the personal proportion of three categories:

A. In agreement: the discrepancy between Z_s and Z_o is less than 0.5

B. Over-estimator: if $Z_s > Z_o + 0.5$

C. Under-estimator: if $Z_s < Z_o - 0.5$

(2) Training demands

The learning demand is an individual’s desire to achieve certain ability, which could be satisfied through education (Scissons,1982). Tom et al.(2011) investigated the competency what employees desire to achieve as the cognitive needs of employees.

Therefore, this paper used the demand of competency developing (self-evaluation) to build the prediction model to reduce the decision costs and identify appropriate trainees.

3.2 Data Analysis

(1) Data pre-processing

Mamdouh (2007) reported data pre-processing is an important step in the data mining process. First, the data do not have main for our research which is deleted, for avoiding that suitable for the analysis of data to being added to the prediction model of data mining. Second, translate the data into the format which can be analyzed. Finally, we will also check the missing data.

(2) Descriptive statistics

This study used the competency data to do descriptive statistics for obtaining the competency status and integrated with the competency gap to determine the order of educational training demands.

(3) Data mining

This study used the C5.0 classification algorithms of data mining to handle the issue on the competency developing demand of 360-degree competency assessment for building a prediction model.

4 Results

4.1 360-Degree Competency Assessment

This study used the competency data to do descriptive statistics, showing the basic population statistic, and integrated three parts (competency self-evaluation, competency

gap and competency developing demands) grade of 360-degree competency assessment model to determine the order of educational training demands.

1. Basic population statistic:

(1) Gender

The gender of employees who responded to the survey are females (n=444, 69.6%), and males (n=194, 30.4%), females are higher than males.

(2) Age

The age of employees who responded to the survey are between 40s and 49s (n=216, 33.9%) takes the most part in effective samples. The age above 56s (n=32, 5%) takes the least part in effective samples.

(3) Job level

The job level of employees who responded to the survey are include job level below level seven (n=470, 73.7%) and job level above level eight (n=168, 26.3%).

(4) Superior rank

The superior rank of employees who responded to the survey are supervisor (n=369, 57.8%) and non-supervisor (n=269, 42.2%).

(5) Work experience

The work experience of employees who responded to the survey are higher than 21s (n=171, 26.7%) and less than 5s (n=170, 26.6%).

2. The order of educational-training demands

This study integrated three parts grade of 360-degree competency assessment model to determine the order of educational-training demands, as following are:

(1) Personal Analysis (self-evaluation)

This study listed the competency grades of personal analysis of two groups for top three and last three. Top three are the strengths, last three are weaknesses. The results could provide useful information for managers give priority to educational training programs, as shown in Table 3.

Table3. Self-Evaluation Competency Grade of Two Groups Statistic Table

	Job level below seven		Job level above eight	
	Competency	Mean	Competency	Mean
Strength	Team Motivation	4.34	Customer Service	4.51
	Customer Service	4.32	Communication Ability	4.38
	Conflict Management	4.23	Knowledge Management	4.37

Weakness	Personnel Regulation	3.90	Performance Management	4.15
	Emotional Management	3.88	Innovation Service and Procedure Management	4.15
	Crisis Management	3.80	Problem Tracking and Solving Ability	4.04

(2) Competency gap (self-other evaluation)

This study used three categories to present the consistency results, in agreement, over-estimator and under-estimator, showing gaps exist between personal (self) and position (third-party) analysis. To calculate the personal proportion of three categories into training demands order.

(3) Demand Analysis

The descriptive analysis of competency demanding development shows the grades of each competency item. The grades present employee's desire or needs to develop the competency.

According to the results of 360-degree competency assessment, this study integrated above three parts to determine training demands order, the results report that the government employee whose job level is lower than level seven should enhance "Personnel Regulation" competency, and whose job level higher than level eight should prove "Leadership Challenge" competency as the first concern. The specific research outcomes are shown in Table 4 and Table 5 .

Table4. The order of training demands-job level below seven

	Personal Analysis		Competency Gap		Demands Analysis		Educational Training Decision	
	Mean	Order	Overestimate Rate	Order	Mean	Order	Total of Orders	Training Demands Order
Customer Service	4.32	10	33 %	2	4.01	2	14	2
Personnel Regulation	3.90	3	35 %	1	4.02	1	5	1
Performance Management	3.94	4	28.5%	10	3.89	6	20	6
Information Technology	4.20	7	32 %	5	3.98	3	15	4
Communication Ability	4.22	8	32 %	5	3.88	7	20	6
Team Motivation	4.34	11	31.5%	7	3.90	5	23	9
Emotional Management	3.88	2	32.5%	3	3.61	11	16	5
Crisis Management	3.80	1	32.5%	3	3.82	10	14	2
Time and Procedure Management	4.12	6	31 %	9	3.87	8	23	9
Conflict Management	4.23	9	28 %	11	3.94	4	24	11

	Personal Analysis		Competency Gap		Demands Analysis		Educational Training Decision	
	Mean	Order	Overestimate Rate	Order	Mean	Order	Total of Orders	Training Demands Order
Knowledge Management	4.09	5	31.5%	7	3.87	9	21	8

Table5. The order of training demands-job level above eight

	Personal Analysis		Competency Gap		Demands Analysis		Educational Training Decision	
	Mean	Order	Overestimate Rate	Order	Mean	Order	Total of Orders	Training Demands Order
Customer Service	4.51	13	36.7%	1	3.56	3	17	4
Personnel Regulation	4.28	7	30 %	12	3.53	4	23	9
Performance Management	4.15	2	31.3%	9	3.48	5	16	2
Information Technology	4.34	10	25 %	13	3.58	1	24	10
Goal and Performance Management	4.18	4	31.7%	7	3.41	10	21	8
Innovation Service and Procedure Management	4.15	2	32.3%	5	3.44	9	16	2
Problem Tracking and Solving Ability	4.04	1	31 %	10	3.47	6	17	4

Legal Capacity	4.28	7	34 %	3	3.41	10	20	7
Cultural Capacity	4.19	6	30.7%	11	3.58	1	18	6
Leadership Challenge	4.18	4	34.7%	2	3.46	7	13	1

4.2 Data Mining: Decision Tree

This study used the C5.0 classification algorithms of data mining to handle the issue on the competency developing demand of 360-degree competency assessment for building a prediction model. Therefore, the classification's target is the recommendation for training.

First, this study divided the grades of demand analysis into three groups for predicting, high willingness, medium willingness and low willingness, as shown in Table 6. Second, we used confusion matrix to verify the accuracy of the model. Confusion matrix, also known as a contingency table or an error matrix, is a specific table layout that

allows visualization of the performance of an algorithm (Stehman & Stephen, 1997). Each column of the matrix represents the instances in a predicted class, while each row represents the instances in an actual class. The confusion matrix results are shown in Table7 and Table8 .

Table6. The Grades of Demand to Groups of willingness

The grades of demand analysis	Three groups of willingness
5 points	high willingness
3~4 points	medium willingness
1~2 points	low willingness

Table7. The Confusion Matrix-Job level below seven

Predicted \ Actual	High Willingness	Medium Willingness	Low Willingness
High Willingness	135	34	14
Medium Willingness	26	152	19
Low Willingness	11	32	47
Accuracy	71.06%		

Table8. The Confusion Matrix-Job level above eight

Predicted \ Actual	High Willingness	Medium Willingness	Low Willingness
High Willingness	49	7	4
Medium Willingness	18	36	4
Low Willingness	8	7	32
Accuracy	70.91%		

The classification rules generated from C5.0 classifier is human readable and easy to understand which do not require any domain expert knowledge or parameter setting. This technique can produce both the decision tree and rule-sets and can construct a tree for the purpose of improving the prediction accuracy (Delen, 2005). The C5.0 classifier generated 17 classification rules from 470 training datasets whose job level below seven,

and 10 classification rules from 168 training datasets whose job level above eight. The sample rules that are extracted from the tree are shown in Table 9.

Table9. The Sample of classification rules-job level below seven

Rule No	Classification Rules	Result
1	If (Superior rank=supervisor) And If (work experience > 21s) And If (job level= p06-07) And If (age < 49s)	High Willingness Priority to Train
2	If (Superior rank=non-supervisor) And If (work experience > 5s) And If (job level= p04-05)	Low Willingness
3	If (Superior rank=non-supervisor) And If (job level= p04-05 or p06) And If (gender= male)	High Willingness Priority to Train
4	If (Superior rank=non-supervisor) And If (job level= p04-05 or p06) And If (gender= female)	Medium Willingness
5	If (Superior rank=supervisor) And If (work experience < 5s) And If (gender= male)	High Willingness Priority to Train

5. Discussion

This research attempts to use 360-degree of competency assessment and the application of data mining technology to identify the most appropriate training programs and the most crucial trainees. We used three parts of competency data, personal analysis, position analysis and demand analysis to determine the order of educational training demands. Moreover, this study used the C5.0 classification algorithms of data mining to build a prediction model for training demands.

5.1 Competency Assessment to Educational Training Order

This study integrated three parts grades of 360-degree competency assessment model, personal analysis, position analysis and demand analysis, to determine the order of educational-training demands. In our analysis, “Personnel Regulation” should be enhance first to employees whose job level below seven, and “Leadership Challenge” competency should be improved priority to employees whose job level above eight.

5.2 Prediction Model on Training Demands

This study used the C5.0 classification algorithms of data mining to build a prediction model for training demands. We divided the grades of demand analysis into three groups for predicting, high willingness, medium willingness and low willingness. The

classification's target is the recommendation for training. Using confusion matrix to verify the accuracy of model, the results show both our prediction models were greater than 70%.

5.3 Proactive Educational Training Strategy

Based on our research findings, the 360-degree competency assessment model is effective for identifying the competency gap and competency status, also in determining the order of educational training competency. Moreover, the prediction model we developed for training demands can be used to reduce costs when making human-resource decisions.

We can focus on the weakness competency, the most high demand competency, or the apparent competency gaps to plan the training programs. In particular, the crucial trainees our prediction model found also should be train first, because they have high willingness to learn and train.

6 Conclusion

6.1 Implications

Taiwanese government spends huge budget in employee training every year, therefore, training demand is an important issue, and organizations have to plan the appropriate training programs with crucial trainees at right time. Now, the private corporations and/or government departments have become interest in increasing employee productivity and efficiency. Central government and local governments have relative employee competency execution plans to ensure the development of their employees. However, competency data were used to do the construction of competency model, rarely used to obtain accurate or valuable information.

Tough (1978) mentioned the learning demands of adults is problem-resolved based, because most adults learn to resolve the problems at work. If the training can't fit the demands of employees, the motivation and training effectiveness will decline. Therefore, organizations should consider the personal learning demands when doing educational training decisions. This paper used the competency data and demands to identify and target the appropriate employees for training.

Many organizations establish comprehensive competency-based employee development programs. These programs are staged development initiatives that include: formal in-class learning events; planned work assignments aimed at developing certain

skills and competencies; self-study components; and, formal assessment to evaluate progress in development as well as to accredit or certify that the employee has gained required competencies and knowledge. In some cases, the employee is promoted to a higher level once certain performance standards have been met. Organizations are increasingly moving to this model of employee development to address current or looming shortages of staff and to ensure that there is a continuing supply of qualified staff to meet future organizational needs (John Burke, 1989). This approach also demonstrates to employees that the organization is committed to their development and advancement within the organization.

Overall, competency development and management have become the most important issue and can't be ignored. Our study used the data of competency assessment to determine the order of educational training, and used data mining technology to identify and target the crucial trainees. We believe these results could provide a useful model for facilitating the decision-making of managers and policy makers to reduce much decision costs. In addition, the results provide insights that the government can use in planning related training programs and policies.

6.2 Suggestions

This article has described the significance of the study on the use of data mining classification techniques for employees' training demands prediction. However, there should be more data mining classification techniques applied to the different problem domains in HR field of research to broaden the horizon of academic and practice work on data mining in HR. Besides that, other data mining techniques such as SVM, Fuzzy logic and AIS should also be considered for future work on classification techniques using the same dataset.

In this study, as we can see from result analysis, C5.0 classifier has a great potential for prediction. The generated classification rules can be used to predict the performance of an employee whether he/she has potential to be promoted or not, based on his/her willingness to develop. In conclusion, the ability to continuously change and obtain new understanding of the classification and prediction in HR research has become the major contribution to data mining in HRM.

6.3 Limitations

Our study has some limitations. First, we used the 360-degree as the assessment method. However, the consideration relationship between evaluator and evaluatee is not perfect, because we have little urgent time to collect the data, few evaluators feel not so familiar with their evaluatee. We suggest the researchers could audit carefully the consideration relationship with perfect way and enough time in the related study. Second, Chinese culture emphasize the “renqing”, “mianzi” and power, in this kind of society, to evaluate objective is not a easy thing, the researchers could have competency assessment seminar, make every evaluator and evaluatee have the right concept about competency assessment, then the data of 360-degree competency assessment could be valuable.

Structured Abstract

Purpose – Globalization enhances traditional managerial models with numerous challenging features. So far isolated companies, focused mainly on local customers, must shortly become valuable units of large multicultural clusters. Beyond the evident business positives, there are also strong appeals, arising especially from unavoidable structural merging. Presented research concentrates on language aspects of globalization, when business units must communicate efficiently both internally (with own employees or internal customers) and externally (market stakeholders). Our goal was to identify and analyse the scope and degree of influence of systematically institutionalized components of organizational language on its performance.

Design/methodology/approach – Balanced scorecard is widely used tool for strategic performance planning and management. According to this approach, enterprise is considered from four perspectives, contributing together to stakeholders' value maximization. In the analytic phase of our research, we selectively identified and quantified the major language-sensitive activities, enhancing companies' learning and growth, customer relations, operations and financial processes. Resultant findings were transferred into system dynamics implementation of BSC in a form of independent but cooperating capacity and human resources development related modules.

Originality/value – There are interesting research results concerning the language management in the sense of its internal production and reception. Other authors study language in organizations from cultural, administrative or technical viewpoints. Consequently, our market oriented approach, projecting language aspects into strategic planning and performance platform is rather new and promising direction in competitiveness research.

Practical implications – Development of soft skills and proper establishment of related processes belong among the key business success factors. Current managers, however, emphasize direct vocational knowledge over general abilities of their staff. This is understandable, because focused professional training influences productivity faster than, e.g., personal behavioural improvements. On the other hand, right systemization and full utilization of official spoken and written language has also evident, although delayed, productive potential. To minimize problem of its quantification, we analyse different ways of language institutionalization by means of interactive management flight simulator. Such tool can be easily adopted and immediately utilized in practical planning and group decision making tasks.

Keywords – Organizational language, strategic planning, performance driver, balanced scorecard, dynamic modelling.

Paper type – Academic Research Paper

1 Introduction

Activities of every company are closely related to and affected by the language used for communication within the company as well as with its external environment. The language functions as one of the determining factors of the company life including interpersonal relationships, cooperation, motivation and managerial processes. Adequate language use promotes competent communication bringing benefit to the company on all levels of its operation, inaccurate language application, on the other hand, may have negative consequences and develop into a barrier impeding business activities and proper functioning of the company. In the modern global business world, issues of language constitute new challenges to multinational companies and their managements where the situation is complicated by diverse language environment. The process of globalization has brought about a widespread creation of multinational corporations. Simultaneously, the role of language as the mediator of effective communication in such companies becomes a pronounced factor possessing the power to influence the corporate business results and achievements and consequently the competitiveness of the enterprise. A number of studies and researches have been published exploring the role of language within multinationals and discussing its influence on their performance and suggesting possible feasible solutions. On the other hand, the discussion and research on the cost effectiveness of such solutions implementation has been rather neglected so far.

2 Language Management and Language Barrier

Both written and spoken language serve as a means of company communication which conveys information internally between managers and employees and also externally facilitating negotiations with partners, contact with customers and company image to the public (Fredriksson et al 2006, Haarmann 1990, Wardhaugh 1992, Welch et al 2005). Language management includes planning, organizing, staffing, leading and controlling of resources related to language (Spolsky 2009). Language used in a proper way might become a powerful tool for building corporate image, act as a connecting factor among the stakeholders leading to better understanding and reducing the possibility of conflict rise. Ignoring the significant role of language in multinational organizations might lead to the loss of resources, impediment of organizational and managerial development due to the lack of communication and knowledge sharing (Lauring, 2007). The managerial approach to the issues of language can be defined as:

- simple – tackles straightforward problems as they occur in communication of individuals (pronunciation, spelling, use of certain words and phrases)
- organized – a more structured approach involving more persons. Language management process in this case is defined, adapted and developed continuously to suit the activities of the organisation, its goals and vision.

Language management is faced with the problems designated as language barrier arising from the increase of communication intensity, language diversity and scale of operations. Unfortunately, the ways to cope with these problems have deserved little attention from the research community so far (Feely and Harzing, 2008). The language barrier can be indirectly monitored in the following areas (Dhir et al. 2002, Enderwick et al. 1994, Guirdham 1990, Henderson 2005):

- Buyer-seller relationship: both groups prefer to communicate in own language,
- Foreign market expansion: language differences make distances ever bigger,
- Joint ventures: companies with international language dominate local partners,
- Headquarter-subsidiary relationship: language barrier cause distrust,
- Staffing policies: in case of single official language, headquarters are usually these foreigners,
- Ineffective inter-unit communication: frequently only one person with fluent knowledge of language acts as an interface, disregarding professional skills,

- Subsidiary role and autonomy: autonomy in own language usually grows with organizational distance from headquarter,
- Social exclusion and power: expats tend to be excluded from local community,
- Staff transfers: realized according to their language abilities rather than expertise,
- Structure, control and coordination: lower teams' cohesion if fundamental knowledge is not available in unified language.

Different authors (Charles et al. 2002, Maclean 2006, Swift 1991) suggest these solutions of language barrier problems and choices of language strategy:

- Lingua Franca, i.e. evolutionary adopted language: strict orientation on a single and too specific language might be dangerous,
- Functional multilingualism: risk of loss or distortion of information,
- Hiring external language resources (translators, interpreters): acquisition of purely language abilities without any domain knowledge can cause mistakes,
- Training: only long term and explicitly evaluated programs are worth,
- Corporate language: slow but efficient and successfully implemented by many global companies,
- Language nodes: predefined standardized communication interfaces inside organizational structure,
- Selective recruitment: straightforward and relatively cheap solution, but difficulty to realize,
- Engage expatriate management: risk of non-locality of management,
- Inpatriation: administratively domesticated staff can be under enormous social and professional pressure,
- Machine translation: rather reactive, short-time solution than a viable strategy. Cannot be used for semantically rich documents like legal or business texts,
- Controlled language: restricted linguistic corpus is helpful for highly formalized,

The basic factors influencing the choice of language strategy might include the language, external environment, the corporation itself, finance and corporate strategy. The language choice will be to a large extent determined by the type of the language, its complexity and commonness. The external factors such as human resources, customers, suppliers and competitors and the languages they use also have an impact on the choice of language strategy for the corporation, which might be influenced by the official language

of the country, language competencies of the managers, common communication style of the customers in relation to marketing and public relations, availability of translation services. The type of corporation, its structure and scope of activities and corporate image constitutes another important factor. Undoubtedly, financing the language integration into the long-term strategy of the corporation requires due consideration. Investments into the language training of employees, testing and maintaining their language skills will on the other hand bring savings owing to information resources sharing, omission of translation services and enhanced possibilities to operate on foreign markets and negotiate with business partners. Corporate strategy representing the ways used by the company to deal with its competitors will benefit from well-chosen language strategy enabling effective addressing of customers.

Although a fundamental research presenting a common base for the solution of language barrier is yet missing, a range of researchers have explored language issues in their case studies of multinationals. Different languages used within one multinational organization might constitute an important barrier slowing down company processes on all levels, increasing costs and thus negatively affecting the company performance. As Thomas (2008) argues it is necessary to consider the language needs of each organization thoughtfully and to develop the language skills of the employees to be able to overcome the communication barrier. Out of the solutions of language barriers named above the concept of a common corporate language is discussed most frequently in the available papers. The discussions address various aspects accompanying the process of common language adoption which the management of multilingual organizations should be aware of and present issues deserving further research. Harzing et al. (2011) suggest in their research a range of solutions to overcome the language barrier including a change of communication patterns, language training and a common corporate language. The effective internal communication often depends on having a shared language as language differences are associated with misunderstanding and conflict.

The most common shared language used in the 21st century is obviously English. Swift and Wallace (2011) focus on a German multinational organization using English as the common corporate language. The vast majority of employees use English for their job but the level of language skills is varying. The authors present a range of provisions to be taken to help the employees to achieve the level of English needed for their jobs. These provisions concern training, job rotation in English-speaking countries but also some

practices to be used in communication within the organization. Ehrenreich (2010) argues that although English has become an indispensable necessity in the business today, it is necessary to realize that it is not English as a native language to be learned but communicative effectiveness in English as a business lingua franca which might include non-native as well as native Englishmen from various cultural backgrounds on different levels of proficiency. An English language policy can be practicable but specific language groups will need promotion and facilitation of language use (de Groot, 2012). Furthermore the implementation of a common corporate language, whether it is English or any other language, presents a number of challenging tasks for the management ranging from translations of necessary documents to staff recruitment and training. As Fredriksson et al. (2006) suggest in their paper, even then the management are faced with the situation when the corporate language may not be as widely shared within a multinational organization due to language diversity, varying language proficiency of its employees and the level of analysis of previous research. According to Welch et al. (2001) adopting a common corporate language may obstruct or alter information flows, knowledge transfer and communication. In their other paper (Marschan-Piekkari, Welch, D. and Welch, L. 1999) the authors explored the impact of language on structure, power and communication in multinationals on a case study of one Finnish multinational. It is argued in their paper that language imposes its own structure on the flow of communication and personal networks. Thus employees with upper levels of language competencies are able to create broad contact networks within the multinational whereas employees with limited language skills rely on personal relationships with language mediators.

Maclean (2006) challenges the assumption that a single corporate language, usually English, is essential for operational efficiency on the basis of its limitations when it is a foreign language to all employees both at headquarters and in subsidiaries in e.g. a bilingual organization. Moreover, Maclean argues that English used as a second language makes the situation even more complex as the difficulties of communicating across cultures are thus contained within a single language, and suggests that more sophisticated, multilingual approaches to resolving language problems will be sought after in future. This is the point where other solutions to language barrier mentioned above or various combinations of them might be considered. For example Crémer et al. (2007) suggest that a manager working as a specialized translator may be used to achieve between-unit

coordination while separate languages are maintained within the organization. Another study carried out by Harzing and Pudelko (2014) proposes that expatriates can facilitate communication between headquarters and subsidiaries.

3 Language and performance

Every forward-looking company strives to establish deterministic, standardized and repeatable strategic planning processes, supporting complex decisions of their managers. Such need is logical consequence of inherent market uncertainty, subjectivity, dynamics and volatility. Furthermore, problematic forecasting of future demand, altogether with blurred consequences of insufficiently justified managerial statements result to internal pressure and loss of motivation, critically threatens the institutional existence. Logically, the main goal of any strategic planning is the maximization of performance. In for-profit companies, performance combines different structural characteristics (e.g. business model) with their implementation and evaluation mechanisms, like strategies, resources and processes. Generally, performance is composed from effectiveness, i.e. measure of success in doing the right things and efficiency, measuring how well we proceed in doing our things. Properly designed performance measurement system must collect adequate amount of data from the both groups. Such temporally and hierarchically distributed definition conveniently predetermines dynamic approach to performance representation, because one-shot time slice can hardly explain complex relations among its leading (resources related) and lagging (output oriented) indicators. Effective, broadly understood structural simplification of performance architecture is yet another prerequisite for correct and prompt establishment of practically applicable, reliable and scalable managerial platform (Davies and Davies, 2011). Consequently, performance management system can be based on the following components:

- Strategy map (Kaplan and Norton, 2004), which is simplified and layered graphical representation of particular business strategy. This diagram acts mainly as systemization and communication tool, helping managers to sort, prioritize and explain their key objectives in single strategic perspectives, including (i) human resources (HR) altogether with their learning and growth policies, (ii) internal operations, (iii) customer relations and (iv) finances. This structure is interpreted in the bottom- up way, meaning that improvement of objectives in HR, learning

and growth perspective leads to better performance of internal processes, which stimulate desired customer-oriented and financial results.

- Balanced scorecard (BSC) - (Kaplan and Norton, 1996) represents refined and restructured version of strategy map, extended with performance drivers and indicators. Originally static document, intended for strategic presentations and discussions, has gradually turned into routinely applicable company-wide executive guideline and also extended to dynamic version by Akkermans and van Oorschot, 2002 or Barnabè, 2011.

4 Tools and techniques

Initial discrete temporal context of BSC is usually captured with Causal loop diagrams (CLD) (Sterman, 2000; Morecroft, 2007), connecting causally coherent internal terms either directly (plus sign) or reciprocally. These edges form complex reinforcing (R) and balancing (B) loops, concurrent contributions of which determine dynamic behavior of the whole system. CLD in figure 1 shows that the proposed problem of language has more reinforcing than balancing loops. Such arrangement says, that there is a growth potential, connected with *Learning and improvement*, *Language quality* and *Active language skills* parameters. Company, indeed, can make money also through proper utilization of its *capacities* and quantitative resources, as well as with responsible management of *customers'* base. On the other hand, *workload* and corresponding loss of *satisfaction* represent the main limiting factor, expressed with the only balancing loop.

Another fundamental tool of BSC dynamization is Stock and flow diagram (SFD). Although it primarily serves as graphical programming language for Systems dynamics modeling, due to the representational clarity SFD can be employed as a computer-independent modeling platform, too. Resources of performance (drivers) are expressed as stocks or tanks, filled and drained by parametrically controlled valves, adjustable with other data, available in system. Corresponding simplified system diagram is system dynamics notation is in figure 2. We can notice that some variables from figure 1 are now expressed with stocks, while others are converted into valves and parameters (invisible in figure 2). Stocks levels, which represent mainly purposely planned and managed quantities, are also called state variables.

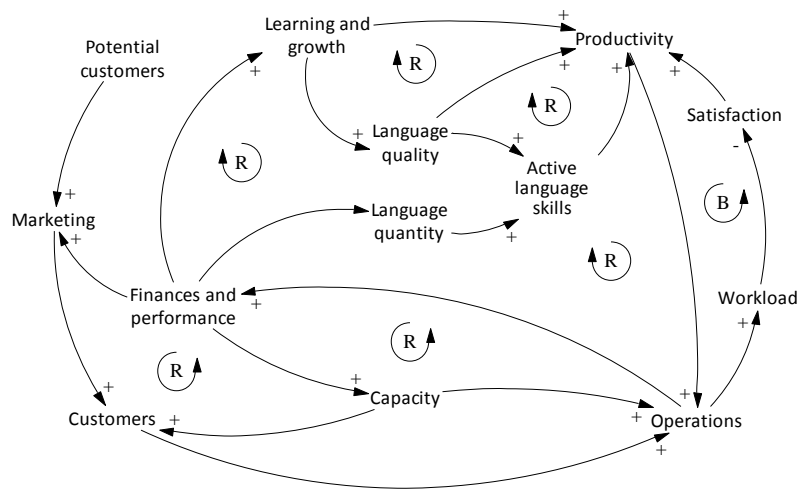

Figure 1 Basic Causal loop diagram of language influence on company performance

Related in- and outflow rates are controlled by generally nonlinear functions of other parameters or stock levels. For example, *Parameter_set_1* can be function of *finances*, (marketing) *staff* and *knowledge* (customer relationship management), *operations* (supply of products and services) and, in our case, also the both *language* stocks. After the model is fully adapted to company processes and external inputs, users can perform sensitivity and scenario analyses or search for viable strategies or policies. All values are constant just between the adjacent computational steps and can be changed whenever afterwards. This nonstationarity option allows adjusting of decision cycles durations based on changing environment.

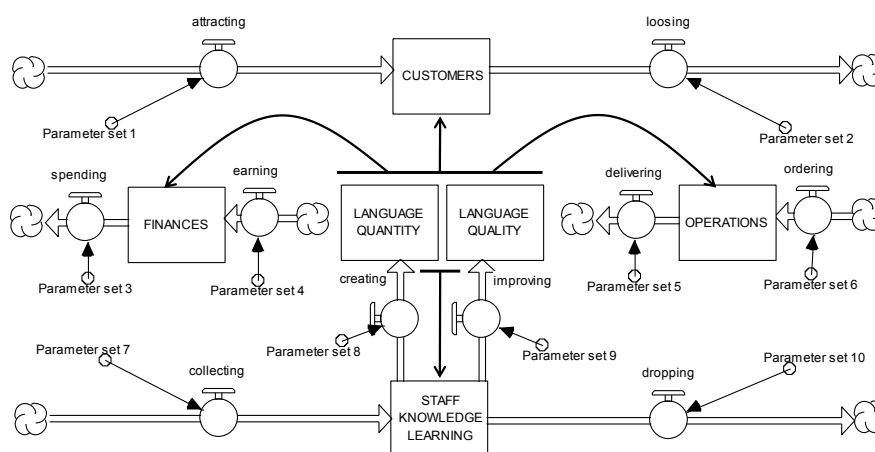

Figure 2 Relation between language and performance, simplified Stock and flow diagram

5 Experiments

We propose the following three ways of projection of the above-discussed language strategies to simulation model:

- a) Installation of language directly to the organizational infrastructure, which is applicable to these strategies:
 - Lingua Franca,
 - Functional multilingualism,
 - Corporate language,
 - Language nodes,
 - Controlled language.

Because the structuring is strategic task, necessary costs become inherent part of primary planning and do not need to be analyzed separately. The set of institutionalized language features thus contributes immediately to basic dynamic behavior. Sample design of such case is discussed in section 5.1.

- b) Development of general language capabilities represented with instantly available and publicly visible quantities, addressing especially the front-end stakeholders, such as prospective customers, suppliers or employees. This can be achieved via:
 - Hiring external language resources,
 - Purely linguistic, professionally unfocused training,
 - Machine translation.

Experiment, analyzing this possibility, is described in section 5.2.

- c) Concentration on development of efficiency enhancing and productivity stimulating HR skills and knowledge (quality of language), which can be realized through the following activities:
 - Active vocational training, delivered in foreign language,
 - Fully utilized positives of selective recruitment, expatriation and inpatriation - for example sharing knowledge in distributed international teams.

Related experiment is shown in section 5.3.

For simplicity, we associated performance with profitability and compare net profits of single alternatives, i.e. differences between sales revenue and total costs. This viewpoint naturally assumes certain level of internal maturity and market stability. In

cases of identical profitability, the number of acquired loyal customers is used as auxiliary performance metrics, because the temporally shifted relation between customers and profitability is evident. Exact structuring of company costs represents a complex problem, influenced with numerous internal factors. Disregarding the accounting details, part of earned money can be reinvested to capacities of structural and human resources (tangible cost drivers). The rest can partially come to the learning and growth sector, where develops human and organizational capital, i.e. individual skills and knowledge, as well as teamwork, management or alignment (intangible cost drivers). Qualitative effort implies continuously improving organizational culture, supports organizational learning and introduces knowledge management practices, which makes company highly efficient and competitive. The both types of cost drivers, utilized in internal operational (core), supportive and managerial processes, yields performance via their effectiveness and efficiency components. Because this research is theoretic, we concentrated on fundamental relational and behavioral aspects rather than on explicit numbers. Let's assume that the costs, associated with company language (C_{TOT}^L) are fixed and make up units of percent of its total costs C . They are split into capability (C_{CAP}^L) and HR development (C_{HR}^L) parts, i.e. $C_{TOT}^L = C_{CAP}^L + C_{HR}^L$. In study of pure capability, we assume that $C_{TOT}^L = C_{CAP}^L$ and search for a reasonable ratio $C : C_{TOT}^L$. The subsequent qualitative analysis uses the previously fixed C_{TOT}^L and strives to find feasible $C_{CAP}^L : C_{HR}^L$ ratio.

5.1 Structural adjustments

Let's suppose that company needs to increase performance through overall extension and intensification of existing infrastructure. This practically means, that managers must find a reasonable balance between quality and quantity supporting investments, resulting in non-decreasing profit during the next two years. Under simplifying assumption of linearity, we gradually adjusted the total additional capacity, then picked its most convenient value and applied the same procedure on HR development sector. Graphical results of the both experiments are in figures 3 and 4.

Figure 3 Analysis of profitability with respect to total extension of structural capacity

Figure 4 Analysis of profitability with respect to extension of overall HR development

Without any changes, profit initially grows as a result of past investments, until a steady state from month twelve on is reached. Since then and under assumptions of internal and market stability, company serves existing customers and generates constant profit. Firms with such passive strategy have no reason to address new customers or spread own businesses, not to say include language extensions. Set of curves in figure 3 shows that any structural, i.e. tangible investments have positive effect on profitability. One can also notice that spending larger than 25% is potentially risky, because it originates peaks on profit curves due to high incurred costs (salaries, maintenance, overhead), unbalanced with income. There are two ways how to handle such situation - either to accept the level of maximal monotonously growing output or to shorten the decision making cycle. From the inflection point on basic (0%) profitability curve we can estimate its time constant on five months, which is significantly less than currently applied two years. For the second adjustment, we chose the first option and applied the variation of HR development money on 25% capacity growth course. Results on figure 4 justify effectiveness of such change. Two times higher profitability improvement indicates, that our sample company runs a value-intensive business, like job-shop or provision of very specific eventually knowledge-oriented services. Noticeable is also nonlinearly varying density of curves for larger HR investments, showing existence of zone of ineffective knowledge excess. That's why we used only 50% of available HR development financing and left the rest as strategic reserve. Resultant suboptimal profitability curve, used in all following cases as a base run, thus incorporates, among others, also fully institutionalized structural aspects of language.

5.2 Extension of language capabilities

Instantly available and flexibly allocable language-based performance drivers should appear mainly on customer side. Marketing, sales or supportive services are straightforward examples of activities, where prompt availability of language helps immediately. On the other hand, fragmented language elements, spread non-systematically inside company, can hardly contribute to its productivity. More likely they can cause unwanted communication and administrative overhead. Sensitivity analysis in figure 5 shows the relation between language capability and total amount of customers. As expected, this amount always grows, but there is a central bottleneck, caused by momentarily insufficient productivity of operations. Customers, initially

attracted by multilingual environment, are served slowly, which lead to disappointment and move to competitors. Then the partially released and recovered resources are able to serve the remaining customers more efficiently, which is impulse for their return. From the managerial viewpoint, such instability is undesirable and must be minimized either with carefully designed campaigns or, rather, the capability enlargement phase must be preceded with HR skills and knowledge development. Because the absolute amounts, spent for language capability development are relatively small and heavily interrelated with other costs, they can be hardly seen in the total profitability, as it is shown in figure 6.

5.3 Focus on active development of personal language skills

This experiment evaluates the efficiency part of proposed language institutionalization framework. We expect that focused training and wide sharing of knowledge can increase productivity via minimization of necessary inputs. Active language proficiency, for example, helps operators to serve international customers faster and closer to their expectations, master complex devices and technologies faster and more precisely, consult problems and exchange knowledge with worldwide colleagues or freely migrate inside global company.

Figure 5 Relation between language capability and amount of customers

Figure 6 Analysis of profitability with respect to language capability spending

Figure 4 shows possible excess in HR development. This phenomenon alerts to limited effectiveness of any overdimensioned HR development strategy. Instead of mechanic provision of unnecessary training, we propose to save this money and use them later for introduction of higher, value generating quality. Consequently, we identified several viable language-related performance drivers and incorporated them to BSC model. All of them are located in the learning and growth sector and determined by particular levels of internationalization, leadership, teamwork or motivation. Dynamic model takes into account also amount, size and age structure of single teams, as well as degree of process orientation. Personal skills, enhanced with language features influence mainly the quality and speed of operations. These improvements drop operational costs, stabilize existing customers and through quality address the new ones. Analysis of sample HR-development focused parametric setting is in figure 7. Mandatory initial language investments are shortly compensated with higher and smoothly growing performance. To avoid aforementioned excess of quality and keep the acquisition of new customers on reasonable level, we recommend $C_{CAP}^L : C_{HR}^L = 2/3$. Behavior of such alternative is shown in figure 8.

Figure 7 Analysis of profitability with respect to language-focused extension of HR development, represented with particular $C_{CAP}^L : C_{HR}^L$ ratio

Figure 8 Relation between language language-focused extension of HR development and amount of customers for recommended $C_{CAP}^L : C_{HR}^L$ ratio

Figure 9 Example of lost opportunity due to weak managerial practices

From the managerial point of view, it is important to mention that inclusion of multiple aspects of people and teams-related dynamics makes the system more parametrically sensitive and, thus, requiring smooth and frequent interactions. In the opposite case, explicit language features can be merged with other HR development activities and finally become indistinguishable. Such poor management downgrades value of initial investment to language quality and embarrasses its exact evaluation. This situation is seen in figure 9. Due to non-systematic implementation, the marked language quality graph loses its initial potential and finally even turns into undesirable overhead.

6 Conclusions

We analyzed influence of different aspects of language institutionalization on profitability and amount of customers. Related experiments were executed in system dynamics version of balanced scorecard. Such solution is internally transparent, scalable and intuitively interactive. Consequently, involved planning officers and managers are capable and willing not only to adopt modeled suggestions, but also actively search for own alternatives and improvements.

After extensive experiments we propose the following strategic recommendations for those, who want to systematically introduce language artefacts to their firms:

- Total language costs should vary in units of percent of the total costs. Moreover, this area can be easily overinvested!
- Language can be developed in the following two directions:
 - Capacity, i.e. engagement of mostly quantitative, publicly visible features. Building of capacity/capability addresses mostly prospective customers and extends business potential of a firm. Profitability, however, remains unchanged. According to our experimental findings, capacity is supporting worthwhile up to 40% of total language budget.
 - Quality, i.e. direct employment of language in operations, which are thus more efficient and productive. Although this orientation requires additional one-shot investment and initially negatively affects the amount of attracted customers, later it always turns into a profitable and viable strategy. There is, however, a risk losing the identity of quality oriented language training over time, which must be mitigated by careful management.

Presented experiments confirmed our research hypothesis on positive influence of explicitly structured and controlled language on organizational performance. Our next research strives to refine the both suggested language directions and identify convenient development scenarios for different types of companies.

Structured Abstract

Purpose – In the last years, there is an increasing attention to define and implement effective policies and strategies for support Green Energy Sources and Systems (GESSs) both at sovra-national, national and territorial level. On the base of the general objective and the priorities of the EU Horizon 2020 program and in order to create major attractiveness as a location for defining and implementing GESSs and to effectively link advanced knowledge, research, science and innovation and business, recently different national and regional systems have decided to elaborate and develop a new strategy and different policy interventions based on the creation of specific and right “ecosystems” able to connect world-class science base, advanced knowledge and business in GESSs. Specifically, the design and the creation of Technology Districts (TDs) have been identified as relevant engine for the definition and implementation of policies and strategies for support GESSs in many Countries according to EU general addresses.

The aim of the paper is to examine the state-of-the-art of policies and strategies for Green Energy Sources and Systems (GESSs) in the Italian context. Particular attention is given to the role played by the Technology Districts (TDs) - in particular related to the energy industry – as engines for an effective implementation of GESSs policies and strategies. First, it is briefly analyzed the scenario about the European Union (EU) and Italian strategies and policies and related framework on research and innovation, setting the position and the main challenges that business and policy are facing today. According to the priorities identified by the EU Horizon 2020 program and by the Italian National Energetic Strategy, the industrial and organizational model of the Technology Districts is

then introduced and analyzed as particular engine for an effective implementation of GESSs policies and strategies. Finally, we present the successful experience of the Italian National Energy Technology District (DITNE) as case of excellence in implementing effective GESSs policies and strategies and supporting smart growth dynamics according to EU and national programs.

Design/methodology/approach: To support our arguments we integrate some conceptual frameworks with the analysis of a case study of an Italian Technological District operating in the energy field. We provide the case example of DiTNE which has effectively planned and implemented innovative strategies and policies aimed to activate and support national and regional strategic development. The paper combines then a deductive approach with an inductive one. The main dimensions leading the innovation strategies and policies of European Union and Italy are identified through a review of the academic literature and policy-oriented reports. Then, the conceptual framework is integrated by the analysis of a case study aimed to enrich the proposed conceptual arguments with empirical evidences.

Originality/value: This paper contributes to further develop the understanding the role of the Technological Districts (TDs) as engines for an effective implementation of innovation policies and strategies. The analysis of the case-example shows in particular that Italy has been able to engage new mechanisms of sustainable and smart growth in which the development and the implementation of innovative strategies and policies in the energy sector sources have driven virtuous dynamics of value creation.

Practical implications: The paper provides implications for future research and useful insights for management and policy making. Our empirical work is based on an interpretation of the innovation dimensions levered and developed within the EU and Italian development strategy in the energy sector. Its nature is mainly explorative and intends to provide an interpretive platform for understanding the role and relevance that TDs may act as engines for an effective implementation of innovation policies and strategies. However, one case study can just provide insights for developing other more in-depth empirical studies.

Keywords – Technological Districts; Innovation; Innovation policies and strategies; Energy sector; DiTNE

Paper type – Practical Research Paper

1. Introduction

The global economy is changing at an unprecedented rate: energy sources, sustainability, science, technology, knowledge and innovation are widely recognized at the hearth of these transformations. In particular, future energy development currently faces great challenges. These include an increasing world population, demands for higher standard of living, a need for less pollution, and a possible end of fossil fuels. Without energy, the world's entire industrialized infrastructure would collapse: agriculture, transportation, waste collection, information technology, communications and much of

the prerequisites that developed nations take for granted. A shortage of the energy needed to sustain these infrastructures could lead to a world catastrophe (IACOBONE et al., 2012). This translates into developing energy technologies that are cost-efficient, have practical applications, provide greater safety and are environmentally sustainable. Renewable, green energy sources and systems (GESSs) and related industries emerge with the main aim to develop and use power through sustainable and environmental-friendly technologies (HUGGINS et al., 2009; LERRO et al., 2012).

At the same time, national and regional systems are strongly involved in understanding and exploiting these dynamics about sustainability and GESSs to derive competitive edge and to address smart growth paths, in which environmental, business, social and institutional factors integrate to create employment, wealth, widespread well-being.

Accordingly, in the last years, there is an increasing attention to define and implement effective policies and strategies for support GESSs both at supra-national, national and territorial level. On the base of the general objective and the priorities of the EU Horizon 2020 program and in order to create major attractiveness as a location for defining and implementing GESSs and to effectively link advanced knowledge, research, science and innovation and business, recently different national and regional systems have decided to elaborate and develop a new strategy and different policy interventions based on the creation of specific and right “ecosystems” able to connect world-class science base, advanced knowledge and business in GESSs. Specifically, the design and the creation of Technology Districts (TDs) have been identified as relevant engine for an effective implementation of innovation policies and strategies, and in particular for the definition and implementation of policies and strategies for support GESSs in many Countries according to EU general addresses.

2. The Renewable Green Energy Sources and Systems (GESSs): overview

The energy industry comprises all companies historically operating in oil refining, oil and gas exploration and development, power generation, power transmission, nuclear materials plus companies involved in the emerging alternative and renewable energy sector. The oil industry is generally a very profitable industry, and it is foreseen to remain

so for at least the next 50 years. The International Energy Agency stated that energy use “is on an unprecedented increase, with most coming from developing countries, led by China and India (...) and this makes a significant contribution to meeting future road-transport energy needs, helping to promote energy diversification and reducing emissions”.

Due to such pressures, the renewable/alternative energy sector is increasing in importance in the energy industry. This is related to several reasons: fossil fuels, such as oil, natural gas and coal, become depleted; there is expected to be a doubling of energy use and a tripling of electricity demand in the next 50 years; fossil fuels, when burnt, are seen by many scientists as a main cause of global warming due to the creation of carbon dioxide (CO₂); alternative energy sources have a much smaller environmental impact and are renewable. Alternative energy is described as “renewable energy sources ...which create less environmental damage and pollution than fossil fuels, and offer an alternative to nonrenewable resources” (Alternative Energy Industry Knowledge Guidebook, 2006, p. 7).

At the national and international political level, there is movement toward creating the conditions to allow for alternative energies to flourish as well as the amount of new employment derived from alternative energy sources and more generally from the so-called “green economy”. Recent research has focused on the viability of constructing a new economic engine that generates financial incentives for reducing environmental damage. Rather than promoting environmentalism as such, the focus has switched to ways of selling environmentally-friendly decision-making.

At the industrial level, new start-up or expanding business units of multinational companies are emerging, but the sector is extremely fragmented and mainly made-up of SMEs facing significant challenges. Developing infrastructures to deliver renewable energy needs considerable investment by governments and often these installations meet with criticism from environmentalists concerning their negative impact on the landscape. Moreover, there are many arguing that renewable energy installations cannot act as a means to serve large-scale energy resources due to an unreliability of sources patterns, the cost-structure involved for an efficient production, as well as technological difficulties associated with storing energy created in non-peak usage periods. The activities in the renewable energy sector are very similar across the globe. Although current performance of large renewable companies has been affected by the economic climate, further

government objectives on renewable energy and CO₂ emissions provide a clear ground for future growth in the sector.

At policy level, the European Union's (EU) approach to the renewable energy sector is more coordinated than the individual-state-set regulations. The European Commission has decided to regulate the renewable energy sector growth and its environmental effects by setting limits on CO₂ emissions and levels of renewable energy supply in the EU's total energy market. Therefore, by 2020, the EU aims to achieve an average level of 20% of its total energy final supply from renewable, and 10% of transport fuels supplied by bio-fuels (Renewable Energy Policy Network for the 21st Century, 2007). The European region's energy consumption has been on the rise in recent years, led by fossil fuels. Therefore, the energy sector still holds its position as a major pollution contributor. Scientists, companies and policy-makers argue that in the coming years the renewable energy sector will face some great challenges. Among them, it is possible to note an increasing need to define and implement effective policies and strategies for support GESSs both at supra-national, national and territorial level.

Accordingly, the design and the creation of Technology Districts (TDs) have been identified as relevant engine for the definition and implementation of policies and strategies for support GESSs in many Countries according to EU general addresses.

3. The Technological Districts: background

More recently, there has been a wide debate in academic, economic and policy circles finalized to identify the 'better' scale in which knowledge communities emerge and knowledge-based dynamics activate real development paths. The clustering of R&D activities, new technology creation and implementation, high-tech manufacturing of knowledge-intensive industrial and business sectors, relationships and networking among local, national and international stakeholders have been traditionally identified as key-levers to activate and support these virtuous mechanisms.

Accordingly, the creation and the development of Technological Districts (TDs) have gained an increased prominence among entrepreneurs, manager and policy-makers, influencing the development strategies of local and national systems and luring the attention towards knowledge-based and technological industries as a significant driver of local and national growth. The economy of a TD creates high-value added products and

services using research, technology and brainpower. In a TD, private and public sectors value knowledge, invest in technology, integrate tangible and intangible assets and, ultimately, harness them to create innovative goods and services.

Although there is not yet a clear and shared identification and definition of “Technological District” at economic theory level, and they have been often conceptualized as a modern and dynamic variant of the Industrial Districts, the same literature, together with the managerial one, has provided different perspectives of analysis and it has highlighted specific features characterizing a TD.

Regarding the definition of TD, after reviewing the wide literature involved on these issues, a working definition of TD has been elaborated as “*value chains – geographically or not defined - particularly rich of activities on scientific and technological fields, in which it is often possible to trace profiles of excellence both at the beginning of the value chain in terms of outstanding scientific and technological research and at the end of the value chain, in terms of productive systems and markets in which output and insights might have potential applications*” (LERRO and JACOBONE, 2013a, b).

On the base of the ongoing debate in the academic literature as well as in the managerial and policy circles, it seems to emerge two constituent elements of a TD: the *governance model* and the existence and the *role of the stakeholders* – as any group or individual who can affect or is affected by the achievement of the organization's objectives. Moreover, there has been growing interest at academic and policy level about the factors underpinning TDs' creation and their high performance. Broadly speaking, a set of partly overlapping arguments within this literature have been proposed: these are identified in *economic efficiencies, knowledge and innovation dynamics, geographical agglomeration and systems of relationships* (see LERRO and JACOBONE, 2013a, b for a more-in-depth analysis).

4. The model of the Technological District: evidences from Italy

The model of the TD has been particularly successful in the Italian context. On the base of the three priorities of the Horizon 2020, such as excellence science, industrial leadership and societal challenges and to exploit these opportunities and their related impacts on the dynamics of the economic systems, in Italy it has emerged the relevance of strategic, industrial and organizational models characterized by the presence of different stakeholders – in particular big companies and multinationals, small and medium

enterprises, Universities, research centers, public institutions such as Regions or Chambers of Commerce - finalized to effectively integrate business, research, training and innovation and finally territorial development (LERRO and JACOBONE, 2012). It has been recognized, in fact, that EU policy objectives - climate, environment, energy, transports and so on – cannot be easily achieved without cutting-edge research and innovation paths, and breakthrough solution may effectively derive from multidisciplinary and international collaborations.

According to this picture, the Italian Minister of University and Research (MIUR) by proper laws has attributed strategic importance to the creation and the development of the Technology Districts (TDs) as effective model acting as engines for a smart and sustainable growth of the territorial systems as well as of the whole Country. In particular, on the base of the national and EU strategic agendas and of the analysis of the Italian business, scientific and technological structures, in the last years the MIUR has recognized and supported various TDs operating in the supply chains of the green chemistry, agrifood, technologies for living spaces, life sciences, technologies for smart communities, means and systems for mobility on hearth and sea, aerospace, smart factory, energy sources and systems.

Specifically on these latter, practically, different regional TDs on energy issues were created in Italy, in particular in regions such as Piemonte, Lombardia, Trentino, Liguria, Emilia-Romagna, Toscana and Sardegna.

5. The case of the Italian National Energy Technological District (DiTNE)

Beyond the previous regional TDs, on the base of the strategic relevance of the energy sources and systems, and in order to better tackle societal challenges, specifically about the production and the use of secure, clean and efficient energy, on 2008 the Italian National Energy Technological District (DiTNE) (since now *District*) was created in Puglia region, in the South-East of the Country, specifically around the city of Brindisi, in the local area entitled “Cittadella della Ricerca” (www.ditne.it).

It is based on the excellence of the most important Italian universities, research centers big companies, multinationals and small and medium enterprises. In general terms, the aim of the *District* is to support in the energy's field development of research in the

productive sectors, encouraging technology transfer, promote the links among the world of research, business, financial institutions and the local system, strengthen relationships and scientific cooperation between research and industrial sectors.

More in detail, the *District* acts as relevant engine for the implementation of effective policies and strategies for support GESSs both at supra-national, national and territorial level, and operates to support the institutions promoting scientific and technological research to stimulate interest, coordination and the start of events and projects relating to energy both at the national and international level, to join all the issues involved in the supply chain of the technologies to harness energetic sources, renewable energy and related research. The main research areas of the *District* are mainly components and energy conversion systems, CO2 reduction, new technologies for smart grids, innovative components and systems for renewable energy, efficiency and energy saving.

It also proposes strategies, tools and technologies to revitalize the market for renewable energy sources in Italy. The governance of the DiTNE is entrusted to a Consortium Company with Limited Liability in which at least 51% of the authorized capital is held by public shareholders for statutory requirements.

The DiTNE may be considered a successful experience and a case of excellence in implementing effective GESSs policies and strategies and supporting smart growth dynamics according to EU and national programs. In fact, it is traditionally involved in translating into action a series of Green Energy Sources and Systems (GESSs) policies and strategies developed at national and international level. In particular, 5 projects have gained great relevance and impact.

The first project refers to “*Off-shore Renewable Energy Conversion platforms Coordination Action – ORECCA*” and joined FP7 UE - call FP7-ENERGY-2009. The objectives were to create a framework for knowledge sharing and to develop a research roadmap for activities in the context of offshore renewable energy (RE). In particular, the project has stimulated collaboration in research activities leading towards innovative, cost efficient and environmentally benign offshore renewable energy conversion platforms for wind, wave and other ocean energy resources, for their combined use as well as for the complementary use such as aquaculture and monitoring of the sea environment. The use of the offshore resources for RE generation is a relatively new field of interest. ORECCA has overcome the knowledge fragmentation existing in Europe and stimulated the key experts to provide useful inputs to industries, research organizations and policy makers

(stakeholders) on the necessary next steps to foster the development of the ocean energy sector in a sustainable and environmentally friendly way. A focus has been given to the strategies developed towards an integrated European maritime policy. Moreover, the project has defined the technological state of the art, described the existing economical and legislative framework and identified barriers, constraints and needs within. Finally, it has defined the strategic investment opportunities, the R&D priorities and the regulatory and socio-economic aspects that need to be addressed in the short to the medium term to achieve a vision and a strategy for a European policy towards the development of the offshore RE sector.

The second project refers to “*EFFicient Energy buildIng Innovative soLutions – EFFEDIL*” and joined the program “PON Ricerca e Competitività 2011-2013” funded by the Italian Ministry of Education University and Research. The project aimed at the development of innovative and sustainable solutions, for improving energy efficiency in buildings of countries with temperate and warm climate, in order to satisfy the requirements for the voluntary LEED (Leadership in Energy and Environmental Design, Green Building Rating System) certification. Particularly, one of the main aims of the project has been the development of innovative bricks, in terms of product and industrial process, with characteristics of heat insulation, solar shielding and heat inertia, in order to improve performances of the coverings of the main building typologies, actually present in the regions of the Convergence, in the community area of Mediterranean. The research extended to the process of components production, in order to reduce the incremental price of the innovative products in comparison with the traditional ones, and to the components for connecting and finishing the opaque covering of the building, in order to develop an energy efficient solution, complete and able to guarantee a high house comfort level. As regards plants, the project aimed at developing an innovative ICT system for the active optimization of energy consumptions in the buildings, produced through the use of a Sensor Service Architecture, aimed at the control of the absorptions and of the Energy Renewable Sources micro-generation in the last mile.

The third project refers to “*Development of innovative solar concentration technologies – INNOVASOL*” and joined the program “PON Ricerca e Competitività 2011-2013” funded by the Italian Ministry of Education University and Research. The project focused on the development of innovative solar concentration technologies for electric power generation. Particularly, the aims of this project were the development of

innovative solar concentration technologies for parabolic trough high temperature solar plants, the development of innovative concentrating photovoltaic panels, based on CdTe cells, and the development of innovative solutions for waste water treatment by using solar energy.

The fourth project refers to “*Systems research and development of electrical and thermal energy efficient generation, management and storage, integrated and interconnected in a Virtual Power Plant - SMART ENERGY BOXES*” and joined the program “PON Ricerca e Competitività 2011-2013” funded by the Italian Ministry of Education University and Research. The project had as main objectives the development of units, called Energy Smart Boxes, equipped with high-efficiency technologies, able to manage different energy carriers in an integrated and optimized way in order to satisfy the energy demand of residential and industrial complex of medium size, and the study and implementation of innovative technologies for the production of energy generation, which can be integrated with the management of a SEB, like other technologies currently more developed (photovoltaic, mini / micro wind, etc.).

Finally, the fifth project refers to “*Sustainable development using renewable energy sources in rural villages of Balkan Adriatic region – SUNRISE*” and joined Adriatic IPA Cross Border Cooperation 2007-2013. The idea was to use innovative technology, based on the renewable energy sources, for achieve electric energy independency from grid of a rural Balkan Adriatic village. The project activities encompassed actions such as the optimal design and planning of a renewable energy based microgrid considering various renewable energy technology options and with realistic inputs on their physical, operating and economic characteristics, the break-even distance for connection of the microgrid with the main grid, the comparison of the overall benefits from the optimally designed renewable energy based microgrid with existing microgrid configurations, the setting up of a monitoring and control system for managing the different energy sources inside the microgrid and the interface with the distribution company.

6. Conclusions and future research directions

We believe that the insights discussed in this paper may represent a new basis for enriching a conceptual framework on how GESSs may affect effectively overall business performance and improves value-generating activity within energy industry. Future directions for the research can be addressed. The first one is the need for holistic,

systemic and integrated approaches, policies and tools to deal with the ever-increasing complexity and differentiation of energy industry companies – multinationals on one side mainly operating in traditional energy source, and emerging SMEs which are trying to gain markets niches with renewable energy. Another challenge for researchers and practitioners is to work to unify the still-divergent theoretical and policy approaches in the energy industry. For this purpose, we encourage further research to disentangle the complexities in the relationship among GESSs policies, technological districts, business performance and local development. More empirical inquiry and in-depth case studies are needed to define the modalities and procedures that better help TDs to implement appropriate policies and management practices ensuring the effectiveness of their business processes and in turn the value of their products and services.

Organizational Boundaries and their Implications for Competitiveness and Strategic Growth

George Tovstiga

Henley Business School,
University of Reading
Greenlands, Henley-on-Thames
Oxfordshire RG9 3AU, UK

Structured Abstract

Purpose – Organizational boundaries of the firm have long been a central theme in organizational theory. An approach to making sense of the strategic significance of the firm’s strategic boundaries is proposed in this.

Design/methodology/approach – The paper develops the concept of the proposed “unique competing space” framework and presents the findings (descriptive statistics, correlation and principal component analyses) of an empirical study involving 75 UK firms carried out to test the applicability of the proposed framework in practice.

Originality/value – This paper proposes a pragmatic analysis approach that provides the strategic practitioner with a practical “back of the envelope” for the analysis of strategic issues and the derivation of strategic implications from these on the basis of relatively simple yet powerful heuristic approach.

Practical implications – The notion of strategic growth invariably invokes some consideration of the firm’s boundaries; both directed outwardly as well as inwardly. This paper proposes a relatively simple yet pragmatic approach for thinking about the firm’s boundaries.

Keywords – Strategic, boundaries, competing space, issues framing and analysis.

Paper type – Academic Research Paper

1. Introduction

The firm’s organizational boundaries have long been a central theme in management theory. Multiple perspectives have been developed over the years to help create a better understanding of the significance of the firm’s boundaries (Thompson, 1967; Pfeffer and Salancik, 1978), and the implications of these for the firm’s competitiveness and strategic position (Santos and Eisenhardt, 2005a).

Much of the research agenda focusing on the firm’s boundaries has been shaped and driven mainly by the rather limiting perspectives of either transaction cost economics (Williamson, 1981; Coase, 1988) or exchange-efficiency (Poppo and Zenger, 1998;

Nickerson and Silverman, 2003). To a great extent, this has led to a discourse on firms' boundaries that has focused on boundary decisions as make-or-buy choices, the rationale of which is provided by governance efficiency considerations (Argyres, 1996; Poppo and Zenger, 1998; Dutton *et al.*, 1994; Kogut, 2000; Brusoni *et al.*, 2001; Macher and Boerner, 2012; Weigelt and Miller, 2013).

Boundaries research has progressed from efficiency-based considerations to encompass other decision-making factors such as competencies (Argyres, 1996; Poppo and Zenger, 1998; Jacobides and Hitt, 2005; Helfat, 1997; Kachra and White, 2008; Parmigiani and Mitchell, 2009; Yang *et al.*, 2010; Macher and Boerner, 2012) the prevailing analysis approach still appears to be focusing on independent boundary choices in well-structured organizations and competitive environments (Santos and Eisenhardt, 2009; Penrose, 1952; D'Aveni, 2001; Parmigiani and Mitchell, 2009). This has led to a renewed effort aimed at extending the understanding of the firm's boundaries. Santos and Eisenhardt (2005, 2009) argue for a more comprehensive typology of the firm's boundaries that encompasses non-efficiency conceptions of the firm's boundaries. Raisch and Birkenshaw (2008) have extended the research agenda to include the notion of ambidexterity; they propose a more granular view of the firm's boundaries to explain how ambidextrous organizations adapt to changing conditions at their boundaries. Even with recent extensions beyond efficiency considerations, however, the focus of the extant firm boundary research has nonetheless remained primarily theoretically focused. Little of the theory related to the firm's boundaries readily translates to guidance for strategic sense making, and ultimately strategic decision-

The central contribution of this paper is a simple heuristic approach that seeks to address that deficit. The heuristic builds on the basic premise that issues of strategic importance and relevance to the firm invariably make their appearance at the firm's strategic boundaries when they arise. The heuristic is based on a framework that maps the firm's 'unique competing space'. This perspective offers a practice-relevant view of the firm's strategic boundaries within the context its competitive context. The heuristic thereby provides a pragmatic explication of its strategic boundaries; empirical findings presented in this paper provide substantiation of its relevance and potential applicability to management practice.

Key insights, supported by empirical findings, emerging from this research suggest that:

1. The firm's strategic boundaries comprise three interfaces: (1) an interface to the firm's competition (competitors and their offerings); (2) an interface to the cluster representing the needs of the firm's stakeholders (which may include its customers, markets and other stakeholders); and (3) a firm-internal boundary representing a threshold separating the firm's potential basis of competitiveness (e.g. its resources, assets and capabilities) and its actual exploitation of that basis for competitive advantage.

2. Issues of strategic relevance to the firm, when they emerge, invariably crop up at one or more of its strategic boundaries. Focus on the firm's strategic boundaries therefore enables keeping tabs on those really critical issues of strategic importance without 'losing sight of the wood for the trees'.

3. The three boundaries are inextricably linked; changes at any one boundary invariably results in changes at one or both of the other boundaries.

The key contribution of this paper is a simple heuristic approach for making sense of the firm's strategic boundaries – and thereby its competitive position. The paper further provides novel empirical evidence of the heuristics applicability to strategy practice.

2. Simple heuristic based on the firm's 'unique competing space'

The basis of the heuristic approach proposed in this paper is a framework representing the firm's *unique competing space*. This framework is a graphical representation of the firm's unique competitive positioning relative to its customers (and their needs) and competitors (and their rival offerings); its unique competing space is represented schematically by a domain within which the firm seeks to deliver an (ideally) uniquely superior and thereby differentiated value offering in a way in which its competitors cannot (Figure 1). This domain depicts as much where the firm seeks to focus its competitive efforts as it does about where it will not seek to pursue opportunities.

The unique competing space framework has been derived from earlier versions of the "3C's" framework (Ohmae, 1991), and its further portrayal as "strategic sweet spot" (Collis and Rukstad, 2008). These earlier frameworks similarly depict three overlapping circles representing the *corporation*, its *customers* and *competitors* (hence "3C's") in a Venn diagram configuration. However, in contrast to these earlier frameworks, the 'unique competing space' framework introduces two additional elements that significantly enhance the richness of the analysis:

(1) it recognizes that the domain depicted as the unique competing space in *Figure 1* has *spatial* character; it is not a mere one-dimensional ‘spot’ as its earlier designation as ‘sweet spot’ (Collis and Rukstad, 2009) might suggest; and

(2) the domain perspective allows the identification of the firm’s strategic boundaries, represented by the three boundaries that form the perimeter of the firm’s unique competing space.

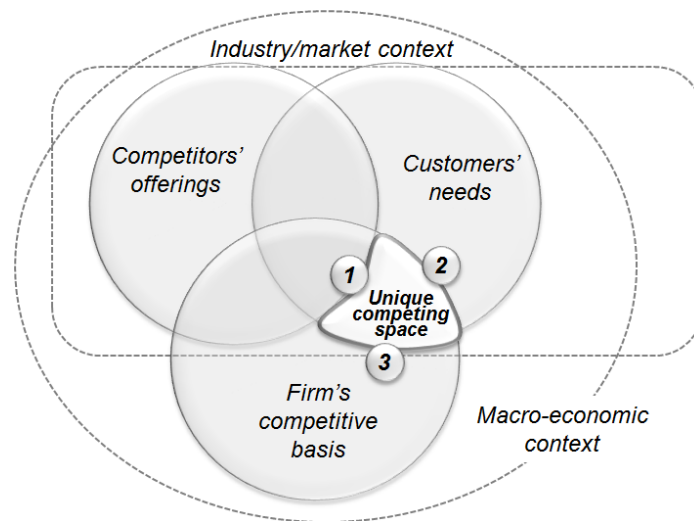

Figure 1: The firm’s ‘unique competing space’ showing the firm’s three strategic boundaries

Composition of the firm’s unique competing space:

- 1. External competitive environment** The *macro-economic environment* (outer circle in *Figure 1*) and *industry/market context* represents all those factors in the firm’s macro environment that are of relevance to its competitive position.
- 2. Competitors and their offering** The cluster in *Figure 1* representing the *competitors’ offerings* narrows the focus of the analysis on the firm’s competitors. In this cluster we find competitors who are vying alongside the firm to fulfill the needs of customers in respective markets.
- 3. Customers (stakeholders) and their needs** *Customers’ needs* are represented by the upper right circle in *Figure 1*. Strictly speaking, this cluster represents the greater community of stakeholders, of which customers represent one particular stakeholder

group. This circle represents the recipients of the value created and delivered by the firm and /or its competitors.

4. ***The firm and its basis of competitiveness*** The lower of the three overlapping circles in the Venn diagram (Figure 1) representing the firm's competitive basis encompasses not only its resources (physical and financial) and capabilities (representing its intellectual capital), but also the greater organizational context embodying the firm's structure, processes, practices, culture and leadership. Therefore, this circle represents the *potential* basis on which the firm competes. The fact that the firm possesses resources and capabilities, however, does not necessarily mean that it is successfully exploiting these for competitive advantage. In order for this to be the case the firm must ensure that it succeeds in *mobilizing* its resources, capabilities and assets *across* the interface designated as "3" in Figure 1. Boundary "3" is therefore about alignment of the organization's resources, structure, culture and other internal factors in a way that most effectively enables the firm to establish competitive advantage from its stock of strategic assets and capabilities.

The firm's unique competing space thus represents the domain in which the firm seeks to position itself competitively with a uniquely differentiated value offering in response to customers' needs in a way that competitors cannot. One can just as easily extend this single value offering perspective to envisage a portfolio of individual value offerings that then collectively s such a differentiated domain. The notion of the 'unique competing space' is, of course, an idealization. In reality, the firm may share its 'unique competing space' with a selected few other competitors. Hence, more appropriately, the firm's 'unique competing space' might be thought of as an opportunity window within which the firm generates above market-average returns on the basis of those activities represented in that domain.

3. The Firm's Strategic Boundaries

Good strategy is about knowing where (and why) to focus the firm's competitive efforts. The firm's strategic boundaries are defined by its *unique competing space*. The strategic boundaries of the *unique competing space* say as much about where the firm's strategic focus is (or should be) as they do about where the firm is *not* focusing its efforts:

1. Boundary '1': represents a *line of demarcation* to the competition – the firm's competitors and their relevant value offerings;

2. Boundary '2': represents the firm's *interface to its markets*; this may include customers and/or relevant stakeholders at large – and the needs of these potential recipients of the value created and delivered by the firm; and
3. Boundary '3': represents an *internal (organizational) threshold* over which the firm must mobilize its resources and capabilities from the repository comprising its competitive basis in order to render them competitively relevant. Simple ownership of resources, assets and capabilities does not suffice if these are not purposefully transferred across boundary "3".

The three boundaries collectively play an important role in defining the firm's strategic agenda. They also provide critical perspectives for the analysis of issues that are of strategic relevance to the firm's competitive position. Issues of strategic relevance, when they arise, invariably do so as a result of changing conditions at one or more of the firm's strategic boundaries. It is this particular feature of the unique competing space that endows this heuristic approach with a powerful means of 'cutting to the chase' and 'not losing sight of the wood for the trees' when examining the firm's strategic position and in setting its agenda in response to changes in its competitive environment.

3.1 Strategic implications of the firm's boundaries.

Two main strategic perspectives on the firm's boundaries present themselves on examination of the unique competing space framework: The first is strategic relevance of each of the three boundaries individually, each of which introduces a unique strategic perspective on the firm's unique competing space. Of particular interest are the implications for the firm's competitive position introduced through changing conditions at the boundary in question. The second perspective relates to the impact of change at any one boundary on one or two or of the other boundaries. In this study we explore both perspectives.

3.1.1 Single boundary analysis

Each of the three boundaries represents an important individual perspective on the firm's competitive position. The three boundaries individually provide perspectives on (1) the competition, (2) the customers (or stakeholders in a broader sense); and (3) the internal competitive wherewithal of the firm. Competitive environments are dynamic; they are continually changing. Changes in the firm's competitive environment inevitably

manifest themselves as perturbations at the boundaries of the firm's *unique competing space*. The firm's boundaries are particularly important in the context of changing competitive contexts. Changes might harbor opportunities as much as they might represent threats to the firm's competitive position. As a result of these changes, a firm's *unique competing space* can expand, or shrink and disappear altogether. Changes at the three strategic boundaries represent quite different challenges – and therefore have different implications for the firm's competitive position.

3.1.2 Multiple boundary analysis

Not only do changing conditions carry very different implications at each of the three boundaries individually, change at one boundary is often inextricably linked to change at one or two of the other boundaries. For example, a competitor's pre-emptive new offering may be in response to changing consumer needs and preferences in the market; this, in turn, may prompt the firm to examine and reconfigure its own portfolio of capabilities for a suitable response. This introduces complexity to the challenge of managing change at the firm's boundaries. Significant and pervasive change simultaneously at all three strategic boundaries very often throws the firm into a tailspin from which it is often difficult to recover. The recent collapse of once dominant industry leaders such as Nokia and Blackberry illustrate the point well; new competitors such as Apple and Samsung with improved offerings in the smartphone sector, changing (smartphone) market needs, and the inability of the two once strong mobile phone players to respond appropriately have resulted in their rapid demise.

4 Research Questions, Propositions And Design

The purpose of the empirical investigation was to probe the suitability of the proposed heuristic for identifying and framing strategic issues relevant to the firm's strategic boundaries. The three boundaries suggested by the unique competing space formed the basis of research questions:

1. Which of the three boundaries most predominantly give rise to strategic issues?
2. What is the nature of the issues arising at the firm's strategic boundaries?
3. (To what extent) are strategic issues arising at the firm's boundaries interrelated?

The following propositions formulated from these questions:

Proposition 1: *The firm's internal boundary representing its ability to configure and mobilize its resources and capabilities most appropriately in response to changing external competitive conditions most often gives rise to strategic issues.*

Proposition 2: *Strategic issues arising at the three boundaries vary individually; typically these revolve changes to (1) competition, (2) stakeholders needs, and (3) to the firm's ability to respond to those changes.*

Proposition 3: *Strategic issues arising at the firm's strategic boundaries are typically interrelated; strategic issues arising at the firm's internal threshold boundary are most often triggered and exacerbated by issues arising at the other two boundaries.*

A quantitative, survey-based approach was selected; senior executives of 75 UK-based firms representing a cross sampling of industries and firm sizes participated in the research. The survey questionnaire solicits the senior executives' perceptions on the incidence and importance of strategic issues arising at various boundaries of their organizations' strategic boundaries. Data collection took place in April and May 2013. Principal component (factor analysis) and correlation analyses were used to probe the incidence of strategic issues at individual boundaries and coupling of effects between boundaries. Statistical analyses were carried out using SPSS v19.

5 Research Findings

59.5 percent of the responses were from organizations with 500 or more employees, while 33.8 per cent of the responses were from organizations with a turnover of £500K or more. The data reliability overall (based on Cronbach's alpha) was 0.747, which indicates a good level of reliability.

5.1 Single boundary analysis

Descriptive statistics, specifically mean values presented in Table 1, indicate the incidence and nature of the issues arising at the individual boundaries. Further exploration of individual boundary effects was carried out with the help of factor analysis (specifically, extraction by principal component analysis). The analysis results are presented in Table 2. These indicates boundary "1" ("emerging new competition") to be most important in terms of strategic issues arising. This boundary contributes 16.5 per cent of the variance; it is followed by boundary "3" ("getting the organizational act

together”), which contributes 15.7 per cent of the variance explained. Boundary “2” then accounts for the subsequent third and fourth most importance components, contributing 14.7 and 14.2 per cent for “emerging markets” and “changes in existing markets”, respectively. The outcomes of this analysis are highly significant at a 99 percent confidence level and a reliability score of 0.605 (KMO).

Table 1. Summary and correlation¹ statistics

Boundary	Coding scheme	Mean ²	SD	1.0	2.0	3.0	1.1	1.2	1.3	2.1	2.2	2.3	3.1	3.2
Competition	1.0 Boundary 1	3.71	.941											
Customers	2.0 Boundary 2	4.15	.896	.132										
Internal	3.0 Boundary 3	3.71	.955	.279*	.193									
Boundary 1 (Competition)	1.1 New offerings	3.48	.795	.462**	.166	.259*

Notes: ¹Kendall's tau (2-tailed); ²Mean values range from 1 to 5; N = 75; *p < 0.05; **p < 0.01

Table 2. Principal component analysis; summary of outcomes (N = 75)

Principal components*	Relevant boundary	Percentage of variance explained	
		Individual	Cumulative
1 Interface to emerging new competition	1	16.5	16.5
2 Internal threshold: getting the organizational act together	3	15.7	32.2
3 Interface to emerging markets	2	14.7	46.9
4 Changes in existing markets	2	14.2	61.1

*Extraction method: Principal Component Analysis; Rotation method: Varimax with Kaiser Normalisation; Kaiser-Meyer-Olkin measure of sampling adequacy: 0.605; Statistical significance: **p < 0.01

5.2 Multiple boundary analysis

Interaction and multiple effects between the three boundaries were examined with the help of a correlation analysis (Table 1). The outcome of analysis indicates numerous correlations between individual boundaries and factors prevailing at those boundaries. These are depicted graphically in the mapping presented in Figure 2, which indicates the density of interactions between the three boundaries.

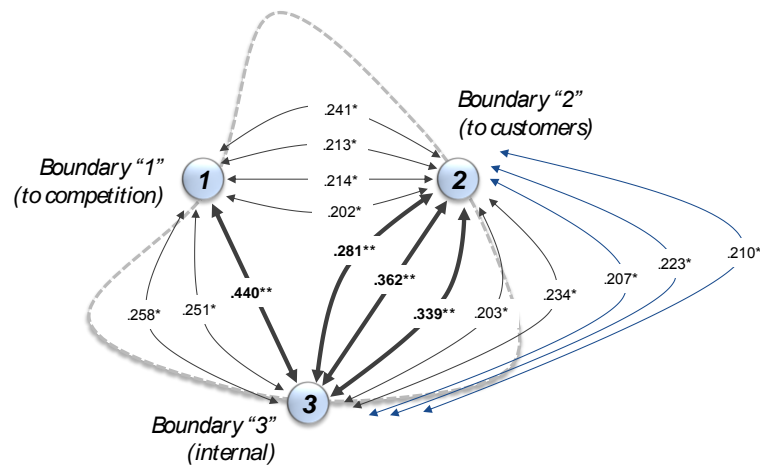

Figure 2. Mapping of interaction effects between boundaries (correlation analysis); bold lines indicate statistical relevance at $**p<0.01$ level; simple lines indicate relevance at $*p<0.1$ level.

The interaction mapping (Figure 2) indicates strong interaction between boundaries “2” and “3”, and to a lesser extent, between boundaries “1” and “3”. The bold lines indicate correlations that are highly significantly (at 99 per cent confidence level); correlations at a $*p<0.1$ level are indicated with simple lines.

6 Discussion And Concluding Remarks

In many ways, the firm’s boundaries define and reflect the essence of the organization; issues of strategic importance and relevance to the firm’s competitive position invariably make their appearance at the firm’s boundaries. The firm’s strategic boundaries represent a demarcation between the firm and its environment. The simple heuristic approach proposed in this paper represents a pragmatic perspective for making sense of the firm’s boundaries; it is based on the premise that the firm’s boundaries represent the interfaces at which issues of strategic importance to the firm arise when the firm is subjected to changes in its competitive position. The underlying framework, the firm’s unique competing space suggests three such boundaries. The empirical findings largely support the propositions formulated: strategic issues arise typically in the face of changing conditions at two of the firm’s interfaces – the interface to its competition and the interface to its stakeholders (*Proposition 1*). Changes at these (external) interfaces

give rise to strategic issues which relate to the firm's ability to respond suitably. Principal component analysis suggests some ranking of the issues clusters. Issues related to changes in competition explain the greatest amount variance, although this is closely followed by internal issues (i.e. issues related to the firm's ability to respond appropriately), and issues related to changing stakeholder cluster (*Proposition 2*). Correlation analysis provides some insight into the interdependencies of the firm's boundaries. The empirical findings suggest that the firm's internal threshold represents a pivotal interface, which largely corroborates *Proposition 3*.

In summary we conclude that the proposed heuristic based on the unique competing space and its boundaries provides a unique strategic lens for making sense of the firm's competitive position, particularly in the face of changing competitive conditions.

Structured Abstract

Purpose – The paper aims to investigate learning processes in organizations characterised by a corporate culture (Hellriegel et al., 2004; Harrison and Stokes, 1992) that might be labelled “play culture”. The paper explores the extent to which a “playful approach” might generate and affect learning processes among organizational members. The paper aims to show that a playful culture is able to support both generative learning processes and double loop ones. It explores how the design of physical spaces intersects with a ‘play culture’ and how this impacts on socialization processes and the enhancement of knowledge creation.

Design/methodology/approach – The article research design is based on a case study approach. The paper focuses on a project named “Play Factory”, developed since 2008 by an Italian small firm (Loccioni Group). Our case study is based on a mixed method approach consisting of three main sources of data: 1. Interviews with organization managers that have implemented the *Play Factory*; 2. Participant observations, where the researcher becomes part of the everyday working life; 3. Archive documents (annual reports, etc.) from the company. The benefit of this type of inquiry is that it permits a detailed understanding of the phenomenon through a richer data collection

Originality/value – The article wants to fill a gap in the current organization studies literature, in order to further investigate the relation between play culture and learning. Indeed, traditional literature has focused on a description of learning characteristics, whilst less has been done to understand which types of tools enhance learning processes. The analysis shows that in some organizational contexts, play can become a powerful tool. A culture of play can be conducive of generative learning processes, thus shaping working practices.

Practical implications – This papers shows the effects of “play culture” on learning processes, along with their physical and spatial consequences and expressions. Indeed a “play approach”, especially if synergized with other interventions oriented to create BA architectures, seems to help organizations to become physical places that stimulate knowledge creation and SECI process triggering and enhancement. Finally, starting with this successful case, it would be possible to show the importance of play culture in supporting creative intelligence inside organizations. It would be then possible to draw some conclusions that can be extended to other organizations, especially regarding the relationship between play culture and generative learning.

Keywords – Organizational learning, Ba, Play culture, Play organization, Sustainability.

Paper type – Academic Research Paper

1 Introduction

A wide and varied literature has investigated play activities as a learning catalyst in human sciences field. However, except for few authors (Costea et al. 2007; Fleming, 2005; Warren, 2002), the topic has been poorly researched by scholars writing in organizational fields.

Scholars writing from different disciplines, such as sociology, psychology or anthropology have recognized the relevance of the ludic dimension. For instance, many psychologists have suggested that play is an essential part of human development and as such, deserves not to be underestimated (Carr, 2003). According to Huizinga (1950), play represents a necessary condition to learning throughout human evolution. In his popular essay, Huizinga discussed about “homo ludens”, and he traces back in the man who plays, the necessary condition to become “homo sapiens”, the man who knows.

Organizational researchers have recognized that play within organizations can have significant benefits such as learning, personal fulfillment, and even performance (Starbuck and Webster, 1991; Hatch, 1999). Fortune-500 companies were consulted on how to incorporate play into businesses and it came out that various companies such as

Google, Patagonia, Gore, Motorola, and Du Pont encourage their employees to use up to 20% of their work time to play freely with new ideas (Kark, 2011)

In sociology researches, play is considered as a process nurturing a dynamic relationship between the self and society. The individual who plays imagines the self “as if” it were other, creating a kind of estrangement (Carr, 2003): this peculiar flexibility of play activities allows new possibilities to be imagined and to come real, increasing people adaptation and evolution capability (Statler, 2009). When it comes to organizational contexts, the role of play activities and a playful culture should not be underestimated. According to the earlier mentioned psychological literature, play activities help in developing individuals’ cognitive and emotional capacities necessary for effective, productive work.

This paper aims to investigate learning processes in organizations characterised by a corporate culture (Hellriegel et al., 2004; Harrison and Stokes, 1992) that might be labelled as “play culture”. The paper explores the extent to which a “playful approach” might generate and affect learning processes among organizational members.

In this vein, the article wants to fill a gap in the current organization studies literature, in order to further investigate the relation between play culture and learning. We aim to show that a playful culture is able to support both generative learning processes and double loop ones. In this regard, a culture of play can be conducive of generative learning processes, thus shaping working practices.

This paper is structured as follows. The first section explores the concept of play within the managerial literature. The focus then moves to the literature on organizational learning, looking in particular at Nonaka and Takeuchi’s (1995) SECI model and “learning places” called Originating BA. The empirical section analyses an Italian small firm and it focuses on a project named “Play Factory”, developed since 2008 by this company.

Considering this case study, it would be possible to describe empirical evidences of “play culture” effects on learning processes, along with their physical and spatial consequences and expressions. Indeed a “play approach”, especially if synergized with other interventions oriented to create BA architectures, seems to help organizations to become physical places that stimulate knowledge creation and SECI process triggering and enhancement.

2 Exploring the connection between play and work

Play activities emerged as pivotal to develop imagination capability, helping children to distinguish between the real and the hypothetical; in this fashion adults can develop an ability to understand meaning within cultural contexts that are framed by more or less complex and explicit roles (Statler, 2009). Moreover, as play involves cooperative interaction, it has been conceptualized as a major organizing principle of human culture and civilization in anthropological studies. Indeed, certain types of play when socially enacted can enhance community building and develop a sense of communal identity (Kark, 2011). In this sense, although play may be considered unproductive because it doesn't result directly in any valuable artifacts, it can produce higher-order benefits at both a cultural and individual level (Statler, 2009).

The anthropological interpretation provides a group level approach to organizational play, that can be conceived to shape culture and identity of organization itself. In addition, at this level of analysis, sociological literature can lead to consider play in organizations as an activity through which people frame and adapt the social contexts and relationships necessary for work (Statler, 2009).

It follows from the above considerations that play and work could be two tightly intertwined concepts. Actually, the postindustrial revolution has firmly separated work sphere from leisure and play, to focus on organizational efficiency, rationalization, and profitability (Kark, 2011). Therefore "play" has been interpreted as opposed to "work". Nevertheless organizational culture (Schein, 1984) may represent and provide a general factor legitimizing or denying this opposite dichotomy. Indeed, as theorized by several authors (e.g. Harrison and Stokes (1992) or Hellriegel et al. (2004)), there are different kinds of cultures, some of which are more focused on trustfully and caring relationships and a sense of "camaderie" to build sense of belonging and commitment, along with self-initiative and personal growth to enhance the organization flexibility and innovation. Thus, work and play notions do not represent incompatible activities, but they rather represent different ways of approaching activities or different frames for acting.

"Play" can be defined as a behavioral orientation (Kark, 2011), and it is distinguished from "work" by different purposes, processes, and spaces in which it takes place. Play has been particularly described as an imaginative, ethical and autotelic process (Statler., 2009). Indeed, while playing, people are involved in a threshold experience. Within organizational contexts, play activities may lead to imagine different forms of

organization, exploring alternative modes of sense-making and social interaction, and constructing new forms of possible identity for the organization itself (Kark, 2011). Consequently, an important characteristic of play process is represented by its boundaries in time and space. Play is, then, circumscribed within limits represented by its constitutive rules. It keeps existing and going on only as long as the self-imposed rules defining play mechanisms are respected. We then speak about ethical play because, as the rules become more complex, they distinguish between right and wrong actions.

It is important to better stress that while work is by definition a means to an end, that is producing value, play produces no concrete or monetary. Play can have no goal or outcome apart from carrying out play activity itself: it is a purposeless activity (Bekoff and Byers, 1981). Although imaginative and ethical are necessary play conditions, this autotelic character is the effective sine qua non condition to completely fulfill the definition of play and definitively distinguish play from other organizational behaviors (Statler, 2009). In order to clarify the organizational usefulness and benefits coming from a purposeless activity, it is necessary to emphasize that the ontology of play is not that of rational and deterministic natural laws, but rather that of uncertainty, complexity and chaos. It is precisely this ontology that allows the possible benefits of play to emerge at different levels, going beyond the frame of the activity itself (Statler, 2009). Play activities rehearse possible future scenario and alternative forms of organization, providing significant agility and possible benefits in facing organizational change. However, play is not a production machine: play processes generate variety not consistency (Kark 2011).

3 Play culture and learning

Piaget (1962) stated that in early childhood, play provides a rich context in which children interact with the environment and create their own knowledge about the world. That is, play is a stimulus-seeking activity that represents a fundamental cognitive processes leading to learning. As noted by Senge (1990: 314), whilst playing with dolls, children rehearse ways of interacting with people. When they play with blocks, they teach themselves basic principles of spatial geometry and mechanics. Later in life they will learn the general properties of the pendulum through swinging on a swing (...).Through experimentation (...) children discover principles and develop skills that are relevant in reality beyond play.

Indeed play is central to the practice of experiential learning, defined by Kolb (1984: 41) as a learning spiral process whereby knowledge is created through the combination of grasping and transforming experience. First, for learners have to set game rules and conduct standards on their own, there are called to take responsibility for their own learning. That is, play encourages learners to achieve authentic and higher order learning. Second, play pays attention not only to the outcome of learning, but on the learning process too. Indeed, implying utility and fun, it permits a fully and truly educational experience to take place. Third, play supports and gives birth to a complete experiential learning cycle by allowing players to look back to a familiar experience with a fresh new perspective. Thanks to play recursive nature, individuals can mature gradually and consciously. Thus, play can be a central form of deep learning, that can be nurtured within formal organizational contexts insofar as they allows participants to express themselves in authentic ways, self-organize, and create boundaries for recursive, timeless play (Kolb and Kolb, 2010). Therefore, the experiential learning triggered by play, as described by Kolb, is not a simple adaptive learning: it is a process that implies a double loop learning (Argyris e Schön, 1978), characterized by a deep and transformational reflection on one owns mental models, beliefs and *modus cogitandi*.

Therefore play processes within organizations can naturally and effortlessly engage people in open-ended processes of continuous learning. Actually, play can foster not just continuous learning activities, but can also trigger a “meta-learning” process, allowing people and organizations to learn how to learn, to introspectively analyze their own cognitive processes. It leads to wisdom, that Weick defined as an attitude taken by persons toward the beliefs, values, knowledge, information, abilities and skills that are held, a tendency to doubt that these are necessarily true or valid and to doubt that they are an exhaustive set of those things that could be known (Weick, 1993). Organizations have better to continually adapt, innovate and reinvent themselves, and consequently, individuals ought to be flexible enough to learn from mistakes, change their assumptions and beliefs, and refine their mental models. Play could be very useful to this attempt, contributing to the development of relevant skills, because it can provide a less risky situation, in which the potential for negative consequences is minimized and, then, people can learn by doing without fears or worries. This safety context enables exploration to discover hidden variables or opportunities, and practice to refine skills in complex and difficult parts of work, stimulating risk taking and learning from errors.

In addition, play offers the chance to gain experience and skills people need to learn, but also the chance to further develop and practice with them by ongoing rehearsal. Play is often seen as a way of practicing skills needed in the future, for example, through reversal pretending for challenges and ambiguities.(Kark 2011).

Within organizations, play activities can be fundamental in providing a supportive and relationally positive context and enhancing trust, dialogue and cooperation, necessary to facilitate knowledge sharing and knowledge creation. Indeed group or organizational play can reinforce or create a collective self and a communal identity, easing socialization process. Through play activities, individuals with different backgrounds and diverse characteristics join in and interact in a playful mode, bringing and sharing their peculiar set of knowledge and competencies. People that engage seriously with play in an organizational context, take part in a process to bring into question the overall significance of who they are as individuals or as a collective. Through this complex, nonlinear process of identity formation, the context and purpose of work itself may, in turn, change radically (Statler, 2009). This re-shaping activity can also affect external environment: through play process individuals and organization can make the world they've imagined and envisioned together, come real, giving birth and committing themselves to a creative learning process (Senge, 1990).

Another important distinction between work and play is the physical, temporal and psychological space in which they take place. As we already stated play is bounded in space and time. Within organizations, play often occurs in a narrow space and time when the dialectical tensions between *agon* (contest) and *paidia* (play), reaches a tenuous balance, with neither dimension overshadowing the other (Huizenga, 1950). Indeed, organizations seem to face the dilemma of balancing two different goals: high productivity and efficiency or creativity and learning. Nevertheless, these goals are complementary and need to coexist to create an environment where members can be creative and productive (Kolb, 2010).

Kolb and Kolb (2010) spoke about ludic learning space: an holistic concept that integrates learning play, describing a free and safe space that provides the opportunity for individuals to play with their potentials and ultimately commit themselves to learn, develop, and grow. These play spaces represents "protected milieux", that have boundaries to partially keep out the world, that reduces disturbing affect and facilitates sense making (Kark, 2011).

Individuals need to step sideward into another reality in order to rediscover play, free from economic pressure and organizational responsibilities. This frame represents a differentiated level of reality, where people ‘play’ with the elements of the familiar and defamiliarize them. Modell (1996: 27) noted that the concept of play is linked to the illusion one: even the etymology of the world illusion, can be traced to the latin world *inlusio*, *illudere*, which means literally “in play”. Such “illusion” can be sustainable only if it is kept within a frame which seeks to separate it from ordinary life. Rules are particularly important in achieving that. The temporary world of play is a self-organizing system where participants set the rules on their own, defining the play space. In this view, the ludic is an autopoietic system that continuously generates its own existence and shape its own identity. The players join the game by choice, imposing on themselves rules and constraints they vowed to observe in order to continue to play. Therefore, on one hand, the fundamental essence of play is the freedom to create and be set apart from ordinary life. Yet, on the other hand, for this be accomplished, constraint is required in the form of rules and other factors related to space and time (Carr, 2003)

Nevertheless, these spaces are presumed to be not just play spaces: a fortiori, they can represent knowledge spaces, in which knowledge creation can be located. Eventually, they could be called Ba: shared spaces for emerging relationships in which knowledge can be shared and created (Nonaka and Konno, 1998).

Playing spaces could be related to both Originating and Interacting Ba concepts. Indeed, the former is the context for socialization. Through sharing common experiences and physical proximity, individuals are enabled to share their own tacit knowledge, ranging from technical expertise and know how, to assumptions and personal beliefs. In this space, sympathizing and empathizing processes let subjects remove barriers between the self and others, in a climate of care and trust. The latter, is defined as a more consciously constructed context, where tacit knowledge is turned into explicit. Externalization process requires the expression and the translation of tacit knowledge. Thus, it involves dialogue and figurative language or visual techniques as key-factors to support the articulation. It let express tacit knowledge, creating a self-transcendent mental world and, then, a shared amount of integrated knowledge, made up with common terms and concepts.

The playing space is presumed to be a support that can represents a trigger for the creation of knowledge. Starting from playing activities among individuals, a spiral of

knowledge (Nonaka and Takeuchi, 1995) can be activated and reach wider epistemological levels, reaching the whole organization.

4 Research Methods

The article research design is based on in-depth qualitative study (Charmaz, 2003). Therefore, to investigate the research problem, the paper adopts an inductive method, rooting the research within a tradition of studies that give credibility to the research findings of an inductive approach (Gioia et al, 2012; Corley et al. 2011; Tracy, 2010; Creswell, 2000). As noted by Gioia et al. (2012) one of the merits of inductive research is its undeniable capacity to extend the existing theoretical knowledge over what is already known. Thus, to produce data, the paper adopts an approach consisting of three main sources of data: 1. Interviews with organization managers that have implemented the *Play Factory* and *2Km of future* projects; 2. Participant observations, where the researcher becomes part of the everyday working life; 3. Archive documents (annual reports, etc.) from the company.

As what concerns the interviews, the paper was heavily influenced by the approach delineated by Roulston (2010). Indeed, the quality of interviewing and the possibility to generate ‘credible’ data are crucial aspects to consider when this method is adopted. The analysis is based on interviews that the researcher (s) had with several managers at Loccioni group. In particular, interviews were undertaken with key informants, such as:

- Loccioni Group Founder and General Manager; Business Units Top Managers and research areas Top Managers, to verify the homogeneity and comprehensiveness of play approach within Loccioni Group;
- Loccioni family second generation, to verify play approach sustainability;
- Communication Manager and one of the external design consultants that have been involved in the concrete realization of “Playfactory” and “2 Km of future” projects.

Key Informants	
Enrico Loccioni	Entrepreneur and Loccioni Group Founder
Renzo Libenzi	General Mnager
Maria Cristina Loccioni	Process Analyst and Procurement
Claudio Loccioni	Humancare Business Unit Manager
Damiano Loppi	Energy Business Unit Manager
Marco Pacenti	Industry Business Unit Manager
Tommaso Puerini	International Seats Manager
Cristina Cristalli	Research and Innovation Manager
Gino Romiti	Research and Development Manager
Maria Paola Palermi	Communication Manager
Lorenzo De Bartolomeis	Isao Hosoe Design

The interviews covered the following points:

A) Play and work: this section has aimed at understanding the relationship between play and work. In particular we wanted to understand if play and work activities are spatially, temporarily and psychologically distinct.

B) Reasons and achievements of play culture implementation: this section has aimed at inquiring causes and effects of play approach formalization within Loccioni Gorup. Particularly we wanted to inquire if play activities are really purposeless within organizations as well.

C) Play and learning: this group of questions were asked to learn about the relationship between play and learn. In particular, we wanted to know if play activities can enact experiential and rehearsal learning.

D) Play and Ba: these questions were to know more about the relationship between play and knowledge creation space. Specifically, we were inquiring the existence of a link between space designing and play activities, on one hand; between space designing and knowledge sharing and creation, on the other.

E) Game and play: this section was aimed at making play concept more explicit. In detail, we wanted to know which kind of play Managers referred to.

Interviews typically lasted between 20 and 40 minutes and were tape-recorded. Besides, the researcher (s) took part in the everyday working life of the organizational members. Participant observation lasted for about 4 months. The researcher (s) participated in the company's working life and she was able to observe in detail learning

processes within the Play Factory. In fact, this method allows investigating a contemporary phenomenon within its real-life context. Indeed, as observed by Hammersley (2007), the benefit of this type of inquiry is that it permits a detailed understanding of the phenomenon through a richer data collection. At the same time, documentary evidences were produced, by collecting archive documents (websites, annual reports and internal house organ). We looked through archival documents in order to track the history and the present-day activities of the organization.

4.1 The research setting

The setting for our data production occurred over the months of October-February 2014 at Loccioni Group. Loccioni Group is a medium-sized Italian company based in Ancona (Italy) and specialised in technological solutions addressed to diverse clients in the field of automotive, home appliance, environment, and health care. In particular, the company provides energy and environmental solutions, quality control for industrial processes and health care, assembly, testing and quality control systems for automotive components.

The intensive technological sectors in which Loccioni Group operates oblige it to consistently invest on innovation processes to keep up the technological entry barrier, to preserve its competitive advantage and its leadership position in heterogeneous niche markets. Consequently, learning and knowledge creation processes are fundamental in Loccioni Group everyday activities and they deeply affect company production and economical results.

Nowadays Loccioni Group operates in five different business areas (Mobility, Environment, Home, Humancare and Energy), has four headquarters (Italy, Germany, USA and China) and has its solutions installed in more than 40 countries worldwide. What makes it a more interesting and consistent case of study are also its economical performances over the years: trends are clearly positive, showing a continuous and solid growth. Below, some key figures are highlighted.

Figure 1: Sales Turnover and Staff trends.

Nevertheless, the main reason why the company was selected is because it has been considered as a unique case within the Italian context to introduce 'play' politics and for implementing them.

The paper focuses on a project named “Play Factory”, developed since 2008 by an Italian small firm (Loccioni Group). Loccioni Group initiated a project of ‘Play Factory’ in 2008, with the purpose to ‘encourage and spreads a new culture of work and “creative doing”’ (Social Balance, 2012). The project “Play Factory” has aimed to promote a playful culture, stimulating collective and generative learning loops.

Moreover Loccioni Group was ranked third in the Italian Best Places to Work in 2014, distinguished itself for camaraderie, respect, pride, credibility and fairness: all values that show a strong sense of belonging and a deeply rooted team spirit and, for instance, create an ultimate atmosphere and climate to develop an organizational play approach.

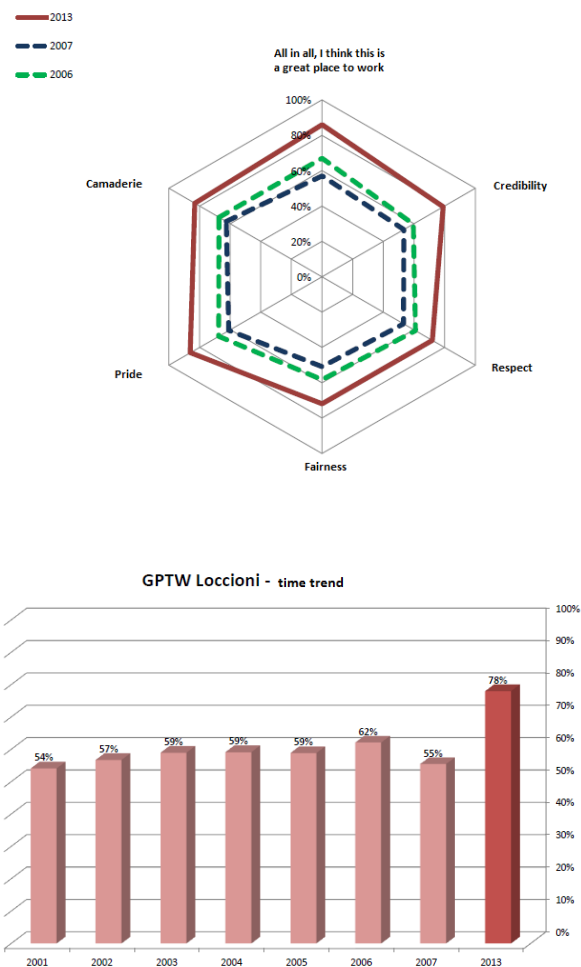

Figure 2: Loccioni Group elaboration of GPTW data survey over time.

'Play Factory' was born from the collaboration between the company and a Japanese engineer and designer, Isao Hosoe, specialized in studying workplaces and their impact on people. Indeed, along with Play Factory, Loccioni is developing a wider knowledge company model focused on the learning aspect strongly characterizing its culture. "2 Kilometres of future" is another project aiming to contextualize Loccioni Group in a sort of macro-BA space, thanks also to Thomas Herzog's urban planning.

In this sense, Loccioni's focus on enlighten human resources policy, such as the opportunity to stimulate creativity and individual growth, become extremely interesting for our analysis. The next section will be devoted to the present of the findings coming from the interviews.

3 Findings

Play culture

As emerged from the analysis of data, Play is interpreted as an approach to the work through which it is possible support socialization process and learning processes. Enrico Loccioni defines Play Factory as follows:

"on one hand, Factory is an environment that is not the traditional manufacturing place: it is wider and its definition includes also all the collaborators. On the other, play is the most important part of the work, because thanks to play people can meet and speak with each other".

Indeed the Factory is the organizational concrete recipient that has to follow market logics and give birth to economical production activities. Play Factory is the combination of these two co-existing concepts: it is the organization where it is possible to apply play approach in order to pursue economical goals. Loccioni Group and Enrico Loccioni himself have developed the awareness that play culture approach is rooted in children behavior and that it is aimed at adopting free thoughts typical of childhood. Consequently, being a play organization is a cultural and attitudinal matter: *"the organization itself is not a game, but people's attitude in facing problems, dealing with clients or life should be play"* claims R&D Manager, Gino Romiti. That means that play culture supports attitudes that consider problems as growth chances and opportunities, and as ways to get self-gratification and sometimes fun.

As observed during the fieldwork, a specific organizational culture is envisioned by the top manager. For example, General Manager Renzo Libenzi one afternoon was coming back at work with a big smile after lunch. As soon as he entered the office that he shares with other top managers, he claimed to be very excited and satisfied of his day. He added that he and another Loccioni BU manager went out for lunch because they were having lot of problems with an order of a client. He surprisingly stated that they had to celebrate this situation of trouble: as successes, problems need to be ritualized as well and, moreover need to be faced with cheerful mind and approach to avoid to stuck in unproductive behavior and complains. He added that they go out for lunch and they even got a big ice-cream cup to celebrate their problems.

Play Factory is then considered by Loccioni managers as a place where it is possible to create innovation through creative processes triggered by play activities and playful ultimate atmosphere and context. Innovation is interpreted not just as a final result, but as a pervasive modus agendi. "Our Play factory is a place where creativity and innovation moments are stimulated by play approach and where these ideas turns into a concrete and tangible reality of the industrial dimension", reports R&I Manager, Cristina Cristalli. Adopting an organizational Play culture requires interpreting the organization as an everlasting start up, where there is both the innovative recipient and young entrepreneurs that become knowledge workers. Knowledge workers are particular organization figures with no timetables or physical boundaries, but they are always productive (active). Indeed, their work does not end up with a mere task execution, but it goes further developing a thoughts. As in the words of the Humancare BU Manager, Claudio Loccioni.

"Play culture is, for example, me that right now, at 10.30 pm, I'm heading to Bologna airport for a business trip. It would be stressful and tiring, if I hadn't travelled with a colleague with which I have fun" claims"

For almost all the interviewed managers, being a corporate culture rooted in play means trying to also have fun while working, while putting forward the corporate mission. In this vein, motivation is crucial:

"Play is doing things you like doing. "We do a job requiring us to be available almost 24 hours per day: if there is a pleasure in doing so, it becomes possible to even have fun while working" (Communication Manager, Maria Paola Palmeri)

More specifically, Play Factory is considered as an environment where life and work goals are interconnected (for someone they are even exactly the same), because there's a tight symbiosis between the two spheres. According to almost all managers, Loccioni play culture lives outside workplace and time as well. Indeed, they pick out the person not the profession, because play is not just an approach to face work, but to face the whole life. In fact they believe that there are no boundaries between personal life and work, but there is a continuum.

There are several examples of pervasive play culture from different business units and functions of Loccioni Group, showing how play culture crosses work place and time boundaries.

In the past Humancare BU was a young start up, made up by young people with a local market and team used to go out very often after work, and many appointments were become fixed every week. Now it has become more difficult to organize because team members are always around the word.

As regards Energy BU, the guys of the team have created a Whatsapp community to constantly exchange cheerful moments of their own lives not strictly linked to work. Or again, every Friday going to a local village (Genga) at lunch to eat the local bread (crescia) it has become a regular thing for Research for Innovation team. There is even a photo of them hung on the stand wall.

Obviously this kind of relations have fruitful implications on team building and team spirit rooting. It also emerges that managing a play organization means not only supporting collaborators' creativity preventing them from getting annoyed during their work daily routines, but at the same time it means being able to set goals. Managing a Play Factory is challenging because it is a very unconventional way of managing and relating with people. Nevertheless it is also difficult because, as stated by Industry BU Manager, Marco Pacenti:

"goals have to be achieved anyway and it is important to make it clear that while playing, people focus has to remain on the results and on being on time".

Being a Play Factory means doing all the activities in a dynamic and fluid manner, without rigid structures or hierarchies. *"This way of working could appear as a play if observed from the outside, but it is not just that"* adds Industry BU Manager. A play organization is somehow opposite to pyramidal hierarchic structure that prevents from speaking and exchanging information freely with anyone within the organization. But it

doesn't imply the absence of responsibility or specified roles. Someone even think that, by definition, play factory can be managed, but can be just guided towards a goal by anyone within the company, there's not a hierarchy to be observed. Moreover at the base of this culture, trusting people is essential. Moreover Loccioni is a company that adopts team working as constant modus operandi, so its collaborators need to be very tight-knit. *"Trust is something to conquer bit by bit, it takes time to be built up and, consequently, it's expensive"* (International Seats Manager)

It's not hierarchical but is related to the coherence between one's words and actions. Consequently if some serious errors occur and undermine shared values and principles, managers strongly believe that they can break up trust relationship and, then, it would be difficult keeping working on team. Having fun doesn't imply being careless about rules or not following a strict ethics; on the contrary, *"at the base of our play culture there is a strong and well defined organizational and personal ethics, and play helps us putting it into practice"* (Energy BU Manager)

While the researcher was interviewing GM Renzo Libenzi, we were interrupted and a new intern was introduced to us. He said to him *"Enjoy yourself immediately and please do not hesitate to bother anyone within the Group to obtain information you need!"*

Loccioni Group main Results and Achievements through Play Factory formalization

Loccioni Group along with the "play designer" Isao Hosoe gave birth to this series of projects ranging from renewable energies to medical devices field, from ideas generation (with *Play 40*) to corporate values communication (*Pro-gettare* behavioral installation), from proxemics concept application to work emplacement to software design of new interfaces. Design through play has been transformed into a tangible element pervasive in all corporate divisions and processes.¹

However all the interviewed managers agree in saying that the formalization of Play Factory has been useful to qualify a pre-existing model, stressing work convictions and behaviors that didn't need to change to fit in an the model proposed by Hosoe. That means that the definition is an ex-post definition: "the reality of our valley and our territory was already strong in hosting our customers, we already took care of them with Shatzu massages for example; play activities for our guys were already implemented and Professor Butera had already developed with us revolutionary Leaf House

¹ 15th December 2011 post on Play Factory Blog

project”recounts Communication Manager. Play approach is considered to be innate within Loccioni Group, so since formalization things haven’t change a lot. It has been mainly a matter of communication tools that have helped the Group to describe itself and become fully aware of its own identity. It has pointed out some peculiar attitudes that Loccioni people unconsciously have or that were taken for granted.

Working at Loccioni Group for one of our engineer is play itself, because they are involved in continuous innovation paths during which, for definition, boredom doesn’t exist and moreover, the Group has chosen to work with young people entering the world of work, with extremely high enthusiasm. The impact of this formalization was particularly strong on the external relationships with Loccioni Group customers because “it’s not common seeing people enjoying themselves and smiling while working, showing workplace as a place where it is possible to do more than work” claims Energy Bu Manager, Damiano Loppi. Actually the focus of Loccioni activities to gain customers’ attention and loyalty remains on distinctive highly technical competences in solving complex problems. Play approach is an intimate part of the higher and more abstract part of Loccioni approach, that is distinct from the “Factory” one, that is more operative and pragmatic: *“the challenge of our Play Factory is to merge these two complementary distinctive aspects and make them coherent with each other, letting people work hard with play spirit” (R&D Manager, Gino Romiti)*

Play factory formalization has resulted in important achievements for Loccioni Group, from both external and internal point of view. Indeed play approach has been not just an external communication approach, but it has significantly affect on organizational culture, bringing the focus of work activities on clients and collaborators. “Play culture importance is all about surprising others, both colleagues and customers” affirms General Manager.

Moreover Play culture formalization have had also internal effects, making organizational vision more vivid to be reached and bringing collaborators at the hearth of technical challenges: *“Play factory formalization has represented the starting point of our knowledge company model” recounts Communication Manager.*

Play and learn

Learning processes are crucial to Loccioni activity and to its success: all managers are really aware that risk is ubiquitous and unavoidable in their work and markets, dealing

with cutting edge technologies and innovation boundary. In this sense, in Loccioni culture, *“playing is not being more risky, but turns out to be simply a kind of approach to risk”* (Industry BU Manager)

Adopting play approach prevents people from over thinking about risk because playing requires the irrational and spontaneous approach of children affirms Enrico Loccioni, perfectly matching with the aforementioned theoretical play concepts. In this reality, it is obvious that accepting errors is important according to every interviewed manager. *“Errors represent our everyday normality because we have chosen to invest on young guys without working experiences and moreover, because we realize prototype. Consequently we have decided to balanced errors with ad hoc projects, such as Silverzone that places side by side one of our young collaborators and a major retired person with lots of experience and successes, to ease learning processes and preventing errors”* (Cristina Loccioni, Process Analyst and Procurement)

In effect young people that entered the Group are suddenly called to action: they have to cope with major customers or contact potential clients, they take part to important events or meeting representing the company. They are requested to be proactive and be purposeful and have their luggage always ready to leave.

Anyway, it emerges from managers' answers that Loccioni risk concept is not extreme: it is always balanced by a strong confidence in their own capabilities and competencies in doing their job. So play doesn't mean being more inclined to risk, but rather being more motivated in achieving the goals that have been set and doing better the things that they want to do because of the pleasure and fun they get in doing so. Indeed playing in team, makes people be more enthusiastically involved in achieving goals, putting less attention on risk. In addition *“being with others is more pleasant and it helps us with risk analysis: playing with others doesn't mean acting irresponsibly”* (Cristina Loccioni, Process Analyst and Procurement)

International Seats Manager, Tommaso Puerini, explains this concept with an effective play metaphor:

“It's like a football match that is the results of equilibrium among strategy, our own capabilities, adversary and place evaluations. But if there is perfect equilibrium, the two teams will always tie the match. Then, if you want to make the difference, you need to plash out every now and then. But this is a calculated and prevented risk”.

For example, when they have recently decided to enter the food and beverage market, it was a completely new challenge. They decided to face it not moving big resources and energies to this sector: they started introducing just a new person, co-financing a doctoral research student, to gather information to elaborate a coherent strategy and elaborate a preventive risk analysis. Play let the Group researchers continually deal with innovative challenges and projects. Obviously, afterwards, rational thoughts are necessary as well. This is particularly true in Research for Innovation, coordinating long term research activities, as reported by its Manager: *“we always repeat our mantra -if you do nothing, you break nothing- to remind ourselves that if we didn’t take risks we would end up following the beaten path”*.

Play culture means stimulating a positive culture that is not aimed at punishing errors, but rather at rewarding positive attitudes, supporting risk taking and action taking. Indeed, according to all manager sample, the error represents a way to learn, so it doesn’t have to be punished: it should be underlined to prevent other people from repeating it. For Enrico Loccioni mistakes represents a damage only if they’re hidden or denied. They agree that it’s normal being wrong one or two times, but it’s important to question yourself why you are keeping mistaking, giving a huge relevance to double loop learning implementation. When errors occur, they are focused on analyzing and understanding the causes not to further repeat them. R&I Manager, Cristina Cristalli adds: *“In this culture, errors are welcomed: they are one of the unavoidable aspects of playing activities, but obviously we are not speaking about errors caused by ignorance or carelessness”*.

For example, some years ago Research for Innovation team bought a very expensive robot: they were working on it, but they couldn’t connect the cables in the right way. They tried, but they didn’t succeed and the robot miserably got burnt. That represented a huge cost for the company, but it represented a fundamental step to learn something as well. *“During the history of Loccioni Group there were lots of projects like this that didn’t have positive results and represented mere costs, but being play means being able to take the positive side from all the situations to always learn something”* recounts Cristina Cristalli.

When something gets wrong, they all declared not to look for someone to blame, but they aim at valorizing the error. *“The biggest is the error, the highest are the chances to have chosen the wrong approach and direction to face the whole order. Consequently it’s*

not one individual's fault, but the blame is to be put on the whole team" (Energy BU Manager)

Play and space

According to Enrico Loccioni "Work spaces are educational spaces. Every space needs to be projected according to the activity it is destined to: spaces represent not just work quality, but also life quality. For this reason, it is important never giving up to improve spaces: *we have still lots to do, but we are working on it.*" In this sense, spaces become crucial for people to work harmoniously and efficiently together and, for instance, to get more significant results. It is easy to team up in suitable spaces.

Nevertheless, there are many managers that don't see the evidence of this relationships within Loccioni company and culture: they stress first of all that in order to have a play culture, play people are needed, otherwise having fun and feeling comfortable is not possible, even in a nice space. Play culture lies more on people attitudes and behavior rather than on space design: Claudio Loccioni states "*good ideas can occur also in terrible spaces, history is full of important people that had genial ideas while in jail*".

Play Factory started with a design projects that is quite strange for a machine seller: it is the result of Isao Hosoe's external stimulus that has made Loccioni Group reflect upon the corporate identity itself. Lorenzo de Bartolomeis, Isao Hosoe collaborator, stated that the aim of this design project is to design a new concept of workplaces. Indeed nowadays there is a tendency to design offices that look a little bit like children's playground or playroom. The fundamental motivation is to delete the formality concept at work to enhance a new and deeper openness among people to sustain ideas exchange and dialogue. We have chosen to mainly focus our attention on play tools (Play Forty, Progettare, Behavioral Energy and Energetic Meridian) to enable people's interaction and reasoning through play.

As regards internal spaces, managers stated that spaces in order to implement play culture, should be livable, luminous, tidy to enhance people collaborating and being more positive. They should be open and flexible, according to the idea of a common place for team dialogue and confrontation. Loccioni space design is actually sober in order to maintain and preserve order and accuracy, that are reflected in the attention that ever collaborators should reserve to punctuality and cleanness of spaces, desks and emplacement. Claudio Loccioni notes "*In this sense, we are quite different to Google play*

and space culture: I think that in realities like Google the focus is too much on design and furniture, diverting the attention from people and their smiles”.

Open space concept does support sharing and contamination of cross projects: within Loccioni Groups there are almost not personal offices and there are a lot of meeting rooms. Loccioni employees often move easily from one room to another, switch their emplacements according to their needing and activities and are often busy with meetings with their colleagues. *“It’s the same concept of a locker room shared by the sportive team where there are not singular chairs, but benches”* affirms one of them. In this regard, several managers, instead, wish there were larger and homogeneous spaces. For example they suggest there should be a creative space ad hoc to ease interaction. This place should be distinct from production spaces or spaces dedicated to other activities, but it should not be a private space and visible to everyone. They suddenly declare that’s a work in fieri: *“we are always experimenting new solutions”*. For example only some years ago Humancare team was set in the middle of production spaces and it was difficult to build a real team spirit, but now they have a dedicated space and things have got sensibly better.

On the contrary, each manager that was interviewed agreed with the existence of a tight relationship between knowledge sharing and place designing. For instance every Loccioni laboratory has been projected to have production at the center of its map, to let the activities be visible from any point of view.

Workplace should ease communication among people: open spaces, despite their negative aspects, such as noises and commotion that are frequently present within Loccioni offices, make it possible to maintain direct contact with activities and people and to stimulate ideas through everyday observation. Open space ease information and ideas sharing and spreading.

In Loccioni Headquarters, there are ad hoc areas dedicated to physical play, like ping pong or billiard table. Then there are also some spaces devoted to play as real fun where visitors, ranking from MBA students to children of elementary schools, can learn something while playing. In the new building they, *“want to integrate the reception hall with Pro-gettare behavioral installation to show to each of our hosts the importance of merging professional and private sphere since the beginning of the company tour”* states General Manager. In fact, as noted by several interviewed managers, if work activities are interpreted as play, all the spaces of Loccioni Group can be considered as play spaces, also interpreted as non physical spaces built from people relationships. It is a working

kind of play that has to be contextualized in a company environment, nevertheless it implies taking oneself less seriously.

For example, Claudio Loccioni tells *“when I worked in Germany with some Italian colleagues we brought a coffee machine into the office. German colleagues seemed to be quite disoriented, but after a few time it has become an excuse to arrive earlier at office and have breakfast all together with brioche and cappuccino”*.

Clearly, observing a large organization reality, it could be noted that play approach is not equally perceived and equally pervasive at all levels and in all the organizational units: it certainly depends upon individual personality and inclinations, but it's also a matter of one own' role or activity. There are some organizational functions, such as administration ones, that are far away play approach and in which this particular modus operandi can't be applied, because a certain rigor is required and hence rehearsal profitable learning through play wouldn't be applicable or favorable. Being a play organization is also offering a more pleasant environment along with more friendly people to welcome visiting people: for example, it implies taking the incoming clients out for dinner or schedule their week-end, to make them discover the surrounding territory and its typical dishes.

Consequently, this design project is concerning both internal and external places, going out company boundaries to *“avoid being a non-integrated oasis in the middle of the desert”*, as suggested by R&D Manager. General manager affirms *“Our vision is to become famous not just as a single company with ad hoc rooms or spaces to implement play culture, but as an entire integrated heritage area (the Vallesina valley). We are currently working on it”*. In effect, they started a public-private co-operation to restore two Kilometers of river Esino flowing next to their headquarters and they are thinking about building areas to let people always gather together autonomously and respectfully.

Hence play factory formalization has been particularly useful for the internal and external dynamics linked to people relationships, rather than for becoming a communication slogan for enhance Loccioni Group external perception.

Play and Game

“When I think about play within Loccioni Group I think about a game to invent every day, actually a real play supply-chain, starting from designing and arriving at result achievement and satisfaction” states Enrico Loccioni. Indeed Loccioni Group perceived

itself as a real team and, hence, it needs to have supporters, that are collaborators themselves but also clients, that should be ambassadors of the company and wear “Loccioni Group shirt” showing team fondness, affirmed General Manager. The team, then, needs to win and convince in the market fields. The game that is often used for representing Loccioni Group is Isao Hosoe’ Play 40 cards because they represent corporate values and culture, letting groups of people playing with ideas and imagines.

In this context, this choice appears particularly important, because the description of this game seems to be particularly suitable and coherent with the concept of play that has emerged from the literature theories previously analyzed

“With Play40 it is possible to invent different ways to play, since the aim is not what but how we play. (...) The aesthetical education develops through the game since it is not subordinated to a rational goal nor the intellectual moment is sacrificed to the sensible impulse: the only goal of this activity is itself.”¹

Then the metaphor of sport team is frequently used, even if sport team are normally more structured than Loccioni team. Basket was chosen to represent the Group some years ago, when the contribution of the individual, especially in certain role, was more significant and used to make a great difference. Football was chosen for representing the shift towards a team spirit focus, but also for requiring creativity and fantasy rather than relying on physical strength. Some others managers wanted to further stress the importance of the team work and then chose sports like curling (where there is one person proposing an idea, but there are other team members that are fundamental as well to push it further) or motorsport (where there is a mix of fundamental components: the team, the machine technology and the driving leader).

This team sport orientation is particularly evident earring Loccioni collaborators chatting: it’s not infrequent earring them scheduling some football, tennis, beach volley matches with the colleagues, or planning trip during the week-ends to go to watch rugby or basket matches. During hiring interview, young guys are often explicitly asked about the sports or hobbies they practice, interpreted as team working discriminant factors. Indeed lots of Loccioni Group members have not only significant experience in playing team sports, but also in training teams.

Particularly interesting is the metaphor proposed by GM Renzo Libenzi *“the Group is a kind of breeding ground for young talents, so it would take part at youth*

¹ 20th November 2008 post on Play Factory blog <http://www.play-factory.it/>

championship". Anyway everyone agreed in saying that Loccioni Group would be a team playing to win its championships: the majority of them stated without any doubts that the Group would play in the highest world championships. "We want to play with the best teams in the words and be the best team in the word" affirmed Enrico Loccioni referring to their declared vision statement that is "Loccioni: the Open Company. The choice of the best in the world".

As regards external competition, it is an important factor, because the goal to win the concurrency and to conquer the leadership position is deeply and widely shared, but it is mitigated by the open company culture that aimed at building partnership relations when possible, and because of the technological differentiation strategy that sets the Group in a market niche with high technological barriers. Enrico Loccioni says "Play approach starts to fall apart when it starts requiring a sacrifice, I mean when competition appears and play is no longer spontaneous, but it becomes a commitment to prevail."

Actually from our survey rises a significant role of competitiveness in Loccioni Group. Indeed it is commonly believed that good and transparent competitiveness is healthy, but it should be first of all a competition with one own self and then a chance of confrontation with others, aiming at continuous personal improvement rather than at battling and being in conflict with others. More interestingly, some managers perceive a strong push coming from internal competition: "the positive and healthy competitiveness existing among the different business units in which the group is organized, the engine that sustains Loccioni Group growth" significantly sustains Industry BU Manager, Marco Pacenti.

In this vein, we believe that this competitive orientation should be seriously taken into account as a major interesting aspects because as stated by one of the interviewed manager "Actually there is a very strong competitiveness: play is a tough challenge for the victory. I think that, in this respect, it could be more appropriate speaking about game rather than play".

7 Concluding discussion

Through this case study, we have aimed at inquiring the relationship between play and learning. We have started from the theoretical analysis, considering multidisciplinary contributions to finally arrive at organizational context enriching the study framework with a concrete example. Play has been introduced as a behavioral orientation (Kark,

2011) that can be applied also within organizational contexts. Anyway, playing activities have to be circumscribed within specified boundaries in time and space and moreover they are defined as autotelic activities, as to say, they can not have a preset goal or purpose to achieve (Statler, 2009).

As emerged from our analysis, play can be considered as an approach linked to personal attitudes and behavior, but it also clearly appears how boundary-less is play approach: on the contrary, all the interviewed Loccioni Managers, wish for play to be an approach affecting not just work, but more generally the whole life.

In this vein, our case study goes further in applying play within organizational context and exploiting its beneficial characteristics: play approach at Loccioni Group has not stopped at individual behavior applications in developing individuals' cognitive and emotional capacities necessary for effective, productive work. But it deeply influenced the organizational culture, becoming a *modus operandi* to face the heterogeneous and complex technological markets they constantly have to deal with. Play is not a purposeless activity on its own, or at least it's not just that.

However, we think that it's not reasonable speaking about play culture *latu sensu*, but rather we prefer speaking about a play aspect that stands out from organizational culture. In fact, although play approach is a distinctive Loccioni characteristic from an external point of view, it is not as homogeneous and widely shared as its core values from the internal perspective. Indeed, as stated in findings paragraph, play approach depends on personal inclination and functional requirements as well; and moreover the essence of play lies in players' freedom to join the game by choice, accepting and observing roles in order to continue to play (Carr, 2003).

Certainly, it could be misleading and over-simplificating to consider Loccioni Group success as a result of play approach that could be translated in other realities. The sectors and markets Loccioni Group operates in, are highly complex and continuously challenging: the competencies are needed to meet customers exigencies and needs are mostly grounded in pure rationality, meticulous precision and careful planning. Then, it could happen that sometimes play approach that is instinctive and creative, comes into conflict with organizational exigencies and production logics, as stated also by Kolb (2010). "The challenge of our Play Factory is to merge these two complementary distinctive aspects and make them coherent with each other, letting people work hard with

play spirit” stated R&D Manager, Gino Romiti: it’s clear that it is not easy neither obvious to achieve.

Indeed, play principles within organizational culture aren’t to be blindly and exclusively followed, but they need to be mitigated by and matched with other principles of management. Play aspects should represent a support and a stimulation for an organization to turn into a performing and successful one, inviting organizational members, if possible, to work and participate in a playing way to organizational activities.

Consequently, we believe that from an organizational point of view it is relevant to merge the concept of game with the play one. Thus, as already noted during our case study analysis, competitiveness is a fundamental factor for an organization: it pushes organizational members and organization itself to continuously learn to improve and adapt to external changes. Moreover, a more structured approach better reflects organizational realities, making it possible to properly match play approach with economical world and rationality, without losing play flexibility. Play and game often interact in a synergic relationship determining a sort of “plame” approach to organizational reality.

Loccioni Group and organizations, in general, need not to stop reinventing themselves and innovating their activities to maintain their technological competitive advantage; they have better to be flexible and reshape themselves activating creative learning processes.

As affirmed by all Loccioni Managers, play has to be intended as a way of facing uncertain and new situations, balancing risk with an objective evaluation of their capabilities and competencies in doing their job. Then, play represents a way to practice experiential learning (Kolb, 1984), gradually and consciously learning by doing from mistakes and errors, thinking about causes and reasons of the mistakes, not punishing them. This peculiar flexibility of play activities enhances people and organization adaptation and evolution capability, triggering imagination and problem solving capabilities (Statler, 2009).

Play organization is then considered by Loccioni managers as a place where it is possible to create innovation through creative processes triggered by play activities and playful ultimate atmosphere and context. Consequently, play activities in Loccioni Group, if intended *latu sensu*, can really be the start for learning processes, or, as stated by Nonaka and Takeuchi (1995) can be the start for a spiral of knowledge creation, that from individuals can reach team and organizational ontological levels, letting individual or

team experiential learning be profitable for other business units or the whole organization as well. In other words, Loccioni spaces can be intended as BA, knowledge creation spaces, with a particular focus that has emerged on socialization and proximity dimensions: space projecting and designing are aimed at easing dialoguing and sharing of ideas, not at building up ad hoc playing spaces. Accordingly, play approach is focused on play people rather than spaces: first of all trustfully and caring relationships and a sense of camaraderie are needed to build a sense of belonging and commitment. Obviously this is made easier by suitable spaces existence: at Loccioni Group spaces are open to get rid of formality and hierarchy and to ease ideas and knowledge exchanges, but they are also sober to maintain and preserve order and accuracy, to reflect the attention that ever collaborators should reserves to punctuality and precision. Actually, space conception itself represents the co-existence of a “play” and a “game” side; the existence of a creative and playful aspect of Loccioni culture within the essential organizational nature of its purposes. Finally, this particular combination is the foundation of this organizational model sustainability.

Appendix

Research tool: semi-structured questionnaire

Section A- Play and work

- A1) According to you, what does it mean being a play organization (or Play Factory, as you have defined it)?
- A2) What does it mean working and managing a play organization?
- A3) How intensely and extensively do play culture and philosophy live outside working time and place?

Section B- Reasons and achievements of play culture implementation

- B1) Which changes or effects have been caused by the formalization of your play approach (through Play Factory definition)?
- B2) Which are the main reasons that lead you to undertake such a peculiar path?
- B3) Did you expect the results you have achieved? In particular, which did you expect and which not?

Section C- Play and learning

- C1) According to you, what is the relation between game and risk? Does playing mean being less rational and more risk-lover?
- C2) How important trust and error tolerance are within Loccioni Group?
- C3) What happens when someone makes a serious mistake while playing?

Section D- Play and Ba

- D1) Which is the role of designing and planning physical spaces, in play approach implementation?
- D2) How these designing activities affect ideas and competences sharing?
- D3) Are there ad hoc spaces for playing activities at Loccioni Group?

Section E- Game and play

- E1) Which kind of play you mostly refer to?
- E2) Do you remember some interesting playing activities of your childhood that affect your personal growth and your managerial style?
- E3) According to your opinion, which is the relationship between Loccioni Group and a sport team playing in a league? In which championship Loccioni Group would play?

Structured Abstract

Purpose – We aim to describe how knowledge is collected in smart cities contexts and projects as knowledge management is pivotal to support strategic decision-making (Lee et al., 2013). We want to depict the set of knowledge and other resources collected (van den Hooff, de Ridder, 2004) and coordinated in *smartization* processes. We analyse the paths leading to the continuous improvement of the knowledge available thanks to partners involved (Lee et al., 2013) to identify how to create a potential set to improve cities' management. We propose a model to describe knowledge collecting and mixing towards new knowledge generation (Wiig, 1997).

Design/methodology/approach – We found 144 projects launched in recent years through the recognition of activities carried on and reported by industry players and Institutions when partnering local agencies in *smartization*; we selected the ones started at least in 2010, in order to opt for relevant information. To prevent the analysis of projects based just on episodic interventions, we focused on projects involving at least two of the *smartization* domains. Hence we had a final list of case studies (Yin, 2003), composed by 19 projects in different cities. These cases took into account cities from Europe, America, Asia, and Oceania.

Originality/value – The most important models useful to describe the interactions emerging in smart cities contexts are based on actors. Among them there are the triple (Etzkowitz and Leydesdorff, 2008), quadruple (Lombardi et al., 2011) and quintuple (Carayannis et al., 2012) helices paying attention to the involvement of different actors as carriers of resources, without a focus on them. In our perspective the focus on resources is pivotal, leading to a more complex model useful to describe the different and several kinds of resources needed - with particular reference to knowledge - and the phases to combine them in a process.

Practical implications – The model we want to propose can allow the definition of a particular set of resources, to be considered as necessary in *smartization* processes. Knowledge has to be considered as embedded in territories (Komninos, 2006), thus the analysis of empirical evidences lead us to reflect on customization for each city; by the

way knowledge and the other resources are combined to favour the implementation of model and the circulation (Anttiroiko et al., 2013) of new knowledge can be favoured. This last outcome can allow the improvement of smart performances; hence new knowledge generation can catalyze better results.

Keywords – smart cities, knowledge, resources, smartization.

Paper type – Academic Research Paper

1 Introduction

Smart cities projects are flourishing all over the world in last decade, in order to improve metropolitan and urban contexts and in particular to achieve a better provision of services and a higher quality of life. Interventions to favour the development of smart cities go back to about 15 years ago (Hartley, 2005) when the first approaches described a focus on hardware as the most relevant feature was the creation of a hi-tech basis to improve city services. The city went towards its first evolution in the so-called *digital city* (Qi and Shaofu, 2001). It was just the first phase of the process leading to smart city, both in management literature and from an empirical perspective. Several definitions described this process, often overlapping (D’Auria et al., 2014) one another. Indeed at the beginning the idea of digital city was sometimes forestalled and some other times joined (Nam and Pardo, 2011) by concepts like *intelligent city*, *ubiquitous city*, *wired city*, and so on (Hall, 2000; Lee et al., 2013). The evolution process kept going on both from a definitory perspective and in the interventions performed by different actors in city contexts. Time by time more attention has been paid to people shaping these contexts, with particular reference to a set of issues grouped with the ‘software’ label, leading to the concept of *inclusive city*, as «a city well performing in a forward-looking way in economy, people, governance, mobility, environment, and living, built on the smart combination of endowments and activities of self-decisive, independent and aware citizens» (Giffinger et al., 2007). The ‘software’ characteristics consist of people involvement and in their awareness about the contribution they can give to the improvement of a city.

The two approaches, namely hardware-based and software-based, arose one after the other, and they were considered as mutually necessary as interventions in cities were performed. So a perspective merging both of them is needed to better describe the interventions, leading to a context aiming to a higher quality of life (Anttiroiko et al.,

2013), conceived around the contribution of technology and the involvement and the active participation of citizens.

The role of resources in these projects is strictly related to their carriers, namely both to contexts and to actors involved; the set of resources is heterogeneous, due to the different domains involved in such a kind of transformation, viz. mobility, health, services to businesses, environment, governance, energy, ICT, education, tourism, and so on (Giffinger et al., 2007). In a general overview natural resources are the first ones to be considered as they both shape the context and are the object of some interventions, especially as it regards the deployment of a wise management (Caragliu et al., 2009). Moreover as smart city projects are an innovative way to manage metropolitan and urban contexts, the innovation carried on is based on an engine consisting of a set of resources in an open approach to make resources available to both “users and developers” (Schaffers et al., 2011).

Knowledge as a resource plays a fundamental role in smart interventions, as it has to be used and generated together with the other available resources; among the topics related to knowledge more attention is paid to the most important ones, such as its circulation (Anttiroiko et al., 2013), its generation and transfer (Vaattovaara and Kortteinen, 2003), its role as a performance indicator (Yigitcanlar and Lönnqvist, 2013), its usefulness as a lever (Coe et al., 2001), its support to service provision (Rodier and Shaheen, 2010), and as a gap to be filled for citizens (Bingham et al., 2005). Its multifaceted role and the need to manage and generate it in smart city projects in connections among all the involved actors are the basis to focus on interventions to be made on it and through it.

2 Literature review

2.1 Overview on smart cities

The evolution towards a conceptualisation about smart city has to be described through an entangled path, both in literature and in whatever empirical analysis. In the former it is necessary to describe the path towards this concept starting from some ancestors linked to investigations based on the so-called hardware or software components. In the latter it is requested to take into consideration Official Reports issued by Local Agencies or Corporations leading the projects and coordinating the activities

performed by different actors taking part to the complex systems built around the notion of smart city.

A smart city is a metropolitan or urban context where services are provided in an efficient way through the implementation of an ICT infrastructure; even if the path towards a definite notion of smart city was time-consuming and something full of misunderstandings, there are different helpful conceptualisations to better understand what it is. One of the most accurate definitions was proposed by Hall in 2000 and this depiction has to be considered as a ground-breaking idea when looking at the time in which it appeared. Hall highlighted smart city as “a city that monitors and integrates conditions of all of its critical infrastructures, including roads, bridges, tunnels, rails, subways, airports, seaports, *communications*, water, power, even major buildings, can better optimize its resources, plan its preventive maintenance activities, and monitor security aspects while maximizing services to its citizens”. The depiction of this concept emerging in the following years were similar but in the same time they miss some focus and they add the relevance of ICT in smart projects. This happens in one of the most cited definitions, presented by Caragliu et al. (2009) stating that a city should be considered smart “when investments in human and social capital and traditional (transport) and modern (ICT) communication infrastructure fuel sustainable economic growth and a high quality of life, with a wise management of natural resources, through participatory governance”. The approach by Caragliu et al. is particularly useful as it overtakes a recurring problem in this domain of the literature, namely the focus on hardware or software features to describe a smart city. At the beginning of the 21st century more attention had been paid to hardware components, viz. to elements like internet broadband, ICT and its related networks, level of connectivity and so on. A similar perspective is adopted by Schuler (2002) when considering a city “that is being transformed or re-oriented through digital technology”. This definition and other ones similar to it are closer to the concept of digital city, namely as a city in which the investments have been focused on ICT and this is just a myopic vision when talking about smart city. If we take into account one of the most relevant conceptualizations about digital city by Qi and Shaofu (2001), it appears as a “substantively an open, complex and adaptive system based on computer network and urban information resources, which forms a virtual *digital space* for a city. It creates an information service marketplace and information resource deployment center”. Thus, digital city is far from being something similar to smart city

and even if this is in some way easy to be understood, the misusages of both terms are very common, even in Official Reports (Tregua et al., 2014). In order to move towards a suitable and recent definition of smart city the so-called software features have to be considered together with the hardware ones. This is the shift from the half of the first decade of the 21st century leading to the definition of smart city, thanks to a crossed consideration of both hardware and software aspects.

As a consequence of the above considered kinds of features recent contributions on this issue recall what Hall has stated about 15 years ago, when considering both ICT and people contributions to achieve a smart development of metropolitan and urban contexts. Among the authors embracing this way of thinking we want to underline a couple of contributions; firstly the one by Washburn et al. (2010), considering smart city as a collection of smart technologies, namely as “a new generation of integrated hardware, software, and network technologies that provide IT systems with real-time awareness of the real world and advanced analytics to help people make more intelligent decisions about alternatives and actions that will optimize business processes and business balance sheet results”; secondly European Union (2012) in one of its project launched to encourage smart development in European cities, defined the smart city by looking at “the whole range of subjects involved in smart cities management shape an ecosystem, considered as an urban laboratory, and in a more detailed way an urban innovation ecosystem”.

In the definitory path towards smart city there are lots of definitions starting from digital city and continuing with a series of adjectives coupled to city to shape some new definition, like intelligent, wired, information, knowledge, and humane city. Time by time scholars (Nam and Pardo, 2011; Lee et al., 2013) tried to depict the path towards a conceptualization for smart city and different definitions seem to act as a support in achieving a complete definition.

2.2 The knowledge city

We want to focus on one of the definitions among the ones from the above cited path towards the conceptualization of smart city; in particular we highlighted the so-called *knowledge city*. One of the first scholars proposing the notion of knowledge city – and its definition – was Edvinsson (2003), depicting it “as a city that was purposefully designed to encourage the nurturing of knowledge”. This approach was embraced by Yigitcanlar et

al. (2008) in investigating the interventions in urban contexts in Australia. Moreover – on the basis of their empirical research – they defined the making of a KC as “a long and complicated process, but it is evidently a path to follow for the most sustainable urban development”. The role of knowledge in this perspective is obviously crucial as it is the main element of what actors are requested to do and of the way activities have to be performed. Starting from knowledge the authors tried to define the layers shaping a model to build a smart city, even by referring to a previous contribution by van Winden et al. (2007). These layers are the knowledge base, the industrial structure, the quality of life, the urban diversity and the cultural mix, the accessibility, the social equity and inclusion, and the scale of a city. Apart from going deeper in introducing these elements it is relevant to underline how several kinds of actors are asked to take part to the process of building a knowledge city by bringing their own knowledge to create a unique set to lever on. Yigitcanlar went on in depicting knowledge cities even outside Australia (2013), by performing an analysis through the above cited layers to evaluate the achievements in Helsinki. What is even more relevant from its contribution – co-authored by Lönnqvist – is the chance to extend the knowledge-based development to regions instead of restricting it to a city; in this approach knowledge acts as a mechanism to put together cities in a common effort toward a regional development.

Knowledge city is considered in a slightly different way by Nam and Pardo (2011), as they parallel it with other notions in this domain, like intelligent city and learning city, due to the central role played by knowledge in favouring the deployment of these typologies of project. The focus in their definition differs from the previous cited perspectives since there is a stress on innovation as a result to be achieved through knowledge and as an equipment to be used in order to support the achievement of the expected aims.

Finally it is possible to position the contribution by Marsal-Llacuna et al. (2014) on a similar perspective to Nam and Pardo, as they considered knowledge city as a bridge between the intelligent city and the smart city. The knowledge is considered as embedded in initiatives connected to specialized education and it represents a “flywheel effect” to improve quality of life to city stakeholders.

2.3 The role of knowledge in smart cities

In a more general way we want to frame the role of knowledge in city management, apart from knowledge city and in particular in connection with smart cities. Berman and West (1995) were pioneering in providing contribution considering knowledge in cities management; their investigation with city managers underlined the role of knowledge as a necessary support to favour the implementation of TQM.

Knowledge is considered as an unavoidable element to favour both specialization and social learning (Paquet and Roy, 2002) and because of this a governance structure should define actions to coordinate knowledge arising from each actors of the context, and knowledge distribution to favour the expression of its potential. ICT is one of the most effective solutions in favouring collection and management of knowledge in contexts like cities. The need for knowledge coordination is as greater as wider is the knowledge and governance should be able to manage it in a suitable balance between centralization and decentralization (Roy, 2005).

The central role played by knowledge is confirmed when considering the innovative context created to implement smart cities projects, as the interventions rely on “architecture of knowledge networks” (Komninos, 2006). The author framed knowledge in intelligent cities, and ICT is considered as a facilitator towards the combining of creativity and knowledge, but knowledge is defined as the “connecting substance of all network” for all partners. His vision was enlarged some years later (Komninos, 2006), when knowledge is expected to be sustained through smart cities. The relevance of knowledge is introduced in a different way by Anttiroiko et al. (2013), when they propose to favour its circulation through electronic networks among partners in the so-called *learning organisations*, viz. actors aiming to create, acquire, cultivate and transfer knowledge in smart cities. The same authors go deeper in depicting the usefulness of knowledge in *smartization* projects, when they connect it to the ICT infrastructure to provide services, known in literature as *platform*. The platform is a facilitator in services provision to city stakeholders and knowledge is itself a facilitator for the workability of platform; the support from knowledge is classified on the basis of governance in four categories, namely: routine processes, individualised decision-making, negotiations, and democratic deliberation. With particular reference to the last categories among the four cited above the role of actors owning knowledge is highly interesting, as every single author is taken into account as a contributor, due to the held knowledge.

The knowledge accumulated among actors has to be addressed to others sharing mechanisms – based on ICT – to enhance the participation to democratic city governance (Batty et al., 2012). The authors stated the accumulation process should take place by mixing different typologies of knowledge, since there are differences among stakeholders and because knowledge from experts, the one from users, and the one from organizations and institutions are one complementary to the other.

A description of the way knowledge has to be mixed, no matter of the subjects holding it, is provided by Hernández-Muñoz et al. (2011); they consider the required capacities, their scalability and interoperability and its development and innovative applications to support the design of the “Future Internet” architecture. The Future Internet consists of three pillars: Internet of Things, Internet of Services, and Internet of People. They respectively represent the communication protocols, the open approach, and the role of people into intelligent networks.

Finally the knowledge is pivotal in the definition of the most important model describing innovation in cities management and in particular in smart cities; the so-called *helices models* are based on knowledge, first of all when the Triple Helix Model was launched to represent a networks consisting of relations among university, government, and industry (Etzkowitz and Leydesdorff, 2000). The result of these interactions support the processes of cross-learning among different typologies of knowledge. The Quadruple Helix Model (Carayannis and Campbell, 2009) extended the set of relationships by involving the public too; in this way the variety of knowledge becomes bigger, leading to a context known as *creative class*. The more recent evolution is the Quintuple Helix Model (Carayannis and Campbell et al., 2012; Lombardi et al., 2011), with a further expansion of the actors contributing to the knowledge mixing, as it takes into account the natural environment linked to the four actors previously considered.

3 Research methodology

3.1 Aim and research question

The aim of our research is to describe the role of knowledge in different innovation projects linked to smart cities; more in detail as the domains of activities in smart interventions are several we want to investigate the contribution arising from knowledge in relation to different domains and to describe the way in which different actors support

these processes together. As a consequence we will be able to portray the relevance of different activities collected to knowledge and the necessity to collect and combine them towards the achievement of the expected aims.

In our analysis we want to describe the process leading to the combination of knowledge starting from the literature perspective provided by the so-called helices models (Etzkowitz and Leydesdorff, 2000; Carayannis and Campbell, 2009; Carayannis and Campbell et al., 2012; Lombardi et al., 2011). In addition to what is already proposed in these contributions we want to be in line with Berry et al. when defining the call for a mix of different sources of knowledge and we want to fill the gap about the ways to collect and manage knowledge in smart projects. In particular we refer to Hernández-Muñoz et al. contribution as it represent the starting point to depict an approach to knowledge, but a careful description of such an activity is missing.

Our intervention on this gap can become a guideline for city managers when creating the actions useful to favour support by everyone to the platform, by considering it as a collector of knowledge to be put together and managed to catalyse processes useful for the achievement of the overall goals.

3.2 Method and context of investigation

We found 144 projects launched in recent years all around the world to achieve smarter contexts. The word context is necessary to group all different possibility, like smart cities, smart regions, smart districts, and so on, as they are different as it regards the scope of the actions, but they are comparable as it concerns the basic idea inspiring the interventions to be performed.

The recognition of activities carried on by industry players and Institutions (like European Union or similar) when partnering local agencies in *smartization* where collected through Official reports, and this process took place both from literature and from official websites. Literature was helpful as several scholars have based their investigations on case studies, leading us to a series of useful information to be analysed again in order to achieve the aim of this research. Parallel to this a selection of the websites publishing information through reports on smart interventions has been performed. The websites took into account were the official ones from Municipalities, Local Agencies, Associations (Copenhagen Cleantech Cluster, 2012), Industry players – like IBM, Microsoft, Accenture, Vodafone –, and bigger Institutions, like European

Union or European Commission, especially as it concerns the smart projects carried on in the framework of international financing program led by these actors (FIREBALL, 2012; JESSICA, 2012).

After the selection of the websites we acquired documents and we selected the ones related to projects started at least in 2010, in order to opt for relevant information as the interventions had performed activities and results in last three years, leading to relevant information.

Moreover we prevented the analysis of projects based just on episodic interventions, since we focused on projects involving at least two of the *smartization* domains (mobility, society, environment, services to citizens, participation, economic growth). Hence we had a final list of case studies (Yin, 2003), composed by 19 projects in different cities. These cases took into account cities from Europe, America, Asia, and Oceania, favouring a wider research approach and a potential higher relevance to the results we can achieve through the investigation.

4 Findings

The cases we selected on the basis of what we presented in the previous part of this research are shown in the following table. The information provided are referred to the cities, the year in which the projects have been launched and the Industry player or the Institution supporting the planning activities and the performance of the interventions by local agencies. Some cities are linked to more than one project (i.e. Amsterdam), due to their choice to benefit from knowledge and experience of a specific partner, with a specialization acquired in relation to a domain of intervention.

City	Year of intervention	Leading industry player / Institution
Amsterdam	2008	Siemens
Barcelona	2008	European Union
Brno	2008	European Union
Busan	2010	Cisco
Copenhagen	2009	Accenture
Dubuque	2005	IBM
Firenze	2009	European Union
Gent	2010	Alcatel
Hamilton	2010	Oracle
Honolulu	2010	IBM
Houston	2008	Schneider Electric
Leipzig	2007	European Union
Melbourne	2010	Arup
Portland	2010	IBM
Qatar	2009	Vodafone

Starting from the cases presented in the table above, we presented the most relevant ones, useful to describe different ways of approaching to knowledge in smart interventions in metropolitan and urban contexts; this kind of investigation is useful to depict the alternative paths based on knowledge, aiming to analyse its role in these projects, addressed to *smartization*; more in detail we want to depict the whole process carried on through knowledge, starting from the actor - or the actors - attracting partners to collect knowledge, going towards the way knowledge has deployed its effects, the way it is shared and finally the reason why the usage of knowledge can be even useful to make a clear distinction between the *so-called* 'knowledge city' and a 'smart city'.

The City of Amsterdam decided to have more than one project in the process towards a smart city and different partners have been involved in these interventions. Among the industry players it is possible to find Arup, Cisco, and Siemens and they all have been chosen by the governance of the city on the basis of their experience. The other actors involved are the citizens, some local businesses and some other organizations from the international context, due to their experience. This wide range of actors depends on the different domains of interventions, namely facilities, environmental issues, mobility, and waste management and this is the reason why Amsterdam can be considered as a smart city instead of a knowledge city. Thus, the knowledge has been carried on by different actors collected by city governance, then it has been developed by them and finally it has been shared through the different domains of intervention and through apps, prepared during the projects.

Barcelona is one more city developing more than one project and among the actors taking part in them, the most important are European Union and Microsoft, both for their relevance in this issues and for the role they had in the city to support the Municipality when carrying on these processes. The involvement of actors depended on a top-down approach, as the governance of the city decided to have an open data approach involving all citizens in the choice of the projects to be carried on in the so-called "22" a Urban Living Lab grouping a wide range of different actors. Microsoft created a platform to favour the sharing of data and to provide services during the projects. Since the domains of the projects are several, Barcelona can be considered a smart city as it happened with

Amsterdam. These domains are citizen services, business services, environmental issues, and culture. The knowledge was developed starting from the open data by citizens, then they were used through smartphones and finally the sharing of the results took place through an official website and through apps, and it was the chance to favour the beginning of a new process.

Busan started its path towards smart interventions when the Local government decided to involve Cisco and they carried on the whole process together. The range of knowledge necessary to perform the project is wide, and it is embodied in actors creating a flow of knowledge. More in detail the University was chosen as starter of this project; then the proposals were evaluated by Cisco and the Municipality, before favouring the intervention of apps developers. The specificity of this approach depends on the role of citizens as they take part to the project just to test new services through the apps created and through the platform created by Cisco. The domains of interventions are several - as in the other smart cities - and the most important ones are health services, environment, mobility, and services to businesses. The knowledge and the services are embedded in apps to feed a system giving interesting feedback to better perform services as the time goes by.

Honolulu is different from the other cases, as the interventions started with the willingness to fill the gap about the technology. Then the municipality thought about the high level of performance achieved in ICT and considered it as a tool to solve the other issues of the city, first of all some services to citizens. In order to leverage on the ICT system, the partnership with IBM was enforced and a platform of smart services was created. Together with this a model known as "Honolulu311" enabled interventions from people all over the island to give new ideas about the projects to be launched and managed. The domains involved in these interventions were the environment, the services to citizens, the tourism, the culture, and the services to businesses. For each of these domains at least one app has been created to favour the dialogue among citizens and institutions and even to the provision of new services.

Melbourne had a unique way to perform its projects, as the interventions started with a workshop and this idea was carried on and managed by the Municipality, thanks to the support of a partner, the Arup, with a high experience in different cities all over the world. No other partners were involved as everything took place through meetings similar to the workshop and citizens were the main actors. More in detail periodic meetings took

place to decide how to perform some interventions, based on the collection of knowledge by people, through the managing action by Arup and the Municipality. The domains of intervention are mobility, health services, other services to citizens, and business services too, leading to the definition of smart city.

San Francisco is one more interesting case as Arup played a relevant role as it happened in the above cited of Melbourne. The city launched the project and as first task the governance involved Arup, Cisco, and Microsoft as main partners; then other partners were involved, but the most important were the citizens, as subjects expressing the needs, testing the apps, and reporting the results. Mobility, waste management and services to citizens were the most relevant domains of intervention and the knowledge carried on by different actors was an important factor in supporting the development of all interventions and the coordination among them. As it regards this last point, the coordinating activity was performed by the Municipality together with Microsoft, to favour the sharing of knowledge as a tool supporting different projects.

5 Implications

As the cases took into consideration showed, the role of knowledge is so relevant in this kind of projects. More in detail knowledge permeates the different phases in which these interventions took place, from the beginning to the reporting of the performance, becoming the fuel of a virtuous path.

The projects starts when one actor (a Local or Central Institution) focused on an issue and decides to involve partner due to the necessity of collecting knowledge to be used in the activities to be performed. The partners can be big organizations (as we have seen with IBM, Cisco, Microsoft, and so on) or SMEs (especially if there is a local issue to be solved), and the citizens as they are carriers of knowledge directly linked to the needs of the metropolitan and urban context of intervention.

After the first task, namely the collection of knowledge, the leading actor has to decide how to lever on different sources of knowledge and in all cases we took into account it has always been necessary the support of one of the partners among the bigger ones, due to the expertise on the usage of ICT, as a tool to favour this process.

When the collection of knowledge is considered as passable to start with the projects, the actors are all involved in the decisional process to use knowledge and to combine the different sources, as it happens with open data, meetings, apps to be created and so on. the

leading role is fading in this phase as all actors are relevant and the managing mechanism are already running.

The mix of knowledge starts to perform its effect and the first results are decisions, interventions, and apps and different actors took part to testing phase, to reporting results about the first usages, and to propose changes.

As the results are considered as satisfying, the sharing of knowledge takes place, as all actors can benefit from it, apart from being or not direct beneficiaries of the smart interventions. Moreover this sharing activity is relevant even for one more reason, as the knowledge arising from the usage of the apps or from the provision of new services can be useful to activate again the process thanks to the knowledge generated.

This process can be considered as a guideline to city managers or to firms supporting city management, to better understand the means of collection and the ways to manage knowledge, before deciding the actors to be involved. Moreover the sharing activity appears as necessary due to the role played by knowledge in giving new inputs for the improvements of the projects already started and to perform new ones.

6 Limitations and further research

As a qualitative study we based our investigation on detailed reports from city management actors or from industry players supporting them. The use of report is common in qualitative research and due to this it is significant, but an approach on the field can be useful to support our consideration. Moreover we would like to focus on ongoing projects, in order to better understand the different phases we described. In this case we would like to choose an action research approach. The context we are interested in analysing to perform this different kind of investigation is Naples, as the project OR.C.HE.S.T.R.A. (ORganization of Cultural HEritage for Smart Tourism and Real-time Accessibility - in the Italian National Operative Program 2007-13) is based on a series of interventions similar to the on described in the cases above.

Structured Abstract

Purpose - The development of smart cities has become a topic of huge interest in the academic and public debate (e.g. Albino et al. 2013; Bouton et al. 2013; ISTAT 2013). Specifically, scholars have highlighted the critical role that smart cities exert to improve the quality of life of their citizens (Lombardi et al. 2012; Ballas 2013). Therefore, the present study aims at shedding further light to this emerging issue, by providing empirical evidence on the factors which affect quality of life in smart cities. The focus is on the effects that environmental management may have on quality of life.

Design/methodology/approach - This study is divided into two phases. The former consisted of a literature review about smart cities, their objectives, and implemented solutions. The latter analysed the influences exerted by two smart city characteristics, *smart environment* and *smart energy*, on a third characteristic, *smart living* (Giffinger et al. 2007). To this aim, we collected data regarding 133 different indicators referred to the city of Bari in Italy. To this purpose we used different data sources, among which ISTAT, ENEL, TERNA, Sole 24ore, and Legambiente. Then, we tested correlations between *smart environment* and *smart living* indicators as well as between *smart energy* and *smart living* ones.

Originality/value - Literature has widely discussed the influence of mobility on pollution (e.g., Anderson, 1998; Wilson and Chakraborty, 2013), or how new sustainable mobility favours environment protection (e.g. Kenworthy, 2009; La Greca et al., 2011) and better health conditions (e.g., Karvonen et al., 1999; ISTAT, 2013). Nevertheless, the interactions between living conditions of cities and other factors, such energy and environmental management, have been scanty investigated. In this line of inquiry, only some empirical evidences have underlined the problems perceived in more sustainable cities (e.g. Southworth and Ben-Joseph, 2004; Yang 2008). Hence, we investigated the elements of energy and environmental management which influence the citizens' quality of life.

Practical implications - This study provides interesting policy implications to enhance quality of life in smart cities. Specifically, we identified energy and environmental indicators having the greatest number of significant correlations with smart living indicators. Some of them are the consumption of water for domestic use, the number of pollutants, the separate collection of rubbish, and the consumption of electricity.

Keywords – smart city; quality of life; environment; energy

Paper type – Academic Research Paper

1 Introduction

The smartness of a city has been shifted from the use of information and communication technologies (ICT) to the capacity to improve the living conditions of inhabitants (e.g. Chen, 2010; Gabriel Cretu, 2012; Lombardi et al. 2012; Turcu, 2012; Ballas 2013). In fact, recent studies have specified that quality of life is the main purpose of a smart city (e.g. Geller, 2003; Caragliu et al., 2009; Chen, 2010; Thuzar, 2011; Lazaroiu and Roscia, 2012). Therefore, the investigation about factors affecting the quality of life may be interesting for both scholars and policy makers.

This kind of research could be based on the six characteristics of a smart city which are broadly adopted in the literature (e.g. Giffinger et al., 2007; Van Soom, 2009; Fusco Girard et al., 2009; Albino et al., 2013). Indeed, one of them is *smart living* which groups factors related to the quality of life, as health, safety, education and cultural facilities, quality of buildings, social cohesion, and touristic attractivity (Giffinger et al., 2007). Hence, if we use *smart living* as a proxy of life quality, it is possible to analyse how other characteristics (economy, mobility, environment, people, governance) impact on it.

Existing studies have hugely explored how mobility affects the natural environment and the quality of life. Specifically, the literature analysed the implications of local accessibility systems on pollution (e.g. Hansen, 1959; U.S. Department of Transportation, 1994; Anderson 1998), environmental protection (e.g. Kenworthy, 2009; La Greca et al., 2011), and health conditions (e.g. Geller, 2003). Although these research works have been a useful beginning for understanding the relationships between cities' characteristics, an investigation about the relationships between other key characteristics of smart cities and quality of life is still lacking. Therefore, the present study aims at shedding further light to this emerging issue, by providing empirical evidence on the factors which affect quality of life in smart cities. Specifically, the focus is on the effects that environmental

management, considering energy and environmental factors, may have on quality of life. This choice is also justified by the effort that cities should make to become more sustainable because of their critical role as worldwide natural resources consumers (e.g. Mori and Christodoulou, 2012; Turcu, 2012; Albino et al., 2013).

The paper is organized as follows. First, a theoretical framework is developed to introduce the literature about smart cities and the effects of mobility and other characteristics on living conditions. Secondly, we explain the methodology used to collect data and to analyse them. Thirdly, we summarize results regarding the correlations between energy and environmental factors and quality of life. Finally, the last section provides an overview of the key implications, limitations, and an outlook on future research directions.

2 Theoretical Background

2.1 Smart City

The term “smart city” was initially used to discuss the role of modern information technologies in urban daily life (Mahizhnan , 1999). However, the smartness of a city is linked to the existence of networks of sensors, devices, real time data and ICT infrastructure which effectively improve various aspects of human life (Chen, 2010; Gabriel Cretu, 2012) such as traffic, mobility, security/safety, electrical transportation, and consumption of resources (Benner 2003, Komninos 2007, Giffinger et al. 2007, Caragliu et al. 2009, Chen, 2010). However, the complexity of these issues requires the intelligent and coordinated implementation of all available technologies (Barrionuevo et al., 2012) and the involvement of various competencies (Holland 2008; Winters, 2011; Kourtit et al., 2012; Zygiaris, 2013). To this purpose, a smart city has to invest in the human capital development and in citizens’ participation in decision-making processes (Caragliu et al., 2009; Thuzar, 2011). Afterwards, the focus of a smart city has been shifted from technology implementation to the capacity to respond to people’s needs (Turcu, 2012). Indeed, recent studies have specified the improvements of inhabitants’ quality of life as the main objective of a smart city (Geller, 2003; Caragliu et al., 2009; Chen, 2010; Thuzar, 2011; Lazaroiu and Roscia, 2012). Within this literature stream, Guan (2012) defined smart a city that “provides conditions for a healthy and happy community” (p.25). In fact, only a city with the better living conditions can be

competitive and attract the best talented workers through which a sustainable economic development can be pursued (Thite, 2011). Therefore, the identification of factors that influence the quality of life in a smart city is critical for scholars and policy makers. To this aim, it could be useful to exploit the six characteristics of a smart city as economy, mobility, environment, people, living, and governance (Giffinger et al., 2007; Van Soom, 2009; Fusco Girard et al., 2009; Albino et al., 2013). In fact, smart living characteristic may provide information about quality of life by using indicators on health, safety, education and cultural facilities, quality of buildings, social cohesion, and touristic attractiveness. Thereby, it is possible to analyse the effects of each characteristic on smart living, and consequently on quality of life.

2.2 Mobility and Quality of life

Prior research has especially focused on the effects caused by mobility on environment as well as on living conditions of people. At first, scholars investigated how accessibility to commercial, industrial, and residential locations influence pollution (Hansen, 1959; Anderson 1998). Typically, the choice to travel depends on price and duration of trips (Anderson 1998). Therefore, the structure of cities has been changed during the last century by engine invention that allowed people to move over long distances with reduced costs and duration. In fact, people had the possibility to live in distant areas from cities' centres at much lower densities (Cervero, 1995; Giuliano, 1995; Glaeser and Kohlhase, 2004). This phenomenon created the "sprawl" which is characterised by a widely dispersed population, a network of roads with huge blocks, a rigid separation among homes, shops, and workplaces, a lack of well-defined activity centers such as downtowns and town centers (Geller, 2003). One of the most significant results of sprawl is dependence on the automobile whose motor is responsible of over one-quarter of the nitrogen oxide, carbon monoxide, and volatile organic compounds released into the air each year (U.S. Department of Transportation, 1994; Anderson 1998). The resulting effects on the human health are significant if we consider that asthma affects 17 million adults and 4 million children in the United States (e.g. Geller, 2003). In addition, automobile dependence promotes sedentary lifestyle habits which has created an epidemic rise of chronic diseases such as obesity, diabetes, high blood pressure, coronary artery, osteoporosis, cancer and stroke (e.g. Geller, 2003; ISTAT 2013). Another effect on living conditions due to automobile dependence is the high number of people that is killed

every year because of traffic fatalities (e.g. Geller, 2003). Hence, recent solutions for transport systems are designed to avoid private car usage by reducing car trip frequency and trip lengths, and shifting to alternative modes of transport, which includes walking and cycling (e.g., Kenworthy, 2009; La Greca et al., 2011). The tool that could be a promising solution is the Transit Oriented Development (TOD). This concept is based on the idea to locate new construction in and around transit nodes (TCRP Report 102, 2004, p.3). The implementation of this strategy considers an optimal walking distance between a transit stop and core urban area within 2000 feet, which equates to 0.6 km. The result may be an urban area that combines transit accessibility and well-connected networks to be accessed by walking, biking, or leaving the car in park-and-ride facilities. Hence, the city with a smart mobility could be more liveable because of its capacity to mix “residential, retail, office, open space, and public uses in a walkable environment, making it convenient for residents and employees to travel by transit, bicycle, foot, or car” (Calthorpe, 1993 p. 56). Real examples are converging to Bus Rapid Transit (BRT) model which has a system of distinct buses running on their own infrastructure without interactions with usual car traffic. Furthermore, the stops are spaced at 300-600 m in the city centre and at greater distances if in suburban areas. This solution allows higher speed, reliability and safety than a common bus transit system (Vuchic, 2007). Nevertheless, it is needed a complementary system which makes it simpler to reach destinations from bus stop points. In fact, cities as Paris, London, Rennes, Berlin, Amsterdam, Copenhagen and many other cities in 33 countries around the world are managing bicycle-sharing schemes (Associated Press 1998, De Maio, 2009). This solution has become sustainable thanks to the introduction of smartcard technology and subsequent improvements which has limited vandalism and thefts (Associated Press 1998, De Maio, 2009). However, the bicycle-sharing has still a limited impact on the car dependence reduction. Indeed, the percentage of car or motorcycle trips replaced by bicycles does not overcome the 10 per cent (Midgley, 2011). The next generation of this system could be more attractive thanks to the introduction of solar-powered docking stations, electric bicycles and mobile phone applications providing real time services (Midgley, 2011). At the end, we can say that both BRT and bicycle-sharing can improve the life quality of smart cities’ inhabitants. They may favour air pollution decrease as well as the raise of physical exercise of people. In fact, a more physical activity plays a critical role to protect the human body against cardiovascular, musculoskeletal, cerebrovascular, and metabolic diseases (ISTAT, 2013).

2.3 Other smart city characteristics and quality of life

The interactions between living conditions of cities and factors not related with mobility have been scantily investigated in the literature. In this line of inquiry, some empirical evidences underlined problems that citizens encounter when policy makers implemented actions to protect natural resources such as the urban density increasing (Baldassarre, 1982; Krupat, 1985; Kearns, 2001; Southworth and Ben-Joseph, 2004; Yang 2008). In fact, a city with high density could indicate a minor distance to reach work places, houses, and commercial areas and consequently it means a less energy consumption per person in transport (Yang, 2008; Shell International BV, 2014). Hence, higher density of urban areas significantly drops CO₂ emissions per capita (Hammer et al. 2011; Shell International BV, 2014). Nevertheless, existing studies observed how the possibility to live in an environment of single family houses is perceived as an element positively affecting the quality of life for their sense of privacy and relaxation (Kearns and Parkinson, 2001; Southworth and Ben-Joseph, 2004; Yang, 2008). Instead, people living at higher urban densities have highlighted problems such as frustrations, crime, traffic, noise, air pollution (Lofland, 1973; Krupat, 1985; Southworth and Ben-Joseph, 2004; Verbrugge and Taylor, 1980; Yang, 2008). However, there is also a strong correlation between higher density and accessibility to urban amenities such as public transportation, close shopping, and community services (Yang, 2008).

Despite the debate over the influences on quality of life in smart cities, there is little empirical evidence on the actual effects on citizens' life conditions provoked by factors strictly related to environmental management such as attractivity of natural conditions, environmental protection, sustainable resource management, and pollution. In addition, the necessity to make this analysis is witnessed by the fact that most resources are nowadays consumed in cities worldwide (e.g., Hammer et al. 2011; Mori and Christodoulou, 2012). Specifically, the actual proportion of global energy use due to cities is around 66% and consequently they cause large shares of GHG emissions (e.g., Hammer et al. 2011, Shell International BV, 2014). Furthermore, cities will use 80% of global energy by 2040 (Shell International BV, 2014). At the same time, if we consider that most urban energy consumption is centred in buildings, both homes and offices, and is driven by heating, lighting, and appliances (Shell International BV, 2014), we can appreciate how the environmental management could affect the quality of life of citizens.

Thereby, if policy makers decide to improve environmental conditions, they have to know how the quality of life could change. Consequently, we investigated which elements of environmental management influence the living conditions of citizens.

3. Methodology

3.1 Data collection

3.1.1 Data source

In order to investigate the effect of factors, which received scant attention in the literature so far, on citizens' quality of life, we tested the existence of correlations of energy and environmental indicators referred to cities with smart living indicators. To this purpose, we collected data for several indicators referred to the city of Bari in Italy. The choice of the city of Bari is motivated by several reasons. The city of Bari adheres to the "Covenant of Mayors", an initiative of the European Commission to create a community of municipalities that draw solutions for climate protection and CO₂ reduction. The adhesion at the Covenant is subsequent to the submission of a SEAP (Sustainable Energy Action Plan) which comprehends energy efficiency projects, urban planning, improvements for heating and lighting infrastructure and networks, intelligent buildings, the introduction of renewable energy sources, and education campaigns. The SEAP of Bari was awarded with a mention for "Green Employment Program" by technical and scientific committee of A+CoM, a competition for municipalities organised by Climate Alliance Italy and Kyoto Club. Some results that Bari achieved with the implementation of the measures included in the SEAP are: 1) the creation of 18,800 new housing units with energy consumption systems through which CO₂ emissions were cut by approximately 8,752 TOE (tons of oil equivalent); 2) optimization of water supply contracts which led to the achievement of economic benefits to Bari amounting to € 5,949,012; 3) optimization of electricity supply contracts for municipal assets that led to the achievement of economic benefits amounting to € 634,215.

Data collection revealed particularly hard due to the multi-dimensional feature of the smart city characteristics "smart environment" and "smart living" as well as to the lack of a single database wherein all data were included. Thus, prior to data collection we needed to identify the data sources wherein relevant data were available. Data sources include ISTAT, ENEL, TERNA, Sole 24ore, and Legambiente.

From each source, we collected data referred to several years. Since different data sources have been used, it should be noticed that different indicators are non-homogeneous in terms of data availability years.

3.1.2 Database building

Indicators have been grouped within three *Smart city characteristics*:

- *Smart environment*: identified by Giffinger et al. (2007), it includes indicators referred to attractivity of natural conditions, pollution, environmental protection, and sustainable resource management.
- *Smart energy*: despite not explicitly included in Giffinger et al. (2007), due to the more and more relevant and strategic role of energy resources management within cities, we believed it appropriate to make this dimension explicit and consider it separately from the smart city characteristic “*smart environment*”. This smart city characteristic includes indicators referred to the efficient use of energy and to the use of renewable energy sources.
- *Smart living*: identified by Giffinger et al. (2007), it includes indicators referred to several dimensions of quality of life such as cultural facilities, health conditions, safety, housing quality, education facilities, social cohesion and touristic attractivity.

Within each of these *smart city characteristics*, we defined several thematic areas and sub-areas, consistent with those identified within the Smart City Index (Between, 2013). Thus, the database reports the values of different indicators referred to several available years (ranging from 2000 to 2012). For each indicator we specified the smart city characteristic, the thematic area and the thematic sub-area.

3.1.3 Indicator selection process

Before conducting correlation analysis, we performed a selection of indicators within the database. In particular, we removed all indicators:

- for which data were not available for at least five years;
- for which data were the same for each year (this is the case of binary variables whose value was always 1 or 0);
- that represented a score or a position in a specific ranking.

This selection process led to build a database made of 133 indicators, each of which identified with a number, grouped into the three *smart city characteristics* as follows:

- *smart environment*: 35 indicators (identification numbers 1-35);
- *smart energy*: 11 indicators (identification numbers 36-46);
- *smart living*: 87 indicators (identification numbers 47-133).

The whole lists of indicators are reported in Appendices I, II, and III..

4 Data analysis and Results

Correlation analyses have been conducted between energy indicators and quality of life indicators as well as between environmental indicators and quality of life indicators.

Due to their large dimensions, correlation tables will not be appended to the paper but can be provided upon request.

Table 1 reports a summary of significant correlations ($p < .05$) between environmental indicators and quality of life indicators, while Table 2 reports a summary of significant correlations ($p < .05$) between energy indicators and quality of life indicators.

Correlation analysis revealed the existence of a high number of correlations both between environmental indicators and quality of life indicators and between energy indicators and quality of life indicators.

With regard to correlations between environmental indicators and quality of life indicators, Table 1 shows that environmental indicators with the greatest number of correlations are those identified by the numbers 1, 3, 4, 6, 8, 9, and 33. These indicators are related to water consumption and purification, air quality, and selective waste collection.

With regard to correlations between energy indicators and quality of life indicators, Table 2 shows that environmental indicators with the greatest number of correlations are those identified by the numbers 38, 40, 41, and 42. These indicators are related to electricity consumption.

5. Implications, limitations, and future research directions

This study is a preliminary study in a quite unexplored research area, related to the relationships between different dimensions of a smart city, such as energy, environment, and quality of life. It has important implications as well as limitations that should be acknowledged.

With regard to implications, this study provides interesting insights for policy makers on how to enhance quality of life in cities. In particular, we identified the most important energy and environmental indicators that impact on citizens' quality of life, thus highlighting the factors that should be carefully and primarily managed by policy makers to favor the best living conditions in cities, an important feature for a smart city. Specifically, we found the energy and environmental indicators that have the greatest number of significant correlations with quality of life indicators. These factors are the consumption of water for domestic use, the percentage of population connected to wastewater treatment plants, the number of air quality monitoring stations, the number of pollutants, the separate collection of rubbish, and the consumption of electricity.

With regard to limitations, first of all, the number of available data points (years) for each indicator is quite limited (minimum 5 and maximum 12 years). Some indicators, despite conventional transformation attempts, showed departure from normality (in terms of kurtosis), so limiting the effectiveness of correlation analysis. However, we believed it

useful to leave these indicators in the analysis to have a complete set of indicators and first evidence of correlations among them. Secondly, only correlations have been analyzed while causal relationships between indicators have not been explored. Further, the analysis has been conducted only on one city, so limiting the generalizability of results. Future research could be devoted to deepen the analysis of the relationships between the indicators that revealed to be the most strategic ones also seeking for causal relationships between them as well as to extend the data collection and analysis to other cities.

Appendix I – Environmental indicators

ID	Area	Sub-Area	Indicator description
1	Natural Resources	Water	Household water consumption (m3 per inhabitant)
2	Natural Resources	Water	Per capita daily consumption of drinking water for domestic use (litres per inhabitant)
3	Natural Resources	Water	Water dispersion in the network (Difference between water input and the consumed water for domestic, industrial, agricultural)
4	Natural Resources	Water	Population percentage which is connected to sewage disposals
5	Natural Resources	Water	Purification capacity
6	Natural Resources	Air	Number of air quality controllers per 100,000 inhabitants
7	Natural Resources	Air	Number of air quality controllers per km ²
8	Natural Resources	Air	Number of pollutants
9	Natural Resources	Air	Number of exceedances of PM ₁₀ limit quantity
10	Natural Resources	Waste	Quantity of municipal waste (kg per inhabitant)
11	Natural Resources	Waste	Quantity of municipal waste (tons)
12	Natural Resources	Waste	Per capita urban waste production (kg/inhabitant*year)
13	Natural Resources	Waste	Per capita urban waste production (kg/inhabitant*year)
14	Natural Resources	Waste	Population served by separate collection of rubbish (percentage value)
15	Natural Resources	Waste	separate collection of rubbish (percentage value)
16	Natural Resources	Waste	separate collection of rubbish (percentage value)
17	Natural Resources	Waste	separate collection of rubbish (percentage value)
18	Natural Resources	Waste	separate collection of rubbish (kg per inhabitant)
19	Natural Resources	Waste	Wastepaper collection (kg per inhabitant)
20	Natural Resources	Waste	Glass collection (kg per inhabitant)
21	Natural Resources	Waste	Plastics collection (kg per inhabitant)
22	Natural Resources	Waste	Metal collection (kg per inhabitant)
23	Natural Resources	Waste	Selective collection (used batteries, drugs, etc.) (kg per inhabitant)
24	Natural Resources	Waste	Organic waste collection (kg per inhabitant)
25	Natural Resources	Waste	Collection of other types of waste materials (kg per inhabitant)

ID	Area	Sub-Area	Indicator description
26	Natural Resources	Pollution	NO ₂ annual average values (µg/m ³)
27	Natural Resources	Pollution	PM ₁₀ annual averages values (µg/m ³)
28	Natural Resources	Pollution	Number of exceedances of Ozone limit quantity
29	Natural Resources	sustainable resource management	Number of ISO 14001 certifications per 1,000 firms
30	Natural Resources	sustainable resource management	Index of Environment planning and participation
31	Natural Resources	sustainable resource management	Eco Management Index
32	Natural Resources	sustainable resource management	Responsiveness of municipal government (percentage value)
33	Service Quality	sustainable resource management	Separate collection of rubbish (percentage value)
34	Environment Health service	Climate	Difference between the warmest month and the coldest one
35	Environment Health service	Ecological Report	“Legambiente” Urban Ecosystem Index

Appendix II – Energy Indicators

ID	Area	Sub-Area	Indicator description
37	Renawble Energy	Energy	Home Energy Policy Index
38	Energy Efficiency	Smart building	Electricity Consumption (GWh)
39	Energy Efficiency	Smart building	Electrical Energy consumption in Agriculture (GWh)
40	Energy Efficiency	Smart building	Electrical Energy consumption in Manufacturing (GWh)
41	Energy Efficiency	Smart building	Electrical Energy consumption in Service Industry (GWh)
42	Energy Efficiency	Smart building	Household Electrical Energy consumption (GWh)
43	Energy Efficiency	Smart building	Household Electrical Energy consumption per capita (kWh per inhabitant)
44	Energy Efficiency	Smart building	Household Electrical Energy consumption per houses (kWh per house)
45	Energy Efficiency	Smart building	Household consumption of natural gas per capita (m ³ per inhabitant)
Of na46	Energy Efficiency	Smart building	Annual Household consumption of Electrical Energy per capita

Appendix III – Living Indicators

ID Indicators	Area	Sub-Area	Indicator description
47	Liveability	Noise	Noise barriers in the municipal area
48	Liveability	Urban Environment Index	Green Spaces extension (percentage of urban surface)
49	Liveability	Urban Environment Index	Green Spaces availability (m ² per inhabitant)
50	Liveability	Urban Environment Index	Usable Green Spaces (m ² per inhabitant)
51	Liveability	Urban Environment Index	Total surface of green spaces (m ² per inhabitant)
52	Liveability	Ranking	Annual Urban Ecosystem ranking
53	Health	Eating Habits	3 years old people and older who make a proper breakfast (percentage value)
54	Health	Eating Habits	3 years old people and older who make breakfast with milk and something else (percentage value)
55	Health	Eating Habits	3 years old people and older who lunch at home (percentage value)
56	Health	Eating Habits	3 years old people and older who lunch at canteen (percentage value)
57	Health	Eating Habits	3 years old people and older who lunch at restaurant (percentage value)
58	Health	Eating Habits	3 years old people and older who lunch at cafeteria (percentage value)
59	Health	Eating Habits	3 years old people and older who lunch at work place (percentage value)
60	Health	Eating Habits	3 years old people and older who define lunch as main meal (percentage value)
61	Health	Eating Habits	3 years old people and older who define dinner as main meal (percentage value)
62	Health	Smoking	14 years old people and older who smoke (percentage value)

Structured Abstract

Purpose – The objective of the paper is to prove how it is possible to enhance relational capital in the football industry by proposing an innovative approach in the evaluation of football clubs and football players founded on their popularity on the social network. The research is directed in representing how the value created by social networks can be a determinant of relational capital value, by increasing strong and trustworthy relationships, especially, with young clients.

Design/methodology/approach – The methodology is based on a qualitative and quantitative approach. Following the analysis of existing literature on intellectual capital and on social media, research has been across two analyses. The first analysis has been carried out by international professional football clubs on which popularity on social networks may have an important influence. The second objective is to check whether the economic value of footballers is taken from the total of human capital value and their value of relational capital developed through new digital platforms. Empirical research aims at proving the correlation that exists between the decisive factors indicated above.

Originality/value – The methodology puts in evidence the existence of economic opportunities, deriving from the management of web platforms, especially with reference to the needs of managers to take advantage of competences deriving from the social media to transform fans and followers in consumers. The analysis configures future research through the integration of social networks impact in the evaluation formula of relational capital of professional football clubs and players, with reference to their transfer prices.

Practical implications – From a comparison carried out with the sales' value of a sample of clubs belonging to the Top 30 ranking, drawn up by Deloitte in the Football Money League 2014 Report, and their level of popularity on social networks, research investigates into the existence of a correlation between sales of football clubs and the number of fans present on the web platforms. The aim is to prove that social networks are indicators of the relational capital value. Using the same approach, the analysis focuses on the transfer prices of a sample of footballers playing in the most important European League clubs.

Keywords – relational capital, new media, social networks, football clubs, football players.

Paper type – Academic Research Paper

1 Introduction

The paper investigates the relational capital in order to evaluate the social media impact on its assessment as knowledge generators.

The purpose of the study is to demonstrate in which measure social networks are able to endorse relational capital in the football industry.

The research is directed in representing how the value created by social networks can be a determinant of the relational capital value, by increasing strong and trustworthy relationships, especially, with young clients.

Some authors (Prahalad e Ramaswany, 2000; Bernestein, 2005; Hamil and Chadwick, 2010) argue that clients satisfaction and engagement represent the first source to obtain companies competitive advantages. This aspect is valid for football clubs by referring to supporters.

In this direction, a primary role is recognized to the web and to the new tools of interaction between individuals, such as social media (Enders et al., 2008).

In the field of social media, the social networks takes on a relevant position. They are a tool both in evaluating brand and in engagement of fans and supporters. They are also a tool in developing a range of relationships on global scale.

The company mission permits to define social networks as useful means in going near fans and supporters in real time, as well as an access means with exclusive contents. The aim is to transform fans and followers in consumers.

Research approach is based on qualitative and quantitative method. The objective is to propose an innovative approach in the evaluation of football clubs and football players relational capital, founded on popularity on the social networks.

Among the analysed dimensions there are the football clubs sales and the footballers transfer prices.

The sources are of secondary nature. The research approach is exploratory (Hair, Celsi, Money, Samouel, Page, 2003) with the aim to fill the literature gap in the field of impact evaluation of social media on relational capital.

The article has the following structure. After the introduction, section two provides a literature analysis of intellectual capital, by referring principally to relational capital and to the impact of social media on relational capital in the football industry. Section three describes methodology and research approach. Section four proposes the research findings and the discussion, by including implications on research. Section five illustrates the limitations of the study and suggests future research.

The research question is the following: Are social networks determinant factors of relational capital value of professional football clubs and footballers transfer price?

2 Literature Review

2.1 Intellectual capital

Intellectual capital of contemporary companies is a strategic asset able to increase added value and to create competitive advantages on the market in the long term (Teece and Pisano, 1998).

Knowledge is the mainly strategic resource that permits to create new knowledge (Stewart and Ruckdeschel, 1998).

In the perspective of value creation, the Resource Based View (Barney, 1991) has stated how intangible assets, such as know how, patents, management skills, image, relationships, reputation, brand, are essential resources.

Many authors (Teece, Pisano, Shuen, 1997) argue that company's value is related to the dynamic capabilities by their internal organization.

Particularly, it is possible to refer to the capacity of strategic management to adapt, integrate and configure again resources, knowledge, management skills, both inside and out of the company, by proposing an answer to the needs of a changing market (Dumay, 2012).

In this way, contemporary company is a coordinated system of tangible and intangible assets; it interacts with external environment with which there are exchange of energy, information and knowledge (Zanda, 2011). The above exchanges are important because they give to the company the possibility to survive and to growth on the basis of continue and repeated relationships.

Stewart recognizes as intangible assets or intellectual capital the following dimensions: the human capital (Edvinsson, Malone, 1997), the structural capital (Bontis,

1991) and the relational capital (Prahalad and Ramaswamy, 2000; Martin de Castro et al. 2011).

Among these dimensions, relational capital represents the knowledge incorporated in a set of relationships, of paths, of business networks that influence organization (Prahalad e Ramaswamy, 2000; Dorrego et al., 2013).

Relationships with stakeholders are the essential condition to build, to keep and to renew resources, structures and processes during the time. The reason is that companies are able to access to critical and complementary resources through external relationships.

The concept of relational capital is based on the consideration that organizations are not isolated system but they have maintained relationships of different type with clients, suppliers and other stakeholders (Roos et al., 2001). It permits to obtain critical information about market opportunities and needs. This type of information is a guide for companies in order to develop and implement new knowledge (Martin de Castro et al., 2011).

The rapid changings of context dictate to the companies to assume a dynamic organization model by involving all clients, suppliers and other strategic partners. Therefore, there is the activation of relationships establishing high level of creativity and satisfaction. In other words, there is the born of significant relationships.

The relational appearance is particularly essential because it is characterized by committed and durable relationships.

This logical assumption leads companies to have a confrontation with clients and suppliers. It is possible to build a connection over the usual phases of companies life with the perspective of long term relationships (Shirouyehzad et al., 2013).

Some authors (Prahalad, Ramaswamy, 2000) state that, among different stakeholders, client represents the new source of competitive advantage. From here, relationships implementation, client satisfaction and loyalty are became the primary objective for contemporary companies with the aim to obtain higher business performance and to increase their value in the long term.

Many authors (Bontis, 1998, Nives and Osorio, 2012) argue that the utilization of relational and marketing channels established with clients are the two principal elements of relational capital.

Relationships need to be evaluate in order to provide a right representation of companies economic value. Infact, relationships influence companies performance through the new knowledge (Chen, Zhu and Xie, 2004).

Economic value of a company is strictly connected with intellectual capital value (Zanda et al., 2005).

Specifically, relational capital of a company is related both to the trustworthy relationships built up between firm and clients and to the plurality of relationships that organization maintains with its stakeholders. Finally, relationships permit to work on the market.

2.2 Social media function

In the last years, the companies competitiveness is focused on capturing consumer attention; in obtaining a competitive advantage, each company needs to use opportunity coming from new media in order to maximize the utility deriving from interaction with clients (Hea, Zhab, and Li, 2013).

Social media represent a group of application internet-based. They are built on the ideological and technological basis of web 2.0 (Kaplan and Haenlein, 2010). They permits to create, transfer and exchange of user generated content.

They represent a new and revolutionary trend that is directed to modify the behaviour of contemporary companies; managers and consultants try to determine key elements for the adequate utilization of the above application.

With the born of internet-based social media (Mangold and Faulds, 2009), communication between individuals is grown and the exchange of information and opinions about goods and services has generated the need to manage relational paths. The impact of relationships is directly linked to relational capital.

Actually the utilization of social media required new ways of companied thinking and operating. For this reason, there has been the establishment of new professional figures such as digital web master and new media managers.

The new media and entertainment revolution is associated to the collaboration mass. It changes economy and business models utilized by companies.

Blogs, chats, search engines, auction advertisings, personal broadcasting are new form of entertainment and interaction able to create value also at commercial level (Tapscott, Williams, 2008).

Therefore, social media identify different new sources of online information. The last one are created, propagated and utilized by consumers by referring to products, brands, services, well-recognized people and problems of every type (Mangold and Faulds, 2009).

Social media are all web-based services such as blogs, forum, social networks that allows message socialization in term of transfer and transformation. In other words, they permit people to be an active figure in the communication (Kietzmann et al., 2011).

Advantages generated by social media are various. First of all, they allow prompt and direct communication between companies and their consumers. In this scenario, there are low costs and more efficiency than traditional communication tools.

Secondly, social media promote comparison among consumers to which they allow to establish direct relationships with companies assuming a perspective both top down and bottom up.

Finally, social media permit to companies to obtain potential profits. The reason is that they are tools able to loyalize users and they allow the market penetration.

Moreover, by comparing with conventional standards, various studies demonstrate as metrics of social media are essential predictive indicators of the companies' market value tasting the power that they have in transforming organization (Luo, Zhang and Duan, 2013).

Among social media, it is possible to recognize the relevance of social network.

The last one is an application able to connect users among them through the creation of personal profiles, by inviting friends and colleagues in sharing personal data. The method of interaction is in sending email and instantaneous message.

Several companies utilize social networking sites in order to create brand communities. Infact, the brand's relational evaluation can be improved and pursued through the utilization of new digital technologies (O'Reilly and Madill, 2007).

Some company utilizes Facebook or other social networks such as distribution and informative channels to show new products and services with sale alerts (Kaplan and Haenlein, 2010).

In this way, companies use the implementation of new relational channels in order to obtain an increasing in the sales.

All the above configures social media as generator of relational capital that are essential both for multinational companies and for medium-small companies. Social media are also relevant for no profit and conventional agencies.

2.3 Social media and professional football industry

Modern professional football companies are high intensity business enterprises (Piantoni, 1999) and their intellectual capital is composed of the players, the brand and the right to participate to competition: they can be considered respectively the human capital, the relational capital and the structural capital of the firms (Lacchini and Trequatrini, 2012).

Synergic relations between sport and new media is facilitated by the increasing demand of sporting contents from global mass media and by the fast convergence of the consumers needs all over the world (Hamil and Chadwick, 2010).

Sport industry is always characterized by an elevated media attention. Particularly, football is one of the most popular mean of broadcasting of sporting contents: the first source of revenues for most European clubs is generated by television rights (Deloitte, 2014).

Football entertainment and his contents are goods that, by attracting new consumers, sponsor and partnership, can cause significant revenues.

Social media revolution has contributed to develop the football content value. It has created a full range of new distribution channels on different digital platforms (Boyle and Hayenes, 2004), inventing original and dynamic connections with the consumers of the football show. In this way, it has allowed the massive reproduction of the sporting product, facilitating the market expansion and increasing the value of the relations between football clubs and their stakeholders (Hamil and Chadwick, 2010).

In order to pursue their company mission and to contribute to the realization of the performance objectives, many football club managers are being oriented towards the implementation of strategies for the optimal social media exploitation (Molina, 2014).

At present, the most popular social networks in Europe are Facebook (www.facebook.com), Twitter (www.twitter.com), Instagram (www.instagram.com) and Google Plus (www.plus.google.com): they represent platforms that allow to the clubs and to the football players to communicate directly with the fans. Therefore, football clubs are

valuing possible investments in the development of websites, mobile applications and games, in order to increase fans loyalty.

In a context of progressive globalisation and internationalisation, competition is focused on the skill of football club managers of capture consumer's attention and of inglobe new multimedial technologies inside the organisation. Therefore, new professional roles are emerging in football clubs organisations, like digital web masters and new media managers.

Social media are modifying the ways to produce, distribute and consume sporting contents and football managers are understanding the benefits and the potential opportunities connected with the exploitation of such tools, in the perspective of a increasingly competitive and technologically complex environment (Bernstein, 2005).

Social networks are also able to create strong relations between fans, activating significant links that can be transformed into economic returns for the single footballers and for clubs. The most important opportunity is constituted by the possibility of develop bidirectional relations with consumers and increase the relational capital value in the long period.

In a perspective strongly business oriented, a footballer can be considered as an enterprise that offers his services to other enterprises operating in the sporting entertainment industry.

Similarly, the transfer price of a footballer can be considered as an expression of his economic value and the social media become the driver for the promotion of the image and the popularity of the footballers all over the world.

In first approximation, transfer price of a footballer has been estimated by the same methods used for the human capital evaluation, considering three principal variables: variables relating to the morphological characteristics of the player, performance variables and context variables (Carmichael, Forrest and Simmons, 1999; Dobson and Gerrard, 1999).

In following studies, the relational capital component, with reference to its media value, has been included in the algorithm estimating transfer price of a player, considering exclusively the popularity and the notoriety obtained through the traditional mass media (Garcia-del-Barro and Pujol, 2006), without taking into account of social media.

Other studies investigate the issue of footballer's image rights in the new media era (Haynes, 2007) and the link between professional player popularity and his emolument

compared to the marginal productivity. They recognize the superstar effect, calculated on the basis of the higher price a spectator is ready to pay to see a specific football player. Such an issue, included in a work on Italian footballers with reference to the season 1995/96 (Lucifora and Simmons, 2003), does not investigate the social media role.

Therefore, the study aims to evaluate also the contribution of the popularity on the most popular social networks to the transfer price of a footballer. The objective is to demonstrate that the above-mentioned popularity constitutes a determinant part of the relational capital of a footballer.

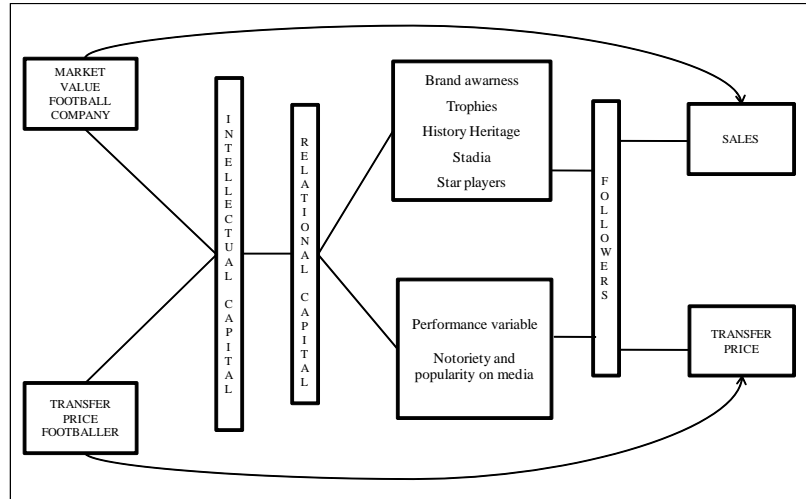

The work is based on the logical assumption that the ability of attracting fans for the popularity allowed by the mass media could be defined relational capital of the single footballer and that his price of transfer (W_f) is strongly connected with his human capital and the relational capital.

3 Research approach

The methodology is based on quali-quantitative method. The research approach is exploratory. The analysis is based on the evaluation of football clubs and football players relational capital, through their popularity on social networks.

The research framework (Figure 1) starts with the analysis of market value of football clubs and of transfer prices of footballers. The value of both variables depends on intellectual capital, which includes relational capital. The relational capital of football companies reflects brand awareness, trophies wins, history heritage, quality of facilities and stars players members of the clubs. Instead, the relational capital of footballers depends on performance variables, popularity and notoriety on all types of media. The numbers of fans and followers are related to relational capital and they impact on sales and transfer price respectively of football clubs and professional football players.

Figure 1- Research Theoretical Framework

In order to answer to the research question, the next hypotheses have been structured:

Hp1: *Does a correlation exist between the popularity on social networks of the professional football clubs and the value of their relational capital?*

Hp2: *Does the popularity on social networks of the professional footballers have an influence on their transfer price?*

On the first level of analysis a study on professional football clubs is carried out, considering as main variable the company’s sales.

The analysis sample consists of thirty professional football clubs belonging to the major international federations. These have been selected by the ranking edited annually by Deloitte and published in the report Football Money League 2014, identifying companies with the highest amount of sales for 2012-2013 season.

Particularly, it is possible to define the following characteristic of the sample (Table 1), in order to explain its representativeness:

Table 1- Characteristics of the football clubs

	Numbers of clubs	%	Total
Nationality			
<i>English</i>	8	27%	30
<i>Italian</i>	6	20%	

<i>German</i>	5	17%	
<i>Spanish</i>	4	13%	
<i>French</i>	2	7%	
<i>Turkish</i>	2	7%	
<i>Netherlands</i>	1	3%	
<i>Portuguese</i>	1	3%	
<i>Brazilian</i>	1	3%	
Sales			
$100 < x < 150$	14	47%	30
$150 < x < 350$	11	37%	
$x > 350$	5	17%	
International Trophies			
$x < 5$	18	60%	30
$5 < x < 10$	5	17%	
$x > 10$	7	23%	

On the second level of analysis a study on professional football players is carried out, considering as main variable their transfer price.

The sample consists of forty professional footballers, who are active in the major European Leagues, in the role of striker and who were object of outright transfer in the last three seasons.

The sample selection was made on the basis of the following characteristics (Table 2), in order to determine its representativeness:

Table 2- Characteristics of the football players

	Numbers of players	%	Total
Nationality			
<i>European</i>	22	55%	40
<i>Extra-European</i>	18	45%	
Age at transfer			
$19-23$	13	33%	40
$24-28$	21	53%	
$28-31$	6	15%	
Matches per age			
$x < 10$	18	45%	40

$10 < x < 15$	16	40%	
$x > 15$	6	15%	
Minutes per Goal			
$x < 150$	10	25%	40
$150 < x < 300$	24	60%	
$x > 300$	6	15%	

The empirical analysis contributes to enrich the existing literature, in order to offer, both to the scientific community, both to the industry, an updated conceptualization of how the relational capital of professional football clubs and the transfer price of professional football players are evaluated.

Data sourcing has been carried out using the following sources (Yin, 2003):

a) direct access to the official pages of the major social networks in Europe. In particular, for each football company were found at the same date, the number of fans on Facebook, the number of followers on Twitter, Instagram, and the number of followers on Google Plus;

b) relating to the market value of football players transfers, consulting specialized websites (transfermarkt.com, fullsoccer.eu, calciomercato.it), and press releases on outright acquisitions or disposals;

c) relating to the popularity of football players, direct access at the same date to the official pages of footballers on social networks such as Facebook, Twitter, Instagram;

d) sites of collection of data on social networks, which process the global media charts.

Overall, the research sources are of secondary nature (documents, reports, news, journal articles in open sources, scientific papers and books, databases).

Empirical research is conducted using a statistical software and is directed to demonstrate the correlation between the variables previously identified.

The analysis integrates, updates and extends the existing literature on the determinants of the relational capital value, expanding the issue to the professional football industry.

4 Findings and Discussion

4.1 Results on Hp1

The findings of the research are based on the systematization of the literature and on the analysis of data defined earlier.

The analysis of the collected data has been made using the statistical model of bivariate linear regression, assuming the following variables:

- the popularity of the social networks of professional football clubs, as the independent variable;
- companies sales of the thirty clubs belonging to the statistical sample, as the dependent variable.

Values resulting from the popularity of thirty football clubs on four social networks (Facebook, Twitter, Instagram, Google Plus) were examined at the date of 31.01.2014 and four separate linear regressions has been created.

In the following tables, for each social network, the correlation with the companies sales has been identified trough Pearson coefficient. Subsequently, the regression line has been drawn ($Y = B_0 + \beta X$).

With reference to the analysis on Facebook (Table 3; Figure 2), the coefficient R is equal to 0,826. This indicates a reasonably strong linear relationship between sales and popularity on Facebook of football clubs. R^2 coefficient value is 0,682.

Table 3 - Results of correlation analysis of Facebook (Sales)

Model	R	R-square	Adjusted R-square	Std. Error of Estimate
1	,826 ^a	,682	,671	72,77690

Figure 2- Regression line of Facebook (Sales)

The results of analysis of Twitter (Table 4; Figure 3) show the coefficient R equal to 0,655. A moderate correlation between sales and Twitter popularity is demonstrated. R² coefficient value is 0,429.

Table 4 - Results of correlation analysis of Twitter (Sales)

Model	R	R-square	Adjusted R-square	Std. Error of Estimate
1	,655 ^a	,429	,408	97,63581

Figure 3 - Regression line of Twitter (Sales)

The results of the analysis on the social network Instagram (Table 5; Figure 4) show the value of the coefficient R equal to 0,792. A moderate correlation between sales and Instagram popularity is shown. R² coefficient value is 0,628.

Table 5 - Results of correlation analysis of Instagram (Sales)

Model	R	R-square	Adjusted R-square	Std. Error of Estimate
1	,792 ^a	,628	,614	78,81203

Figure 4 - Regression line of Instagram (Sales)

Finally, for the analysis relating to Google's social network (Table 6; Figure 5), the coefficient R is equal to 0,723. This means a moderate correlation between sales and Google Plus popularity of the football companies. R² coefficient value is of 0,522.

Table 6 - Results of correlation analysis of Google Plus (Sales)

Model	R	R-square	Adjusted R-square	Std. Error of Estimate
1	,723 ^a	,522	,505	89,26146

Figure 5 - Regression line of Google Plus (Sales)

The analysis, based on the first hypothesis (Hp1), shows that the value of social networks is a determinant of the value of professional football clubs relational capital, as demonstrated by the parameters identified (Table 7).

The results of analysis are statistically significant ($p\text{-value} < 0,05$) with a confidence level of 95% for all analysis carried out and it is possible to assert that the sample is representative of the total population consisting of the companies with sales of more than 100 million euro. Furthermore, the analysis on the sample shows the statistical significance of the estimated regression coefficients by the statistical t-test.

In fact, the empirical values of t of the two coefficients are major than the critical value identified in the table of Student ($t_{(\alpha,df)} = 1,699$, where: $\alpha = 0,05$; $df = 29$).

Table 7 - Summary of results Hp1

	Sales						
	R	R ²	B ₀	t _{B0}	β ₁	t _{β1}	Sig.
Fans Facebook	0,826	0,682	136,392	8,098	0,000007297	7,758	0,000
Followers Twitter	0,655	0,429	174,746	8,721	0,000001795	4,582	0,000
Followers Instagram	0,792	0,628	162,969	9,952	0,000256042	6,87	0,000
Followers Google Plus	0,723	0,522	149,264	7,336	0,000006006	5,534	0,000

Based on the formula to determine the economic value of relational capital, the popularity on social networks can affect the percentage of sales attributable to the relational capital. This is evidenced by the positive correlation between popularity and sales of football companies for each social network analysed.

4.2 Results on Hp 2

With regard to the empirical analysis on the value of outright transfers of forty strikers playing in the major European Leagues, has been used three social networks (Facebook, Twitter, Instagram). Particularly, the second analysis does not consider the social network Google plus, because not all the football players of the sample are active on this platform.

Using the same method adopted for previous investigation, the following variables are hypothesized:

- the independent variable is the popularity on social networks of forty football players;
- the dependent variable is the price of the outright transfer of players.

In the following tables, for each social network, the correlation with the football players transfers prices has been identified through Pearson coefficient. Subsequently, the regression line has been drawn ($Y = B_0 + \beta X$).

Specifically, the results of the analysis of Facebook (Table 8; Figure 6) show the coefficient R equal to 0,562. This means a moderate correlation between the economic value of football players and their popularity on Facebook. R^2 coefficient value is 0,316.

Table 8 - Results of correlation analysis of Facebook (W football player)

Model	R	R-square	Adjusted R-square	Std. Error of Estimate
1	,562 ^a	,316	,298	13075264,967

Figure 6 - Regression line of Facebook (W_f)

Concerning the Twitter analysis (Table 9; Figure 7), the coefficient R is equal to 0,665. This shows a moderate correlation between the economic value of the football players and their Twitter popularity. The coefficient R^2 has a value of 0,442.

This social network identifies the highest correlation value of the second level of analysis. It is the most suitable for the interaction between single player and fans.

Table 9 - Results of correlation analysis of Twitter (W football player)

Model	R	R-square	Adjusted R-square	Std. Error of Estimate
1	,665 ^a	,442	,427	11806061,217

Figure 7 - Regression line of Twitter (W_f)

Finally, the analysis has been elaborated with reference to the social network Instagram (Table 10; Figure 8), according to which the coefficient R is equal to 0,517. This shows a moderate correlation between the price transfer of football players and their Instagram popularity. R^2 coefficient value is 0,267.

Table 10 - Results of correlation analysis of Instagram (W football player)

Model	R	R-square	Adjusted R-square	Std. Error of Estimate
1	,517 ^a	,267	,248	13529075,244

Figure 8 - Regression line of Instagram (W_f)

With regard to the second hypothesis (H_{p2}), it is shown that the value of social networks is a determinant of the price of transfer of the football players, given by the sum of the value of human capital and relational capital, as demonstrated by the parameters identified (Table 11).

The results of analysis are statistically significant ($p\text{-value} < 0,05$) with a confidence level of 95%. Furthermore, the analysis on the sample shows the statistical significance of the estimated regression coefficients by the statistical t-test.

In fact, the empirical values of t of the two coefficients are major than the critical value identified in the table of Student ($t_{(\alpha;df)} = 1,685$, where: $\alpha = 0,05$; $df = 39$). Therefore, it is possible to assert that the behaviour observed on the sample approximates that of the population.

Table 11 - Summary of results Hp2

Transfer Price							
	R	R ²	B ₀	t _{B0}	β ₁	t _{β1}	Sig.
Fans Facebook	0,562	0,316	14757961,35	6,499	2,339	4,185	0,000
Followers Twitter	0,665	0,442	13953087,61	6,784	5,045	5,486	0,000
Followers Instagram	0,517	0,267	16232198,02	7,25	13,874	3,722	0,001

The positive correlation, identified from the empirical analysis between the transfer price and football players popularity profiles on social networks, allows to say that the greatest value given to players because of their reputation is directly attributable to relational capital, in the mean of capability to attract fans and followers.

It should be noted that football players have lower levels of popularity on social networks than clubs. The greater capability to attract fans by professional football clubs is due to several factors, including supporters loyalty and history heritage. So, an increase of social network popularity for players is more relevant than the same increase of clubs popularity.

Finally, it is considered that no strong correlation could be due to the lack of management strategies based on social networks. Football clubs and professional players have not yet identified a model for the profitable management of this resource, minimizing the associated risks; as for all media, a distorted use can be counterproductive.

In this sense, there are some proposals to regulate the use of social networks, or even forbid its use, in some competitions especially for athletes. This happened, for example, for the Olympic Games of London 2012 and for the final stages of Euro 2012; at the next World Cup 2014, also the coach of the Italian national football team has announced he is going to forbid the use of social networks to the players.

5. Conclusions, limitations and proposal for future research

The research has analysed the impact that social networks have on the professional football clubs value and on the footballers transfer price as their relational capital's value drivers.

By the definition of stable and lasting connections with the fans and the followers, there has been verified the existence of a positive correlation between social profile of the clubs and the footballers and their relational capital value.

In this perspective, the research can be useful to identify corrections for the traditional methodologies for the evaluation of:

- a) the professional football clubs relational capital, in the meaning of corporate brand;
- b) the footballers transfer price.

With regard to the first aspect, corporate brand value is generally calculated multiplying company sales for a coefficient (royalty) expressive of numerous factors between which brand's popularity has a preeminent position. Modifying the formula, it is possible to include the popularity on the social networks as additional component for the relational capital definition: in particular, to higher levels of popularity on the social networks will correspond a royalty more elevated to attribute to the relational capital, in its meaning referred to the brand.

With regard to the second aspect, it is demonstrated that popularity on social networks of the footballers affects positively their fair market value.

Therefore, in the formula for the estimate of the transfer price, which generally takes into account traditional variables tied to characteristics of the player, individual performances and variables of context, there must be included the component tied to the footballer relational capital; this last one is expression of variable "popularity", whose value must be connected also to the number of followers on the social networks.

In the strategic and managerial perspective, the research has remarked the existence of economic opportunities deriving from the management of the new platforms, with particular reference to the demands of the managers of exploiting knowledge deriving from social media in order to transform fans and followers in consumers.

Company relational capital is influenced by the satisfaction and the loyalty of clients; in this sense, social media represent a tool to realise strategies one to one with consumers, as knowledge and strong relationship generators.

Popularity of social media is in strong expansion between citizens: the result is that companies can extract value with this tool to innovate their business models and their managerial practice.

In order to increase relational capital value, professional football clubs can use social media and, in particular, social networks as distributive channels to the e-commerce and as tools in support of the brand diffusion.

At the same time, footballer also have to learn to exploit social media in ways of increasing his popularity level, avoiding abuses able to put in danger his image or the image of the club in which he plays.

The work presents relevant limits; it is possible to mention, first of all, the fact that the empiric analysis has presupposed constant all the other determinants of the companies sales and of the footballers transfer price.

With reference to the professional football clubs, the future research will have to be orientated to validate the results by the insertion in the analysis of other drivers of the relational capital value and, particularly, to integrate in the formulas the impact of new and old media, avoiding possible overlaps and duplications.

With reference to the football players, the aim of future research will have to be oriented to identify new models of evaluation keeping in due consideration traditional variables and variables deriving from the player's popularity on social media in addition to the determinants deriving from the popularity on press and television.

Structured Abstract

Purpose – The purpose of this paper is to explore numerous new tools, which have been developed to track and capture customer preferences, behavioural patterns and attitudinal responses, in order to improve firm's knowledge management (KM). In this way, authors present the most important determinants of a 'unified' approach to knowledge management and provide directions for further research.

Design/methodology/approach – We propose to develop and present a comprehensive framework for managing knowledge, which can be acquired from external sources with purpose of improving managerial outcomes. In this context, we place a special emphasis to the 'social technologies', such as social networking, corporate blogging, customer/brand virtual communities, etc. These tools represent novel sources for cultivating external information which affect all aspects of management process: from ideation and new product development which nowadays rely on co-creation with customers and open-source innovation; to process improvements and long-term relationship development with customers and other stakeholders.

Originality/value – Our approach brings together in a single framework management of both the external, customer-held knowledge, as well as internal sources of knowledge, examined by the traditional knowledge management discourse. It is based on an integration of relevant theories and practices from the fields of management and marketing, which provides an inter-disciplinary approach to knowledge management. Therefore, we propose that future research equates an organization's market orientation to the fundamental activities of knowledge management, since this would also enable

researchers to use the well-accepted tools, such as MARKOR scale/questionnaire for market orientation in a new research setting.

Practical implications – The outcomes of previous application of different tools, contributing to the ‘unified’ knowledge management approach are explored. In addition, potential practical benefits of such an approach are explored throughout three different dimensions: (a) managing credibility of peer-to-peer communication about an organization, its products, activities, etc.; (b) using social media as major, low-cost customer support channel; (c) making use of external knowledge sources to include customers’ input into the new product development as value co-creators.

Keywords – Knowledge management, Unified approach, Customer knowledge management

Paper type – Academic Research Paper

1 Introduction

More than ever, sustainable competitive advantage depends on firms’ ability to utilize a wealth of data that contemporary customer relationship management (CRM) tools provide (from Internet sources to loyalty program data to social media, etc.). These tools represent novel sources for cultivating external information which affect all aspects of management process: from ideation and new product development which nowadays rely on co-creation with customers and open-source innovation; to process improvements and long-term relationship development with customers and other stakeholders through CRM and social media tools.

We believe that an analysis of contemporary practices in using peer-to-peer and customer-to-company sources of knowledge may assist other practices relevant for management of overall knowledge available to an organization. Therefore, the objective of this article is to use the overview of state-of-the-art collaboration and networking sources and tools, in order to ‘sketch’ the most important determinants of the comprehensive, ‘unified’ model of knowledge management, as well as to provide directions for further research.

2 Background

As knowledge emerges as a central resource essential to the development of capabilities and competitive advantage of firms (Barney, 1991; Grant,1996a; Grant, 1996b), both theoretical and practical discussion focused on the knowledge creation,

transfer and application either within organizations (Alavi & Leidner, 2001) or through strategic alliances (Meier, 2011). Theoretical perspectives identify several manners in which knowledge can be used to obtain such a strategic advantage. They include development of innovative strategies, better execution of existing strategies, development of new products/services (or enhancing the current products/services) and more efficient execution of business processes (Liebowitz, 1999).

However, there seem to be many different *forms of knowledge*, such as (Nonaka et al., 1995; Quinn et al., 1996): (a) *know-what*, which is related to the classification of the facts known, without any reference to the context in which these facts could be used; (b) *know-how*, i.e. knowing how to apply the facts in a given context; (c) *know-why*, i.e. the ‘in-depth’ understanding of the known facts and their relationships with the elements of the context, as to predict and manage possible outcomes in advance; (d) *care-why*, i.e. having motivation for creative application of knowledge in the best possible way.

Data from different sources are incorporated into these forms of knowledge, with the *internal sources of data on customers* being predominant in traditional organizations. In this context, management of knowledge is ‘just’ a rational process, expected to systematically collect, organize, secure, share and facilitate the utilization of knowledge (Lehaney et al., 2004). However, this approach presupposes that knowledge is (more or less) readily available for processing and that an organization simply ‘*does not know what it knows*’, which can be solved by an introduction of a rational management process. At the other hand, it should be analyzed whether an organization *knows everything that it should know*, i.e. if it has acquired all relevant knowledge *from* and *about* its customers and the environment.

This article will, therefore, build upon the well-known distinction on *knowledge for, from* and *about customers*, as related to (Salomann et al, 2005): (a) information that should be provided to (*for*) customers, in order to ensure their satisfaction and loyalty, (b) information collected *from* customers, relevant for product, service and/or business improvement and (c) information *about* customers’ needs, expectations, etc., usually captured by the customer relationship management (CRM) tools and approaches. However, we strive to build a ‘unified’ model, addressing management of all these sources of knowledge, as well as relevant relationships among employees - fundamental actors of knowledge work.

3 New developments in knowledge acquisition

We believe that in an era of increasing development of information technology (IT) and empowering end-customers, the locus of power in knowledge creation is shifted from companies to consumers. As Lager (2007) stated: “*The future of business may not be in the hands of the executives, but those of the customer instead*” (p. 23). Empowered with social media like Facebook, LinkedIn, Twitter, MySpace, customer review’s sites and similar social media channels, customers are not anymore passive spectators waiting to be sold products to, but rather active participants in the two-way interaction with product- and service providers. In such an environment, the previously neglected dimension of knowledge management can be identified in the knowledge creation, based on appropriating customer experiences and discovering knowledge in customer interactions. It is, therefore, crucial to bridge the gap between what is traditionally seen as management of customer relationships to discovering customer-based knowledge and ‘fitting’ it into the knowledge management system of a firm.

Namely, the rise of information and communication technologies, as well as development of business intelligence (such as data warehousing, data mining, etc.) influenced the popularization of CRM and its tools as ways to access and manage the wealth of data on customer behavior and preferences (Winer 2001). Traditionally, the role of CRM includes the building of a single view of the customer across all contact channels of this customer with the firm and companywide distribution of customer intelligence (Reinartz, Hoyer & Krafft, 2004). *Data on customers* is gathered and managed by using tools like call centers, loyalty programs and salesforce automation, i.e. by using the one-dimensional corporate interaction. However, with the development of new communication channels, such as social networks and other social media, it became much more difficult to obtain the single view of a customer and its decision-making parameters. Contemporary customers obtain information from various sources to increase information credibility and facilitate comparisons between products. In addition, any of their experiences, either good or bad, can be disseminated faster and more efficiently than ever, since consumers spend about 700 billion minutes per month on social media (Beck, 2011).

This creates a large potential for incorporating knowledge from 'social technology', such as ‘liking’ a specific product or a brand on Facebook, ‘tweeting’ about a product or a firm on Tweeter, blogging about one’s customer experiences, into the traditional customer

relationship management (CRM) systems, which is sometimes referred to as CRM 2.0 or social CRM (Lager, 2007; Stone, 2009). The social media proliferated in recent years, creating remarkable changes in business environment. In 2011 activity on Twitter reached 140 million tweets daily, while Facebook attracted more than 500 million active users in more than 70 languages (Beck 2011). The total minutes spent on Facebook increased by remarkable 700 percent year-over-year (Nielsen Company, 2009). As a result, companies are shifting their attention and resources to leverage the information from social media. According to the leading IT consulting company *Gartner*, the developing social CRM application market reached \$600 million in 2010, and it is expected to reach \$1 billion by 2013. By the year 2015, Gartner predicts that as much as 80 percent of consumers' discretionary spending will be influenced by digital strategies, such as social and mobile marketing (Gartner Inc., 2011).

One of the main advantages that companies can achieve with successful integration of social media is a wider reach (spread of the word) and higher credibility of peer-to-peer communication for customers (the word-of-mouth recommendation). For example, CEO of social targeting platform CrowdFactory, Sanjay Dholakia (cited by Beck, 2011) found that about 78 percent of consumers trust recommendation by their peers, compared to only 15 percent of consumers who trust advertisements from a company. In addition, the social media provides an instant feedback, which allows product/service providers to respond to 'critical incidents' in customer relationships in real time. Therefore, it is not a rare case that organizations employ professional 'social media officers', who follow the comments which customers post on social media websites and solve the potential service problems. For instance, the experience of an US-based designer and maker of bicycles and related equipment and apparel, *Specialized Bicycle Components*, has been discussed by Klie (2011). Screening what customers posted on social media channels allowed the company to predict and solve potential critical incidents and in turn obtain a positive word-of-mouth and loyalty from customers active in social media. This motivated Specialized Bicycle Components to move further and create its own virtual customer community. Today, the company reports that its social community platforms account for 15 percent of all company's interactions with consumers (Klie, 2011).

As the second important advantage, companies such as the UK mobile virtual network operator *Giffgaff*, or the similar Croatian counterpart *BonBon* (a rebranded part of the T-Mobile Croatia network), use social media as major customer support channels to reduce

the operating costs. Instead of having a costly customer contact center, Giffgaff asks customers to post their questions on their help forum, while *BonBon* uses its 'official' Facebook and Twitter accounts. Such an approach can lead to substantial cost savings, as demonstrated by *Linksys*, which markets networking products on the SOHO (Small Office/Home Office) market. By introducing the online customer support community, Linksys was able to substantially reduce the number of calls to their customer support centers and completely eliminate the email support service. More than 120 000 potential service requests per month are addressed by customers themselves, since they are able to find the previously posted solutions. Moreover, some 1000 service requests per month are re-routed from the traditional channels to the new online support community of customers (Klie, 2011).

Thirdly, companies can use external knowledge sources to include customers' input into the new product development and serve as value co-creators. Co-creation as a practice can be described in terms of collaborative product development by firms and consumers, in which consumers actively contribute and select various elements of a new product offering (Hoyer et al., 2010). This allows companies to increase effectiveness of innovations since such co-created products better reflect true customer needs and to reduce costs by replacing costly internal (employees') input in the new product development with the external input from customers. For instance, *Procter & Gamble*, through its *Connect+Develop* innovation program collects now more than 50 percent of all its product initiatives from collaboration with customers and other external parties (Procter & Gamble, 2011).

Very often, the easiest way for a company to engage in co-creation is by setting up a product innovation contests for customers. In 2005, one of the world leaders in mobile phones, the Finnish *Nokia* launched highly successful *The Concept Lounge* competition, which invited users to help create the new phone. Nokia now harnesses the customer-centric knowledge management opportunities through Nokia Developers online communities which are tailored to receive input at different stages of product development through creation of specialized communities. In addition, the *Nokia Beta Lab* community members are provided with free access to product development tools and releases of software in testing ('beta') stage, which allows customers to provide feedback and interact with Nokia software developers. Finally, launched in 2005 under the original name of Lego Factory, *LEGO's* current initiative *Lego Design by Me* allows customers to

design their own models of *Lego* toys with an easy-to-use, freely downloadable software. The designs can then be uploaded to the Lego website and shared with others to receive feedback and see what other creators have uploaded. Such co-created product can be then ordered to delivery. Lego Design By Me users are motivated through participation in contest for the best product or design. According to TrendWatching (2006) in one of such contest winners were awarded with a 5 percent royalty on each set sold.

4 Toward a unified model of knowledge management

Previously described marketing-based dimension of acquiring relevant external knowledge can be successfully incorporated into the knowledge management framework developed by Ackerman et al. (2003), who believe there are two fundamental viewpoints of knowledge management. The ‘technical’ viewpoint is concerned with the transformation of tacit forms of knowledge into the explicit, as well as collection and organization of explicit knowledge by using databases and repositories. The ‘collaborative’ viewpoint is related to the socio-cultural aspects of connecting and empowering employees, as to enable knowledge sharing and the development of ever ‘deeper’ forms of knowledge, i.e. moving from ‘know-what’ toward ‘care-why’.

In this context, unification of knowledge management should also move in two different, but complementary directions. On one hand, it should be ensured that all information, regardless of its origin, is placed within a comprehensive and systematically created ‘knowledge map’, which is made available to all knowledge workers via adequate technical means. On the other hand, associated processes among knowledge workers should be aligned with the knowledge acquisition, transformation and distribution tasks of the knowledge management system.

What seems to be most important, our framework requires explicit identification of knowledge concepts and their sources, as well as of inter-personal processes leading to the ‘knowledge flow’ (i.e. adequate utilization of knowledge). In addition, we wish to provide the *‘market-aware’ context for the functioning of knowledge management, i.e. bridge the gap between the internally-oriented management of knowledge assets and customer-oriented tools of knowledge acquisition.* This is achieved by using the classical Kohli & Jaworski’s (1990) concept of market orientation, defined as a sequence of three activities: *generation, dissemination and response to market stimuli.* These activities

constitute the fundamental elements of an organization's agility for a continuous (re)orientation, directed by market intelligence.

We believe that the *stages of knowledge management*, as identified by previous research, should be (re)interpreted in terms of ensuring that knowledge collected, stored and used is relevant for the customers' needs. Building on this proposition, the conventional knowledge management cycle (Mertins et al., 2003), consisting of knowledge generation, storage, distribution and application, can be augmented. We believe that such a model should be integrated with the activities related to market intelligence, as a form of acquiring relevant external knowledge.

A comprehensive model, bridging the existing gap between the market intelligence/orientation and knowledge management theories is proposed and demonstrated by the following figure. The model also especially refers to new sources of customer knowledge, i.e. on *knowledge from the customer or external (to company) knowledge*, which can be acquired both via traditional tools and approaches (such as market research), as well as the non-traditional ones (e.g. social media). These linkages between managerial and marketing aspects of relevant constructs, actors and processes should constitute the 'technical' viewpoint of the knowledge management.

In addition, there are enablers and tools to be used by different stages in the entire process. While knowledge storage especially benefits from those emanating from the field of information technology, the adequate organizational culture is especially relevant for the stage of knowledge distribution, in order to avoid the orientation toward knowledge management as 'appropriation' of individual (expert) knowledge (Bahra, 2001). It could be also stated that such a culture may also represent a significant factor for the success of the *entire knowledge management cycle*, which corresponds to the literature, representing the 'cultural school' of market orientation. Namely, Narver & Slater (1990), Deshpande et al. (1993), as well as other studies, have indicated that customer-oriented organizational culture both increases the efficiency of organizational processes and their final output, viewed in terms of organizational performance. In the knowledge management context, we propose that this kind of culture serves as a comprehensive 'enabler' of activities and processes relevant for all knowledge management activities, i.e. that it represents the 'collaborative' viewpoint of the overall knowledge management cycle.

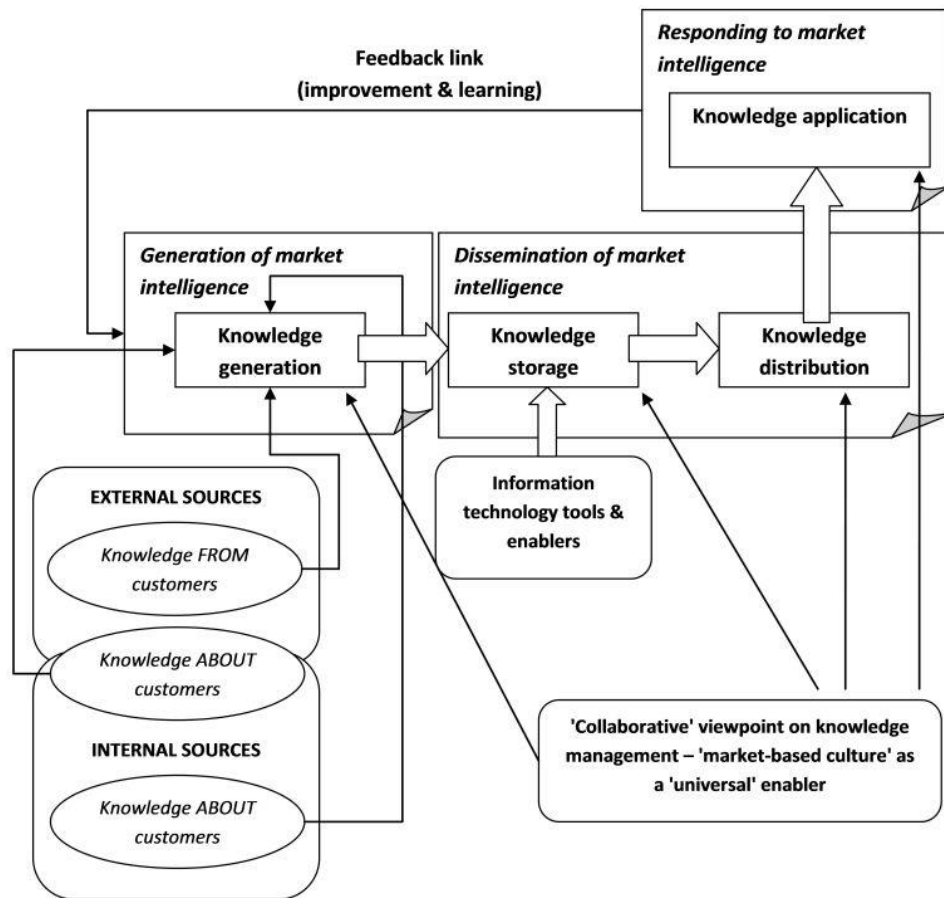

Figure 1. The proposed 'unified' model of knowledge management

5 Future research directions

In this article, we discuss novel developments in knowledge management coming from external sources of knowledge creation and propose a comprehensive theoretical model, which brings together multiple theoretical streams, especially those from the fields of marketing and management. Our main concern has been the fact that the knowledge management *per se* does not provide 'reality check' for the usefulness of knowledge assets being collected and accounted for as valuable basis for further action. In addition, there may be multiple mechanisms for collecting knowledge within the firm, especially in the field of marketing intelligence, which may be addressed by means of customer relationship management (CRM), market research, social media management, etc. Those

mechanisms may not be mutually coordinated, as to provide a consistent ‘unified picture’ of customers’ requirements and responses to actual products and processes. Human resource and leadership practices, leading to a culture of sharing and collaboration among employees, are also considered to be significant enablers of knowledge management, but could be overlooked in technology-focused knowledge management initiatives.

Two dimensions of knowledge management (‘technical’ and ‘collaborative’), as well as multifaceted character of research in this field and complexity of practical application of the knowledge management concept, require a sound integration of relevant marketing and management paradigms. We believe that the stages of ensuring organization’s market orientation should be equated to the fundamental activities of knowledge management (in its ‘technical’ dimension), while multiple enablers of the entire process (in its ‘collaborative’ dimension) could be merged into a single one - the market-oriented culture. The resulting model is, therefore, oriented to overcoming potential shortcomings of knowledge management by connecting it to the relevant customer-centric practices.

Such a conceptual model calls for further improvements and empirical verification. As to facilitate such a process, we have used the conventional marketing constructs, related to the understanding of the market orientation, in order to augment the existing knowledge management models/theories. Namely, these constructs can be easily measured and empirically validated by using well-accepted tools, such as MARKOR scale/questionnaire for market orientation (Kohli, Jaworski & Kumar, 1993).

6 Conclusion

We propose that the potential shortcomings of the knowledge management models in contemporary business settings can be addressed by integration of relevant marketing concepts and novel approaches to collecting customer-based knowledge. Based on such a proposition, this chapter develops a new conceptual model of knowledge management, which brings together relevant theories and practices from the fields of management and marketing.

From the viewpoint of knowledge utilization in contemporary corporate environment, theoretical contributions developed by considering both managerial, as well as marketing perspectives, are not a common place of the literature. This should serve as an encouragement for studies dealing with the issue of integrating additional perspectives into the existing knowledge management models. In such a context, our model may serve

as a sort of a 'rough sketch', which needs to be further empirically tested, especially regarding our hypotheses on: (a) existence of relationship(s) between the stages of the knowledge management cycle and the market intelligence activities and (b) functions of the customer-oriented organizational culture as a comprehensive enabler of knowledge management. We also hope that additional theoretical dimensions, especially those reaching into the business/marketing strategy, could be successfully integrated into the proposed model.

Structured Abstract

Purpose – The purpose of this paper is to show how knowledge workers from research institutions use social media tools for networking, information search, and idea generation. This paper aims to examine how social media may enrich the practices of knowledge transfer, knowledge management and creativity.

Design/methodology/approach – On the basis of structured interviews with knowledge workers from universities and public funded research institutes in Germany, the sources of information and inspiration in the course of idea generation as well as the impact of social media on creative processes are analysed.

Findings – The paper shows that most interviewees, who are heavily involved in creative processes, confirmed the utilisation of variable social media tools. They primarily use social networks to endure relationships with business acquaintances, to keep in touch with colleagues, partners and friends, which can be seen is first step in getting access to their knowledge base. Although, the study could not show that social media is explicitly important for knowledge acquisition or idea generation.

Research limitations/implications – Further research should include large-scale surveys to analyse causalities of the minor importance of social media in knowledge-intensive work fields. Upcoming research involving knowledge workers from other technological areas could help extracting effects caused by specialisation or industry-related influences.

Originality/value – The authors present insights on work principles of knowledge workers whose primary tasks are to exploit knowledge and to implement ideas.

Key words – Creativity, knowledge workers, social media, idea generation

Paper type – Academic research paper

1. Introduction

External forces such as an increasing international competition, advances in technology, and other influences have escalated demands on all kinds of organizations to be innovative (Andron, 2013; Lawson & Samson, 2001). Therefore firms are pressured to innovate, to adapt and to use all types of knowledge available. Research shows that the diversity of knowledge is positively related to divergent thinking and, consequently, positively related to creativity (Williams, 2004). Thus, personal and situational factors that affect knowledge acquisition and divergent thinking, and might also influence the creative performance of organizations (Williams, 2004).

The emergence of social media technologies has dramatically changed the Internet. The term social media indicates mobile and web-based communication technologies that are typically used to connect people and communities, as well as to share, discuss, co-produce and modify user-generated content (Kietzmann, Hermkens, McCarthy, & Silvestre, 2011; Lewis, 2010). Recently social media has been categorised into four main groups (Mao, 2014):

- Social networking tools and instant messengers such as Facebook, Skype, Tumblr and so forth.
- Tools for social publishing, social sharing, bookmarking, and collaborating, including tools like blogs, wikis, Twitter, Delicious, Flickr, Youtube, Picasa, GoogleDocs, Spreadsheets, Slideshare, Dropbox, Glify and so on.
- Social tools for content management as well as calendars, surveys, and polls such as Moodle or Edmodo.
- Virtual worlds and gaming environments such as SecondLife, WeeWorld, Webkinz and so forth.

In this study we define social media as applications that utilize web technologies and allow users to create and participate in communities through functions such as communicating, interacting, sharing, collaborating, and publishing. It is obvious that social media has generated new opportunities to create content and to provide and capture interdisciplinary knowledge, particularly regarding the existence of a wide variety of information (Leftheriotis & Giannakos, 2014). Different social media technologies, like social networkings, online forums, wikis, blogs, and microblogs are becoming a reliable platform for sharing information to target audiences in a contemporary manner (Osatuyi, 2013). In social media networks (e.g. Facebook, LinkedIn, MySpace, Google+, Xing) or

collaborative communities people share experiences and information, which pertain not only personal interests but also professional matters. Therefore a large number of professional forums and professional networks have evolved (e.g. ResearchGate, Academia, Mendeley).

Social media becomes more and more important for various types of organisations and in the near future it will probably be an indispensable building block in the innovation management process. By using social media applications, employees gain access to varied and diverse knowledge, which influence their propensity for original, independent, and unconventional thinking and problem solving (McCrae & Costa, 1997). Reconsidering that the link between openness to experience and divergent thinking is empirically tested (McCrae, 1987), it can be assumed that individuals who have access to diverse knowledge and diverse social networks tend to show divergent thinking and to be more creative (Williams, 2004). Social Media may enrich the practices of knowledge transfer, knowledge management and creativity in organisations (Luo, Zhang, & Duan, 2013).

Aim of the study is to get new insights on how the use of social media channels by knowledge workers affect creativity, idea generation and innovation management in organizations. We also want to understand what triggers knowledge workers to use social media for profession-related communication and knowledge exchange.

In section 2 we introduce related work and some theoretical viewpoints upon which this research is grounded. In section 3 we introduce the research approach and the methodology. In section 4 we present the empirical results. In closing, we discuss the outcomes of the study, and highlight the limitations and the implications that arise for researchers, practitioners, and executives.

2. Social media and work creativity

There is a lot of existing research on how social media is generally used in a professional or corporate environment (Kaplan & Haenlein, 2010). There have been studies on the values of using social media for work purpose (Leftheriotis & Giannakos, 2014). Many studies analyse a specific social media tool, e.g.: corporate community weblogs (Liao, Pan, Zhou, & Gan, 2012), micro-blogs in a corporate context (Riemer & Richter, 2010), social bookmarking (Millen, Feinberg, & Kerr, 2006), social networking

(DiMicco et al., 2008; Morris, Teevan, & Panovich, 2010; Skeels & Grudin, 2009), and enterprise wikis (Grudin & Poole, 2010).

In the following sections we will first discuss existing research and theories on social media for work purpose in general and we will then focus on knowledge workers, their sources of inspiration, and their social media use.

2.1. Social media for work purposes

Different social media channels are becoming integral parts of work environments. Expected advantages consist of maintaining external professional networks, creating and strengthening ties with colleagues, gathering professional information, and promoting knowledge sharing (Leftheriotis & Giannakos, 2014; Skeels & Grudin, 2009). Social media applications seem to have the potential to provide knowledge and communication, and to increase work performance as a consequence (Tsay, Dabbish, & Herbsleb, 2012). They offer peer-based communication and collaboration. Recent studies of user behaviour show that employees use internal social networking to build stronger bonds with their weak ties and even to reach out to employees they do not know (Leftheriotis & Giannakos, 2014). Thus, social media not only reinforce ties but also create new ones. Motivations in doing this include connecting on a personal level with coworkers, advancing their career with the company, and campaigning for their projects (DiMicco et al., 2008). Although the contribution of weak ties to productivity is difficult to prove, some authors anticipate a fast uptake of social networking applications by organisations (Skeels & Grudin, 2009).

Other studies argue that social media use at workplace may reduce productivity of employees due to the fact that they spend long periods of time online and chatting (GFI, 2011). Moreover some authors examine major potential risks and call attention to the fact that social media may be time-wasters and security traps (Turbana, Bollojub, & Liangc, 2011). Altogether, we still know very little on specific social media's impact on work principles and work performance.

2.2. Knowledge workers, their sources of inspiration, and social media usage

Research scientists from universities and non-university institutes are ideal types of the so-called knowledge workers. Scientists can be seen as specialists with the main task of creative performance, which may be defined as the use and combination of knowledge,

imagination, and skills to invent a novel process, product, procedure or idea (Amabile, 1997; Scott, 1995). Scientists primarily offer knowledge and creativity to their employers, partners, and customers. Therefore scientists need to manage knowledge and creativity as their strategic resources. In order to create new knowledge, researchers seek to combine and exchange information and know-how with colleagues and must often go outside the boundaries of their institutes to obtain the needed resources (McFadyen & Cannella, 2005). As knowledge creation is affected heavily by exchange with others, both within and outside the organisation, social media may enrich work practices. Although McFadyen and Cannella (2005) argue for a curvilinear effect between distance and knowledge, in that spatially close and distant exchange partner locations will have a greater effect on knowledge creation than middle-sizes distances.

Social media have dramatically changed the way how people work and interact socially and professionally, impacting scientific research in a number of way. The free and rapid flow of information, ideas and documents both requires and fosters new habits of collaboration among researchers (Rinaldi, 2014). Worldwide many scientists recognize the potentials of social media tools for visibility and constructive conversation . Science blogs for example have sprung up over the past few years. Pioneers like Christie Wilcox, a biologist from the university of Hawaii, argue that scientists have the responsibility to bring to the public the results of their studies and that blogs seem to be a straightforward method (Wilcox, 2012). Others see blogs and social networks as eligibly tools to reach a wide audience, which is seen as an integral part of science (Fenner). One of the most popular twittering scientists with more than 210,000 followers – the British physician Stephen Hawking (Hawking, 2014) – does not only tweet his research results but also expose parts of his personality to get stronger personal connection between his follower and himself (VanEpperen & Marincola, 2011).

Research scientists currently use social media for two primary reasons. The first reason is networking with colleagues, partners, and customers; the second reason is making results more visible to funders, policy makers, and even the public (Rinaldi, 2014). Social media helps to build dialogue and constructive conversation with the public, particularly about sensitive topics, like genetic engineering and stem cell research (Rinaldi, 2014). Therefore social media channels are bearers for communication strategies for universities and major scientific corporations.

From a theoretical perspective social influence plays an important role in the field of using information and communication technologies. Many studies have explored a significant effect of social influence on technology adoption in general (Olschewski, Renken, Bullinger, & Möslein, 2013). We assume that social media usage by knowledge workers and other employees is evidently influenced by role models and by the perceived organisational support. The former can be defined as the degree to which employees perceive that important colleagues use social media in their everyday work. The latter – perceived organisational support – can be defined in terms of the extent to which employees perceive encouragement, respect, and recognition from the organisation for those who use social media. Wilcox (2012) stated that scientists may feel a “need to be engaged in new media platforms because everyone else is already talking about their thoughts and feelings, having discussions about things they care about, and generally—as the name implies—being social.”

Beyond networking, visibility, and public dialogue, social media may also help in collecting information, gathering knowledge, and getting in conversation with customers and partners. As research scientists are always in search of knowledge and science-related news, social media may be an interesting source of information. Information sharing among individual researchers is assumed to be benefit-oriented (Osatuyi, 2013). According to social exchange theory people evaluate costs, time, and benefits before sharing information with others. Therefore social media could offer timesaving and cost-effective ways to get access to a wide range of different information in particular. Benefits anticipated by social media information exchange have been found to be the building of social capital and reputation (Constant, Sproull, & Kiesler, 1996). Osatuyi (2013) stated “sharing information socially also gives an intrinsic benefit to the provider by confirming their ability to provide information that is considered useful by the social network in which they belong”. This applies even if there is no personal connection between information provider and information seeker (Constant et al., 1996). Social media affects networking ability, which might have an impact on creativity and idea implementation. Moreover, social media activity can have an impact on the formation of domain relevant skills, which according to Amabile (1997) can be seen as an important factor associated with individual creative performance. Domain relevant skills include knowledge about the domain itself, technical skills required, and special domain-relevant “talent”.

Despite the evident pros of social media usage, information shared on social media sites face a credibility problem (Osatuyi, 2013). Therefore from a users perspective, verifying the information provider and the information itself is necessary and increases the costs of sharing information. Trust and authenticity issues might be reasons why some professional user groups still use social media very moderately. Many scientists show a critical scepticism and perceive mainstream social media sites (e.g. Facebook) as unprofessional platforms that firstly do not provide an environment conducive to productivity and secondly may even compromise serious research (VanEpperen & Marincola, 2011). Although, other authors state that social networking sites hold a huge potential for sharing information among scientists (Osatuyi, 2013).

Thus a high level of social media activities can have a positive impact knowledge worker's information base as well as on their ability to adapt existing knowledge. On the other hand habitually users of social media platforms need large time resources for their social media activities, which may shrink productivity, in particular when these activities are done during working hours. These assumptions indicate an ambiguous relationship between social media activity level and creativity of knowledge workers. Moreover, we assume that this relation is influenced by their personal characteristics (such as motivation) as well as the type and quality of social media interactions.

2.3. Research questions

Research scientists are prototypes of knowledge works. They need to combine different knowledge to solve challenging problems. Therefore, research scientists are permanently in search of new knowledge and up-to-date information on very interdisciplinary topics. Many authors state that most scientists use social media for networking and visibility (Rinaldi, 2014), but it is still not clear if and how social media usage enhanced the development of creative ideas. Moreover there is still a lack of knowledge on factors influencing social media usage in everyday work, like acceptance and organisational support. Therefore profound recommendations for practice and research cannot be given.

We seek to answer the following research questions through a qualitative study of knowledge workers employed in the scientific sector.

RQ1: To what extend do knowledge workers use social media?

RQ2: For what purposes do knowledge workers use social media?

- RQ3: Which opportunities and threats feel knowledge workers in connection with the use of social media?
- RQ4: What influences social media usage by knowledge workers?
- RQ5: Does social media usage have an impact on knowledge management and idea creation?

3. Research approach and methodology

To get more information about the use of social media for the purpose of knowledge creation and idea generation we undertake a case study among a specific sample of employees, namely research scientists from university and non-university institutions, which can be seen as prototypes of knowledge workers. In contrast to universities, non-university institutes are partly private-funded. They operate similar to private firms or private research companies because of a competitive environment.

The research study described in this paper used structured in-depth interviews to gather individual perceptions toward the idea generation and the use of social media sites for that purpose. Consequently, we collect and analyse information on individuals' creativity, sources of information and inspiration, as well as social media activities. Moreover, we collect information on the personality and the institutional affiliation of the scientists – university or non-university – which may have an influence on the impact of social media activities on personal creativity and work performance.

Participants were research scientists in the field of photonics from a university and a non-university institute in Germany ranging from 30 to 45 years of age. Due to the gender ratio of photonics research, most of the participants were males. Although the unfavourable gender ratio the photonics area of research is an appropriate test sector due to its interconnectedness with many other disciplines.

Up to the moment we conducted structured in-depth interviews with four research scientists. We plan to undertake more interviews with other research scientists to expand the database. In this respect we also plan to broaden out the scientific area, which currently is limited to the field of photonics. Therefore, we target to be able to present more profound results at the conference in June 2014.

The interview transcripts were subjected to a content analysis in order to systematically examine the qualitative data. Empirical categories were developed

concerning the emergence and development of ideas, social media experiences of knowledge workers, social media for profession-related communication and knowledge exchange, and the general conditions for social media usage for work purposes.

4. Results

4.1. Emergence and development of ideas

The results show that research scientists are knowledge workers because their main capital is knowledge. Their work is characterised by the primary task of project-based and non-routine problem solving, which need a combination of different knowledge. Interviewees spend a high amount of their time searching for new information. All interviewees have at least university graduation; half of them have a PhD, which shows that they all have a deep background in education.

All respondents state their high dependence on information technology. Even though, the sources of knowledge and the inspirations for new ideas differ. Main sources of information and inspiration are four: (i) the Internet especially search engines – e.g. Google, Google Scholar – and relevant websites, newsletters, newsfeeds, and magazines but also Wikipedia and different specific databases; (ii) direct (and e-mail) contact with colleagues and meetings with partners from industry and science; (iii) scientific conferences and congresses; (iv) requirements from industry and other partners, previous research results.

Several interviewees state that periodically occurring talks with question-and-answer session within the own organisation seem to be very inspiring. Thereby a wide range of knowledge evolves on what the colleagues are working on.

Apart from the Internet, daily newspapers, TV and radio programmes seem not to be noteworthy sources of knowledge and inspiration. Also patent specifications are of secondary importance as idea providers, given that interviewees look at patents not until a statement of a problem or an idea is on hand. The results also show that knowledge workers demand leeway for ideas and freedom of action to show the best results. Good ideas frequently appear outside the office, on business trips, on the way to work, and even during leisure time and sport activities. The following table summarises the main sources of information and inspiration.

Table 1: Sources of information and inspiration.

Internet	Direct conversations	Conferences
- Search engines	- Conversations with colleagues (at the office or at the break room)	- Knowledge on what others do
- Websites	- Presentations and question-and-answer sessions within own organisation	- Information can be combined with own work
- Newsletter, newsfeeds	- Conversations with partners from industry and science	- Sharing of interesting problems and challenges with others
- Wikipedia		
- Professional and scientific journals are widely read online and not as print versions		

In the following we show statements given by the interviewees relating to the sources of knowledge, inspiration, and ideas (interview number and age of the interviewee in parentheses).

Ideas result from requirements. Like when partners say what they need or want. First ideas often evolve in the course of the conversation. [...] Conferences and talks are good. There I get input. I think about it and sometimes I try to combine it with my own stuff. [...] I do sports; that clears my mind for ideas. (No. 1, 33 years)

Somehow ideas are result of previous projects. [...] Exchange with long-standing partners helps a lot. [...] Optics and photonics is a small sector, people know each other and relationships are often very long-lasting. It seems like a big family. This can be good and bad for idea exchange and for cooperation. (No. 2, 45 years)

There ... [at conferences] ... I pick up ideas and I ask myself how can we do this better with our own means. [...] I don't start with patents; I start with an idea or a problem. Patent language is not my much-loved language. (No. 3, 35 years)

Stimuli come from outside the institute; firms ask for solutions and we try to find them. [...] We need this external perspective to get new inspiration for our work. (No. 4, 32 years)

Knowledge workers not only have to collect information and to think by themselves, they also are involved in teams, have to communicate, to exchange knowledge, and to network with colleagues and partners for enhancing and refining ideas. Knowledge exchange happens both within and outside the organisation. Although department meetings seem improperly for substantial knowledge exchange but rather suited for organisational instructions. Interviewees prefer small groups of colleagues and partners

even though many of them recognise the value of one or two outsiders, which are not directly involved in the project.

Most of the time we meet for a coffee in the break room. That's always a good choice when you are at a loss. (No. 1, 33 years)

I know many people at the institute. I just go there and ask. Most of the time I get an answer, or at least a recommendation where to ask again. [...] Sometimes it's good to have some outsiders in the discussion; they open up new vistas and bring new ideas. (No. 2, 45 years)

Our group leader has the most part of customer relations. He supplies us with task and we try to solve and to implement. (No. 3, 35 years)

Large meetings of 30 people or more are too big. They are just to organise duties and responsibilities. [...] Once a while we meet groups from other disciplines like material science or chemistry; we tell them what we do and they tell us what they do. These kinds of meetings are very helpful to get inspirations for new projects. (No. 4, 32 years)

4.2. Social media experiences

Nearly all respondents state that they have personal experiences with social media to a certain amount. It can be confirmed that researchers generally use a variety of different tools. Moreover, it appears that a strict separation of private and work-related social media use is irrelevant for scientific researchers. The interviewees justify this behaviour with two main reasons. First of all social media are seen as one communication channel with same content and same rules of conduct due to the fact that often friends are colleagues or partners at the same time and some colleagues are close friends. Second, the interviewees state that many parallel social media profiles by one person might be tremendously time-consuming, inefficient, and with no added value for information chasing. Anyhow all interviewees keep in mind not to share any confidential information on social networking platforms such as Facebook, LinkedIn or ResearchGate. The respondents of the study are using all four main groups of social media (Mao, 2014):

- *Social networking tools and instant messengers:* All respondents have at least one profile on a social network, where Facebook and Xing (a German version comparable to LinkedIn) are the most common. Some respondents state a request for a corporate or enterprise social network (ESN), which work like Facebook or other social networks but are restricted to use by employees and protected by firewalls – in accordance with Jarrahi (2011). The interviewees argue that people could foster

connections with other members of the same organisation or strategic partners by creating online semi-public profiles (Leftheriotis & Giannakos, 2014).

- *Tools for social publishing, social sharing, bookmarking, and collaborating:* scientific researchers use predominantly blogs, wikis, social bookmarking, although the use of this kind of tools seems not to be very intensive. Some respondents use collaboration platforms frequently, in other cases administrators consider tools like Dropbox or GoogleDocs as security traps; consequently the use of collaboration platforms is restricted in these cases.
- *Social tools for content management and calendars:* Group-scheduling tools (e.g. doodle) are used frequently and very informally. This could be connected to the little amount of information, which is shared by such kind of tools. Moreover, some respondents have little experiences with platforms like Moodle, especially those who are engaged in university teaching. The interviewees do not use other tools.
- *Virtual worlds and gaming environments:* Virtual worlds do not attach any importance to the interviewees in both, private and profession-related circumstances. Indeed most of the respondents have heard about Second Life but do not fully understand the operating mode of virtual worlds.

In the following we show statements given by the interviewees relating to the use of social media applications.

A friend of mine moved to Florida. That's when I started using Facebook and Skype. He works in the same business and it's just good to see what he is doing. Most of the time it's not related to work. [...] Private or work, it does not make much of a difference for me. (No. 1, 33 years)

Google, Goolge Scholar and some newsletters – that's it. [...] I am on Facebook and on LinkedIn. My profile on LinkedIn is kind of abandoned; I arranged it for some international cooperation partners, but now this project is over. I used Xing at the time when I was looking for a job; now I just try to keep my profile up-to-date. (No. 2, 45 years)

I am on Facebook. I used to be sceptic but now I agree. It's nice to stay in contact with old friends; sometimes they also work in the same field. [...] I don't use Facebook for official business. Project-information has no right to be on Facebook. (No. 3, 35 years)

I'm also on ResearchGate, but just at the beginning, my track is not very long. But it looks interesting for me. (No. 4, 32 years)

Altogether the results show that knowledge workers use social media applications like any other professional guild members. They probably are worried about vulnerability and security issues much more than other users. Therefore it seems also that knowledge workers pay attention not to spread any or as little as possible of both personal data and confidential information on social media channels. An exception is probably made by social collaboration platforms such as GoogledDocs or Dropbox, given these tools are often seen as protected areas.

The results also show that the intensity of private and work-related use of social media applications seems to be related directly. The more and the manifold knowledge workers use social media for their private needs, the more intense and multifaceted is social media activity for work purposes. However the sample size is too little to draw conclusions on other influencing factors such as age, gender, and other demographical factors. Nevertheless a general tendency seems to be a negative relationship between age and social media activity. This could be also named as “digital native effect”, which could be noticed in the next years when more workers who where born after the introduction of digital technologies poor into executive positions. These workers have often been interacting with digital technologies from an early age and therefore probably a native understanding of social media.

4.3. Social media for profession-related communication and knowledge exchange

The interviews show some trends and commonalities with regard to the application of social media for knowledge management, idea generation, and other work-related issues. First of all, social media is understood as a natural tool for information search, especially when it is about particular information on specific technologies, processes, products, or applications. In this cases knowledge workers use newsletters, newsfeeds, blogs, as well sharing platforms such as Youtube, Slideshare, TED. Sometimes the numerous sources are brought together on one particular social media platform (e.g. Facebook). Especially young users appreciate the accessibility and the easy ways of forwarding and sharing information with colleagues.

Social network platforms are moderate popular among the respondent knowledge workers. This refers not to the simple question “yes or no” but to the nature and modality of application. Knowledge workers use profiles in social networks primarily to offer information to others and not to interact with others. The profiles are used as substitutes

for traditional offline business cards or as public accessible personal data sheets. By this means scientists try to improve the visibility of the own person, group, and research topic. The interviewees use predominantly Xing and ResearchGate for work-related purpose as well as Facebook for both work-related and private purpose. LinkedIn is known by all interviewees but not in use regularly since it is seen suitable for international partners and somehow inappropriate for national partners. One main reason for using social media platforms is to consolidate contacts made occasionally on conferences or business meetings. A social media relationship makes it easy to keep in touch on a long-term perspective with new “friends”, even if the persons change their employers or affiliations. Such weak relationships may shorten the restraints of contacting others with questions or even project proposals. Insofar social media contributes to crosslinking and interconnectedness of stakeholders, which is an essential requirement for co-creation and diversity of ideas. Some interviewees use advanced functionalities and create groups within a social network to provide well-arranged networks within the larger, more diverse social networks. Groups allow for closed or open access, invitation and joining by others outside the group. In some cases, social networking groups have become important to maintain a structure in ones personal social and professional life (e.g. study groups). The study shows some evidence that a small group with less than 8 people may also be used for work-related discussions.

In the following we show statements given by the interviewees on the profession-related use of social media.

It's just to keep the contact if people move to other places. (No. 1, 33 years)

I don't do much. It's just for information search. [...] I'm member of a Facebook group. There I get some news, like fairs and exhibitions. It could be used for recruitment, because the right people is there. (No. 2, 45 years)

Xing, Facebook, all that has little impact on my job. It would be more interesting if the whole organisation would be on; everybody with it's own profile. That could help to get in touch with more people. Maybe also with some other institutes, but then it's always a question of competition or not. (No. 3, 35 years)

On Facebook I have a closed group together with some friends. We are just four. On this place we talk and debate – sometimes also some professional issues. (No. 4, 32 years)

Within universities and research organisations the main application of social media with practical relevance still are public relations, marketing, and recruitment. Some

interviewees use their own private social media network to invite others to conferences and exhibitions, or to inform others about interesting job offers and contests.

4.4. General conditions for social media usage for work purposes

Results show that knowledge workers use social media for networking activities in their personal context and also in their institutional context. Regarding the general conditions for social media usage it is necessary to distinguish between an individual perspective and a more institutional perspective. From the individual perspective the results show that knowledge workers have many options to integrate social media activities in their work processes. However it seems that a professional and creativity-supporting handling of social media applications is not a normal case but makes an exception. Employees use social media mainly for self-profiling and information search and minimally for idea development and co-creation. Therefore it can be assumed that social media is only to a certain extent integral part of the everyday workflow of most knowledge workers.

From an institutional perspective it seems that degree of management level is negative related with social media activity. This of course could be also a question of age, but nonetheless it has an impact on the organisation. Directors, heads of departments, and heads of research groups seem to be very conservative with social media application. Interviewees state that top management does focus solely on offline networking. Workers have the feeling that top management does not appreciate social media activities; in fact social media is often seen as waste of time. Middle management instead uses some social media applications in a very passive way, such as profiles on research-related social networks (e.g. ResearchGate). However the results show that social media is not associated primarily with value generation but rather with security issues and time issues.

In the following we show statements given by the interviewees relating to the general conditions for social media applications.

My Boss does not use social media. However, there are no rules or guidelines for social media use. So we use dropbox quite often to share and collaborate. (No. 1, 33 years)

It's more an object of the younger colleagues. I know some people who do blogs or something alongside. But it's more for fun. It's always a question of time and one's own initiative. (No. 2, 45 years)

I would allege that our department chief is sceptical and does not see much benefit of social media applications. For him it's more like a waste of time or additional work with little added value. Otherwise we never gave it really a try. [...] Also the IT-department has some reservation due to the security issues. [...] We should try some internal applications. (No. 3, 35 years)

Facebook, Xing and all that does not play a big role. That's my opinion. Department head is very sceptic on it. My group leader is on ResearchGate with a nice publication list. It's like a digital publication list with some cross references. ResearchGate is accepted in our group, as well as Xing is. (No. 4, 32 years)

In university and non-university research institutes, which explicitly are hubs of knowledge work, social media is still considered as a “secondary theatre of war”. Social media activities are not appropriate actions to earn stripes in the professional career of most research scientists. However, all interviewees state that social media activities are widely accepted or at least tolerated by their group leaders, but in no way requested. Some social networking platforms with a focus on work-related use (e.g. LinkedIn, Xing, ResearchGate) are accepted while others (Facebook) are associated with fun, leisure, and pastime. Work groups to facilitate internal and sometimes external cooperation, however, use some social media services, e.g. tools like Dropbox or Skype. Altogether, the results indicate that managers and group leaders focus on security risks and time issues, and underestimate the prospects of social media usage to improve creativity and idea generation.

5. Conclusions

This exploratory study shows that social media is indeed an additional but nonetheless important element of knowledge work processes. The knowledge workers are completely aware of the importance and potentials of social media for their processes. However, some actors – Internet agencies, marketing offices – overestimate the current meaning of social media for knowledge work, whereas the knowledge workers themselves and their managers are often unable to utilize its full potential and to promote them. Therefore it is necessary to develop concepts for an integration, exploitation, and promotion of social media activities in creative and knowledge-based work environments.

Indeed it could be shown that knowledge workers use social media to gather information, get stimuli for research, exchange knowledge, and improve their ideas. Although it can be seen that there are a number of uncertainties associated with social media usage. The findings allow drawing some conclusions. First, social media activities are adequate to expand profession-related networks and to strengthen weak network ties. These activities, moreover, assure visibility, traceability, and relevance of single researchers, research groups and research topics.

To support creativity and innovation in organizations, managers of creative groups need to focus on providing individuals with opportunities to develop their networking skills (Baer, 2012; Ferris et al., 2007). In particular, networking and different types of social relationships gives people access not only to like-minded colleagues but also access to a wide range of different information. Therefore social media supports cooperation in an indirect way.

Second, the acceptance of social media technologies by supervisors and executives is an important issue to consider, due to the fact that knowledge workers often emulate their supervisors or other senior employees. Finally, the results provide evidence to support the claim that social media technologies are structurally different; hence they are used differently to convey different purposes. The findings from this study suggest that scientific and technology-related websites, newsletters, and blogs show a great potential for supporting creativity. In addition, social networking sites are used not only for profiling but also as pin of a personal social media framework, when people integrate blogs and newspapers to their personal social network account. A general tendency seems to be a negative relationship between the intensity and variety of social media activity on the one hand and the age of the users on the other hand. The expected “digital native effect” should provoke more workers who were born after the introduction of digital technologies to poor into managing positions.

Kietzmann et al. (2011) provided a honeycomb framework of seven social media building blocks: identity, conversations, sharing, presence, relationships, reputation, and groups. The building blocks are not considered as exclusive, nor do they all have to be present in a social media activity. However the blocks serve as constructs, which describe specific facets of social media user experience. The results of our study show that knowledge workers currently assign their priorities on four of the six building blocks: identity, presence, relationships, and reputation. The other blocks – conversations and

groups – require a better understanding of challenges and opportunities, and need more elaborated concepts how to integrate these blocks in a typical workday of knowledge workers.

Of course the study has some limitations. First of all it is reckoned that the results of exploratory research are not usually generalizable to the population at large. In particular, the restricted number of interviews strongly limits the generalizability of the results. Therefore we plan future research with a large sample. However, the results provide significant insight into how a small group of knowledge workers use different types of social media technologies. This could lead to the formulation of theories to model knowledge management and creativity on social media. Moreover this study was conducted in the photonics sector, an environment with unbalanced gender population, in favour of men. However, prior research has shown that women constitute an important part of social media users.

Since the study has its restrictions further research should continue investigation social media usage of employees for the purpose of information sharing, communication, and idea generation using a larger dataset. There are still a number of uncertainties associated with the use of social media sites for sharing information. The most important one seems to be the credibility of both, the information itself and the information source (Osatuyi, 2013). Therefore further studies should include additional aspects such as the necessity to provide means of verifying information and the costs of sharing information on social media sites.

Limitless learning: An assessment of how a global firm leverage local knowledge through social media

Breunig, Karl Joachim

Oslo and Akershus University College of Applied Sciences
PO Box 4 St. Olavs Pl., 0130 Oslo, Norway

Structured Abstract

Purpose: This empirical paper assesses the ability to leverage learning within a globally dispersed project environment facilitated by the web 2.0 technology of wiki. Extant research on the knowledge transfer within multinational firms emphasise exchange between HQ and subsidiaries. In contrast, recent developments in organizational learning theory suggest that learning occur at multiple levels; organizational-, group- and individual level. In this paper we explore this tension by empirically exploring the research question: *How is social media utilized in the global organization in order to leverage local learning between dispersed individual experts?*

Design/methodology/approach: The study is based on an exploratory, in-depth single case study of the implementation of an internal wiki in an international professional service firm.

Originality/value: The paper extends earlier research and shows how an international knowledge based organization can utilize web 2.0 technologies to leverage knowledge and experiences from multiple geographically dispersed projects, and how the effects of wiki can be conceived at an organization-, practice- and content level.

Practical implications: The findings identify four determinants of the use of the wiki to leverage local learning within a globally dispersed project environment. First, the wiki must directly relate to the daily work carried out in the organizations projects by offering interactive and updated information concerning current project challenges. Second, the system must enable transparency in the daily project work so that on going activities can be searched. Third, the intention with the search is of lesser degree to identify encyclopaedic information than it is to offering visualization of individual competence and expertise, and fourth there needs to be a sort of quality assurance of the data posted at the wiki.

Keywords: Knowledge leveraging, multinational firm, organizational capabilities, social media, sustained competitiveness

Paper type: Academic Research Paper

1 Introduction

Since De Geus (1988) stated that “learning may be the only sustainable competitive advantage”, there has been an increasing acknowledgement of the fundamental importance of organizational knowledge to firms sustained prosperity (Barney, 1991; Grant, 1991; Petraf, 1993; Spender, 1996; Teece, Pisano, and Shuen, 1997). As an extension of the awareness of knowledge as critical to firms competitive advantage its capacity to effectively and efficiently developing and sharing knowledge have been addressed as determining. The nexus of leveraging knowledge is particularly important for knowledge based organizations such as Professional Service Firms (Løwendahl, 1997; Maister, 1993; von Nordenflycht, 2010). In fact, PSFs are pointed to as models for modern business, and it is assumed that increased knowledge about this type of organizations knowledge based value creation dynamics can highlight important aspects of both competitiveness and innovation based on knowledge intensity (Løwendahl, Revang, and Fosstenløyken, 2001; Pettigrew, Thomas, and Whittington, 2002). Professional service firms have traditionally been described as having a national scope and with partnership structure as the norm. However, recent empirical research on professional service firms indicate that these types of firms are more heterogeneous than originally expected (Malhotra and Morris, 2009). It is particularly evident that an increasing number of professional service firms are internationalizing and as they do they seek to reduce internal heterogeneity to maintain coherence in their international operations (Lovelock and Yip, 1996; Spar, 1997). An important element in achieving this is to professionalize the way knowledge is managed within the professional service firm, and these efforts to standardize offers particular challenges to professional service firms that often are dependent on a high degree of local responsiveness and customization in close client interaction to offer their services (Breunig, Kvålshaugen, and Hydle, 2014). Nevertheless, internationalizing professional service firms are simultaneously dependent on their ability to leverage their globally distributed resource base.

Recently technological developments have revolutionized how individuals communicate and share knowledge across boarder through social media. Social media are channels or platforms that utilize the internet to enable interaction between one or several users such as Facebook, LinkedIn, twitter, Google+, blogging, wikis, YouTube and crowd

sourcing to mention a few. Over 1,5 billion people world wide are currently members of various social networks (Chui, Manyika, Bughin, Dobbs, Roxburgh, Sarrazin og Westergren, 2012). The research on social technologies as applications that enable interaction between individuals have predominantly explored how social media affect the private sphere. However, increasingly there is an awareness of the benefits to organizations from the use and integration of social technology also into the work sphere. The utilization of social technology imply improved collaboration and communication, both internally and between organizations (Kiron, Palmer, Phillips, and Kruschwitz, 2012) and is suggested as a potential source of increased productivity of knowledge workers (Chui et al., 2012).

This empirical paper explores the use of social media in the leveraging of knowledge in one global professional service firm. The question addressed is *how is social media utilized in the global organization in order to leverage local learning between dispersed individual experts?* The paper is build up as follows. First, relevant theory on leveraging knowledge within international organization is addressed in relation to the merging body of research on social media. Second, the research method is presented along with a description of the single case of an international professional service firm. Third, the paper reveals the findings from a longitudinal study of the design and use of internal wiki system to leverage the learning between multiple local project environments. The conclusion offers a discussion of both the theoretical and practical contributions of this paper, and the perspectives it advances for future research.

2 Theory

International business theory purports that multinational firms outperform local domestic competitors due to their ability to learn in multiple locations and build organizational capabilities (Kogut and Zander, 1993). While, Kostova (1999) states that internal transfers of practices are important for all types of organizations, but for the MNC it is imperative because the primary competitive advantage compared to local incumbents is its superior knowledge, which can be utilized on scale in its subsidiaries worldwide. Thus, the reason multinational corporations exist is because they utilize knowledge from different locations to compete with local actors. Anderson et. al (2002) states that the subsidiary is a source of important new knowledge and that the HQ has a

specific role as coordination and distribution mechanism between subsidiaries and thus decides what and how much to transfer to the other subsidiaries. However, the assumption that the required organizational capabilities are equally distributed within one same firm does not consider knowledge boundaries (Carlile, 2002, 2004) and knowledge stickiness (Szulanski, 2003). Moreover, much theory on learning in organizations emphasize how learning often is local and individually shared in face-to-face relationships - such as in communities of practice (Brown and Duguid, 1991; Lave and Wenger, 1991). Crossan, Lane, and White (1999), integrating important insight from organizational learning theory and strategic management, suggests a multi-leveled framework where the learning process involve feed-forward and feed-backward linkages across individual intuiting, group interpretation and integration and institutionalization at the organizational level.

The framework offered by Crossan et al. (1999) thus contrast the main unit of analysis in international business theory as it emphasise the multileveled nature of international operations extended beyond the organizational level with its sub-units to also encompasses the individual and group levels. In the international business literature the multinational firm (MNC) is popularly portrayed as consisting of two major levels, the Headquarter and the subsidiary. Subsidiary units are the production units but with a varying degree of administrative and innovational responsibilities. Despite this organization level focus, Anderson et. al. (2002) also emphasize advantages through learning in individual relationships. They state that it is trough individual relationships the subsidiary absorbs new knowledge from the environment, and this will have a positive impact on its own market performance. In addition, Hansen (1999) addresses the quality of these relations within the MNC and the effect on the ability to transfer facilitated either through technology or individual interaction. Tsai and Ghoshal (1998) also emphasize that relations are important for transfer of knowledge. The HQ provides structures and a context with shared values for creation and development of social capital (Nahapiet and Ghoshal, 1998). The need for common values, shared language and familiar work practices can facilitate development of social capital, but most importantly is the ability to work together and learn for the same experiences. Hislop (2002) discuss the challenges faced when communicating and sharing knowledge via information technology and (McDermott, 2000) emphasize that information technology only can inspire but not deliver knowledge management. However, recent developments in social media promise

to provide a solution to knowledge sharing between geographically dispersed individuals in global organizations (Kaplan and Haenlein, 2010).

There are several suggestions to the various web 2.0 applications, services and technologies available. Synthesizing previous research, van Zyl (2009) suggest six main web 2.0 technologies; Web blogging, Wikis, social bookmarking, tagging, really simple syndications (RSS) and collaborative real time editor. Thus, in the MNC a fundamental prerequisite condition can be ICT transmission channels for cross-border collaboration (Gupta and Govindarajan, 2000). Recent research indicates that wikis, even more so than other social media tools, have afforded individuals the opportunity to collaborate while geographically dispersed relative to other knowledge management technologies (Levy, 2009; Papadopoulou, Stamatib, and Nopparuch, 2013; Razmerita, Kirchner, and Sudzina, 2009; Sultan, 2013). Previous studies addressed the challenges facing knowledge management solely aiming at codification strategy due to the distributed, tacit and sticky (Szulanski, 2003) characteristics of knowledge entailing personal involvement in the development, and sharing of valuable organizational knowledge (Michailova and Gupta, 2005) were individuals volunteer their knowledge and experience as user generated content (Shao, 2009). Moreover, empirical studies reports that hybrid knowledge strategies, combining elements of both codification and personalization of knowledge, in fact are more common in i.e. the software industry (Mukherji, 2005). With web 2.0 the internet is no longer static, but is used to communicate, participate and collaborate in the mutual editing of available information. Consequently web 2.0 is referred to as social media (Paroutis and Al Saleh, 2009). An example of web 2.0 is Wikipedia where several distributed individuals cooperate to produce and update information in contrast to established encyclopaedias where information was static and predetermined by a selected experts (Paroutis and Al Saleh, 2009). In the following chapter, the main focus will be on wikis. "A wiki is a web site that allows online collaboration by allowing multiple users to add, remove or edit content and changing content. It also allows linking among any number of pages." (van Zyl, 2009, p. 908).

3 Method

This single case (Yin, 1994) of this study is based on an in-depth qualitative exploration across several subsidiaries within one global firm. We deploy an explorative

inductive research design justified by the lack of unambiguous theory on the utilization of social media to leverage knowledge and experience within international professional service firms. Qualitative data are useful for generating theory when the existing theory contains inherent contradictions or is poorly investigated (Graebner, Martin, and Roundy, 2012). The firm was theoretically sampled (Eisenhardt and Graebner, 2007; Flyvbjerg, 2011) to enlighten issues related to the need to leverage knowledge between local learning situations to achieve globally shared organizational capabilities through the use of social media.

The research setting of this study is Servco. It provides global third part engineering services and has 18 offices in 11 different countries and across all the three globalization zones (Americas, Euro-Africa and Asia-Pacific). The chosen firm is a global engineering based professional service firm with highly educated technologically oriented individuals, accumulating experiences in projects across the globe and with a highly articulated need to leverage the experiences in globally shared organizational capabilities, and is thus deemed particularly relevant for this study. One service delivery can be performed to one client, by different experts at different places, depending on their knowledge, experience, availability, and costs. Servco tests, inspects, and certifies electrical products, machinery, installations, and systems. In order to offer these services worldwide the products are sent to the component experts who test the product in accordance with which market the product is to enter. That is, which international or national standards agreement the product has to comply with. Standards in this industry are documented in volumes of written material that describe the procedure for tests, as well as the acceptable intervals for different measures. Such standards need to be complied with in order to ensure that the products guarantee certain safety requirements to consumers. The international market for these types of services is highly competitive with respect to price sensitivity, speed of delivery, and expertise.

The case study employed a mixed-method approach (Denzin, 1970) consisting of semi-structured interviews, document and report studies (including internal documents, financial reports, presidential decisions, observations at presidential meetings, project plans, organizational and global bi-annual surveys), as well as participant observations. The study is part of a larger research collaboration where a total of 147 semi-structured interviews, lasting from one hour to two and a half hours, following the semi-structured interviewing convention (Robson, 2002, p. 228) have been conducted between 2003 and

2009. The main objective was to examine how the individuals conduct daily work, communicate with other colleagues, document experiences and search for knowledge within the global organization – with particular emphasis on how new ICT enabled their work practices. The interviews were taped and transcribed. The data collection was also supplemented beyond the interview context with document studies (i.e. from company surveys and internal reports), observations (i.e. visits to laboratories as well as participation in company meetings). Other secondary data sources such as project management procedures, standards, and reports to the clients observed through the ICT systems were especially beneficial. Of the 147 interviews, 35 interviews, have explicitly aimed at assessing the development and use of an internally initiated wiki project. The unit of analysis was intra-firm knowledge sharing practices through the wiki system.

In order to make sense of the data, the analysis progressed in several stages and involved a blend of inductive and deductive processes (Graebner et al., 2012). First, the data was coded in light of the research question and was thoroughly discussed between the researchers and summed up in PowerPoint format. The aim was to get a broad understanding of the general knowledge sharing practices and the particular use of the wiki system. Subsequently, the initial findings were summed up and presented to selected employees and managers in a workshop to validate the data's veracity and enhance the trustworthiness of the analysis (Lincoln and Guba, 1985). Finally, the findings were compared with extant theory in order to extend knowledge on the use of social media in leveraging learning experienced in multiple local project settings.

4 Findings

This study has assessed the cross-border knowledge sharing in the international professional service firm Servco when an internal wiki was introduced.

4.1 The Wiki and the organizational level

When the Wiki was launched management communicated how the system would fit in with the existing knowledge management policy for the Servco group and made it clear what the perceived benefits of the wiki system would be: “ *the top management at HQ was adamant that since we have several specialisations across locations, these would benefit from knowledge sharing tools going beyond emails or one-to-one communication*”

and “Small areas of expertise within different local offices needs more external knowledge sharing and learning possibilities from similar experts within the global organization”. Moreover, Management also pointed out that the competitiveness of the Servco group relied on effective and efficient utilization of its globally distributed resource base: “Need more common documents so that all laboratories have the same way to do things...quality systems, work instructions, test instructions...now each lab have their documents and procedures”.

The general impression is that there exist a positive attitude towards helping each other and sharing knowledge and that the organization would further benefit from increased knowledge sharing and collaboration between its subsidiaries: “Feel that the sharing of knowledge is very important and we need to improve that inside the Servco group, will work more efficient if knowledge sharing is effective”, and “Most people get something from something...each location have their specialisation...lets all participate..I will share something because I would learn something back as well...”. However, prior to the wiki launch there existed limited knowledge about the potential expertise offered at other subsidiaries within the group: “In my local office I know what everyone does..outside our office, I only know a couple of persons”, and “[Without transparency] you are missing the richness of the company...look at the experience.....we have about everyone having about 10 years experience...and some are not asked for sharing experience at all just doing their everyday work”.

There is also a general positive attitude towards the Wiki and most informants have visited the system. The wiki is well communicated; everyone knows about the initiative and applauds it. An illustrative quote concerning the attitude towards the implementation of the wiki system can be: “Prior to the wiki we did not have anything in common[...we all worked independently from each other...minimal contact.” In addition, several informants also express that there only exist a limited barrier to use the wiki system: “Exist a low technical barrier to use, but barriers to use are linked to post questions/answers “, and “The wiki system is easy to use, just 5 minutes introduction, then just to use the system”. Consequently, there is consensus regarding the need for an integrating knowledge and collaboration tool across the distributed project environments in Servco: “Servco has really done a good job spreading the resource base around, for instance, in San Diego the expertise is medical and in Dallas it is Telecommunication”.

One of the results from implementing the Wiki system is a sense of increased membership in a truly global organization as a consequence of the wiki system implementation, and the cherished benefits are improved presentations of local subsidiaries and people: *"Prior to the wiki we all worked independently from each other...we did not work together...minimal contact...did not deal with other offices...we did not have anything in common...not an annual event or something"* and *"Wiki – a common group thing...it would bring up our technical ability"*, and *"Presentations of people through the wiki increase could be extended with a global map, click China, get into China approval and find persons that I can contact – that would be useful"*.

4.2 The Wiki and the practice level

In general there is an awareness of the system and how critical it is that user driven content is generated from the start to ensure the success and utility of the system: *"One of those things...unless you use it, you want see the benefits of it"*. Prior to the implementation of the wiki email was the main tool for knowledge sharing: *"My email box is my database....have access many years back, remember and can look through and refer to that if there are questions"*. The use of wiki is motivated by the need of additional knowledge when conducting project tasks locally: *"When we cannot find answers locally, then we search wiki"*. Moreover, it is acknowledged that it is beneficial to use the wiki to respond to questions and answers across the different subsidiaries as it offers a greater transparency of the cross-unit knowledge and experience exchange than one-to-one interaction over mail, phone or Skype: *"I use wiki, it is new..., but it is good for technical issues to ask questions and everybody can see the question"*, and *"If someone post something I can see any changes made...kind of nice because there is one place to go to instead of emails"*.

The main use of the wiki is related to knowledge and experience exchange needs that originate in the daily conduct of project work, and is predominantly related to sharing technical information and experiences with different standards or client segments: *"Not in an active way, but I take a lot of information from wiki: directives, technical questions related to new rules, discussions etc"*. Originally, search for project related knowledge and experience starts locally and is extended to other subsidiaries if necessary. The contact with other subsidiaries have often been based on individual social networks where

contact have been made face-to-face or through email: *"I used to receive about 10-15 emails a week which I need to check for a clear or correct answer...I need to use an hour for each to be able to answer"* and *"Start by email...because of time differences ...very few cases over the phone"*. Locally, there are also formal arenas to share knowledge and experiences. There are local technical meetings on a weekly basis. However, most knowledge and experience exchange is conducted informally as part of small talk, part of mentoring/junior-senior learning or being part of daily work: *"Technically, we share more there and then when we are working on a project"*.

Thus, the knowledge and experience sharing is by-and-large linked to ongoing project activities and is mainly local. If there are exchanges across different subsidiaries it is because the project task requires coordination or clarification. The search for answers will always start locally before other international colleagues are involved: *"We use all the ways: First we try to answer our selves, then we ask local colleagues, then international colleagues"* and *"Ask the first and the best. Then call someone that might know."* However, many informants reveal how they do not necessarily search the wiki for ready-made answers but use the system to identify individual experts whom they then can contact directly, and if the interaction prove beneficial a short post at the wiki can explain the issues addressed: *"Many of the challenges we face in the projects are so complex and context specific that I will not find a ready made answer at the wiki or in any other internally available data base. What I use the company ICT systems for is to identify people in other offices with experience that might be beneficial to the challenge I face in my project. I then contact them directly, mostly over Skype. If the interaction provides a solution to my project I post what we did at the wiki for others reference later"*. However, finding and identifying people with relevant competence at other locations is not necessarily straight forward: *"There are many people involved in finding the right person/expertise"* and *"Questions are not necessarily targeted to the person in charge"*.

Informants express that the benefit of using the wiki is related to quality and available knowledge to ongoing project: *"The efficiency increases since we share knowledge. No one is holding back knowledge. That is bullshit. We all share. Always someone who shares"* and *"Knowledge sharing improves everyone"*. Furthermore, and in addition to direct search for project related knowledge and experiences, some informants also have pointed out that the system offers opportunities to increase individual learning: *"Others use it for knowledge sharing. I would use Wiki for learning something new about a new*

topic". Some informants also addressed more altruistic motives for engaging and spending time on knowledge and experience exchange over the wiki: "...only the good feeling you get from helping people". However, most of the informants addressed the importance of maintaining an reputation of individual expertise within their area: "It is important to have recognition" and "It is linked to own reputation".

The informants also express that the true utility of the wiki system is that the prior need for an internal social network diminish with the wiki, as there is a possibility to post questions and see if some one answers or refer any particular expert: "I gain network through asking colleagues if they know someone...now it is possible to post a question and see if a relevant resource offers its help or refers me to someone relevant". However, many informants still acknowledge the benefit of knowing people in person before they interact and exchange knowledge and experience over social media: "To know people, having met them...having made up an understanding of their competence when having met them physically". Some informants address the issue of incentives to generate content at the wiki: "A symbolic gesture from the organisation for knowledge sharing. To give a gift certificate (electronic shop etc)" for the knowledge sharer at each location" and "There are credits for inter office sales, but no compensation or incentive for talking an hour with someone from another office". However, several informants also point out that: "The main motivation for spending time posting stuff at the wiki is that my expertise gets recognized in other offices. This increases my possibilities and eligibility of participation in interesting projects within my area of expertise".

4.3 The Wiki and user driven content

Several informants address the essence of the wiki system as its ability to enable user driven content from local project experiences but in a way that is interactive and makes these experiences more transparent between the geographically dispersed experts of the Servco group. However, there is expressed concerns about the quality assurance of the information available at wiki system: "Need to be sure that the information is right and useful....should not lead to uncertainty...therefore items should be verified...", and "We would need someone responsible...going though (the content). Somebody could monitor the wiki...have some way to give approval stamp..". In spite of this worry some informants also point out that this worry was also present before the wiki system: "We

were sharing knowledge on wiki about IT...but the project responsible was worried about posting these questions...fear for misinterpretation...therefore preferring to answer this on email”, yet it is not the same to post a wiki post as response to a question than to address the complexities of a project problem verbally over the phone: “feel that it need to be Quality Assured, perfect before post on the web, not the same as a phone call.”

5 Discussion and Conclusion

This study has revealed the experiences with implementing an internal wiki in Servco, and addressed the research question: *how is social media utilized in the global organization in order to leverage local learning between dispersed individual experts?* The findings from the Servco case reveals how an international knowledge based organization can utilize web 2.0 technologies to leverage knowledge and experiences from multiple geographically dispersed projects. In the case of Servco the implementation of a company specific wiki enabled increased user driven content generation. The nature of the highly specialised projects offered by Servco entail that ready made and codified knowledge repositories are less useful to on going projects. However, the interactive format of the wiki enables increased transparency and visualisation of the expertise of different professionals at the globally dispersed locations The Wiki system is used mainly to document who knows what and as a source o identify people that can be approached directly for advice. The study thus reveals how web 2.0 technologies, such as wiki, can have a positive effect on the leveraging of learning between highly specialised and globally distributed knowledge workers within one firm.

The findings of the study show how the effects of wiki can be conceived at an organization-, practice- and content level. In particular the findings of the study identify four determinants of the use of the wiki to leverage local learning within a globally dispersed project environment. First, the wiki must directly relate to the daily work carried out in the organizations projects by offering interactive and updated information concerning current project challenges. Second, the system must enable transparency in the daily project work so that on going activities can be searched. Third, the intention with the search is of lesser degree to identify encyclopaedic information than it is to offering visualization of individual competence and expertise, and fourth there needs to be a sort of quality assurance of the data posted at the wiki.

Thus, the wiki should not be just another source of internal information but address questions and answers related to ongoing challenges faced when conducting projects. The benefit of the system is increased productivity despite employees investing time on publishing articles on the wiki. The main motivation is related to performing better in local projects by enabling the leveraging of knowledge and experience from other locations into the project. This is more important than incentives to create content on the wiki. If content and interaction through the wiki support the ongoing business this incentivizes the publication, and quality assurance of, the user driven content.

Structured Abstract

Purpose – The purpose of this paper is to investigate how organizations work with IC when it enters the organization from an accounting or measurement perspective. More specifically the paper will investigate in depth the IC 'lock-in' process to accounting, which occurs when IC is introduced as a measurement practice in companies which are new to IC, and if and how IC can be 'un-locked' through a more strategic managerial approach, promoting IC management practices.

Design/methodology/approach – In this paper, the phenomenon of 'lock-in' is used to conduct a longitudinal analysis of the design and implementation of IC practices in an Italian firm which was initially a 'newcomer' to measuring and managing IC. The IC measurement system adopted by the company was developed using an interventionist research approach whereby one researcher was directly involved in designing and implementing the system. To interpret the case study we use Callon's 'four moments of translation' (Callon, 1986) which permits us to follow the actors in their construction and deconstruction of the IC concept and practices.

Originality/value – We show that when accounting for IC is the point of entrance into a firm new to IC, the firm remains, for a period of time, locked-in to measuring IC. However, firms can be freed from a narrow accounting perspective and over time allow more attention to be paid to the process of mobilizing IC, leading to management actions which are not possible while IC remains 'locked-in' to accounting. However, we also find that the 'lock-in' to measuring IC is not always detrimental because, at times, the 'lock-in' is necessary to allow actors to make sense of IC.

Practical implications – By understanding the lessons learnt from the case, other organizations who implement IC practices can become aware that the 'lock-in' phenomenon can take place and so, devise strategies to avoid the possible detrimental aspects of 'lock-in' and understand when it may be beneficial to do so. This can help

managers recognise that to be effective more attention needs to be paid to the process of managing and mobilizing IC.

Keywords – Intellectual Capital, IC Measurement and Reporting Systems, IC practices, Interventionist research, Case Study.

Paper type – Academic Research Paper

1 Introduction

Intellectual capital (IC) as an innovative management technology is a very relevant topic in theory and practice. Over the years, IC research has progressively changed its focus. While, at the beginning, it was predominantly orientated towards theory building and raising awareness, IC research has then turned the attention to gather evidence to justify the use of IC as a management technology (Guthrie *et al.*, 2012). Recently, a considerable number of scholars have suggested adopting a performative approach and orienting research in different directions, more specifically to analyze how IC works in organizations, how it manifests itself, and how people, processes and relationships are mobilized in relation to it (Cuganesan, 2005; Mouritsen, 2006; Cuganesan *et al.*, 2007; Dumay, 2009). Thus, a third stage of IC research has been identified using a critical approach, to study how organizations, understand, adapt and apply IC as a management technology (Guthrie *et al.*, 2012).

Some observations, which are worthy of note, can be drawn from recent studies that investigate how the organizations work with IC when it enters from the accounting perspective, to further measurement aims (Chaminade and Roberts, 2003; Cuganesan, 2005; Cuganesan *et al.*, 2007; Dumay, 2009). Chaminade and Roberts (2003), in particular, highlight that the point of entrance of an IC project, in companies that do not have previous experience with IC, has a strong influence on the development trajectories of the project. If accounting is the entrance point, then the focus will be on its measurement and little attention will be initially paid to IC management processes. Therefore a “lock-in” to the accounting domain takes place, whereby the actors’ attention will be predominantly orientated towards measurement issues instead of towards management issues. The authors point out that more benefits are obtained when a different point of entrance is used, specifically a strategic one.

Research conducted by Cuganesan *et al.* (2007) and Dumay and Rooney (2011b) shed further light on the IC ‘lock-in’ to accounting phenomenon. In studying the IC

'codification-ambiguity paradox', the authors show how IC ambiguity can help preventing a 'lock-in' phenomenon. IC ambiguity, in fact, allows managers to apply IC to their problems (Cuganesan *et al.*, 2007) and to achieve their individual goals (Dumay and Rooney, 2011b). These authors also call for further research to understand more in depth the role of IC ambiguity and how this ambiguity helps to mobilize IC practices rather than IC measures.

In keeping with the third stage of IC research, this paper attempts to respond to this call and to the call for performative research on IC, by investigating if it is possible for an organisation to initially implement and 'lock-in' IC accounting and measuring practices and subsequently 'un-lock' IC through a more strategic managerial approach. Thus, we hypothesise that if IC becomes 'locked-in' as an accounting framework, IC will get lost inside the organisation and only by 'un-locking' IC by way of allowing managers to use it to achieve individual goals within a strategic context will it ever be effectual. In order to explore this hypothesis we propose a longitudinal case study, our research site being an Italian utilities company which introduced an IC measurement and reporting system in 2004. Using Actor-network-Theory (ANT), we will follow the actors in their construction (lock-in) and de-construction (un-locking) of IC. The longitudinal analysis will be used to untangle the dynamics which are at the basis of the 'lock-in' to accounting phenomenon and of the un-locking of IC.

2 Literature review

Contemporary research into IC as an innovative management technology has taken a turn towards understanding IC in practice in what (Guthrie *et al.*, 2012) identify as the third stage of IC research. Originally, Petty and Guthrie (2000) outlined two stages associated with developing IC as a research field. The first stage efforts focused on raising awareness and understanding IC's potential of creating and managing a sustainable competitive advantage. The output of this research was the creation of frameworks and guidelines such as the Skandia framework (Skandia, 1994), and the MERITUM (2002) and Danish guidelines (Mouritsen *et al.*, 2003) and firmly establishing an IC discourse. Typically, early academic papers then argued that "intellectual capital is something significant and should be measured and reported", without referring to specific empirical research (Petty and Guthrie, 2000, p. 162).

In contrast, the second stage of IC research established IC as a legitimate management technology and gathered evidence to justify its use (Petty and Guthrie, 2000, pp. 155-6). This research focussed more on applying IC frameworks because of their potential value creation impacts including impacts including increasing profits and their impact upon capital markets. Unfortunately for the proponents of IC, this argument soon began to fall by the wayside as some of the earlier proponents and participants in the original development of IC as a management technology abandoned their initial enthusiasm for managing IC, e.g. Skandia (Dumay, 2008a). Thus, the espoused benefits of managing knowledge resources have often not been realised recognised in practice (O'Donnell *et al.*, 2006; Dumay, 2012).

Therefore the third stage of IC research emanates from the failure of IC to become entrenched as a management technology and “ is characterised by research that takes a critical examination of IC in practice” (Guthrie *et al.*, 2012). Thus, the origins of the third stage are based on reluctance of organisations to take up IC practices despite the evidence that managing IC had beneficial impacts causing some pundits to declare that IC was at a crossroads of relevance (Chatzkel, 2004; Marr and Chatzkel, 2004). Since then there has been an increasing interest in investigating how IC is utilised and taken up inside organizations especially when IC enters from the accounting perspective, that is to say for measurement aims, using a performative approach (Cuganesan, 2005; Mouritsen, 2006; Cuganesan *et al.*, 2007; Dumay, 2009). Thus, the third stage of research takes a critical look at how individual organisations understand, adapt and apply IC as a management technology, especially in organisations who are attempting to manage IC for the first time.

In keeping with the second stage of IC research Chaminade and Roberts (2003) investigated how IC entered into organisations. In their research they compared two different ostensive IC research projects, one in Spain and one in Sweden, aimed at introducing an “intellectual capital management system” into organisations (Chaminade and Roberts, 2003, p. 737). In their paper they highlight that the point of entrance of an IC for firms that do not have previous experience with IC, or newcomers as they call them, is particularly relevant for the development trajectories of the project. Thus, the objectives that drive an IC project and its champion, such as the desire to measure IC, define the vocabulary through which IC is introduced and influence the meaning attributed to IC

therefore affecting the way the organization develops its IC (Chaminade and Roberts, 2003, p. 743).

Chaminade and Roberts (2003, p. 747) also highlight that IC is a vague concept for IC newcomers and its meaning is built as they start experiencing IC practices. Thus, if accounting is the entrance point and the initial objective is to measure IC, then the focus will be on measuring IC and less on managing IC. Conversely, if IC is introduced with a strategic managerial intent, for example, to develop new practices for creating value through the exploitation of knowledge, then IC is used as a means of transforming IC resources rather than as a means for measuring IC. In the process firms aim to discover how value is created from IC and to reflect on how they can further influence its creation. However, Chaminade and Roberts (2003, p. 748) found that when IC enters an organization from the accounting perspective, a 'lock-in' to the accounting domain takes place. Therefore the organization is functionally locked in towards measuring IC rather than managing IC which can be detrimental because it can reduce the "potential for change and novel management actions".

These findings are similar to more contemporary studies of understanding the differences between the focus on measuring and managing IC. For example, Catasús *et al.* (2007, p. 505) found "that that the relationship between indicating and acting is not significant and that the introduction of mobilizing gives a better model fit". Similarly, Dumay and Rooney (2011a, p. 344) found that "that it is possible to effectively implement IC practices without necessarily needing concrete IC measures" because organisational measurement needs continually evolve depending on factors such as the bespoke characteristics of individual organisations; changing internal and external political, social and economic environments; and evolving business plans and strategies". Therefore, from a third stage IC research perspective it would be fruitful to investigate if it is possible for an organisation to initially implement and 'lock-in' IC accounting and measuring practices and subsequently 'un-lock' IC through a more strategic managerial approach. In this regard we are interested in investigating the process that leads to IC 'lock in' accounting as well as investigating the process of 'un-locking' IC.

Some recent research can help explain the 'lock-in' phenomenon. For example, Cuganesan *et al.* (2007, p. 906) highlight a "codification-ambiguity paradox" which limits the ability for the organisation to take-up IC practices. Thus, a highly codified system of measuring IC may well reduce the need for employees to make-sense of IC, but limits the

opportunities employees may have to become interested and to participate in IC practices. Thus, the take-up of IC within the organisation may be limited to those who are 'locked-in' to measuring and reporting IC. On the other hand, the ambiguity of IC allows for employees to connect with IC and to make-sense of it and allow them to apply management practices to "the problems that they perceive themselves facing" (Cuganesan *et al.*, 2007, p. 907) allowing for change and innovative management practices.

Dumay and Rooney (2011b), building on the "codification-ambiguity paradox" in relation to a controversy between the use of IC numbers and narratives, identified how the ambiguity of IC allowed both IC numbers and narratives to be used depending on the context of the problem managers were trying to solve, thus not privileging one over the other. More specifically they showed how the ambiguity of IC prevented a 'lock-in' of accounting numbers which allowed managers to achieve individual goals, rather than stick to a one size fits all measurement system. They concluded that the power of IC as a management technology is based on the ability of the concept of IC to entice people to act thus shifting IC from a *'principle'* to a *'practice'*.

While Dumay and Rooney (2011b) are silent on the power of the ambiguity of IC to help 'un-lock' IC they do propose that further research is needed to understand the ambiguity and how it helps to mobilise IC practices rather than IC measurements as they outline below:

"The challenge for social scientists, researchers and managers is to accept ambiguity where they find it, accepting the power of ambiguity as much or even more than the potential confusion it creates. Should IC be reduced to a 'black box' of codified measures on which researchers and practitioners agree it would make IC stagnant and inflexible."

Furthermore, they draw on Latour (1986, p. 264) to explain that "IC needs to be "negotiable, [...] practical and revisable" mirroring the nature of society as opposed to being a fixed framework to be applied in a consistent manner. Otherwise, it becomes lame and ineffectual" (Dumay and Rooney, 2011b). Thus, we hypothesise that if IC becomes 'locked-in' as an accounting framework, IC will get lost inside the organisation and only by 'un-locking' IC by way of allowing managers to use it to achieve individual goals within a strategic context will it ever be effectual. Thus, in order to explore this hypothesis we present a case study based on research into the implementation of an IC

measurement system at an Italian utilities company. Here we investigate how IC became ‘locked-in’ and how IC was subsequently ‘un-locked’.

3 Theory and research method

Drawing on previous literature we intend to explore further the IC ‘lock-in’ and the ‘un-locking’ phenomena and we will use Actor-Network Theory (ANT), specifically the four moments of translation as identified by Callon (1986): problematization, interessement, enrolment and mobilization.

Problematization is the phase in which an actor formulates a question (a problem) that other actors can be interested in taking up in order to achieve their specific interests. In other words, solving this problem serves as an *obligatory passage point* for the actors to reach their aims. The actor who formulates the question also determines the set of actors to be involved to form the network, defines their identities, their interests and problems as well as the links between them. In this way, this actor ‘speaks for the others’ and can be considered the centre of the network (Callon, 1986, p. 214).

In order to make the actors accept the proposed roles and, therefore, accept to ‘pass through’ an *obligatory passage point* to achieve their aims, the actor at the centre of the network uses a set of *interessement* devices. These devices are aimed at building a *consensus*, between each entity¹ and the centre of the network, around the proposed links. While doing this, the centre of the network attempts to undermine or break all possible links among the entities which could propose a different and competitive problematization. In fact, it is always possible, for an actor, to refuse to being integrated in the initial network, thus defining its identity and its interest in a different way (Callon, 1986, pp. 208-9).

The *interessement* is successful if the involved entities accept the proposed roles and aims, thus forming an alliance. In this case, it is said that *enrolment* occurs. On the contrary, the entities who dissent and do not accept the proposed transactions are not enrolled and do not take part in the network. It has to be highlighted that the alliance, once formed, is temporary, and all links need to be held in place and stabilised continuously. Therefore, the process of translation never ends. All in all, to translate means ‘to displace’ dispersed entities from where they originally are and, through a series

¹ Callon uses the term *entity* to refer to ‘parts’ of the network as opposed to ‘actors’ specifically.

of transformations, to mobilize them so that they form an alliance with other actors, and finally are reassembled at a certain place and point in time (Callon, 1986, p. 216).

As stated, the use of Callon's four moments of translation to interpret the story, as told in the next section, can help us understand the process of IC 'lock-into' accounting and how IC was 'un-locked' and transformed into management actions. The translation process permits us to follow the actors in their construction and deconstruction of the IC concept and, therefore, IC 'lock-in' and 'un-locking'. By understanding how and why the 'lock-in' occurs, and how 'un-locking' process develops can help prevent or lessen the detrimental aspects of the IC 'lock-in' to accounting phenomenon (Chaminade and Roberts, 2003) and help manager's recognise that to be effective more attention needs to be paid to the process of managing and mobilizing IC (Catasús *et al.*, 2007; Dumay and Rooney, 2011a).

In this paper, a case study analysis will be presented using an interpretive approach (Scapens, 1990; Ahrens and Dent., 1998; Denzin and Lincoln, 1998). The case study method is appropriate for our analysis because implementing a system for measuring and reporting IC means introducing a *new* accounting technology, with characteristics and an underlying logic which are *new* for the people involved. Therefore, this has an influence on them and on their way of perceiving the reality of the phenomenon under study. The interpretive case study based approach permits us to 'hear the voice' of the actors which is particularly suitable when ANT is used (Latour, 2005).

Consistent with the interpretive approach we have adopted a narrative approach to tell the *story* of IC 'lock-in' from an accounting perspective and its subsequent 'un-locking'. Along with our narrative, diagrams are provided to help visualize the links among the entities and to clarify aspects which are crucial when forming a network (Callon, 1986), thus supporting the use of a case study analysis (Miles and Huberman, 1984; Scapens, 2004). Additionally, we also need to understand the role and the aims of the actors involved in the project, thus it is important to focus attention also on the method used to conduct the actual research project and develop the story, replete with its characters and their roles. Most importantly, the role of the researcher in this story is central to its outcomes and is explored next.

The case study outlined in the next section was conducted using an interventionist research approach. This approach implies using a case study method whereby the researcher cooperates with the host organisation promoting solutions to actual problems

and contributing to theory, at the same time (Kasanen *et al.*, 1993; Lukka, 2000; Jönsson and Lukka, 2005; Dumay, 2010). As Jönsson & Lukka (2005, p. 4) explain:

In this sense interventionist research is field experimentation where the researcher, not having complete control over the design of the experiment, seeks to determine the experimental situation through observation, acts on that situation in concert with the host organization, observes process and outcome, and analyses findings in view of the relevant literature [...] In principle, interventionist research does not need to limit itself to applying the case method only, but in practice this appears to be the case.

In our story the researcher participated in three distinct phases:

- Phase 1 – from the middle of 2004 to July 2005: Designing, developing and implementing an IC measurement system leading to publishing an external IC Statement (ICS);
- Phase 2 – from late 2005 to the end of 2007: the company worked with IC;
- Phase 3 - from the beginning of 2008 to July 2008: a new ICS was written.

During the three phases a different mode of intervention was adopted. In the first phase, the case study research was conducted using a “strong” interventionist approach (Jönsson and Lukka, 2005, p. 23); more specifically, the constructive approach method was used. Therefore, one of the two researchers cooperated with the organizational actors to design and implement an “innovative construction” being an IC measurement and reporting system. This permitted developing insights into this change process, thus allowing the researcher to make both practical and theoretical contributions (see Kasanen *et al.*, 1993; Lukka, 2000; Jönsson and Lukka, 2005; Dumay, 2010). This construction of a IC measurement and reporting system had already been implemented by the researcher in another organization, therefore, the adoption by the company under analysis permitted her to refine the construction and to further test its usability (Kasanen *et al.*, 1993; Lukka, 2000).

During the ‘strong’ interventionist phase, the role of the researcher was that of a ‘member of the team’, so she was involved in decisions, in actions and was considered responsible for the achievement of the objective together with the organizational participants. Consistent with the interventionist approach, active participant observation is

the main 'research weapon' used; nevertheless data was also collected through interviews and reviewing internal documents (Jönsson and Lukka, 2005; Dumay, 2010).

Over this period, in situ active observation was carried out, therefore, the researcher actively took part in meetings with the company project leader, aimed at designing and implementing the system, at collecting and analysing the information on IC. Several meetings were attended and approximately 50 days were spent in working with the organizational actors for designing and implementing the model; moreover approximately 20 semi-structured interviews were conducted, with executive and practice managers. When managers accepted, interviews were tape recorded. When it was not possible, at least two research assistants were involved in the interviews in order to take notes and transcribe them. Notes, taken during the interviews and in the field, were revised, reworked, put in a more formal fashion and enriched, by the researcher, with aspects and impressions, which were considered to be important for the future analysis, but which it was impossible to write *in loco*, as soon as possible, preferably, within one day (Eisenhardt and Bourgeois III, 1988, p. 741; Scapens, 2004, p. 267).

The risk of 'going native' (Jönsson and Lukka, 2005, pp. 8-9) associated to interventionist research, was dealt with by establishing periods of absence from the company in order for the researcher to keep the 'research gaze' (Baxter and Chua, 1998, p. 77). Moreover situations in which the personal involvement was high were highlighted in the field notes, so as to pay more attention on them when analysing the empirical material collected. An exchange of reflections and ideas also occurred between the researcher and an assistant researcher (a PhD student), who cooperated in conducting interviews, collecting information and analysing company documents. As Atkinson and Shaffir (1998, pp. 57-8) explain these are problems to be addressed by qualitative researchers:

While the issues of researcher neutrality and research objectivity are salient problems in qualitative research, they exist in all forms of research, a fact overlooked when quantitative researchers criticize qualitative researchers for their seeming lack of objectivity [...] The challenge, then, is to recognize that problems of bias and neutrality are common to all research and to determine how to best deal with them.

In the second phase, from late 2005 to 2007, after the first design and implementation, the intervention mode was changed from 'strong' to 'modest' because this allowed the researcher to help the organisation learn how to use the IC it had just discovered (Jönsson, 1999, pp. 9-10). Here, the researcher stimulated the change process and the actors' reflection and articulation on latent ideas, in order to increase their 'awareness' about the actions undertaken and the reasons behind them. The interviews and the discussions were not aimed at telling the actors what they should do, instead they were aimed at understanding how actors were using IC information and to focus attention on what they were doing next. The most important research weapons, in this period, were interviews and talks concerning the 'critical aspects' of what was happening. The researcher provided her point of view on the changes that were occurring but were 'limited' to suggestions rather than strong interventions; therefore the changes which occurred were mainly under the organisation's control (Jönsson, 1999, p. 10) In the third phase, during 2008, the mode of intervention changed again into 'strong', when a new external ICS was designed and implemented¹.

Because this paper is not focused on the IC measurement and reporting system's characteristics, will have briefly illustrated the system used in Appendix 1. We also consider it useful to comprehend developing the IC system rather than critique or espouse its merits because we are concerned with how the notion of IC has been introduced, and how it influences the way IC has been internalised, interpreted and mobilized. As Callon (1986, p. 201) advocates:

...the observer must consider that the repertoire of categories which he uses, the entities which are mobilized, and the relationships between these are all topics for actors' discussions. Instead of imposing a pre-established grid of analysis upon these, the observer follows the actors in order to identify the manner in which these define and associate the different elements by which they build and explain their world.

Thus our story begins...

¹ For a more in-depth look at the different roles that a researcher can play in interventionist research such as 'expert', 'member of the team' and 'comrade', see Jönsson and Lukka, 2005: pp. 20-1.

4 The case study

The story of IC at Company B unfolds over a period of five years from 2004 to 2008. As indicated above, during this time IC developed over two distinct periods, from 2004-05 and 2005-08, each culminating in the production of an external ICS. In this section we will allow the story to unfold of how the entities of the network formed to initially ‘lock-in’ IC as measurement device and then how after the initial objectives of the network achieved the network was transformed, allowing IC to be ‘un-locked’. We will first describe the motivation behind Company B’s foray into measuring IC and then outline the story of IC in each of the subsequent stages. Then, in order to understand the story how IC became utilised in Company B we will follow initially the movements of a single actor, one of the authors of this paper who is an IC researcher, through the construction (‘lock-in’) and deconstruction (‘un-locking’) of IC using Callon’s (1986) four movements of translation. We will first follow them through the process of translation whereby other actors in the network are identified and how they interacted with the development of the first ICS. What follows after that we reveal later.

4.1 Why IC

Company B is a utilities company which manages services related to maintaining water supply (potability, wastewater treatment, sewers), providing energy resources (distribution and sale of natural gas and energy, energy savings, etc.), managing environmental services (waste collection and disposal, street cleaning, composting) and providing public lighting. As a medium-sized company it has 300 employees and its shareholders are 21 municipalities, all located in the northern and central Italy, where it operates. Over the last ten years Italian local public utilities have undergone radical changes caused by the progressive deregulation of traditional monopolies. This has created a competitive market for the supply of public utilities resulting in a push for these companies to take advantage of new growth opportunities.

In this context, company B is pursuing an internal growth strategy aimed at taking advantage of the existing synergies among its core businesses of water, energy and environmental services and exploiting its core competencies enabling entry into new markets such as renewable energy sources. It also is striving to improve the efficiency of

its organizational processes. These choices were by a desire by senior managers to maintain the company's culture consistent with its core value of "doing things well".

Over time we have tried to establish and perform a strategy coherent with our culture and our values. More specifically, we pay great attention to social values and, among these, to correct and fruitful relationships with suppliers, whether they are big or small-sized companies, public or private. Two key words guide our action: 'respect' and 'cooperation' with those we work with. This means a high respect for environmental laws, investments in the geographic area served by the company, cooperation with the stakeholders. We like to do things well which implies a strong attention to competencies, without forgetting the need to control costs and the need to always display ethical behaviour.

[Head of Human Resources, Information Technology and Quality Department (HRTIQD)]

In 2004, the Head of HRITQD took the initiative to launch a project for measuring and reporting IC. Besides the responsibilities related to establishing the strategies and the policies for developing the company's human resources and information technology, he was the person who had been in charge of developing the ISO 9001 quality system and had been one of the promoters and a passionate supporter of Company B's sustainability report. Having read some articles about IC, he began to think that measuring and reporting the company's IC could be the "natural development" of a process begun in the 1990s when the company progressively and explicitly decided to orient management attention towards its softer aspects.

For me measuring IC is both the apex and the new point of departure of the process of managing intangible assets that began in the Nineties when we decided to obtain a quality certification (ISO 9001). This journey reached another important stage a few years ago when we decided to produce a sustainability report. The IC statement should show what we have done, in the last few years, to develop the company personnel and our information system, to improve the knowledge management process, to try to fulfil our customer needs. The quality system implemented some years ago gave a boost to this; through the sustainability report we have disclosed how we

take care of our employees and our customers, but I have a feeling that with this report we can do more, both for improving the company management and the disclosure of information. Measuring IC should help me to show that all efforts made, in the last years, to develop the company information systems, the organizational structure and processes, to be clearer, the company incentive system, the competence measurement system and employees' competencies have yielded important results, have generated benefits for us and for the stakeholders.

[HRTIQD]

The aim of the head of HRITQD was also to publish an external ICS in order to complete the company's external reporting system complementing the financial and sustainability reports. He believed the synergetic use of these three documents could provide company and its stakeholders with a 360-degree view of how the organization utilised its financial, environmental and intangible resources linked to how Company B created value for its stakeholders.

4.2 Phase 1- Accounting for IC: 'locking-in' the ICS (2004-5)

Problematization

As Callon (1986, p. 203) outlines, the first moment of translation is problematization or how a researcher becomes indispensable. In this case the head of HRITQD heard about an IC measurement project one of this paper's authors, as an academic researcher, had carried out in another Italian company and in early 2004 contacted her. As a result, three meetings were organised between the researcher and the head of HRITQD. At first, there was the need to get acquainted with each other as the researcher wanted to understand the company's expectations and know more about its business and strategy whereas the head of HRITQD wanted to understand what it meant to measure and to report IC and if it could meet his expectations. He also wanted to know more about different ways of measuring IC and of the characteristics of the IC model designed by the researcher and used in the other company as he outlined in an early interview.

I want to make a conscious choice of the best way to measure the company's intellectual capital. I have heard about the possibility of

expressing IC value in one single financial measure. Is it possible? How can I understand which part of it is attributable to each intangible resource, to competencies for example?

[HRTIQD]

Afterwards, an abundant exchange of phone calls, e-mails and the forwarding of company documents followed. In return the author prepared Power point presentations on IC as well as *ad hoc* documents specifically prepared for clarifying the manager's doubts on IC measurement and reporting were produced. Initial documents and reports aimed at analysing company IC, on the basis of what emerged from the discussions and company documents, were written by the researcher. A further meeting with the project leader of the first company who was adopting the IC measurement model took place because the Head of the HRITQ department wanted to 'hear the voice' of somebody who had already undertaken a similar project. He wanted to be reassured about the possibility of successfully carrying out this kind of project considering time constraints and the availability of information needed for implementing an IC measurement system in Company B.

It is of the highest importance for us to end the project in one year; we have to be ready to publish the IC statement to supplement next year's Financial Statement. So, you see, there is not much time and we should not underestimate the fact that we usually use financial measures to control company performance, turnover, costs, investments... we have plenty of this information but I think it would be impossible for us to produce all the measures you need, I mean, I saw the ones the other company used and we do not have many of them and we cannot ask for the help of the controlling function, they are too busy.

[HRTIQD]

Thus, even though the head of HRITQ was satisfied that the first company was capable of measuring IC he was not sure Company B was able to. Thus, questions remained. Does Company B have enough information to measure IC? Do we have the resources to measure IC? Will our people co-operate and help us to measure IC? Can enough IC measures be found to justify an ICS?

From the company documents examined by the researcher it emerged that the overall company management control system was predominantly based on financial measures, thus confirming that view that overall company performance was driven by financial outcomes. However on a departmental level, such as the HRITQD and the departments which controlled the company's three prime business areas, there were local management control systems, which produced results which were, predominantly, of a non financial nature. For example, the produced figures on the number of clients and client satisfaction. Additionally, the existence of a well developed company-wide quality system as well as of the existence of a sustainability report supported the provision of data which could be useful for measuring IC. Thus the questions raised by the head of HRITQD were now ready to be answered.

The researcher and her PhD student working on the project offered their help in measuring IC that managers in the operational departments found difficult to discover given, of course, the availability of the necessary data. Thus, the researcher along with her PhD student through their analysis of company documents, their ability to measure IC and by providing an "IC measurement model" became the obligatory passage point (OPP) in the relationships they were building with the head of HRITQ. Thus the problematization became complete as the researchers became indispensable to the project because they held the knowledge about what IC was and how to measure it (see Callon, 1986, p. 204). Because the researcher plays the central role in the alliance she can be considered the head of the network, "the one who speaks for the others" (Callon 1986). In fact, she is the only one who had previous experience in measuring and reporting IC and thus without her presence the network would falter, therefore she has the ability to define the other actors who participate in the network. More specifically, she is able to define how the actors need to combine in order for the network to form. Thus the researcher defines the actors in our story as follows:

The head of HRITQD: this man is very satisfied with the results obtained through the implementation of a Quality Management System and the Sustainability Report, two projects under his control. This made him open and curious about the opportunities offered by new measurement and management technologies which could improve company management and disclosure. He was eager to explicitly show the results obtained through investing in people, technology, knowledge and understanding

customers. In addition, he thought that Company B needed to improve disclosure in a changing business environment.

The president of the board of directors: without the support of the president the project could not be implemented. It is through his symbolic support of the project that adds weight to the participation of the other departmental managers. In turn the president was interested in the economic benefits that measuring and reporting IC could provide. Additionally, the president trusted the head of HRITQD thus adding additional validity to the project.

Other department managers and their subordinates: the cooperation of the three heads of the operational departments and their employees are needed for the network as they are the gatekeepers of the data which is required to measure IC from their perspective. In turn they need to be convinced that it is worth their time and effort to participate and benefits will flow to them from their participation.

Intellectual capital: IC is the non-human actor in the network and is required because its concepts, frameworks and theories are essential to bind the network together. IC needs to impart itself on the network and help answer the questions of whether or not it can help communicate the value created as a result of measuring and managing it.

Apart from identifying the actors in the network the researcher identifies that each of the actors needs to come together through the OPP because no progress can be made towards communication the value of IC until it is measured and reported. Thus in order to accomplish the IC project, a 'holy alliance' (Callon, 1986, p. 206) was required to be formed with different actors at Company B: the researcher, the head of HRITQ, the president of the board of directors, other department managers and their employees, finally, a non-human actor, intellectual capital as outlined in Figure 1.

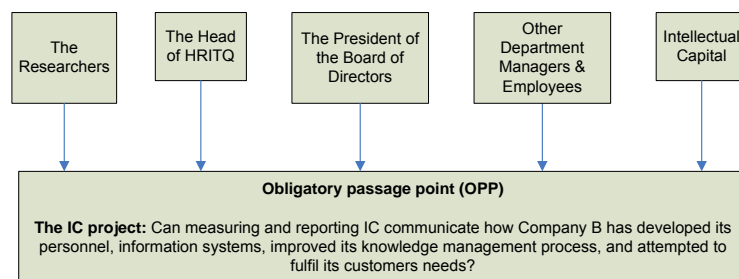

Figure 1: Establishment and linking of the Obligatory Passage Point (OPP)

This is not to say that all of the actors involved in the network were rallied around a common objective. In this sense the goals of each of the actors were different and so too were the challenges they faced in achieving their desired outcomes as outlined in Figure 2.

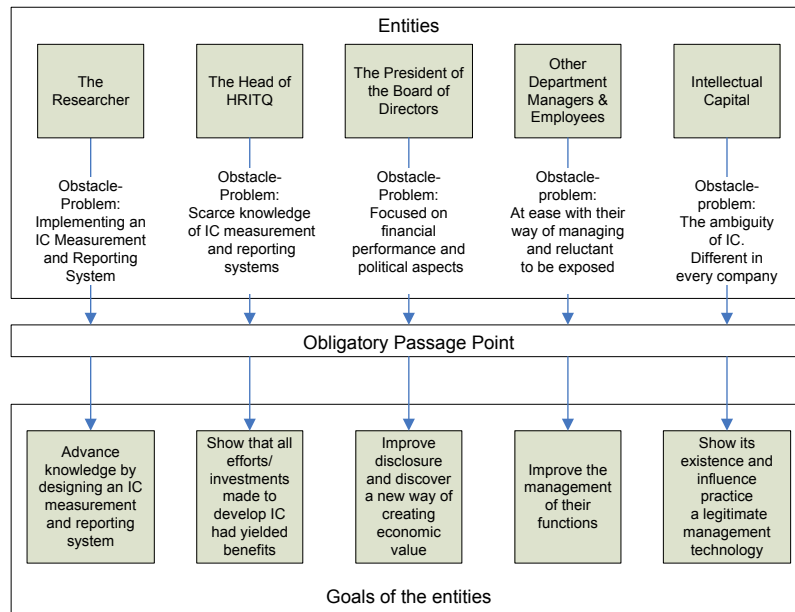

Figure 2: Obstacles and goals of the entities of the network

Interessement

The next moment of translation is interessement because at this stage the network has hypothetical qualities. As Callon (1986, p. 207) adeptly states:

At this point in our story, the entities identified and the relationships envisaged have not yet been tested. The scene is set for a series of trials of strength whose outcome will determine the solidity of our researcher's problematization.

Thus what we are interested in at this point is whether or not actors become part of the network or reject it. In reality this happens on a progressive basis through our interaction with actors, even though we, as does Callon (1986, pp. 207-8), recognise that the network, its problematizations and the identities of the obstacles and goals of each entity of the network are conjointly formed during action. Thus the purpose of the analysis is to understand how the network stabilises, or as in our case 'locks-in' an accounting for IC.

When the project officially started the Head of HRITQ Department decided to assume also the role of company project leader and to share the responsibility of accomplishing the project with the university researcher. So from this point we will call him PL in his new role.

In order to start the project, the PL decided that the support of the president of the board of directors had to be gained. It was the PL who illustrated the opportunity to him of using an ICS to complement the communication towards the stakeholders, showing all benefits related to IC disclosure, especially in light of the need to improve the quality of external communication for cooperating with new partners. As a result the president outlined his support for the project:

Communication transparency towards the stakeholders has dramatically gained importance in recent years. We had to follow new legislation, think of the 'Carta dei Servizi', but we have deliberately chosen to do more, we want to be as open as possible, using our web site, producing a Sustainability Report and using all useful devices. I am very proud of what we have done in the last few years and I think this is the right path to follow in the future.

[Company President]

Even though the president was the official sponsor of the project but in many interviews the other managers referred to the project as “the Head of HRITQ Department’s Project”. The project leader also pointed out the organizational effects of this situation. For instance, talking about the difficulty in involving other managers in the Project, he observed:

“Actually it is very difficult to involve people other than those who are in my Department in the project. I have realized that the possibility of including other people in the design and implementation of the system and in its use depends on the ‘organizational power’ of the project leader. In any case, we can continue even without the cooperation of some of the managers”.

[PL]

The PL was responsible for establishing strategies and policies concerning organization development, company personnel, information systems, quality assurance and security

systems. Being also the Head of the Department, the involvement of practice managers working in this area was relatively easy. Critical relationships such as those with customers, suppliers and technical municipal officers were controlled by managers belonging to other Departments. Therefore, in order to design and implement the IC measurement and reporting system, there was the need to obtain the cooperation of these managers.

I believe that the company, and mostly my colleagues, the other managers, could benefit from IC. We usually use financial measures to control our performance and these measures cannot grasp the real value of good relationships which have to be expressed in a different way.

[PL]

In order to involve company managers in the project, the researcher thought it would have been advisable to organize a company meeting so as to present the project and its aims. In the researcher's intention, this meeting should have been 'open to discussion' in order for the managers to express their opinions and doubts on the project. This would also help to 'clear the way' for further talks during the subsequent interviews. Since it was not possible to organize this kind of meeting, an announcement of the project, through the 'company newspaper', was done. At the same time, in order to gather information, the researcher spent some time in the company premises with the project leader. Being 'around' the offices gave her the opportunity to be introduced to other managers and, thus, to begin talking about the project. In the meanwhile, the project leader acted spontaneously as 'harbinger': he was enthusiastic about the project; therefore, he seized any opportunities to talk about it.

However, the most important opportunity to talk about the project and to interesse managers was offered by interviews. In order to 'prepare' them, the researcher followed two directions. She acquired knowledge about utility companies and their business, in general, and about company B, in particular, by reading several company documents, ranging from strategic plans, to internal managerial control reports, external reports, customer satisfaction analyses, and any other available documents.

The semi-structured interviews were organized as follows. First of all a presentation of the project (e.g. its characteristics, aims, steps, etc.) was provided using a power point file. During this presentation a more in depth illustration of the IC concept was given

(‘where’ IC can be ‘located’ within a company, with examples driven from a previous IC measurement project the researcher had been carried out and also specifically ‘built’ for company B). Attention was also focused on what the IC measurement project could be useful for (with examples driven from a previous IC measurement project the researcher had been carried out and also specifically ‘built’ for company B). Usually this was not a one-way talk and discussion was fostered. The interviewees were incited to intervene asking them questions such as “What do you think about it”? “Do you find similar problems/needs in your company?” Managers were also asked to talk about their activity, the way they managed the intangible resources under their responsibility, the way they managed knowledge and information.

When illustrating the project, managers were told that they would have been subsequently involved in establishing and in discussing all the elements which make up the IC measurement system: the intangible resources and activities selected as well as the indicators for monitoring them. The reason behind this was also explicitly stated: the system was supposed to help them to improve the management of their department/activities. After the interview an e-mail was sent to give a summary of the main issues which had been discussed and usually to ask for another interview aimed at analysing more in depth the critical issues which had emerged. Other e-mails and informal meetings usually followed the first interview to gather documents and information useful to support the analysis of the issues emerged during the first interview.

Enrolment

The enrolment of the managers was more difficult than anticipated in spite of the PL’s ‘belief’ that IC was beneficial, as the initial reaction of the majority of the other departmental managers was different.

I can give you all the documents you need; I can help you to accomplish your task in this way. I really believe that [the IC] project is very interesting and I am sure it would give you many hints for understanding human capital and managing knowledge. But, you see, I am very busy and I cannot participate further in the project.

[Head of ‘Business One’ Department]

I have all the information I need to do my job at best, if you want I can pass it on to you, no problem. Of course it cannot all be published in this new Sustainability Report.

[Practice Manager of 'Business Two' Department].

These managers essentially became 'external spectators' of the project and seemed not to see any utility in it, at least as far as their activity was concerned. The two reported sentences have also been chosen among others recurrent in the interviews because they show how IC was considered synonymous with Human Capital and a "task", or a concern, of the HRITQ department. Additionally, the ICS was being confused with the sustainability report and the confusion between the two of them was not cleared up, until the end of the project among these managers.

Even if the diffused sentiments among many top managers were similar to the ones reported above, other managers did get involved in the project as outlined below.

The relationships with the Municipalities, which are our shareholders and whose citizens are our clients, is very complex and thus very difficult to be monitored, almost impossible. There are the political representatives who judge the quality of how we plan and manage the services but what I really think is that the project could be useful for me to get information about the municipal technical officer's satisfaction. I need this information and you need it too because this relationship is crucial for the company. We can select a group of Technical Municipal Officers and draw up a questionnaire to be sent to them to gather information on their satisfaction and obtain suggestions to improve our operational activities. In this way I could gain information on specific issues which would really help me to manage the services, such as those related to managing the extension of the water system, to hook-ups to the system, to breaks in water mains, to waste collection and disposal, to urban hygiene.

[Top Manager responsible for the relationship with Technical Municipal Officers]

Therefore, this manager, "accepted the transaction", defining his identity and goals in the manner proposed by the researcher (Callon, 1986, p. 207) and thus was enrolled in the project. The latter got enrolled when he understood that the project could be an

opportunity to investigate the relationship with Technical Municipal Officers and get more information on company suppliers that offered their services directly to company clients. The quality of the services provided was a concern for this manager, and he associated IC to this practical concern.

Technical Municipal Officers are the Heads of the Municipal Technical Department responsible, on behalf of the township, for the technical aspects of the geographic area served by the company. In order to effectively carry out its activities, the company must, in fact, provide the information requested and follow the standards established in the service contract (e.g. maintenance checks on the condition of the gas and water lines) and it is the Heads of the Technical Municipal Department who are responsible for ensuring that the contract is fulfilled. In addition, said municipal officers are able to judge how well the company performs when technical problems arise, so their opinion influences that of municipalities as far as the technical aspects of the service provided are concerned. Therefore, the opinions expressed by the Heads of the Technical Municipal Department are held in high consideration by the municipalities, on the same level as those of the citizens-users of the company's services. Therefore, during the IC project, in order to monitor this relationship, a questionnaire was sent to them and information collected. This information proved to be important for the manager to show the aspects where the relationship had to be improved.

We have defined our 'organizational borders' in order to keep inside core competencies and activities and to give to our suppliers the management of non core activities. Thus, among the stakeholders, our suppliers are crucial to provide high quality services to our clients. The Heads of the Technical Municipal Department, in the questionnaires, showed a lower satisfaction as far as the parts of the services provided by our suppliers are concerned. On the contrary, the parts of the services directly provided by our employees got a higher evaluation. IC has given us a good hint! Thus we have just decided to take into consideration these bad aspects when we will 'structure' the contract for cooperating with these suppliers. We think that we must establish 'stable' relationships with these suppliers which is fundamental if we want to productively share with these companies our working methods, our procedures and moreover our values.[...] Productively because we cannot waste time in transferring our know how

with a company we are working with for, let's say, one year. It's contrary to IC, isn't it? Only in this way we think we can be sure to obtain a high quality service.

[PL]

Finally, the president of the board of directors was enrolled as well, being sensitive to the external communication issue and since he trusted the project leader. Therefore he gave his support to the project. During its deployment, he participated in the key-meetings such as the kick-off meeting with the Board of Directors, the meeting for presenting the IC external report to the Board of Directors as well as attending meetings where the ICS was presented to the wider community.

Mobilization

The initial project was completed in almost one year. During this period the company project leader and the researcher worked together in order to implement the IC measurement system. Many initiatives were launched connected to measuring IC resources, identifying activities establishing and calculating the necessary IC indicators. Some example are a thorough analysis of personnel competencies, a company climate survey, a satisfaction survey for the Head of the Municipal Technical Department, an analysis of the IT system supporting company's activities and interviews and a survey to assess IT user satisfaction. Besides the importance of the information gathered, these initiatives kept IC alive, throughout the company, including employees who were not actively enrolled in its implementation.

As part of measuring and mobilizing IC a number of internal documents on IC were written during this period culminating in the production of an internal and external ICS. Numbers, narrative and images were used in the ICSs to make sense of IC. In this regard, it is important to highlight that at the beginning of the project, the PL was interested essentially in measuring IC. From January 2004, when the PL and the researcher first met, to May 2004, when Company B decided to embark on the project, several meetings and phone calls occurred between the PL and the researcher and the latter examined many company documents. The PL was worried that the company did not have enough quantitative and qualitative data to be able present an ICS, therefore he asked the researcher to evaluate this potential problem.

As a result, a list of the indicators that were likely to be used to monitor the company IC was produced identifying which ones could be calculated. The PL was encouraged by the results obtained during this evaluation and decided to enter the project. At the end of the project, all the indicators initially listed were measured and some additional indicators were added which had been not considered in the initial list of indicators. What captures our attention is the proportion between numbers and words in the first ICS. The ICS is 100 pages long and contains 19167 words, 103 indicators and 5 images (excluding diagrams, tables or images that have exclusively an aesthetic function). Therefore narratives appear to have a relevant place in the ICS, more so than numbers. It is also important to highlight that the PL cooperated in writing some parts of the ICS, revised all the drafts. Yet, at the end of the project, he was able to use different technical devices to make sense of IC. He also designed the images used to connect software, process objectives and company value and to represent how employee satisfaction and IT diffusion influence company processes.

If we cannot show, using numbers, how the different software affects certain company objectives, processes and therefore company value, let's try to make it visible through pictures!

[PL]

Thus at the end of the project the usefulness of measuring IC began to be questioned, signalling the beginning of “un-locking” IC from accounting as the PL explained:

When the word ‘capital’ is attached to the adjective ‘intellectual’, an explosive cocktail is created. The word ‘capital’ is misleading because you think you have to give intangibles a monetary value or a non monetary one, but as precise as possible. Now I am sure that it is not necessary, that or it would be better not to use a single measure, you lose all the facets of the company IC, of all the actions undertaken to develop IC; you cannot work with it. At first you think that IC is something that has to be put in a balance sheet; then when you see all the possibilities you have to describe its nuances, a single monetary measure becomes so reductive. Of course, as the other project leader said, it depends on your aims. If you have to obtain a loan from a bank, then probably the measures will change.

4.3 Phase 2- Working with IC: ‘un-locking’ IC from accounting (2005-7)

After the ICS was completed, the cooperative work between the university researcher and the company officially came to a close. Nevertheless, the university researcher and the project leader kept in touch and on many occasions discussed and reflected on what had been accomplished. In fact, they both wrote articles and spoke at conferences about the project. Additionally, the university researcher was interested in knowing and understanding if and how the project was progressing, how the company was working with IC and if it was influencing human actions in any way. At the same time, the project leader was anxious to be kept updated on the innovations in IC measuring practices and was eager to discuss the choices made in managing IC.

Even if no ICS was written over the three years, IC was kept alive: enabled by the actors that participated in the first project through initiatives aimed at improving some of the critical aspects and gaps that came out during the process of measuring IC. For example, new policies for spreading knowledge throughout the company were launched which supplanted the previous ones based on knowledge databases which had proved not to be effective (see par. 4.4). Adding to this, since technical municipal officers had showed that Company B’s sub-contractors did not meet their expectations, more attention was paid by Company B in selecting them and in controlling their activities.

It has to be highlighted that, during these three years, IC was explicitly kept alive through narratives within internal company documents and reports. In several documents, written by the PL, many ‘traces’ of IC could be found where connections were explicitly made between IC or the ICS and the initiatives undertaken by the company. Two examples of this are provided next.

Identifying a new business partner

During this period, changes in Italian law made it necessary for the company to look for a new business partner, (a privately-owned company), to cooperate in managing the water and sewage service and its associated maintenance. The selection of a compatible working partner was a key issue because the company needed to guarantee its current high quality service standards as the PL explains:

The IC statement highlighted that the company’s good performance is the result of a peculiar mix of three key aspects: relationships with the stakeholders, organizational structure and processes and a deeply-rooted

company culture, which has to be preserved. Any changes, including the development of new partnerships, should occur without breakdowns in these areas and strong attention must continue to be paid to continuity in business and in values. Any changes should be shared and accepted by all company personnel. Therefore, we have tried to follow these directions when 'designing' cooperative relationships with partners. Our aim was to overcome the critical aspects that had emerged in the ICS.

With these objectives in mind, in establishing the criteria for evaluating the new partner, we have tried to establish two objectives. Evaluate the new partner's technical and organizational competencies. As for the latter, consistency with company values and capacity to integrate with it were considered of the outmost importance. Establish procedures that could favour the integration between the two of us before the start of the cooperation [...]

The deployment of the bid is characterized by maximum transparency, coherent with the accountability effort we put out in publishing the Sustainability and the Intellectual Capital Report.[...] Among the long list of documents available on the company web site there are also those devoted to very sensitive aspects, such as the intangible ones which are considered to be important. We believe that an in-depth knowledge of our company is an essential and invaluable step towards starting a fruitful cooperation.

[Part of the document prepared by PL for participating in a Quality Premium Competition in 2007]

Therefore, the compatibility of a business partner relied on the effective integration of competencies, processes and information, and not just technical and financial considerations. Thus, this led the company to include among the criteria used to select the new business partner intangible aspects, such as human capital policies, characteristics of their IT system, and their corporate culture. These, in essence, were introduced to compete or even complete more 'traditional' technical and financial criteria:

We have tried to make the prospective partner understand who we are and what we expect from him [...]

[The Company President]

“...we are a delicate organism and there are some elements that have to be considered when merging together: our employees, the way we manage them, the way knowledge is disseminated, the way we are used to doing our job. All in all, the IC statement should help our ‘Chieftain’ make the colonizers understand that we are not exactly cavemen”.

[PL]

The company’s criteria for choosing a potential business partner was novel, especially considering the company is operating in the public sector where the selection criteria and the evaluation methods must be made public. Normally, in this environment, aspects such as strategy, the organizational structure of the potential partner, proposals for integrating IT and human resources and corporate culture are generally buried in an undifferentiated and overall qualitative evaluation which is, at best, generic. Thus, through understanding the core intangibles holding the company together potentially a better fit between the company and a new business partner could be made.

Developing Human Capital Policies

Another example, regarding explicit connections made between the ICS and the initiatives undertaken by the company, concerns human capital policies. Interviews and data collected through the company climate survey, used for measuring Human Capital during the first IC project, had highlighted that some of the organizational projects undertaken were in stark contrast with company culture and were boycotted by personnel. In the first ICS it was observed that the employee incentive system, based on individual competencies, went against the strong group spirit which characterized, and still characterizes, company culture. Therefore, initiatives were undertaken to spread the logic of the new incentive systems, to openly discuss it with the employees and to question, if necessary, the choices made.

One of the most useful considerations brought up about IC is the following: personnel in our company have “bought in”, in a certain sense, through the

employment contract, a company where things are done well and where people get along and now they think that we are changing the terms of the contract. Any changes concerning these priorities create a strong resistance, the more deeply rooted the value the stronger the resistance.

[Part of a document prepared by the project leader for a company meeting
in 2006]

After reviewing company documents produced over the three years, it was evident that several initiatives had taken place to deal with this observation. For example, it was decided that anytime a new policy impacting on organizational and strategic aspects was launched, which potentially clashed with corporate culture, ‘ad hoc’ meetings had to be organized in order to illustrate these new policies in depth and to have open discussions with personnel.

In the company climate survey, “top-down communication” obtained lower results if compared to the other climate dimensions analyzed. These results have been traced back to the fact that the company’s employees are expert, competent and autonomous technicians and, as a consequence, managers usually let them self-manage. Sometimes this causes poor communication and it happens that information, especially when referred to the company’s future or to the recently introduced changes, is not spread. Considering this, starting from 2005, we have decided to launch some initiatives aimed at helping personnel to internalise the organizational changes that are in stark contrast with company culture. To this aim, for example, in 2006, managers organized meetings with employees in order to give information about the most important company commitment: the bid for choosing a new partner.

[Company B’s ICS 2007 – Human Capital – Actions undertaken to improve
HC]

After the end of the first project, the network did not collapse, but rather existed in a state of flux. This was because the problem around which all the entities had been enrolled had been ‘solved’ but while cooperating in reaching their common aim, something had happened affecting their activity afterwards. During the first stage the human entities had

become engaged to a new non-human entity previously unknown to the majority of them: IC. Before the project it was known intimately only by the researcher whereas, at the end of it, other entities in the network started to build a relationship with IC which continued to exist, at varying levels over the three years. After the end of the project, as we have illustrated, IC was mobilized through new initiatives. IC was also the reason why the PL and the researcher continued to meet, talk and discuss. The discussions revolved around the evolution of the IC project, progress in measuring IC and initiatives undertaken. The researcher, in particular, was interested in understanding if the initiatives were related to gaps highlighted by IC measurements, the IC report or if they were based on a higher awareness to IC and to knowledge developed during the project.

Additionally, the researcher was writing, articles about the IC project giving her opportunity to reflect upon the effects of the IC measurement and reporting system. Similarly, the PL wrote articles, prepared internal documents and made presentations about the project as well. These were exchanged with the researcher and provided the stimulus for their discussions. The PL was especially curious to know how IC theory was evolving and wanted to be updated on other projects the researcher was conducting. IC was also the protagonist of discussions between the PL and other company actors.

Thus, a state of flux existed because some of the 'old' associations between actors were broken and were replaced by 'new' associations between other actors being the company's managers, its employees, a new potential partner as they became interested in IC (see Callon, 1986, pp. 208-9). Therefore, after the completion of the project, the researcher was no longer at the centre of the network but all the entities were still bound together thanks to the continuing existence of IC through its mobilisation. This was evidenced in the production of scholarly articles, reports, presentations and of course the discourse between the researcher, PL and other actors. Thus the network transformed its associations over time rather than collapsing because the network had achieved its originally intended purpose. This allowed the potential for the network to be formally revived as we will discuss next.

4.4 Phase 3- IC re-‘locking-in’ ICS (2008)

Problematization

As stated earlier, from 2005 to 2007, the company B did not produce an internal or external ICS. It was only in 2008 that the PL decided it was time to write a new ICS.

The initiatives that originated from the first IC internal report were so numerous and demanding, just to give some examples, the revision of all questionnaires regarding stakeholder satisfaction, the design of a model for measuring the prospective partner’s IC, that we decided to concentrate on them instead of publishing a new external IC statement.

[PL]

In order to write a new external ICS, the project leader decided to again ask the assistance of the university researcher. Similar to the first phase, a question concerning whether Company B was able to report its IC arose. Therefore, before embarking on this new IC measuring and reporting project, a ‘recognition process’ was undertaken by the researcher.

I am not sure we can write another company IC statement. Over these last three years we have not produced all the information that was in the previous report so it would be impossible to make a comparison as far as many IC aspects are concerned. Moreover, many things have changed and probably the new report would contain aspects and that did not appear in the first one and vice versa. I know we can use narratives and images but, you see, the numbers will be few, perhaps too few. The initiatives undertaken are many but numbers referred to them are scarce.

[PL]

Upon first analysis, it became evident that the network had not collapsed but rather had remained in a state of flux and that the relations among the actors had undergone a process of transformation. The associations developed during the first phase, in fact, triggered new events and initiatives and as a result actors did things which were unexpected and which caused the transformation of the network itself. For example, new personnel policies were launched, new sub-contractors controls were introduced and new selection criteria for a business partner was adopted. As a result, during the second phase,

some associations were reinforced such as the one between the PL and the researcher and some others were established such as the ones between IC and the other actors in the network. Similarly, the seeds to create new associations were planted. In fact, the introduction of new criteria to select business partners made the company think of the IC elements involved in this relationship and business partners were 'forced' to reflect upon their IC to respond to Company B's requests. Concomitantly, some relationships became disassociated such as the one between the researcher and the Top Managers because of the lack of strong intervention.

During the second phase, the network had also been kept alive due to non social means other than the ICS (Latour 1986: p.37). In fact, even though the ICS had not been produced at company level, locally in individual departments, specific IC indicators continued to be systematically produced. For example, since the competence system was under revision, it was not possible to use its information to calculate the competence level. Therefore, in the HRITQ Department a lot of other useful information on employees was calculated which could be used to signify changes in employee competencies.

After the 'recognition phase' was completed, the researcher produced a report to illustrate the information gathered and provide a rough index for the new ICS. This report together with the discussions with the university researcher 'convinced' the PL to publish a new external ICS. The PL also expressed the aim to use the external ICS to report the actions undertaken over the three years to improve IC and, more importantly in his eyes, to enrich the communication towards a potential business partner.

In order to write the new ICS a new strong intervention by the researcher was needed because the actors had to be reassociated again around a problematization related to accounting for IC. As in the first phase, the researcher became an obligatory passage point (OPP) and became indispensable as she held the knowledge about how to report IC, through numbers and narrative, taking into consideration information which could be useful for a potential partner. In order to accomplish this project the 'old' alliance was revitalized (Figure 3). The active presence of the researcher was necessary to complete the network and, at the same time, while some of the 'old' entities remained (the Head of HRITQD, the president of the board of directors and IC), new entities entered the network (the manager who was in charge of innovative services related to new sources of energy and the one who managed the door-to-door recyclable refuse collection) and others left it

(the manager who managed the relationships with Technical Municipal Officers). A new external entity entered too: the potential cooperative partner.

Figure 3: Entities in the network (second IC project)

The ‘old’ network, after being in a state of flux, was gradually revitalized around another problematization: “Can IC be used to improve the integration with a potential partner?” In this way, IC, which had been freed from accounting during the second phase and which had acquired a different identity because of changing associations, was again locked into accounting. This is because any potential business partner is likely to be “new” to IC, therefore he needs to understand what IC is, where it can be found and what does it have to do with the company. The potential partner is in front of an IC black-box and needs to explore it to see its shape, contents and inner workings. Similarly, any associations with new actors must also be locked into accounting for IC.

As in the first phase, it was the university researcher who defined the entities, their identities and their aims (Figure 4). Here we will comment only on the potential partner since the description of the other actors, provided during the analysis of the first phase, can be extended to this phase as well. The potential partner is required in the network because all information on IC has to be reported taking into consideration their information needs and the aspects Company B wants to disclose explicitly to them. The potential partner is, in fact, the most important ICS ‘reader’. Moreover the potential partner needs the information in the ICS since, in order to participate in the new partner selection process, they have to provide similar information. The main obstacle here is the likelihood that any potential business partner would have had little if no interest in IC until considering going into business with the company.

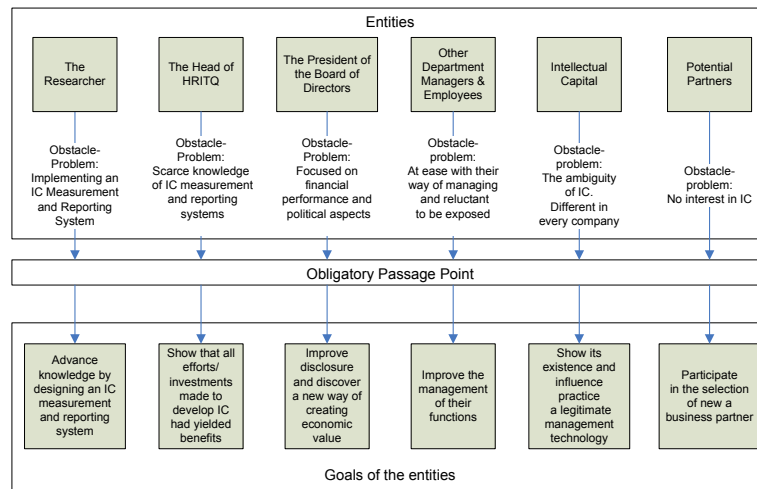

Figure 4: Entities, goals and obstacles in the network (second IC project)

Interessement and enrolment

In order to involve the actors in the network the researcher used the same means that she had been using during the first phase such as interviews, talks and *ad hoc* documents to illustrate the project and its aims. The controversy concerning whether IC is a valid management technology was kept alive, as specified, all during the first phase of the project. Those who were enrolled in the first phase recognized the validity of IC but the support for it was temporary and IC was put to the test. Therefore IC continued to be questioned after completing the first project was over and the PL attempted to show its validity and tried to spread it throughout the company, proposing it as a solution to practical concerns not only in regard to HR policies but also to wider company policies. For instance, the use of IC based criteria to ‘evaluate’ a potential partner is proof that top management recognized the importance of IC in managing relations, un-locking it from accounting concerns. Therefore, supporters enacted IC in material practices, using it as a solution to practical concerns; detractors refused to consider in-acting IC.

When the new ICS project was launched, the controversy, too, was revitalized. Some of the ‘old’ supporters of IC (the Head of HRITQD and the Company President) were easily interested and enrolled in the network since they could see the benefits obtained from their past experience. The top Manager responsible for the relationship with Technical Municipal Officers decided, on the contrary, not to take part in the new project:

I got useful information from the previous project but, I am sorry, I have many things to do and I do not have enough time to participate in the new project. All in all, I got all the information I need and I am still working to improve the relationships in the direction shown by the questionnaire.

The 'old' IC detractors refused to participate in the project continuing not to see any advantages in it.

Ah yes, I remember the presentation of the statement you made some years ago, it was 2004 or 2005, wasn't it? It was interesting [...] I guess it was useful for managing HR, the Head of HRITQD always mentions it but, believe me, it is really of no help to me, and my job is different. I am satisfied with my stuff.

[A Company Department Manager]

Nevertheless, two new managers were enrolled in the project, the one who managed the innovative services related to new sources of energy and the one who managed the door-to-door recyclable refuse collection. The researcher, with the help of the PL, tried to interesse them showing that the way they managed the services under their responsibility was a clear example of how the company used its competencies and knowledge as levers to provide effective and efficient services. This offered an opportunity to these managers to show to the company and to external stakeholder's activities and the actions undertaken using a different perspective. This different perspective 'fascinated' them and they got enrolled into the network.

I cannot affect company turnover that much but I can influence company costs. During the last years I have been making many cost savings, especially when it comes to launch the door-to-door waste collection but, I mean, it is difficult to express them in monetary terms. So if I can use numbers and if I can comment on them, then the project can help me in making the others understand what I did for the company.

[The manager responsible for the door-to-door recyclable waste collection]

In order to interesse the potential partner, for participating in the bid the company asked them to provide information referring not only to its technical resources but also to its organizational structure, management systems and strategy. All of these aspects were then

further broken down into their most important elements and characteristics and were evaluated on the “completeness” of the information provided and on how compatible it was with the company. “Completeness” refers to the fact that, when providing the information, the partner did not overlook any points dealt with in the ICS and, thus, it refers to how well the potential partner could integrate with Company B. For instance, in looking at the potential partner’s capacity to manage and control its own relational and human capital, the use of personnel management systems based on human competencies along with results of employee climate surveys, and measures of customer and supplier satisfaction were evaluated. Aspects such as the formalization of the procedures or the existence of coordinating organizational positions were also scrutinised. The potential partner was also asked to suggest ways to integrate its own services, competence, information systems and personnel management policies with Company B’s ones (Chiucchi, 2008). Therefore the potential partner needed to understand Company B’s IC before it could disclose its own IC and, in order to provide information referring to its IC, the potential partner needed to read and understand Company B’s ICS.

Mobilization

All the actors enrolled were mobilized and displaced in the new ICS. Moreover all of them, except the business partner, were directly involved in producing the second ICS. In the process they were interviewed and helped identify the intangible resources and activities under their control and provide the indicators for monitoring them. They also provided information useful to calculate the indicators and where possible, they calculated indicators themselves. Frequently, since the numbers available to disclose a certain intangible were scarce (e.g. the customer satisfaction measures of the door-to-door recyclable waste collection and the renewable energy businesses) they produced narratives in order to ‘describe’ it as well as the activities performed.

Many of the initiatives undertaken over the previous three years continued to be documented in the new ICS making an explicit connection with past IC measurements. Connections between IC and all entities involved in the network are also described.

I believe that the continuity between the two IC statements can be guaranteed by showing the initiatives undertaken to face the critical aspects that had emerged in the first IC project. This would also justify

why, in the new report, new IC aspects arise and others disappear or are given less importance.

[PL]

For instance, in the new ICS, it is made evident how the ‘old’ policy adopted for structuring and spreading information throughout the company, which was based on creating and using databases, changed over the three years. In fact, the IC indicators measuring the use of knowledge databases, which were a preferred means for spreading knowledge, showed how the databases were actually not used very much. On the contrary, the climate survey had highlighted that direct and informal exchange of information and of personal experience and expertise within small working groups was the most appreciated and useful means for sharing knowledge. Therefore, the use of databases was circumscribed only to very specific cases, for example when knowledge was referred to innovative services.

Structuring information through databases has been kept only with reference to specific situations, for example those related to structuring basic information useful to new-entry employees or those related to very innovative activities that need to be systematized. Next year, for instance, we are going to realize a knowledge management database aimed at structuring information related to renewable sources of energy. Knowledge in this area is ‘under construction’ and is possessed by very few people, therefore we think that knowledge structuration can speed its diffusion and its use in order to increase the personnel competences.

[Company B’s ICS 2007 – Human Capital – Actions undertaken to improve
HC]

Furthermore, narratives were used intentionally instead of numbers because narratives were considered to be more appropriate to show the connections among intangibles which had been activated by the company managers (see Dumay, 2008b). For example, the first ICS contained a list of ‘excellent employee competencies’ which were supposed to be exploited to create and sell new services and which were considered, in 2004, a fundamental lever in the company’s growth strategy. Seventy ‘excellent competencies’ were identified, ranging from technical (e.g. designing water and gas distribution systems,

remote controlling these systems) to managerial ones (e.g. implementing a quality assurance system). The ICS gave the stimulus to identify and monitor the critical aspects of these competencies. Their analysis showed that they pertained to a single or, at any rate, very few individuals within the company. Since it was considered vital that these competencies and the knowledge upon which they are based were shared, the ICS identified the number of employees who possessed “excellent” competencies, their years of experience, and the number of employees trained in these competencies.

The ‘excellent competencies’ are constantly revealed throughout the ICS 2004: when illustrating company strategy, when reporting about human capital and describing the employees’ competencies, when showing how organizational structure is influenced by the strategy and how, in turn, it influences the strategy.

Company B possesses excellent competencies and the organizational analysis, the aptitude to reflect upon our capacities, has increased the consciousness of the possibilities to ‘exploit’ them not only in order to carry out activities in an efficient and effective way, but also as a source of future profits. This is the reason why the company has decided to ‘sell’ its own competencies. In this sense, we have decided to organize in a better way the exploitation of these competencies and to ‘protect’ and ‘preserve’ them through technical instructions, procedures and software. In this way we allow them to become structured within the organization, to become a ‘settled’ wealth and we avoid the risk that they be constrained in individuals’ tacit knowledge.

[Company B’s ICS 2004 – Organizational Capital – Organizational Structure]

Over three years, the Marketing Director decided to narrow down accounting for only some of them, in order not to waste people’s energy and focus on those that seemed to offer a higher monetary benefit.

Nowadays, the number of excellent competencies is 60 and they have decreased by 14% [...] actually we decided to focus only on some of them. We have continued to invest also on the others but predominantly for internal aims, since they contribute to deploy activities in an efficient and effective way.

[Company B's ICS 2007 – Human Capital – Excellent competencies as a
source of innovation]

Therefore very few indicators related to excellent competencies were provided in the new ICS: the distributions (in percentage) of excellent competencies among company departments and the number of employees who possess the “excellent competencies”. In the new ICS, instead of just numbers, narratives showed how some of these competencies were mobilized over the past three years, to provide new services, for example, those related to renewable sources of energy. The narratives highlight how knowledge and competencies were shared and spread among employees, how employees organized their work and which relationships were activated in order to generate and sell these new services.

For some years now Company B has studied, designed and developed innovative solutions to produce energy from renewable sources such as solar photovoltaic, biogas from waste and solar water heating.

Among the ‘excellent competencies’ identified in 2004, three of them were strictly connected to renewable sources of energy. The attention paid to their development brought about, on the one hand, an increase in the level of these competencies and, on the other hand, their diversification.

Company organization was used as a lever to promote these competencies’ development. Employees who possess these competencies were ‘located’ in the same Department in order to promote knowledge sharing through a socialization process and through people interaction in small groups (which the company employees explicitly indicated as their preferred way for sharing knowledge). Since these competencies are used to provide services related to the ‘core’ business and since they are possessed only by a few people, the company is now planning to structure of the relevant information through a database (which will use Wikipedia’s logic).

[Company B's ICS 2007 – Relational Capital – The relationship with the
clients of services related to renewable sources of energy]

When describing the new services provided by the company, narratives are used to illustrate how the company developed these new services by combining human, organizational and relational capital. For instance, in the new ICS, narratives are used in

combination with numbers to show how traditional services, for example the collection of waste, were re-organized within the company to create new services, in this case the door-to-door collection of differentiated recyclable waste. The new services were developed using information on clients available in databases, the competencies of employees and a strong, cooperative relationship with a supplier. An extract from the ICS explains the situation:

The implementation of a door to door service to carry out the differentiated collection of waste is a clear example of how the company has exploited its IC in order to create a virtuous circle leading to value creation. The increase in the collection of differentiated waste from 38% to 76% is a proof of this.

Before analysing the quality of the relationship with door-to door service clients using the information gathered through a customer satisfaction questionnaire, it is interesting to present how the company built the relationship with the clients of the door-to-door service. An intense interaction between human, organizational and relational capital was activated which led, in a short time, to develop and provide a new service ('new' for the company).

The clients of the door-to-door service are a part of the clients of the waste collection service already provided to the "X" by Company B. Over the years, the latter has developed a strong relationship with them and has collected data which proved to be very useful to carry out the door-to-door collection of waste in an effective and efficient way. The good results achieved, in fact, are due to the already existing good relationships with clients as well as to the company capacity to create innovation.

[Company B's ICS 2007 – Relational Capital – The relationship with clients of the door-to-door waste collection]

In synthesis, all entities are represented in the ICS through numbers and narrative. Compared to the 'old' ICS, narratives play a more significant role (see Table 1) and this also shows that, gradually, the lack of quantitative data and the scarcity of comparative information, which was a major concern for the project leader before starting the project, became less important in his eyes.

Table 1: Content differences between the 2005 and 2008 ICSs

Number of Indicators	2005	2008	Variation
Human Capital	23	13	-43.48%
Organizational Capital	41	26	-36.59%
Relational Capital	25	26	4.00%
Activities	14	10	-28.57%
	2005	2008	Variation
Number of words	19167	23952	24.96%

5 Discussion and Conclusions

The motivation of this paper was to investigate in depth both the IC ‘lock-in’ to accounting phenomenon, which occurs when IC is introduced as a measurement practice in companies which are new to IC, and if and how an ‘un-locking’ process can occur. A longitudinal case study concerning the design and implementation of an intellectual capital measurement and reporting system was proposed in order to analyse the above-mentioned processes. The case analysis covers a period of four years, from 2004 to 2008. Following the movements of the actors, using the four moments of translation proposed by Callon (1986), we found that during the first part of the project, IC was progressively ‘locked-in’ to accounting. Therefore, the project allowed IC to manifest itself but a ‘lock-in’ phenomenon to the accounting domain occurred, thus limiting the initial impact introducing IC can have in a company. This can be considered ‘a natural consequence’ of the project undertaken, for its aim after all was to measure and to report IC.

In order to understand how IC was un-locked, we borrow again from the theoretical framework proposed by Callon (1986). The author argues that each entity of a network is the result of the association which links it to the actor who defines the problematization and who succeeds in disassociating it from the other actors who try to give it another definition (Callon, 1986, p. 208). This is what happened in the project illustrated: the researcher built devices to interesse other actors and defined their identities according to her goal of measuring IC. This made it possible to produce the ICS.

At the same time, it is worth noting that the association between the researcher and IC seems fragile, loosely-knit, and presents some peculiarities which, in our opinion, deserve attention in order to understand the ‘un-locking’ process. Thus, the seeds of the un-locking process were planted while the lock into accounting was developing. When IC entered Company B and became part of the network, it entered as a “new” and ambiguous expression, like an “empty” black-box. It needed to be ‘introduced’ and thus to favour its ‘entrance’, the researcher provided a definition of IC, based on the tripartite model of Human, Structural and Relational Capital, and provided examples of its composition and measurement. These identified typical intangible resources, activities and indicator types. We could say that the vase was given a shape but it still had to be filled.

The interestment devices used to enrol the actors and the specific process used to design the measurement system proved to be particularly effective for the actors to make sense of IC. In fact, during the design of the measurement system, actors were involved in reflecting upon the company strategy and its key success factors and in translating them into a strategy for developing IC. In this way, IC progressively gained relevance as a protagonist of the company strategy and of everyday work as well.

Gradually the other actors became acquainted with IC since they were made to think of what were the key intangible resources under their control and of what they did and could do to improve them. Therefore, identifying and measuring intangible resources and understanding how they were created and developed boosted IC as a sensemaking process. At the end of this “journey” the IC vase had been filled with IC measurements. This does not mean that IC would remain stable: the vase was neither full nor its contents stable. Thus, the expression “Intellectual Capital” combined with the process of measuring IC introduced a new way of interpreting the reality and, slowly, IC gained its identity. Measuring IC proved to be a powerful tool for making sense of IC.

Originally IC had been introduced exclusively for measurement aims therefore as a concept able to provide different lenses through which observe the company performance. As stated before, when the researcher introduced IC, a tripartite model was used in order to spread over the idea of IC as a common system. The ultimate aim was to write up an exhaustive ICS. The list of the company intangible resources (see table 1 in the appendix), which was written up by the researcher after the first interviews and approved by the PL, comprises a wide range of company intangible resources. They were all measured and accompanied by narrative in the ICS but the concept of IC getting around

Company B was less ubiquitous than the researcher and the PL had expected because IC was associated predominantly to HR and IT issues and only marginally to the relationships with the stakeholders.

Another aspect we stress is how IC entered as ‘vague expression’ and gradually built relations with the other actors making them do unintended things. Therefore IC behaved as a ‘mediator’ and not as an ‘intermediary’¹. During the interessement, enrolment and the mobilization phases, in a *crescendo*, each actor built its own meaning of IC. In other words, IC was ‘made free’ to be attached to other entities’ concerns and this created the conditions for its freedom and for the un-locking process. Therefore, the interessement devices used by the researcher to involve the actors in the network and the cooperative process used to design the IC measurement system favoured the engagement of each actor with IC. Thus, IC gradually gained an identity and, as the project progressed, the seeds to create an association between IC and the entities were sown and began to grow and to bear fruit. Gradually the engagement between IC and the other entities became stronger, so much stronger, that once the project was over, the network entered a state of flux whereby the association between IC and actors was established and continued to evolve: here IC was allowed to re-enforce associations with the other actors gradually transforming and modifying the meanings it carried. In this way IC was ‘un-locked’ from a strict accounting domain and allowed actors do previously unexpected things. This was enacted in several ways: through a new incentive policy, through new criteria to be used in selecting a new business partner, through new personnel policies.

Did IC stop being accounted for completely during this period? No, even though an ICS was not produced for three years IC inscriptions continued to be made, although predominantly in a narrative fashion. In this way IC was kept alive. All these means proved to be fundamental to sustaining the existence of the network. In this regard, Latour states “... that groups have to be made and remade anew through some other non-social means, and that there is never a grouping that can sustain its existence without some keeping up” (Latour, 1986: p. 37).

¹ “An intermediary, in my vocabulary, is what transforms meanings or force without transformation: defining its input is enough to define its outputs. For all practical purposes, an intermediary can be taken not only as a black box, but as a black box counting for one, even if it is internally made of many parts. Mediators, on the other hand, cannot be counted as just one; they might count for one, for nothing, for several, or for infinity”. (Latour 2005: 39).

If we look at the initiatives and events triggered by the association of IC and the other actors during the second phase, we see that the ‘un-locking’ process, was enabled predominantly by the Head of the HRITQD, that is to say the actor who was convinced of the utility of IC as a management technology, so convinced that, when the new ICS was produced, he suggested focusing the attention on the actions undertaken to improve IC that derived from what emerged in the previous ICS. When the second ICS project was launched, IC was again briefly ‘locked-in’ to accounting so that new entities in the network could make sense of IC before understanding how they could use it. For example, in the third phase, the network was revitalized in order to disclose IC with specific reference to a potential business partner and to foster the integration with this entity. IC was involved in the network for measuring and communicating Company B’s aims and this is the reason why we say that ‘IC was locked again into accounting’. But the new network, which was formed, was different from the previous one and so too the subsequent ‘lock-in’ to accounting. Therefore, the translation process was revived which required ‘lock-in’ to the accounting domain in order to develop interestment from the actors as well as the subsequent concomitant process to free IC from the accounting domain.

In order to explain these differences, we borrow from Lewin’s (1947, p. 32) three stage change process. Lewin advocates that in order to make a desired change it is necessary, first of all, to ‘unfreeze’ social habits, to break them by overcoming forces that constitute a resistance to change. Once a practice has been unfrozen, the practice moves to a new level and finally the changed process is frozen. Unfreezing the present practice and freezing to the new practice implies various problems. When freezing a new practice, the permanency of the new practice can be problematic and there is a risk that it is temporary. “Since any level [practice] is determined by a force field, permanency implies that the new force field is made relatively secure against change (Lewin, 1947, p. 35).”

In the first phase the introduction of IC in the company brought about a change in the accounting domain. The ICS changed managerial and external communication aims, being a new way of measuring and reporting company performance. Therefore IC and its frameworks and theories were used for accounting aims and IC was ‘locked-in’ to accounting. Therefore a new social habit was developed which broke the existing custom of focusing managerial attention and the company’s measurement and reporting systems, away from the predominant financial aspects of company performance. However, this

new social habit applied to only some managers because strong resistance to change was experienced. As illustrated earlier in the first and second phase of the project, in order to ‘unfreeze the previous custom’ the researcher used interestment devices such, as talks, chats, interviews and examples of measuring IC drawn from her previous experience to addressing individual actors concerns, in an attempt to diminish existing financial accounting habits and to strengthen accounting for IC. The use of individual interestment devices instead of group ones could have, in part, influenced the resistance to change, since they are ‘weaker’ than group devices. According to Lewin (1947. p.34),

“If the resistance to change depends partly on the value of the group standard for the individual, the resistance to change should be diminished if one uses a procedure which diminishes the strength of the value of the group standard or which changes the level that is perceived by the individual as having social value. [...] it is usually easier to change individuals formed into a group than to change any one of them separately”.

At the end of the first phase, some of the entities enrolled, namely the Head of HRITQD, the president of the board of directors, the manager that managed the relationships with technical municipal officers had strengthen their association with IC, had built their own meaning of IC and had begun to autonomously use IC information in order to develop actions aimed at its improvement. After the completion of the project, they also used IC for aims which were other than accounting aims. Thus, IC was un-locked (or unfrozen) from accounting and locked into management practice.

When the network was revitalized, the remaining entities who participated in the first phase already knew what it meant to measure IC and built their own meaning of IC. This permitted the network to reactivate and re-lock IC into accounting, but at a different level. Their autonomous production and use of IC information to foster activities based on IC and, more importantly, mobilizing IC over the three years permitted to refreeze IC and the habit to report on it to a new ‘different’ level.

By ‘different’ we do not mean higher or lower but the ICS was focused on different aspects, not merely on IC measures but predominantly on the actions to improve IC that had been undertaken over the three years. Thus in the ICS, more room was given to narratives in order to show how new services were the result of the connectivity between intangibles. Additionally, the new entities enrolled, for example, the managers in charge

of innovative services related to new energy sources and the door-to-door recyclable waste collection, were pushed to think beyond measuring IC, to reflect and illustrate how they used IC to implement their strategies. Therefore, the new IC 'lock-in' was shorter and fleeting and only required to help the new entities make sense of IC.

The network changed as new entities entered and others left, altering the balance between IC and traditional accounting practice. The latter remained in force because of the resistance to change offered by some managers. During the second phase, resistance to change remained among those who did not participate in the first ICS project. Unexpectedly, the manager who managed relationships with Technical Municipal Officers, who was enrolled in the first network decided not to participate even though he found IC useful. For him, the change of the accounting habit was temporary, yet the impact of IC was maintained since he claimed that "All in all, I got all the information I need and I am still working to improve..." Thus, mobilizing IC does not need to replace accounting, nor should accounting supplant mobilizing IC, rather they can coexist.

From an ANT perspective, our paper contributes to the use of ANT by showing how the translation process is continual and not staged. The network formed during the first phase, in fact, did not collapse at the end of the first stage as many would expect after the initial aim of producing the ICS was achieved. Rather, it continued to survive but "in a state of flux" since the associations among the actors, developed during the first phase changed. Some actors built a direct and strong association with IC, and IC played also a pivotal role in building associations between human actors such as the PL and the researcher while others became disassociated such as researcher and some of the other managers who had been involved in the project. Therefore the network continually evolved and never stabilized if not temporarily around a new problematization. It was in relation to a new problematization, thus, that the network was revived as new associations were developed, as new actors became interested (a business partner) as others returned to the network (the Company President) and others definitely abandoned it (the Top Manager responsible for the relationship with Technical Municipal Officers). In this evolution a crucial role is played by inscriptions on IC which were fundamental not only in keeping IC alive but contributed also to build its identity.

In essence our main conclusion and contribution of this paper is that our analysis is contrary to our hypothesis and in some way contrary to the findings of Chaminade and Roberts (2003) in that we challenge the notion "that a dominant accounting perspective

can lead to an excessive focus on measurement issues and little attention to management processes.” On the contrary we believe the evidence from our case study shows how at times a dominant focus on accounting for IC is necessary, especially to allow newcomers to take stock of and make sense of IC. The analogy is much like comparing accounting versus managing IC to the concept of the chicken and the egg: What comes first? In our view, for some newcomers to IC such as Company B, it was essential to take stock of IC by measuring IC thus locking-in IC to accounting so those enrolled in the network could relate IC to their day to day challenges. Once this was done IC was free to be un-locked. In this case the egg is accounting for IC and the chicken is the mobilization of IC.

We suggest that our findings contrast those of Chaminade and Roberts (2003) because of the longitudinal nature of our project. In the case of Chaminade and Roberts (2003) the timeframe was shorter and involved only one iteration of the introduction of IC into a number of companies. In our case we can see how IC evolved over time and changed according to the challenges faced by the company and its managers. This highlights the power of measuring IC as a sense-making device which, when combined with IC narratives is necessary for mobilizing IC as Dumay and Rooney (2011a, p. 352) allude to :

...measures ... help make sense of whether or not [a company] is improving their IC. But these are not concrete measures and may not need to be used again... This is not because the measures are not useful, but because ... reporting needs evolve based on the bespoke nature of its business, political expectations and changing business plans.

Our research also contributes to the understanding of the ‘un-locking’ process by highlighting that, in order for IC to be unlocked from accounting, the way the actors in the network are enrolled, interested and mobilized is of the utmost importance. More specifically, the way the measurement system is designed and implemented plays a pivotal role. In fact, the seeds for unlocking IC are planted during the lock-in process. The case findings show that measuring and reporting IC can be powerful tools for the actors to make sense of IC but as long as IC behaves as a mediator and the head of the network accepts to build a loosely-knit association with IC while letting IC reinforce its relations with the other actors.

This finding refines what Callon observes. As already stated, the author advocates that, in order for the network to be formed, it is necessary that the actor who defines the problematization succeeds in disassociating each actor from the others who try to provide another definition (Callon, 1986, p. 208). The case finding shows that even if this is of the utmost importance for the entities to be enrolled, then, when the alliance is formed, it is necessary that each actor be made free to associate with IC and build his own meaning of IC. This allows IC to gain an autonomous existence and to survive afterwards if the alliance is temporarily or permanently broken. In this way IC can live beyond the network.

At the same time, the paper contributes to the extant literature by showing the importance interessement devices, such as interviews, meetings and talks, have in order for IC to be freed from accounting. In the case under analysis, these devices permitted the researcher create an association between IC and each of the actors involved in the network since each actor had the opportunity to internalise the concept and attach their own meaning to it.

We also note that the procedure the researcher used to make the managers more familiar with IC expression and with the measurement and management issues related, called for their direct involvement in designing the IC system. This process was utilized to lessen the effects connected to what Dumay (2009, p. 205) refers to as the “accountingisation of IC” whereby ‘accountants’ apply accounting solutions to the management challenges they face in an attempt “to make the intangible tangible”. Therefore, the Italian language and the accounting vocabulary with which the project had entered the company could have acted as a barrier to participation. The accounting like expressions such as “*IC Statement*” and “*IC measurement system*”, that the researcher and the company project leader frequently used, entered the managerial vocabulary and thus IC was initially and instinctively attached to accounting concerns by the majority of the managers.

By considering the lessons learnt from the case, taking into consideration the above-mentioned barriers to the involvement of managers in the project as well as the importance of some of the interessement devices used in order to free IC, other organizations, which implement IC practices, can be made aware that the ‘lock-in’ phenomenon can take place and devise strategies to avoid the possible detrimental aspects of ‘lock-in’ and allow IC to be un-locked. More specifically, it is also important for managers to understand that an initial “lock-in” to accounting may be necessary as a

crucial first step in implementing IC management practices as taking stock of the company's IC can act as a sensemaking device and help enrol actors into the network of entities so IC can be mobilized. While it may be true that more can be achieved through mobilizing IC (Chaminade and Roberts, 2003; Catasús *et al.*, 2007; Dumay and Rooney, 2011a) our findings suggest that measuring IC at strategic points in time like the beginning of an IC implementation or when a major strategic change in direction is required may be advantageous, because from time to time we need to take stock of the IC journey and reflect on what has been accomplished and what needs to be done.

The implications for future research are based on our earlier discussion of the performative approach to IC research. In this paper we have exemplified how research into the practice of IC can deliver insights into the actual interplay of IC within the organisation. The problem, as we see it, with more ostensive research into IC is that the findings are generalised to be applicable for all organisations rather than understanding how IC works in specific contexts.

We also want to highlight the role of academic researchers in understanding how IC works inside organisations especially when we examine how deeply involved (or not) a researcher can become in the research. As highlighted in our paper the researcher initially took a strong interventionist approach to developing IC in Company B. This is because when introducing new concepts such as IC into organisation we cannot expect a sufficient number of managers to be "educated" in managing IC. As one of our colleagues suggested IC suffers from the problem of proliferation in practice: "In [my country] I find it's not being practiced by managers far as much as it's being *preached* by us academics". Thus, we argue the future of IC research and practice relies on academics getting out of their "Ivory Towers" their hands dirty with practice. This research project and other recently published IC research (Dumay, 2010; 2011; Dumay and Rooney, 2011a) shows how this can be done successfully without compromising academic integrity. While some more modernist approaches to qualitative research may argue against our view we argue that more interventionist approaches are necessary to help create IC believers who *practice what is being preached* alongside the preacher.

To conclude, the limitations of our study are also highlighted. Our study is limited to the one Italian company studied and thus our results may not be generalized directly to other organizations. It also has been influenced by the active involvement and interventions of one of the two IC researchers. Therefore, the resultant practices will have in part been

influenced by the researcher and by the model and the process used in order to design and implement an IC measurement and reporting system.

Appendix 1

The purpose of the appendix is to present a brief description of the Intellectual capital measurement and reporting system developed by the researchers and adopted by the company. The IC measurement and reporting model adopted by the company was designed in 2001/2002, after a careful analysis of existing literature and taking into account the “state of the art” (Edvinsson and Malone, 1997; Sveiby, 1997; Meritum Project, 2002; Mouritsen *et al.*, 2003), which had gained considerable support at the time and opportunities for further research were still open. The adopted IC measurement framework composed of a system of indicators and a narrative which is used to interpret them. The logic underlying the system maintains that there are *intangible resources* which are influenced by *management activities* as outlined in Figure 5.

Figure 5: The researcher's IC measurement framework

The model is based on the premise that intangible resources represent a potential to create value available to the company. In order to increase this potential it is necessary to manage intangible resources by performing activities that would determine their creation, development and improvement. Intangible resources are intentionally specified as representing a potential to create value because value creation occurs through the interaction of intangible resources and other company resources within organizational processes and operations in the search for organizational excellence. Through this interaction, products and services are created and if they meet customer needs and translate into income, economic value is created.

Keeping in mind that measurement systems are firm specific, just as intellectual capital is, some “rule of thumb” phases to be followed were identified in order to design and implement an IC measurement and reporting system. Specifically, these phases are:

1. *Formulation of the company mission and of the strategy and identification of the key success factors* - This is a preliminary phase, essential for the development of the

rest of the project. By making explicit the company strategy and the key success factors, and by talking about them through *focus-groups*, the managers (and the researcher) improve their awareness of the importance of IC in order to build a competitive advantage.

2. *'Translation' of company strategy into a strategy for creating and developing the company Intellectual Capital* - During this phase, managers are requested to analyse in depth what they do in order to develop company intangible resources. This phase and the first one are essential to begin to identify the company intangible resources and activities as well as the dimensions to be monitored (quality, timeliness, etc).
3. *Mapping of the critical intangible resources* – The intangible resources to be monitored are identified by taking as a point of reference the 'traditional' IC tripartite model: human, organizational and relational capital. It has to be noted that the abovementioned IC categories are used in the mapping phase as a point of reference in order to help managers reflect upon where IC is located. After the intangible resource identification has been accomplished, the concept of category is abandoned and the focus turns to the interactions among resources through the managerial activities. The latter allow for the creation, the development, the transformation and the improvement of company intangible resources;
4. *Identification of actions for the creation and development of intangible resources* – As far as the activities are concerned, they are not referred to the categories because this would be misleading; from a normative perspective, reflecting upon them is considered to be useful for managers since this pushes them to think in terms of connectivity.
5. *Establishment of the indicators for measuring the quality and quantity of intangible resources* - In particular, these indicators are an expression of the intangible resource flows which occurred over a certain period (in terms of, for example, "rate of development" or "rate of renewal" of resources such as competencies, structured knowledge, etc.).
6. *Establishment of the indicators for measuring the effectiveness and the efficiency of the activities undertaken for creating and developing intangible resources*- efficiency can be monitored through measures referred to activities' costs or with non-financial indicators (e.g. for training activities, the per-capita cost and the per-capita hours can be calculated). Effectiveness can be measured in terms of

punctuality, reliability, perceived utility, timeliness, etc. (e.g. for training activities, effectiveness can be monitored by the growth/decline rate of employees' potential or of competencies measured after the activity takes place).

The process illustrated must be considered a rough guideline, because in reality the phases overlap. This process is in fact iterative, since the maps of intangible resources and activities, together with the chosen indicators are fine-tuned and if necessary changed, as the understanding of a company's IC progresses.

Thus to illustrate Company B's IC we outline below the IC measurement system developed. First the researchers developed a map of company intangible resources (Table 2) and a map of development activities (Table 3). From there, a list of predominantly non-financial indicators was developed to express the growth or decline of intangible resources and the efficiency and effectiveness of the management activities (Table 4).

Table 2: The list of company intangible resources (First Phase)

HUMAN CAPITAL	ORGANIZATIONAL CAPITAL	RELATIONAL CAPITAL
<ul style="list-style-type: none"> ▪ Competencies <ul style="list-style-type: none"> – basic – managerial – excellent – ad hoc ▪ Loyalty ▪ Quality of the workplace relationships: <ul style="list-style-type: none"> – Motivation – Trust – Responsibility – Top-down and horizontal communication – Aptitude for teamwork – Alignment with strategy – Involvement in decisions 	<ul style="list-style-type: none"> ▪ Information system ▪ Software and databases ▪ Strategic software and database ▪ Procedure ▪ Manuals ▪ Product catalogues ▪ Patents ▪ Organizational processes and structure 	<ul style="list-style-type: none"> ▪ Relationships with utility customers (methane-gas, water supply and maintenance and environmental services) ▪ Relationships with the technical municipal officers ▪ Relationships with new service customers ▪ Relationships with the companies which bring organic waste to the composting facilities ▪ Relationships with non-shareholder municipalities ▪ Relationships with the Local authorities (ATO, AEEG, ARPA, USL), the provincial and the regional offices ▪ Relationships with other organizations (artisan associations, cooperatives, etc.) ▪ Relationships with suppliers ▪ Relationships with trade unions and associations ▪ Relationships with educational institutions

Structured Abstract

Purpose - The aim of this study is to propose a method to measure Intellectual Capital (IC) in firms involved in strategic alliances, an area that has received scant attention in the literature, as existing research is focused mainly on organizational level mainly and increasingly on macro-level unit such as regions or nations. There are very few works at the meso-level, (i.e. alliances, clusters), and the paper aims to fill this void, by providing researchers and practitioners with a tool capable of combining measurement and management aims, developed at organizational level with the active participation of the researchers.

Design/methodology/approach – The method of analysis is based on a model formalized through a fuzzy expert system (FES). The FES are able to merge the capabilities of an expert system to simulate the decision-making process with the vagueness typical of human reasoning, maintaining the ability to still have a numeric value as a response. Its construction requires the participation of experts, whose knowledge of the problem is accumulated in the form of blocks of rules. These features make it possible to formalize the decision-making process related to the IC valuation, handling qualitative and quantitative variables, and exploring the cognitive mechanisms underlying this process.

Originality/value – To the best of our knowledge, IC literature lacks methods expressly designed to measure the incremental value of IC originating from collaboration among firms. We think also that fuzzy logic methodology, recently applied in empirical work designed to evaluate IC, represents a reliable methodology because of the “fuzzy” nature of IC. This study contributes to the broadening of the research community’s understanding regarding the alternative measurement of IC created within strategic alliances. From a measurement perspective, the results may be regarded as valuable proof that IC performance within strategic alliances can be measured quantitatively.

Practical implications – The outcome of the application is a system designed to measure the intangible performance deriving from participation in a strategic alliance. On the

management side, the possibility of retracing the determinants of different IC intermediate indicators composing the final IC index allows strategic alliances managers to use this information for decision-making purposes.

Keywords – Fuzzy logic; Intellectual Capital; Strategic Alliances; Performance Measurement

Paper type – Academic Research Paper

Acknowledgments – We would like to thank Walter Cortiana, CEO of 3C Catene srl, for his vital contribution. Though this work is the fruit of joint reflection and collaboration, for academic reasons sections 3 and 6 are to be attributed to Andrea Venturelli, sections 4 and 5 are to be attributed to Giovanni Mastroleo, and sections 1 and 2 are to be attributed to Stefania Veltri.

1. Introduction

In today's knowledge-based economy, intangible assets are seen as elements essential to value creation in companies and, hence, to the economic wealth of nations (Cañibano et al, 2000; Lev, 2001; Martín-de-Castro et al, 2011). Consequently, measuring, managing and reporting intellectual capital (IC) is becoming an increasingly more critical issue.

The definition of IC accepted in the paper is that IC is a dynamic, firm- and context-specific system of intangible-knowledge-based resources and activities, which is key to a firm's competitive advantage (Meritum, 2002; Veltri, 2011).

IC research has mainly focused on individual companies, and, to a smaller extent on macro-level units such as regions or nations (Bontis, 2004). The research at meso-level (i.e. regional clusters, strategic alliances, etc), appears to be scant, with few IC works focused on it (Hervas Oliver and Dalmau Porta, 2008), and papers focused mainly on the theoretical aspect of relationships between IC and strategic alliances (Pöyönen and Smedlund, 2004).

This research gap presents an opportunity to scholars and constitutes the purpose of this study. In detail, the main aim of the study is to propose a method to measure Intellectual Capital (IC) in firms involved in strategic alliances, able to deal with the complexity of IC theme in a network of firms.

We can define a strategic alliance as an alliance in which independent organizations share the benefits of partnership and participate continuously in one or more key strategic areas such as product design, production, marketing, distribution, technology (Arend and Amit, 2005; Gulati, 1998). Alliances can take many forms, ranging from simple agreements with no equity ties to more formal arrangements involving equity ownership

and shared managerial control over joint activities (Chan et al., 1997; Gulati, 1998; Gulati et al., 2000; Elmuti and Khawala, 2001; Todeva and Knoke, 2005) and evolves within time (Marafioti et al., 2013; Castro et al., 2013).

This study focuses on non-equity alliances, in detail on an Italian network agreement, PIB (*Progetto Impresa Business*) involving seven manufacturing firms located in the Lecco province, in the northern region of Lombardy.

The IC is investigated from the perspective of the single firm embedded in the network agreement (Gretzinger and Royer, 2014), the “3C Catene srl”. The aim is to measure how much of the intellectual capital produced by the PIB network is attributable to the individual company “3C Catene srl”.

The paper combines both qualitative and quantitative methodologies. Qualitative data are collected through the tools of semi-structured interview questionnaire to the management of the selected case study (Qu and Dumay, 2011). The qualitative data, interpreted through the theoretical lens of the researchers, become the input of a model formalized through a fuzzy expert system (FES), aimed to measure the IC created and developed by the firm belonging to the network agreement. A FES has been chosen for its ability to merge the capabilities of an expert system to simulate the decision-making process with the vagueness typical of human reasoning, still maintaining the ability to return a numeric value as a response (Zadeh, 1965). Its features allow us to formalize the decision-making process related to the IC valuation handling qualitative and quantitative variables and exploring the cognitive mechanisms underlying this process (Magni et al., 2002; Magni et al., 2006).

The paper contributes threefold to the literature. Firstly, it address the strong call for IC research at organizational level, a bottom-up, performative and critical research typical of IC third stage research (Guthrie et al. 2012; Dumay and Garanina, 2013; Alcaniz et al., 2011; Mouritsen, 2006). Secondly, employing a fuzzy logic methodology, scarcely used in IC research (Bobzura et al. 2007; Zandi and Tavana, 2010; Veltri et al., 2012), it combines the intuition and experience of experts (management view) with the formal rigour of a logic system (measurement view). Thirdly, it sheds light of one of the main relevant new strategic theme of alliance literature, that is the knowledge dimension of networks and its links with competitive success (Baum et al. 2000; Dyer and Nobeoka, 2000; Gupta and Govindarajan, 2000).

The originality of the paper resides in applying a model formalized through a FES for measuring the IC of firms belonging to a network. IC literature lacks of methods expressively designed to measure the incremental value of IC originating from a collaboration among firms and, at the best of our knowledge, this is the first research exploring the possibility to use a FES system to deal with the complexity of creating and developing IC in networks.

The main findings of the paper have implications for both theoretical and empirical community. Theoretically, this study contributes to broadening of the research community's understanding regarding the alternative measurement of IC created within strategic alliances. From a measurement perspective, the results may be regarded as valuable proof that IC performance within strategic alliances can be measured quantitatively. On the management side, instead, the possibility of retracing the determinants of the different IC intermediate indicators composing the final IC index allows managers to use this information for decision-making purposes.

The remainder of this paper is organized as follows. Section 2 briefly discusses the literature informing the methodology and thus providing a context within which is developed the research framework. Section 3 illustrates the research framework lying behind the choice of FES method and the criteria that drove to the selection of the Italian firm belonging to a network agreement to which apply the FES method. Section 4 provide a detailed illustration of the FES model developed ad hoc for the research and applied to the selected firm. Section 5 analyzes the main findings of the paper, while Section 6 concludes the paper.

2. Literature review

Strategic alliances among organizations have grown dramatically during the past two decades (Arendt and Amit, 2005) and are supposed to grow in the next future (Elmuti and Khatawala, 2001). A vast literature on strategic alliances and networks has thus emerged in fields such as economics, management, sociology, and organization theory (Kim and Vonortas, 2014), with much of the research focused on the implications of strategic alliances and networks on the performance of firms engaging in such relationship (Gulati et al., 2000; Kale et al., 2002; Lee, 2007; Chan et al., 1997; Lin et al., 2009; Lee et al., 2001; Lavie et al., 2012).

We embed our research into a stream of literature that links value creation in networks to underlying resources (Hervas-Oliver & Albors-Garrigos, 2007; Tallman et al., 2004; Gretzinger and Royer, 2014). We thus take a resource-based view (RBV) perspective (Wernerfelt, 1984; Barney, 1991), or, better, its evolved version IC based view (ICBV).

From RBV perspective, networks may hold a variety of advantages for their members in the form of access to valuable shared and non-shared resources (Das and Teng, 2000; Lavie, 2006). Applying the RBV to networks, the necessary bundle of resources and capabilities are thus internal to the network but external to any single firm (Marafioti et al, 2013)¹.

On the intangible content and cognitive character of the inter-firm relationships focused subsequent studies of the knowledge-based view (Foss, 1996; Grant, 1996; Conner & Prahalad, 1996; Teece et al., 1997; Curado and Bontis, 2006), that assign the predominant role in explaining firm performance variations to the possibility for firms belonging to network to access knowledge potentially able to generate advantages for the single firm and the whole aggregate (Grant and Baden-Fuller, 2004; Dyer and Singh, 1998; Inkpen, 1996; Della Corte and Sciarelli, 2011). Several studies adopt a knowledge-based view approach in studying network of firms, such as Kale et al. (2000), Inkpen and Tsang (2005), Colins and Hitt (2006), Welbourne and Pardo-del- Val (2009), Liu et al. (2010), Gretzinger and Royer (2014).

The IC-based view (ICBV) is the ultimate evolution of the RBV, claiming that firm ICV represents one specific aspect of the more general RBV, in that it more narrowly considers three resources that have been theoretically linked to a firm's competitive advantage (Reed et al., 2007; Martin-de-Castro et al., 2012). Specifically, ICBV deals solely with knowledge that is created by and stored in a firm's three capital components; i.e., in its people (human capital), social relationships (relational capital), and information technology systems and processes (organizational capital) (Edvinsson and Malone, 1997).

Several studies adopt an ICBV approach in studying network of firms, such as Das et al. (2003), Schiuma et al. (2005), Hervas Oliver and Dalmau Porta (2006), Allee (2008); Solitander and Tidström (2010), Peng (2011), Joia and Malheiros (2009), Chang et al. (2008).

¹ *There is an important difference between alliances and networks, though which does not always come out sharp in the literature (Kim and Vonortas, 2014). This difference has to do with the extent of relationships: an alliance involves two or more partners working together on a single project whereas a network is made up of a collection of relationships (formal alliances or other relationships) that binds a group of organizations together (Dyer and Singh, 1998).*

In our study we argue that the embedded instability and uncertainty associated with alliances make strong demands on IC. Because IC represents an organizationally embedded competency that is valuable in managing uncertain situations, we argue that IC should have a positive influence on the management of alliances (Chang et al., 2008). In other words, firms with better IC should realize greater gains from inter-firm collaboration.

Following thus an IC perspective, we need to clarify which conceptualization of IC we accept and, above all, how we posit towards the measurement problems of IC within networks of firms (Bitcici et al., 2012). As regards the first issue, we define IC as is the dynamic, firm- and context-specific systems of intangible-knowledge-based resources and activities, at the base of a firm's competitive advantage (Meritum, 2002; Veltri, 2011). This implies that we do not believe that IC has a set of fundamental properties that exist prior to any interactions carried out by organizational actors and that IC is a value per-se, instead, following the performative approach under the third wave IC research, we believe that IC is part of a configuration of knowledge management and, consequently, it is firm- and context-specific and it is dynamic by nature. However, the issue of measurement remains relevant even in the third stage of the IC research, characterized by critical and performative analysis of IC in action (Mouritsen, 2006; Guthrie et al, 2012) even if, under this approach, IC measurement, managing and reporting models should be developed for a specific situation (Dumay and Garanina, 2013; Murthy and Mouritsen, 2011; Chenall et al., 2010).

Several papers dealt with IC measurement issue in networks, with the aim to produce an IC index (Chen et al., 2004; Grimaldi et al., 2013; Hervas Oliver J.L. and Dalmau Porta, 2006), but no study used a FES model to measure IC, except Veltri et al. (2012).

In the paper, our starting points are the scorecard measurement approach, and in detail from the advanced scorecard methods, that look for quantitative and qualitative indicators able to measure intangible resources and activities², but the IC indicators are integrated in

² *Methods for IC measurement can be classified in four basic categories (Sveiby, 2010): (1) Market capitalisation; (2) Return on Asset; (3) Direct Intellectual Capital; and (4) Scorecard. The first three models belong to the measurement perspective, as they focus on the financial side of measurement and the monetary value of intangible assets, whereas scorecard approaches belong to the management perspective. They look for quantitative and qualitative indicators able to measure intangible resources and activities and aim at showing the role of IC in a firm's value creation (Chiucchi, 2004; Veltri, 2007). It is important to highlight that scorecard methods have evolved from pioneering IC measurement and management models (Edvinsson & Malone, 1997; Sveiby, 1997) to advanced ones (Meritum report, 2002; DMSTI, 2003). The advanced models adopt the evolved notion of IC as a dynamic system on intangible resources based on knowledge. These models focus their attention on the interactions between the IC items, at the basis of the organization's value creation, and on intangible activities which are essential in the production and development of intangible resources. The assumption behind*

a FES model that return an IC index from the aggregation of three main indices, related to human capital (HC), organizational capital (OC) and relational capital (RC).

Our main research hypothesis in the paper that a FES model is able to address all the issues underlined in the literature review section, i.e. , it is able to combine measurement (FES has the formal rigour of a logic system) and management perspectives (FES combines the intuition and experience of the experts) by developing an IC index. FES technique is able to give a ‘numeric’ measurement of an organization IC still taking into consideration the fuzzy nature of IC (‘O Donnell, 2006), and its firm- and context-specific nature. Moreover it is able to deal with the dynamic nature of IC and with the potential of value of IC, all relevant features that should be taken into consideration by researchers who deal with the IC measurement issue³.

Next following sections illustrate the research framework (Section 3) and the features of the ad hoc FES model developed for this paper (Section 4).

3. Research framework

This section aims to illustrate the research framework. After having analysed in the previous section the theoretical perspectives that drove our research, this section focuses on the methods chosen to address our research hypothesis. The research uses both qualitative and quantitative methods. First of all, we rely on the qualitative methods of the case study, as we adopt a firm-level perspective, then the data needed as inputs for the FES model has been collected through the qualitative tool of the semi-structured interview and of the questionnaire, and interpreted by researchers in the light of interpretivist approach⁴.

On the basis of the qualitative data, researchers act as experts (content expert) and, together with an expert of the FES models (methodology expert), worked on developing an ad hoc FES quantitative model.

Yin (2003) suggests the case study method as a useful approach when “how” and “why” questions are addressed and the researchers do not have control over events. For analysing the selected case study the following data sources have been used: expert

these models is that the measurement of IC is necessary for the management of knowledge and their main aim is to identify the paths of an organization's value creation based on knowledge (Veltri et al., 2012).

³ *IC is a concept in evolution, which undergoes change over time and which must be constantly understood and interpreted (Kianto, 2007; Giuliani, 2009). In order to create value, IC subcategories have to interact with each other and with tangible resources, developing vague, not univocal interactions (Chiucchi, 2004) and, above all, IC can create but also destroy value (De Santis and Giuliani, 2013).*

⁴ *In the light of interpretivism, sociological phenomena cannot simply be observed but must also be interpreted by the researcher. This means that there is not one absolute reality, but rather different possibilities are generated by the perspective adopted to interpret the facts (Crotty, 1998; Ryan et al., 2002).*

interviews, newspaper articles, information about the network agreement and network actors from the internet in general as well as from the homepage of the selected network agreement cluster. The aim was a data triangulation, which gives us a rich set of data as the basis for analysing deeply the case study (Yin, 2012). By the triangulation of data from different sources we aimed for internal validity of the finding. So far, some in-depth semi-structured interviews with the general manager of the selected organization. The semi-structured interview was chosen as a method for collecting qualitative data because of its high degree of flexibility and because it offers the opportunity to address themes that come to light during the interviews, allowing the enhancement of the understanding of the motivations that drove the interviewee's actions as well as his/her interpretation of the reality (Qu and Dumay, 2011). The interviews took place in a face to face setting and based on a semi-structured questionnaire with the focus on the role of IC for the firm belonging to the PIB network agreement. Then a closed questionnaire has been prepared and made available on web resources (Crotty, 1998). The authors have analyzed the data separately in a first step, before they compared and discussed them. By this procedure consensual validity has been reached.

In summary, the reason for choosing a case-study approach is that a case study is an empirical inquiry that investigates a contemporary phenomenon within its real-life context, especially when the boundaries between phenomenon and context are not clearly evident (Yin, 2003). Especially IC in network has so many different manifestations, and the choice to focus on a single case study respect the mandates of the third wave IC research, according to which, to produce outcomes useful to advance IC knowledge, IC research should no focus on general and theoretical models, instead it should focus on IC management practices and ad hoc, focused models (Dumay and Garanina, 2013). Our aim of this study is to come to a suitable tool to conceptualize and measure IC in the reality of the firm network agreement. The findings should serve to come to first pragmatic implications for the investigated network (i.e. the IC measurement) but also help us to further elaborate our theoretical resource-oriented perspective on IC based competitive advantage realization in clusters. When this is achieved further empirical investigations are planned to follow with more interviews, as well as other ways of data collection.

In this study, we explore the role of IC for a firm belonging to a network using a sample of non-equity strategic alliances. Instead of joint ventures, we have chosen non-equity, contractual strategic alliances as contractual alliances are likely to involve greater

risks and uncertainty than joint ventures. Since IC and experience are expected to be more important when the transactions involve greater risks and uncertainty, we believe the influence of IC and experience will be stronger in non-equity alliances than in joint ventures.

In detail, we adopt a firm-level perspective (Gretzinger and Royer, 2014) and we choose to focus on a firm belonging to an Italian network agreement, the 3C Catene srl, belonging to the PIB network, localized in province of Lecco, in the northern Lombardy region in the Italian territory. The reasons why to focus on an Italian network agreement, disciplined by the Law 33/2009, are several.

Firstly, Italian networks are governed by a flexible legislation; network agreements can be supply chains, dyadic relations etc, so they are a good proxy for analyzing the complex theme of strategic partnerships. Secondly, network agreements are a form of strategic alliance largely used for intangible purposes (Caputo et al., 2014).

Moreover, we selected a domestic network, i.e. a network in the Italian context because of it is a context in which cooperation between companies is particularly relevant, as the economy is mainly driven by SMEs (Marafioti et al., 2013).

In particular, the choice of PIB network was not random, in the sense that the strategic objective stated in the network contract (drawn up on 26 September 2011) is to increase innovative capacity and competitiveness in the companies' markets through the creation of highly innovative products and services.

The seven companies in the PIB network operate in the manufacturing sector and are, moreover, joint holders of a product patent; the form of integration in the network is of a horizontal nature.

Next section illustrates the main features that drive us to choose a FES model to measure IC in a network of firms, and illustrates the FES model created ad hoc for measuring IC in the Italian PIB network agreement.

4. The fuzzy logic methodology

This work is based on the analysis of a model formalized through a fuzzy expert system (FES). A FES model is an information system based on an algorithm that creates aggregated evaluation of a multi-criteria problem. Behaviours and decisions are encoded in blocks of rules, and processed through a fuzzy logic inference engine. The FES are able to merge the capabilities of an expert system to simulate the decision-making process with

the vagueness typical of human reasoning, which is present in fuzzy logic (Magni et al., 2002; Magni et al., 2006).

The model has been used for a number of advantages: first of all, the use of a model improves the description of the benefits of belonging to a network and increases the ease of understanding and implementation of the problem, but it also has the capacity for having a numeric value as a response, although not all data are quantitative; the model allows to manage a large number of inputs, and through the use of intermediate variables it increases clarity simplifying the design of the entire system.

Its construction requires the participation of experts, whose knowledge of the problem is accumulated in the form of blocks of rules. These features meet the needs of the proposed methodology: to formalize and automate the decision-making process relating to the valuation of intellectual capital, handling qualitative and quantitative variables, exploring the cognitive mechanisms underlying this process, reducing the distortions often found in the real decision-making context.

Based on the identified elements (input variables, intermediate and blocks of rules) and the material available, the implementation of the system has been divided into the following phases:

- [1] focus group with experts to define the inputs and conditions for the aggregation of intermediate variables;
- [2] layout of the model (decision tree);
- [3] definition of the range of variables and blocks of rules;
- [4] trial processing and optimization;
- [5] analysis of the final output.

The main structure of the model is based on the aggregation of the three main components of human capital (HC), structural capital (SC) and relational capital (RC).

Figure 1 – Main structure of the FES model

The construction of the model is modular; evaluation is developed according to later stages (similar to the decision-making process of the experts). From the input variables through the intermediate variables and blocks of rules you reach your final output.

The design of a FES is the first and most important step of the study. With the help of a panel of experts a modular system has been selected, consisting of three assessment areas. Starting from the final evaluation “ICinNetAgr” and disaggregating the evaluation according to the main factors, you get to output of the three subcategories HC, RC and SC. All the knowledge needed to design and build the system components (variables and elements for their evaluation, blocks of rules and weights for aggregation) is 'pulled' by the experts using various techniques of investigation. In this paper we have used Focus Group with discussions partially structured.

Going beyond, you break down the areas of assessment elements in ever more specific ones, until you get to the input. From a mathematical point of view, the connection between the set of the n input variables and the output may be represented by a function f of n independent variables $x_i, i= 1, 2, \dots, n$, affecting the dependent variable y (intermediate variable), so that $y = f(x_1, x_2, \dots, x_n)$.

Each value assumed by an input must be translated into a fuzzy number. This occurs in the input variables. For example, the variable “M_ExpOnTC” (Marketing expenditures / Total costs), is composed of three sets (Low, Medium, High) that evaluate the degree of membership (between 0 and 1) of the terms Low, Medium and High, of the percentage indicated on the abscissa. To this value (2 %) a membership equal to 0.75 is attributed at the term Medium and a membership equal to 0.25 at the term High. This means that a value equal to 2% is more considered by experts High than Medium.

Figure 2 – The input variable: “M_ExpOnTC”

All the variables that are not initial drivers are called intermediate variables. They are not, from the beginning, directly measurable, but provide an indication of the intermediate evaluation under the modularity of FES. Each subsystem has its own specific development required both for the structure and for the compilation of the blocks of rules. In a Rule Block you assess the levels of the input variables to provide an assessment of the intermediate variable, which is the output of the block. For example, in block of the intermediate variable “Contract”

Figure 3 – Block of the intermediate variable “Contract”

two inputs are valued according to the rules given in Table 1,

Table 1 – Rule Block for the intermediate variable “Contract”

#	IF		THEN	
	ContrDuration	AllianceType	DoS	Contract
1	low	low	1.00	low
2	low	medium	1.00	low
3	low	high	1.00	medium_low
4	medium	low	1.00	low
5	medium	medium	1.00	medium_low
6	medium	high	1.00	medium_high
7	high	low	1.00	medium_low
8	high	medium	1.00	medium_high
9	high	high	1.00	high

to obtain an assessment of the variable Contract.

Figures and tables below show the structure and the variables that make up the subcategories.

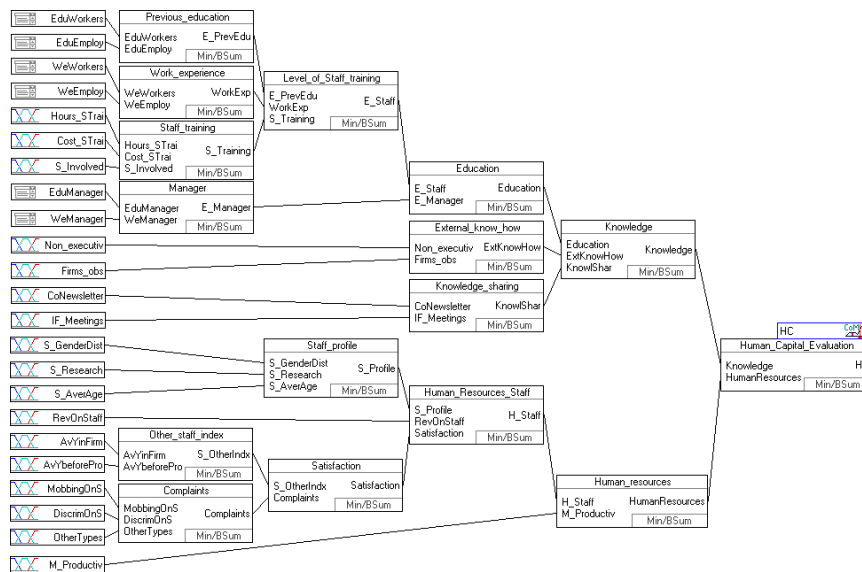

Figure 4 – Structure of Human Capital subcategory

The HC System is based on the evaluation of two large areas: the level of knowledge, understood both as level of education and as ability to perform well on their own work, and human resources, evaluated through the profile and the staff satisfaction and through an index of the productivity of managers. The System is constructed by aggregating 23 inputs through 16 blocks of rules, to get 15 intermediate variables, and final evaluation (the HC output).

Table 2 – List of abbreviations: input of HC system

Label	Input
AvYbeforePro	Average years before professional growth
AvYinFirm	Average years in the firm
CoNewsletter	Company newsletter
Cost_STrai	Cost of staff training
DiscrimOnS	Discrimination complaints / tot staff
EduEmploy	Level of education of the employees
EduManager	M_Previous education
EduWorkers	Level of education of the workers
Firms_obs	Firms of other business sectors
Hours_STrai	Hours of staff training
IF_Meetings	Inter-functional meetings
M_Productiv	Productivity: Revenue / manager
MobbingOnS	Mobbing complaints / tot staff
Non_executiv	Non-executives
OtherTypes	Other types
RevOnStaff	Revenue/staff
S_AverAge	Average age of staff

S_GenderDist	Staff gender distribution
S_Involved	% of staff involved
S_Research	% research staff
WeEmploy	Work experience of employees
WeManager	Work experience in the business sector
WeWorkers	Work experience of workers

Table 3 – List of abbreviations: intermediate variables of HC system

<i>Label</i>	<i>Intermediate variable</i>
Complaints	Complaints
E_Manager	Manager - Level of training of managers
E_PrevEdu	E_Previous education
E_Staff	Level of staff training
Education	Education
ExtKnowHow	External know-how
H_Staff	Staff
HumanResources	Human resources
Knowledge	Knowledge
KnowlShar	Knowledge sharing
S_OtherIndx	Other staff index
S_Profile	Staff profile
S_Training	Staff training
Satisfaction	Satisfaction
WorkExp	Work experience

The evaluation of the RC is made by combining the assessment of Market and Network areas with the input “SupStability” (stability of suppliers). This input was initially the result of the aggregation of other variables; after further discussion with experts, it was considered sufficient to assess the number of years of relationship with key suppliers and simplify the model. The input is evaluated at equal weight with the other two intermediate variables. The System is constructed by aggregating 21 input through 14 blocks of rules, to get 13 intermediate variables and the RC output.

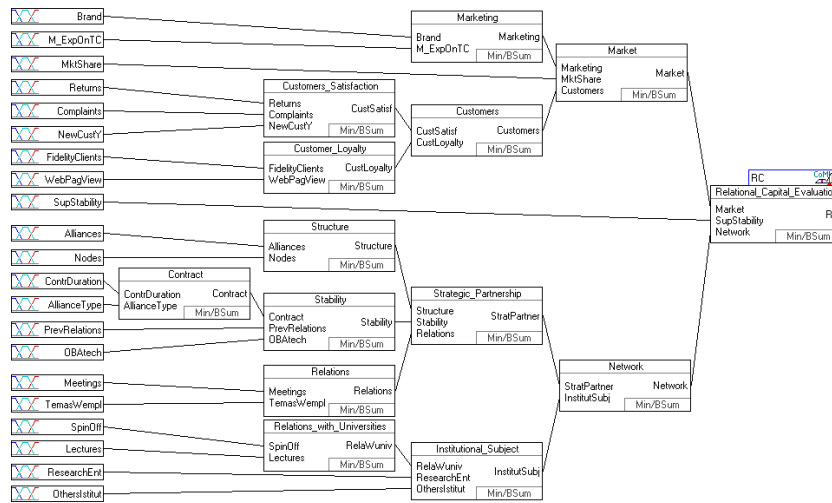

Figure 5 – Structure of Relational Capital subcategory

Table 4 – List of abbreviation: input of RC system

<i>Label</i>	<i>Input</i>
Alliances	N° of alliances
AllianceType	Alliance Type
Brand	Brand
Complaints	Total Complaints / total revenues
ContrDuration	Contract duration
FidelityClients	% Fidelity clients
Lectures	Lectures at scientific conference
M_ExpOnTC	Marketing expenditures / Total costs
Meetings	Meetings between managers of nodes
MktShare	Market share
NewCustY	% new customers for year
Nodes	N° of nodes
OBAttech	Use of OBA techniques
OthersIstitut	Relations with other istitutional subjects
PrevRelations	Previous relations
ResearchEnt	Relations with research entities
Returns	Total Returns / total revenues
SpinOff	Spin off in Uniersities
SupStability	Supplier stability
TemasWempl	Temas with employees of different firms
WebPagView	Web page views

Table 5 – List of abbreviation: intermediate variables of RC system

<i>Label</i>	<i>Intermediate variable</i>
Contract	Contract
CustLoyalty	Customer loyalty
Customers	Customers
CustSatisf	Customers satisfaction
InstitutSubj	Institutional subjects

Market	Market
Marketing	Marketing
Network	Network
Relations	Relations
RelaWuniv	Relations with universities
Stability	Stability
StratPartner	Strategic partnerships
Structure	Structure

The output of the SC System is essentially an assessment of the Research area. Except for the input “Patents”, all the inputs of this system are indices that are constructed by combining information provided by the questionnaire with values that can be derived from the financial statements, and needed to have a measure of the commitment and achievements in the field of innovation. The evaluation of SC System is obtained by comparing the result of the substructure Research, composed of 11 inputs, with the index (the twelfth input) that compares the amount of investment in IT to the total of investments. The aggregation is done through 8 blocks of rules and 7 intermediate variables.

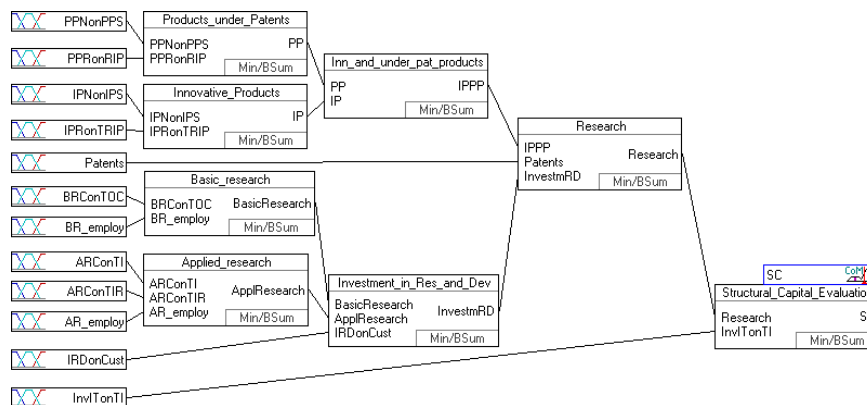

Figure 6 – Structure of Structural Capital subcategory

Table 6 – List of abbreviation: input of SC system

Label	Input
AR_employ	% Employees in applied research
ARConTI	cost of applied research / total investment
ARConTIR	cost of applied research / total investment in research
BR_employ	% Employees in basic research
BRConTOC	Cost of basic research / total operating costst
InvITonTI	Investments in IT / Total investments
IPNonIPS	IPN number of innovative products sold / IPS innovative products sold
IPRonTRIP	IPR patented products revenue / TRIP Total revenues invoiced products

IRDonCust	Investment in R&D / N° of customers
Patents	Patents
PPNonPPS	PPN number of patented products sold /PPS patented products sold
PPRonRIP	PPR patented products revenue / RIP revenues invoiced products

Table 7 – List of abbreviation: intermediate variables of SC system

<i>Label</i>	<i>Intermediate variable</i>
ApplResearch	Applied research
BasicResearch	Basic research
InvestmRD	Investments in R&D
IP	Innovative products
IPPP	Innovative products and products under patents
PP	Products under patents
Research	Research

5. Results and discussion

The output from the system created makes it possible to classify the values for the contribution of IC in the individual companies to the network, but not to assign absolute data values.

The final results produced by the system are displayed in the table 8.

Table 8 – Final results

1° level int. Var.	1° level int. Var.	HC System	input	1° level int. Var.	1° level int. Var.	RC System	input	1° level int. Var.	SC System	output
Human Resources	Knowledge	HC_02	SupStability	Market	Network	RC_02	InvITonTI	Research	SC_02	ICinNetAgr
1,00	0,28	70,31	very high	0,68	0,45	76,13	very low	0,14	0,11	52,68

The main result, measuring the contribution made to IC formation in the PIB network by the firm that is the subject of this study, 3C Catene s.r.l., is the figure of 52.68 out of 100 given in the last column. This is an extremely positive result for the company although quantifying the real contribution made will not be possible until the relevant data has also been collected from the other firms in the network, at which point comparisons of the respective IC contributions may be made.

The final figure is the result of the aggregation of the values for the HC (70.31), RC (76.13) and SC (0.11) systems.

These values are in turn derived from the aggregation of intermediate variables and input as reported in the table.

In particular, as regards HC, the relevant contribution in terms of the specific experience of the staff is worth noting.

As regards RC, it is worth noting the significant contribution of the stable relationship with suppliers and of the high market share.

In contrast with these positive results is the poor result in terms of SC, which is essentially due to the very low-level contribution made by intermediate variables connected with research. This is understandable, in the sense that the company intends to increase its research and development activities through the PIB network, the objective of which – as mentioned above – is concerned with product innovation.

6. Conclusions

The main aim of this study was to find an alternative method for measuring the comprehensive IC index of an organisation, able to combine the management and measurement views, qualitative and quantitative data, to reflect the newest concepts of IC and to consider the ‘vague’ interactions between IC variables and categories.

We have shown that an FES model can address all of these issues. The model presented in the article, designed ad hoc for the Italian PIB network agreement, is a pilot model which, like all measurement and management systems that deal with knowledge-based processes, faces the methodological problem of measuring ‘soft’, nonphysical processes and outputs. Further corroboration within the other network of firms, in Italy and abroad, are therefore needed.

The presented model applied to the PIB Italian network represents a good reference for other realities, as it is flexible enough for individual adaptations and adjustments.

Once that phase is completed, it will in fact be possible to apply the model, with a minimum of modifications, to other, vertically integrated types of Italian network where the strategic objectives are not the expansion of research and development activities but the promotion of a shared brand, the protection of the environment, the exploitation and acquisition of patents, etc..

The main advantage of the IC score developed through a FES model is undoubtedly that it returns a reliable IC index, based on its inner features.

FES combines the measurement and management perspectives, allowing codification of human knowledge in the form of a mathematical algorithm. Moreover, it is easy to understand and implement, as it derives from a heuristic approach based on logical implications (‘if-then’ rules), so even those not expert in mathematics can easily understand the formal applications and hence can support the implementation of a FES.

A FES model can handle a high number of value drivers, simplifying the design of the whole system, thus reducing its complexity and intelligibility: the system is modular, therefore not explosive, since we run it from branch to trunk.

Moreover, FES is an extremely flexible model, as it is possible to introduce several value drivers and change the rules connecting drivers and intermediate variables at any time and is a transparent model, as the experts involved put their experience and knowledge into the building of FES and their choices are transparent, visible and manifest at any given step.

In this way, their opinions are subject to debate and eventual change if not accepted by the majority of involved researchers .

The model of intellectual capital evaluation and disclosure in financial statements

Agne Ramanauskaite

Department of Finance and Accounting
Vilnius University, Kaunas Faculty of Humanities
Muitines 8, LT-44280 Kaunas, Lithuania

Structured Abstract

Purpose – According to the current accounting standards, only a minor part of intellectual capital is presented in financial statements as it usually fails to satisfy one of the criteria of asset recognition in accounting, namely, reliable evaluation. Consequently, stakeholders obtain only a part of the data about an enterprise and its activity, which directly impacts the decisions they are committing to. Considering this, the scientific issue has been formulated and dealt with in this paper: *how to present information on the intellectual capital of an enterprise in financial statements?* Therefore the purpose of this paper is to develop a model of intellectual capital evaluation and its disclosure in financial statements of an enterprise.

Design/methodology/approach – When outlining a solution, this paper strives to concentrate on: 1) *pragmatism* in order to avoid overly extensive, complicated and subjective systems of intellectual capital valuation; 2) *quantitative monetary* expression of results thus providing opportunities for comparisons; and 3) intellectual capital accounting and accountability *integrated* into the current system of financial accounting. When analyzing methods of intellectual capital valuation suggested in academic works in terms of their theoretical and practical aspects, the methods of synthesis, grouping, systemization, descriptive and comparative analysis were being employed. When developing a model of intellectual capital evaluation and its disclosure in financial statements, deduction, synthesis, comparison and modeling methods were being applied.

Originality/value – Various methods of the evaluation of the intellectual capital suggested in academic works have been researched. On the grounds of possibilities of their integration into the system of financial accounting, a generalized scheme of the classification of these methods has been drafted. A generalized list of classification of intellectual capital valuation methods revealing similarities of some methods due to their attribution to the same groups in different classifications has been drawn as well.

Practical implications – The model of intellectual capital evaluation and disclosure in financial statements has been developed, theoretically motivated and empirically verified. Taking into consideration the successful application, this model is suggested to supplement the current financial statements and to regulate the duty of enterprises to include the data on the intellectual capital. As a result, development and filling out of additional reports would be avoided; meanwhile, stakeholders would obtain more data for taking investment decisions.

Keywords – Intellectual capital; Valuation methods; Financial evaluation; Disclosure.

Paper type – Practical Paper.

1 Introduction

Habitually enterprises disclose the results of their activity to stakeholders by presenting financial statements. The information, the form of its presentation, the minimal extent and the type of the presented information in the statements are regulated and are mandatory for each and every enterprise operating in a specific legal environment. This way, stakeholders may compare different enterprises by considering various financial indices, and well-grounded investment decisions may be taken. However, due to the rapid development of economy and the spread of business processes, the information presented in financial statements becomes restricted and incapable of satisfying the increasing needs of stakeholders.

Recently, it has been complicated to take well-grounded investment decisions solely on the grounds of the information presented in financial statements of enterprises as the intellectual capital has been gaining ever more prominent importance due to its ability of creating added value. However, only a minor part of the intellectual capital is reflected in financial statements of enterprises as it frequently fails to satisfy one of the key criteria of asset recognition in accounting, namely, the reliable evaluation. As a result, the major part of the intellectual capital is not valued nor is it disclosed to stakeholders due to the indefiniteness and the intangibility typical of this type of capital. Consequently, stakeholders obtain only a part of the data about an enterprise and its activity, which directly impacts the decisions they are committing to. That is why the interest of the participants of the market towards this type of information has been increasing lately together with the need for novel methods of evaluation allowing enterprises to establish the values of the intellectual capital and/ or its constituent parts. The disclosure on intellectual capital of an enterprise is particularly important in today's competitive environment and gives both internal and external advantages. First, enterprises will be stimulated to analyse and develop their intellectual capital. Second, stakeholders will receive more data on sustainability and growth potential of an enterprise as well as its ability to create added value while the values calculated with the help of the same methodology would provide conditions for comparisons of different enterprises. To sum up, the multiplicity of methods of intellectual capital valuation and the absence of established regulations concerning the presentation of the data on the intellectual capital of an enterprise to stakeholders requires further investigation in this field.

It should be noted that this research deals with physically intangible capital which has no definite price tag and is impossible to calculate. In order to provide the most precise estimate of this capital, most researches concentrate on the accumulation of the intellectual capital from the management point of view; as a result, the suggested models are extensive and complicated while their result is usually qualitative and not always possible to compare. The Author of the paper having generalized on previously conducted researches and taking foreign experience in this field as a background strives to derive a model of intellectual capital evaluation which would allow to value the intellectual capital of an enterprise in monetary units and would not be hard to apply in practice. Besides, it would be easy to integrate into the current system of financial accounting thus avoiding a separate accounting system for the intellectual capital as well as drafting and presentation of additional reports. Consequently, the selection of this trend in the paper partly limits the precision of the obtained results.

2 Intellectual capital and its disclosure

The concept and structure of the intellectual capital have been researched by Lev (2001), Daum (2003), Lev et al. (2003), Andriessen (2004), Saez et al. (2007), Abeysekera (2008), Fitz-enz (2009), etc. The issue has also been investigated in various contexts: when dealing with the significance of the intellectual capital regarding the development of an enterprise (Engstrom et al., 2003; Dubra, 2010, etc.), when analyzing the disclosure of information on the intellectual capital of an enterprise (Abeysekera and Guthrie, 2004b; Ordonez de Pablos, 2005; Campbell and Rahman, 2010; Mention, 2011; Husin, 2012; Wagiciengo and Belal, 2012, etc.), when investigating specialized reports on the intellectual capital (Campos and Ordonez de Pablos, 2007; Marr, 2008, etc.), when seeking to establish the relationship between the social responsibility of an enterprise and its intellectual capital (Pedrini, 2007; Yaghoubi et al., 2010, etc.), when exploring opportunities of valuation of this capital (Borneman et al., 1999; Bontis, 2002a; Sedlacek and Konecny, 2009, etc.) for both external and internal (Chen et al., 2004; Borneman and Alwert, 2010, etc.) purposes, when comparing it with the intangible assets (Kuzmina, 2008) or when evaluating opportunities for its audit (Abeysekera, 2001), etc. In spite of the high numbers of conducted researches, there is no uniform opinion regarding the term for 'intellectual capital'. A number of terms have been used to refer to this capital, e.g. "intellectual capital", "intangible capital", "intangible assets", "knowledge-based assets",

“knowledge capital”, “organization intellectual capital”, “intangibles”, “intangible resource”, “invisible resource”, “information assets”, “human capital”, “hidden value”, “organizational capacity” as well as many other synonyms. There is neither systematic interpretation nor any consistent agreement regarding the structure of the intellectual capital. The interpretation of the intellectual capital in specific academic works is manifested by the strife to outline its various constituent parts (usually as many as possible) and by attempts to define the difference between the intellectual capital and intangible assets when comparing it to other types of capital or when merely designing a new definition of the intellectual capital. To sum up, various academic works provide different reasoning which further complicates subsequent academic research in this field.

When analyzing the concept of the intellectual capital, it is usually claimed that there is no universal agreement in the field of social sciences regarding the general definition of the intellectual capital. This is a consequence of the concept being mostly used in contexts of sciences of economics, management, law and sociology. As a result, various interpretations are possible (Taljunaite, 2010). If interpretations of the concept of the intellectual capital in academic works are compared, several trends may be singled out:

- 1) strife to enumerate various (and, if possible, all) the structural parts of the intellectual capital and avoidance to define the intellectual capital in its entirety (Bontis, 2002a; Vaskeliene, 2003; Andriessen, 2004; Goh and Lim, 2004; Bareisis, 2004; Hitchner, 2006; Fitz-enz, 2009);
- 2) presentation of the difference between the intellectual capital and intangible assets in order to define qualities typical of the explored type of capital (Lilly and Reed, 2004);
- 3) comparison between the intellectual capital and other types of capital (Borneman et al., 1999; Lev, 2001; Vaskeliene, 2003);
- 4) strife to produce a new definition of the intellectual capital (Daum, 2003; Palumickaite and Matuzeviciute, 2007; Palumickaite, 2008).

The variety of definitions of the intellectual capital in academic works has been investigated by a number of scholars. The results of the conducted researches (Engstrom et al., 2003; Westnes, 2005) showed that 1) there is no universally accepted definition of the intellectual capital; 2) the concept of value creation is often mentioned, which shows that if the intellectual capital does not create any added value to the enterprise in any way

it is useless; and 3) most definitions employ the same key words: knowledge, skills, know-how, experiences, intangible assets, information, processes, and value creation.

The variety of ways of splitting the intellectual capital into constituent parts (components or smaller parts – elements) in academic works leads to complications in terms of comparison testified in multiple researches. Their results show that the division of the intellectual capital into three *components* – human, organizational and relational – is the most widely accepted (Borneman et al., 1999; Engstrom et al., 2003; Westnes, 2005; Saez et al., 2007, etc.).

According to Bontis (2002a), Daum (2003), Vaskeliene (2003), Hitchner (2006), Saez et al. (2007), Fitz-enz (2009), Dubra (2010), Giziene and Simanaviciene (2012), the *human capital* is realized as the entirety of the knowledge, skills, education, experience, talent, innovativeness, competence, motivation, loyalty, creativity, ability to perform the task and to deal with the arising issues, leadership, business initiative, management and idea generation when going for new products possessed and exhibited by the staff of an enterprise. This capital is denoted by inability of being owned by an enterprise. It is claimed that this capital is one of the key and most influential resources of an enterprise in the competitive fight as the ability of an enterprise to compete in a market depends on the knowledge and skills possessed by its staff, i.e. on the efficiency of the human capital.

According to Bontis (2002a), Daum (2003), Vaskeliene (2003), Hitchner (2006) and Saez et al. (2007), the *organizational capital* is conceived as the organizational and financial structure of the organization, its strategic processes, technologies, procedures, process documentation, risk assessment methodology, software, systems, application of information technologies, databases (e.g. ones covering information on the market and its clients), patents, trademarks, methods of sales management, communication systems and all other organizational opportunities maintaining the productivity of the staff and facilitating their cooperation. It also includes the value of the enterprise, its culture and philosophy. It may be claimed that the organizational capital covers those technologies, methodologies and processes which allow the enterprise to operate. In other words, these are the things which remain at the enterprise after a working day when the staff have left. Differently from the human capital, this capital may belong to the enterprise and thus it may be possessed. This capital is considered to be the second most important capital at an enterprise after the human capital.

According to Bontis (2002a), Daum (2003), Vaskeliene (2003), Saez et al. (2007) and Fitz-enz (2009), the *relational capital* is treated as the awareness of the enterprise, its brand awareness, image, ability to operate in a network and to fulfill the orders it wins, supply channels, longterm contracts, license and franchise agreements and relationships with external entities constituting the marketing of the enterprise and its commercial abilities. External entities in this context represent clients/ consumers, business partners, suppliers and regulating institutions.

Various academic works mention different *elements* of the intellectual capital. Having systemized the elements on the grounds of their classifications provided by Abeysekera (2008), Campbell and Rahman (2010), Mention (2011), Husin (2012), Wagiciengo and Belal (2012), the Author of the paper systemizes these classifications and provides the following scheme of the structure of the intellectual capital (Figure 1).

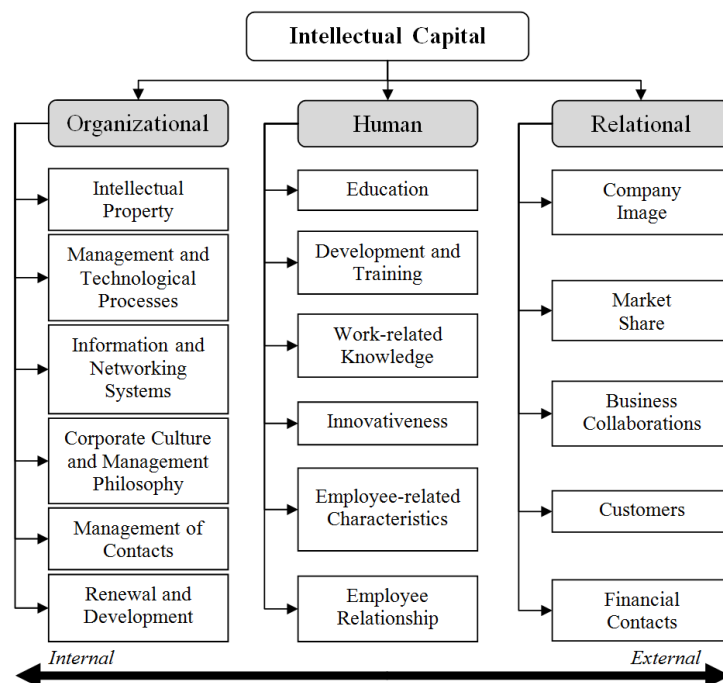

Figure 1. Scheme of the structure of the intellectual capital

Finally, on the grounds of the conducted analysis of the concept of the intellectual capital, the Author of the paper provides a definition of the intellectual capital and claims that the intellectual capital is the resources created in, purchased by or maintained by the enterprise which has no tangible form and together with the material and financial capital

of the enterprise helps to create the added value. The intellectual capital may be divided into minor constituent parts – components and elements. This definition strives to highlight that:

- 1) the intellectual capital has no tangible form (or this form is not predominant);
- 2) the intellectual capital may be purchased, created or merely maintained within an enterprise irrespectively of the property rights (e.g. the human capital cannot belong to an enterprise yet the enterprise may invest into it or use other methods of its involvement into the process of value creation);
- 3) the intellectual capital is divided into three components: the human capital, the organizational capital and the relational capital which considering the needs and the specificity of the enterprise may be split into further constituent parts – elements;
- 4) the intellectual capital or its components cannot operate independently *per se*: they only operate all and together and only together with other resources of the enterprise will the value creation be possible in the future.

In the last decade, an increase has been observed in the investigation of the trends concerning the presentation of information on the intellectual capital in financial and other annual statements (Standfield, 2005; Fitz-enz, 2009, etc.). Even though the requirements of contemporary financial accounting and accountability ignore the phenomenon of the intellectual capital (Lilly and Reed, 2004; Marr, 2008, etc.) yet enterprises conceive it as an important value-creating object in the enterprise (Van der Meer-Kooistra and Zijlstra, 2001; Westnes, 2005, etc.). Apart from the financial statements aimed at stakeholders, enterprises undertake the initiative to present additional information on their intellectual capital (Bontis, 2002b; April et al., 2003; Abeysekera and Guthrie, 2004a; Goh and Lim, 2004; Abeysekera and Guthrie, 2005; Campbell and Rahman, 2009; Ismail, 2009; Saad and Salleh, 2009; Rashid, 2010, etc.). Nevertheless, the specific culture within an enterprise, its type of activity and the attitude of the management condition differences in terms of the ways of the valuation, interpretation and disclosure of the intellectual capital. This leads to the absence of the possibility of comparison of the data. Even though the issue is recognized in a number of academic works, there is no uniform solution for dealing with it.

A number of authors (Borneman et al., 1999; Van der Meer-Kooistra and Zijlstra, 2001; Hitchner, 2006; Ismail, 2008; Fitz-enz, 2009; Mackevicius and Jarmalaite, 2011; Uziene, 2012, etc.) emphasize the limitedness of financial statements and indicate the main differences of the statements and the employed systems of the presentation of intellectual capital-related information (Table 1) obstructing the presentation of the intellectual capital-related information together with the annual financial statements.

Table 1. Key differences in the presentation of financial statements and information on the intellectual capital

Features	Financial Statements	Intellectual Capital Reporting
1. Valuation Methodology	Monetary expression, fixed amount	Expressed in indicators, fixed features
2. Target Group	Shareholders, investors, other interested parties	Stakeholders covering both internal and stakeholders
3. Disclosure	Full disclosure	Selected information
4. Decision support	External	Internal
5. Time perspective	Historic (past-oriented)	Forecast (future-oriented)
6. Validity / Standards	High	Low
7. Extent of the employed data	Only the data which may be reliably evaluated	Any possible quantitative and qualitative evaluations
8. Attitude to the intellectual capital	Consequence of future actions (i.e. the data which will be the grounds of producing accounting data in the future)	Condition of value creation
9. Degree of availability	Unlimited for the owner	Harder to access while the information is only inside the heads of the staff or in such ephemeral phenomena as the chemistry of the organization, its innovativeness or business culture

With the growth of importance of the intellectual capital in the market, the interest of external and internal information users in being presented more data on the intellectual capital of an enterprise was growing as well. This fact has been researched by numerous scholars (Bontis, 2002b; April et al., 2003; Abeysekera and Guthrie, 2004a, 2004b; Goh and Lim, 2004; Abeysekera and Guthrie, 2005; Ordonez de Pablos, 2005; Campos and Ordonez de Pablos, 2007; Vaskeliene and Selepen, 2008; Campbell and Rahman, 2009; Saad and Salleh, 2009; Rashid, 2010, etc.). Having produced generalizations on the results of the research, it is possible to state that:

- 1) considering the needs of information users, enterprises present increasingly more information on the intellectual capital in their financial or other annual statements, i.e. they cover its specific components and elements;

- 2) when disclosing various intellectual capital-related information, enterprises avoid the usage of the term “intellectual capital”;
- 3) enterprises see the human capital as the most important type and it is covered in statements most of all (however, in some countries the relational capital predominates);
- 4) the predominant form of presentation of data on the intellectual capital is qualitative, e.g. diagrams, photos, texts, tables without any numbers;
- 5) enterprises of different countries provide different amount, type, sequence and form of information; this stems from different levels of country development and different requirements set by governments in the fields of politics, social structure and economics;
- 6) enterprises lack a systematic methodology and guidelines for presentation of the intellectual capital.

Consequently, the voluntarily presented data is different and hard to compare which is a core drawback faced by stakeholders when evaluating enterprises and comparing them. According to Van der Meer-Kooistra and Zijlstra (2001), Marr (2008) and Lakis (2008), presentation of information to stakeholders sets specific requirements: 1) information users want to be able to compare data about different enterprises; 2) they expect the presented information to be reliable, objective and containing protection from the involvement of subjective data; as a result, the quality of information must be possible to verify by independent auditors. Even though the need for public presentation of information on the intellectual capital is known and universally understood, there are no universally accepted and established principles of presentation of this data.

3 Methods of intellectual capital valuation

Numerous scholars have been researching methods suitable for valuation of the intellectual capital as well as their advantages and drawbacks (Skyrme and Amidon, 1998; Bukh et al., 2001; Ratnatunga, 2002; Rodov and Leliaert, 2002; Andriessen, 2004; Kannan and Aulbur, 2004; Firer, 2005; Kasselmann, 2006; Van den Berg, 2007; Fragouli, 2010, etc.); however, no uniform opinion regarding the way of conducting the valuation of the intellectual capital of an enterprise has been reached yet. A wide variety of works suggest approximately sixty different valuation methods, some of which are purely theoretical while others are actually applied in enterprises of various types; there are

methods based on traditional financial theories as well. In order to systemize the multiplicity of methods for the valuation of the intellectual capital, authors group them (Bouteiller, 2002; Lev et al., 2003; Muller, 2004; Sitar and Vasic, 2004; Rodriguez-Castellanos et al., 2007; Tan et al., 2007; Jurczak, 2008; Kuzmina, 2008; Sveiby, 2010; Salman ir Mahamad, 2012, etc.); however, even in this field there is no uniform agreement as different criteria of classification are applied or different methods of intellectual capital valuation are analyzed and grouped in these works. There is no research which could cover and generalize the whole spectrum of methods applicable for intellectual capital valuation as well as their theoretical and practical peculiarities, which complicates further researches in this field.

Having conducted a research and considered all the classification aspects of intellectual capital valuation methods presented in academic works, a generalized scheme of classification of these methods has been developed (Figure 2). It has been discovered that methods of intellectual capital valuation may be classified on the grounds of four criteria and divided into groups accordingly.

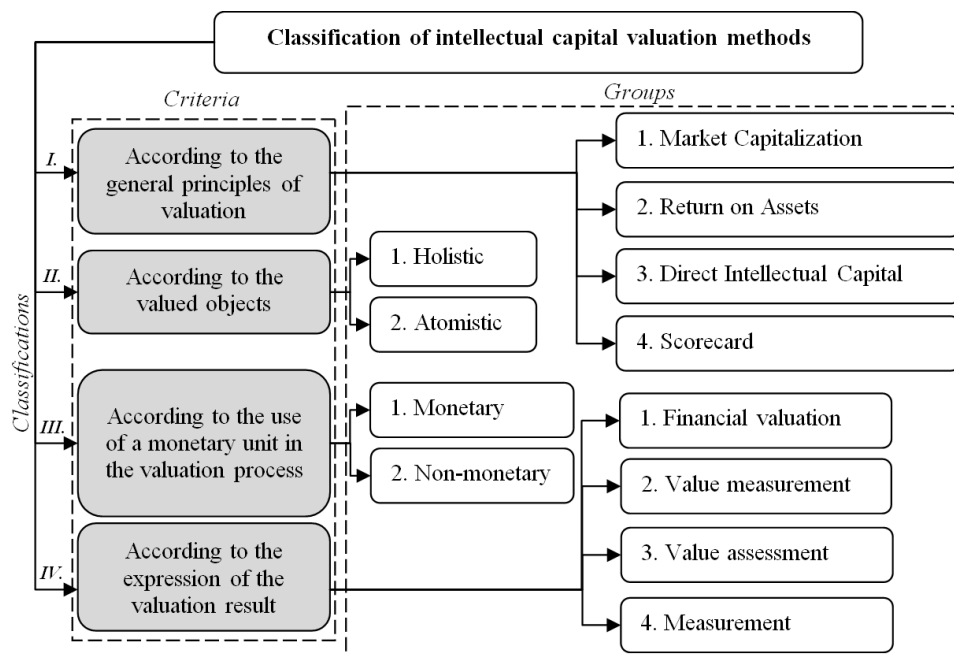

Figure 2. Scheme of classification of intellectual capital valuation methods

According to the first classification, most methods are assigned to the 'scorecard' group, i.e. the intellectual capital is valued without employing monetary units but rather

by attributing indices or indicators to its specific components. This is corroborated by the number of methods presented in the ‘atomistic’ group of the second classification, i.e. most methods treat the intellectual capital not as an entirety but rather deal with its specific components. In the third classification, the number of methods attributed to either group is more or less equal; yet, in the process of valuation, the majority of methods do not use this unit of measurement. According to the fourth classification, most methods are assigned to the group of ‘financial valuation’ methods; however, considering the fact that this classification has been researched the least of all in academic works it is possible to claim that this field has not been adequately explored yet and that these results shall impact the generalizing conclusions to the least extent.

When summarizing the obtained results it is possible to claim that most methods of intellectual capital valuation are based on scorecard, they tend to assess specific components of the intellectual capital and do not employ monetary units in the process of valuation; as a result, the expression of the valuation result is non-monetary, i.e. it is qualitative and presented as text or quantitative and presented as an index.

Considering the aim of the paper, the Author restricts the research in the field of intellectual capital valuation methods and further researches only those *evaluation* methods which allow the evaluation of the entirety of the intellectual capital of an enterprise (i.e. the *holistic* methods) and/ or the establishment of the enterprise value in monetary expression (i.e. *financial valuation* methods) by applying corresponding general principles of valuation (*market capitalization*, *return on assets* or *direct intellectual capital* methods) and a monetary unit of measurement in the process of valuation (i.e. *monetary* methods). In order to achieve this objective, 19 methods applicable to these groups have been selected for further research.

The conducted analysis of the theoretical and practical aspects of the selected methods in academic works contributes to a more precise classification (Table 2). The Author also supplements the Table with the column “Applicability in financial accounting” where “+” stands for the method being suitable for the evaluation of the intellectual capital and its disclosure in financial statements thus complementing the methods applied in financial accounting; “+/-” means that the method may be applied while “-” indicates that the method is unsuitable and cannot be applied.

Table 2. Methods of intellectual capital *evaluation* and a revised classification

No.	Classification Group Method	I.				II.		III.		IV.			Applicability in financial accounting	
		Market Capitalization	Return on Assets	Direct Intellectual Capital	Scorecard	Holistic	Atomistic	Monetary	Non-monetary	Financial valuation	Value measurement	Value assessment		Measurement
1	Market to book value / Market to book ratio (MTBV / MTBR)	X				X		X		X				+
2	Tobin's q (Tq)	X				X		X		X				+/-
3	Calculated intangible value (CIV)		X			X		X		X				+
4	Intellectual capital index				X	X			X		X			-
5	Technology broker (sometimes referred to as Intellectual capital audit)			X			X	X		X				-
6	Economic value added (EVA)		X			X		X		X				+/-
7	Market value added (MVA)	X				X		X		X				+
8	Value added intellectual capital coefficient		X			X		X		X				-
9	Total value creation			X			X	X		X				-
10	The value explorer / Weightless wealth tool kit (TVE / WWKT)		X			X		X		X				+
11	Citation-weighted patents			X			X		X				X	-
12	Knowledge capital earnings (KCE)		X			X		X		X				+/-
13	Accounting for the future		X			X		X		X				-
14	Investor's assigned market value (IAMV)	X				X		X		X				+/-
15	Human resource (costing &) accounting			X			X	X		X				-
16	Intellectual assets valuation			X			X	X		X				-
17	Inclusive value (sometimes referred to as valuation) methodology			X			X	X			X			-
18	Human resource statement			X			X	X		X				-
19	Financial method of intangible assets measurement (FiMIAM)	X				X		X		X				+

The analysis of the results presented in Table 2 leads to two groups corresponding to the aim of the paper and applicable in financial accounting being singled out (Table 3). Having conducted a synthesis of Group A methods, the Author concludes and emphasizes that these methods typically exhibit the subjectivity of a valuator as a part of the data employed in the process of valuation is forecast-based. Besides, lack of use of average data is not eliminated. Furthermore, the rate of return of specific capital groups and their indirect calculations applicable in the process of valuation remain unclear. It is possible to claim that no variable in this calculation process is precise, and their establishment is inseparable from the factor of subjectivity thus depriving one of an opportunity of comparing the obtained results among themselves. Consequently, in relation with the aim of the paper, the Author rejects these methods.

Table 3. Classification of intellectual capital *evaluation* methods corresponding to the aim of the paper

Group	Methods assigned	Features
A	CIV EVA TVE / WWKT KCE	These are financial valuation methods allowing to calculate the total value of the intellectual capital of an enterprise (holistic methods) in monetary units (monetary methods), and the calculations are based on the <i>evaluation of the return on assets</i> .
B	MTBV/MTBR Tq MVA IAMV FiMIAM	These are methods of financial valuation allowing to calculate the total value of the intellectual capital of an enterprise (holistic methods) in monetary units (monetary methods), and the calculations are based on the <i>capitalization of market value</i> . Consequently, these methods may be applied only for the enterprises whose market value may be established reliably.

Having conducted a synthesis of Group B methods, the Author concludes and claims that the usage of market value in the process of valuation helps one avoid the valuator subjectivity-related disadvantages; this value is precise and possible to establish at any given moment. It measures an enterprise as an entirety by covering both identifiable and unidentifiable objects of the capital as well as the liabilities of the enterprise. The comparison of this value with its book value simply and plainly reveals whether the enterprise possesses any capital which is not presented in its financial statements. It should be highlighted that before establishing the balance value of an enterprise it is useful to check whether the values of the assets and liabilities of the enterprise are similar to their fair values (as the standards of accounting require).

One of Group B methods, namely, FiMIAM by applying the weights established within the enterprise distributes the obtained difference across the three intellectual capital components, i.e. the human, organizational and relational – thus establishing their value in a monetary equivalent. This identification of the values of intellectual capital components is well-grounded and logical just because of the fact that all the intellectual capital components and elements are interwoven as they are worthless separately; hence, the separation of their values is an extremely complex or even insurmountable challenge. Considering this, *the model of intellectual capital evaluation and disclosure in financial statements* is based on principles typical of Group B methods.

4 Model of intellectual capital evaluation and disclosure in financial statements

The theoretical *model of intellectual capital evaluation and disclosure in financial statements* consists of six steps (Figure 3). *Step One* is the calculation of the difference between the market value and the book value of the enterprise which is equaled to the value of the realized intellectual capital of the enterprise. It should be remarked that this idea originates in IAVM method. In *Step Two*, within the enterprise, those elements of the intellectual capital are identified which define and explain the future monetary flow. Then they are assigned to the corresponding components of the intellectual capital of the enterprise. In *Step Three*, on the grounds of *Step Two*, the weights of the components of the intellectual capital of the enterprise in the general context are outlined in order to reflect the relative influence and importance of each of them upon the entirety of the intellectual capital. This step should be performed by the management of the enterprise on the grounds of their experience and on the basis of their understanding of value creation within the enterprise. It should be noted that additional regulation and/ or recommendations for *Steps Two* and *Three* are required at national or regional levels; these steps could apply various quantitative non-monetary and qualitative methods of intellectual capital valuation; however, this requires a more profound research into the methods of the intellectual capital *measurement* that has not been performed in the framework of this paper.

On the grounds of the established weights of the components of the intellectual capital within the enterprise, *Step Four* calculation represents the discovery of the value of intellectual capital components in monetary units. These values are consequently presented in the balance sheet of the enterprise (*Step Five*): 1) in the assets side by including the additional position “*Intellectual capital*” and its components “*Human capital – HC*”, “*Organizational capital – OC*” and “*Relational capital – RC*” while 2) the position of “*Equity*” on the side of the equity and liabilities of the balance sheet is supplemented with a line “*Unrealized profit (losses) of the intellectual capital*” thus restoring the expenses that the enterprise underwent when maintaining its intellectual capital which were treated as expenses (in the case of profitability) or when acknowledging consequences of inefficient use of the intellectual capital (in the case of losses).

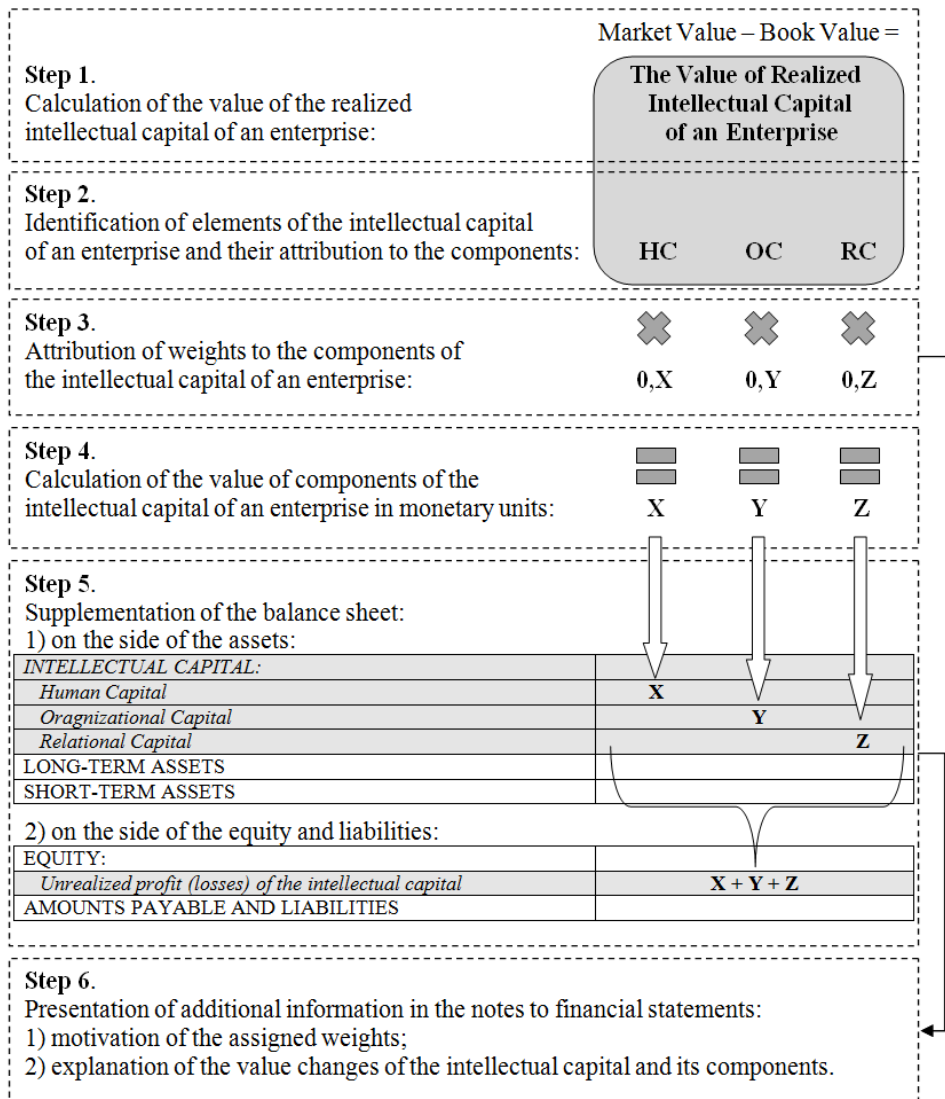

Figure 3. The model of intellectual capital evaluation and disclosure in financial statements

On the grounds of *Step Six* of the model, the explanatory note should contain additional information in order to explain the values of the intellectual capital and its components presented in the balance sheet better: 1) to ground and argue the weight attributed to specific components of the intellectual capital of the enterprise; and 2) in order to explain alterations of the value of the intellectual capital and its components. This

step also requires useful additional regulation(s) and/ or recommendations at regional or national levels.

Consequently, if enterprises apply this model, they not only present the values of the realized intellectual capital and its components in the balance sheet but also provide motivation for the calculation of these values and the explanation of changes in the notes to financial statements. As a result, stakeholders are supplied with additional information on the capital possessed by the enterprise while creation, filling in and presentation of new statements is avoided.

5 Application of the model of intellectual capital evaluation and disclosure in financial statements in Lithuanian enterprises

This part establishes the methodology of the research of the model application and assessment of the obtained results. On the grounds of this methodology by employing data of annual statements of publicly listed enterprises operating in dairy products and alcohol industries of the Republic of Lithuania, the possibilities of integrating *the model of intellectual capital evaluation and disclosure in financial statements* developed by the Author of the paper into the system of financial accounting and the significance of the model for the decisions based on the information provided in financial statements are evaluated.

5.1 Methodology of the research of the application of the model

The object of the research is the model of intellectual capital evaluation and disclosure in financial statements. *The aim* is to assess the applicability of the model and its significance for consumers decisions based on the information presented in financial statements. In order to achieve the aim, the following *objectives* were set in the research: 1) to highlight issues encountered in application of the model in practice; and 2) to analyze the significance of the integration of the model into the system of financial accounting regarding the decisions taken by stakeholders.

Methods of the research. In order to achieve the set objectives, the inductive method of research was selected. Induction is a method of empirical research of phenomena when, after the investigation of specific objects and the discovery of a specific quality of the phenomena, a conclusion is drawn that all the objects belonging to the class possess the same quality (Pleckaitis, 1978; quoted from: Tidikis, 2003). Research statements are

correspondingly set to be followed during the course of the empirical research: T(1). The model of intellectual capital evaluation and disclosure in financial statements **is not** applicable in practice; and T(2). Financial statements supplemented with data on the intellectual capital of an enterprise **do not alter** the results of financial analysis conducted on the basis of these statements. In order to verify the selected claims, case study was selected. This research involves document and content analysis methods.

Sample of the research. When establishing the sample of the research, it was considered that the core data element necessary for the application of the model is the market value of an enterprise. In Lithuania, the market value may be reliably established only for these enterprises whose shares are publicly traded in the market. There are 33 enterprises of this type. Enterprises have been selected for this research considering the branch of economy they represent and the date since which they have been continually listed. These enterprises and branches of industry were attempted to be selected whose data may be compared both among enterprises and between/ among branches of industry. As a result, eight enterprises operating in the branch of industry “food and beverages” have been selected for further analysis, four of which are involved in alcohol production and trade while the four others deal with the production and trade of dairy products. A four-year period from 2009 to 2012 inclusive was selected for exploration.

Organization and course of the research. In order to accomplish Objective One, the instrumentation of the research was described which is based on systematic implementation of the steps of the verified model. In the course of the research, publicly available information posted on the internet was being used, i.e. the data of the annual statements of the enterprises and the data of the stock exchange internet website was being employed. Data on the elements of the intellectual capital of the enterprises (Step Three of the model) and the weights assigned to the components (Step Four of the model) were obtained by using alternative methods, namely, by performing content analysis of the publicly posted data.

In order to implement Objective Two, financial analysis of the enterprises was conducted on the grounds of information presented in the financial statements of these enterprises: horizontal, vertical and financial ratios (profitability, turnover and financial leverage) were considered. On the basis of this information, the research statement T(2). *Financial statements supplemented with data on the intellectual capital of an*

enterprise **do not alter** the results of financial analysis conducted on the basis of these statements is divided further and verified in terms of five operative claims:

T(2)₁: Supplementation of the balance sheet assets side with the data on the intellectual capital of an enterprise **does not alter** the results of horizontal and vertical analysis;

T(2)₂: Supplementation of the balance sheet equity and liabilities side with the data on the unrealized profit (losses) of the intellectual capital of an enterprise **does not alter** the results of horizontal and vertical analysis;

T(2)₃: Supplementation of the balance sheet with the data on the intellectual capital of an enterprise **does not alter** the results of the analysis of financial profitability ratios;

T(2)₄: Supplementation of the balance sheet with the data on the intellectual capital of an enterprise **does not alter** the results of the analysis of financial turnover ratios;

T(2)₅: Supplementation of the balance sheet with the data on the intellectual capital of an enterprise **does not alter** the results of the analysis of financial leverage ratios.

These statements have been selected by the Author of the paper for verification in both selected branches of industry (alcohol and dairy industry) separately; hence, each statement is split into two and ten operative claims T(2)_{1A}, T(2)_{1P}, T(2)_{2A}, T(2)_{2P}, T(2)_{3A}, T(2)_{3P}, T(2)_{4A}, T(2)_{4P}, T(2)_{5A} and T(2)_{5P} are verified where index *A* stands for the industry branch of alcohol while index *P* stands for the industry branch of dairy products. The outlined statements are empirically verified in the course of the research. *Microsoft Excel* software is employed for statistical and graphical data processing.

5.2 Results of the model application

Having implemented Objective One, four core issues in the implementation of the verified model in real life were established. The first issue is *the impossibility of the establishment of the market value of these enterprises whose shares are not traded in the market*. In order to eliminate this drawback, a method or methods offering reliable establishment of the value of a specific enterprise in monetary units should be involved into the model of intellectual capital evaluation and disclosure in financial statements. However, this requires additional research in the field of enterprise value establishment which was not conducted in the framework of this paper. On the other hand, investment decisions are usually taken by individuals involved into the stock market and they are mostly interested in those enterprises whose shares may be traded in the market.

The second issue of the practical application is the *identification of elements of the intellectual capital of an enterprise and their attribution to the components of the intellectual capital of the enterprise*. The third issue in the application of this model is closely related with the previous one; it is the *assignment of weights to the components of the intellectual capital of the enterprise*. In order to help enterprises properly implement these steps of the model, additional regulations or recommendations may be required and useful which would: 1) extensively explain the concept of specific elements of the intellectual capital of an enterprise; 2) present potential methods for their identification and assignment to components of the intellectual capital; and 3) recommend ways for assigning weights to specific components of the intellectual capital of an enterprise.

The fourth issue regarding application is the *presentation of data in the notes to financial statements*. Here, additional regulations are also required and useful at national or regional levels. In order to harmonize the type and shape of information, the minimal scope of information related with 1) the assignment of weights to specific components of the intellectual capital of an enterprise and 2) changes in the values of the intellectual capital and its components should be presented in the notes to financial statements.

Considering the issues of the model identified during the practical research it is possible to claim that the developed *model of intellectual capital evaluation and disclosure in financial statements* **is applicable** in practice and providing that the necessary regulations and/ or recommendations are passed/ drafted it may be successfully integrated into the system of financial accounting. *On these grounds, the Author of the paper negates the research statement T(1).*

When dealing with Objective Two, a research of the impact of the model integration into financial accounting taking into consideration the effect on decisions taken by stakeholders was conducted. The generalized data of the investigated operative statements is presented in Table 4. When exploring the obtained results, it is evident that six out of ten operative statements were negated which determined the negation of the initial research statement.

When generalizing on the conducted research, it may be stated that financial statements supplemented with data on the intellectual capital of an enterprise **do alter** results of the financial analysis conducted on the grounds of these statements.

Table 4. Results of verification of the operative statements and negation of the initial statement

No.	Claim	Result
T(2) _{1A}	Supplementation of the balance sheet assets side with the data on the intellectual capital of an enterprise does not alter the results of horizontal and vertical analysis	Negative
T(2) _{1P}		Negative
T(2) _{2A}	Supplementation of the balance sheet equity and liabilities side with the data on the unrealized profit (losses) of the intellectual capital of an enterprise does not alter the results of horizontal and vertical analysis	Negative
T(2) _{2P}		Negative
T(2) _{3A}	Supplementation of the balance sheet with the data on the intellectual capital of an enterprise does not alter the results of the analysis of financial profitability ratios	Affirmative
T(2) _{3P}		Negative
T(2) _{4A}	Supplementation of the balance sheet with the data on the intellectual capital of an enterprise does not alter the results of the analysis of financial turnover ratios	Affirmative
T(2) _{4P}		Affirmative
T(2) _{5A}	Supplementation of the balance sheet with the data on the intellectual capital of an enterprise does not alter the results of the analysis of financial leverage ratios	Affirmative
T(2) _{5P}		Negative
T(2)	<i>Financial statements supplemented with data on the intellectual capital of an enterprise do not alter the results of financial analysis conducted on the basis of these statements</i>	Negative

Considering this in the context of the opinion of Mackevicius (2006) that 1) the current financial statements provide insufficient information which does not meet the needs of internal and external information users under the permanently changing conditions of the competitive market and that 2) financial statements are required to present such information which should help information users take the right decisions, evaluate events of former, current and future periods, organize economically rational and efficient activity, the Author concludes that the integration of *the model of intellectual capital evaluation and disclosure in financial statements* into the system of financial accounting will provide analysts with additional data for the implementation of analysis thus reducing the limitations of the information which is currently provided in financial statements.

6 Conclusions

Having analyzed the essence of the intellectual capital and its typical qualities, a *definition of the intellectual capital* has been developed. It was established that this is resources having no tangible form which are created, purchased or maintained within an enterprise where, together with the material and financial capital of the enterprise, these resources contribute to the creation of the added value. The intellectual capital may be divided into minor constituent parts – components and elements.

Having researched constituent parts of the intellectual capital presented in academic works, a *structural scheme of the intellectual capital* was developed by singling out three components of the intellectual capital: the human capital, the organizational capital and the relational capital. Taking into consideration the needs and the specificity of the enterprise, all of them may be split into minor constituent parts – elements – which may be grouped on the grounds of the content analysis of various academic works.

Having researched and systemized the conducted empirical research in various countries regarding the trends of the presentation of information on the intellectual capital of an enterprise to stakeholders it was established that many academic works highlight the need to standardize the presentation of the information on the intellectual capital of an enterprise as peculiarities of the enterprise culture and the attitudes of the managerial staff obstruct the natural development of the process and hamper the achievement of the main objective, namely, *the provision of more data on the objects creating value of the enterprise to stakeholders so that the data could be comparable between/ among different enterprises, industry branches or regions.*

Having generalized on the suggested methods of intellectual capital valuation, a *scheme of classification of these methods* is suggested. It was established that at least sixty different methods are suggested for the valuation of the intellectual capital of an enterprise. Most of them are based on scorecard, assess specific components of intellectual capital and do not employ monetary units in the process of valuation; as a result, the expression of the valuation result is non-monetary, i.e. it is qualitative and presented as text or quantitative and presented as an index.

Having explored the theoretical and practical aspects of nineteen methods of intellect capital *evaluation*, possibilities of their integration into the financial accounting were explored. During the research, two groups of methods with possible application were developed. On the grounds of synthesis of these methods it was established that the use of the market value in the process of valuation (Group B methods) helps to avoid drawbacks related with the subjectivity of the valuator (Group A methods). This value is precise and possible to establish at any given moment. It measures an enterprise as an entirety by covering both identifiable and unidentifiable objects of the capital of the enterprise. The comparison of this value with its book value simply and plainly reveals whether the enterprise possesses any capital which is not presented in its financial statements.

Considering this, *the model of intellectual capital evaluation and disclosure in financial statements* is based on the principles of Group B methods.

A theoretical *model of intellectual capital evaluation and disclosure in financial statements* consisting of six steps has been developed. Having applied this model, enterprises would not only present the values of the intellectual capital and its components in the balance sheet but would also provide motivation for the calculation of these values and the explanation of changes in the notes to financial statements. As a result, stakeholders would be supplied with additional information on the capital possessed by the enterprise while creation, filling in and presentation of new statements would be avoided.

For the application and verification of the *model of intellectual capital evaluation and disclosure in financial statements*, the empirical methodology of research was applied. The results showed that the developed *model of intellectual capital evaluation and disclosure in financial statements* is **applicable in practice** and provided that the necessary regulations and/ or recommendations are passed/ drafted it may be successfully integrated into the system of financial accounting; and that the integration of *the model of intellectual capital evaluation and disclosure in financial statements* into the system of financial accounting will provide analysts with additional data for conducting data analysis thus decreasing the limitedness of the information provided in the currently presented financial statements.

Structured Abstract

Purpose – Enterprises are facing transforming framework conditions that are manifesting on several levels. Increased competition from emerging markets, limited availability of resources as well as political and societal requirements with regard to the sustainability of enterprises' operations are only an extract of changing factors of influence. The capability to innovate has proven to be a strong competitive advantage and is to be assessed as a major success factor to limit the exposure to the intensified competitive (Schmeisser et. al. 2010), normative or even legal pressure especially for small and medium-sized enterprises.

Design/methodology/approach – In order to identify and describe the interdependences between intangible resources, their management and innovation capabilities the principal terms are put into focus at first. Building up on the theoretical explanations and taking the management method “Intellectual Capital Statement – Made in Germany” as a starting point the interdependencies between intellectual capital and product innovation as well as process optimisation and innovation are analysed. Within this article the interdependences between the standard intellectual capital factors are investigated with regard to product and process innovation on the basis of 38 Intellectual Capital Statements of German enterprises.

Originality/value – The significance of intangible resources for business success has evidently increased and may in some cases already be assessed as higher than the impact of tangible resources. Analyses have indicated some intellectual capital factors as the most prominent and important, yet the impact on the intra- and inter-organizational innovation ecosystems has not been analysed thoroughly. Although the most important factors of intellectual capital are identified, the specific drivers for innovation have not been investigated. This paper seeks to close this gap and draw meaningful conclusions with regard to drivers of innovation and related differences between manufacturing and service enterprises.

Practical implications –The analysis of the correlation between intellectual capital and innovation capabilities allows statements regarding the intellectual capital factors, onto which enterprises should be focused in order to foster innovation. The qualitative content-

related analysis of the 38 intellectual capital statements with regard to the consideration of new and different types of innovation management methodologies allows the identification of existing gaps in intellectual capital management. The close examination of the framework of new types of innovation and cross-reference to practical interdependences shall establish the theoretical basis for future case studies with enterprises that have the objective of establishing new types of innovation to continue this very research.

Keywords – Innovation Management, Intellectual Capital Statement, Knowledge Management

Paper Type – Academic research paper

1 Introduction

Enterprises are facing transforming framework conditions that are manifesting on several levels. Increased competition from emerging markets, limited availability of resources as well as political and societal requirements with regard to the sustainability of enterprises` operations are only an extract of changing factors of influence. The capability to innovate has proven to bear the potential to establish and ensure strong competitive advantages and is to be assessed as a major success factor to limit the exposure to the intensified competitive (Schmeisser et. al. 2010), normative or even legal pressure especially for small and medium-sized enterprises. This contribution aims at analysing the potential contribution of strategic intellectual capital management to improve the framework for product and process innovation. Moreover, the mere product or incremental process innovations are neither a guarantee for success nor sufficient to cope with the emerging information, knowledge and time-competition (Stern, Jaberg 2010). The organizational innovation as a third category of innovation (Stoneman 1983 / Hemmelskamp 1997) and the implications of new types of innovation management as well as new methodologies to generate innovations such as collaborative innovation, design thinking and methodologies alike are put into perspective along with a closer look at the significance of business model innovation in this regard.

The significance of intangible resources for business success has evidently increased and may in some cases already be assessed as higher than the impact of tangible resources. Analyses have indicated some intellectual capital factors as the most prominent and important, yet the impact on the intra- and inter-organizational innovation ecosystems has not yet been analysed thoroughly. Although the most important factors of intellectual capital are identified, the specific drivers for innovation have not been investigated. This

paper seeks to close this gap and draw meaningful conclusions with regard to drivers of innovation and related differences between manufacturing and service enterprises.

2 Description of Principal Terms

In order to prepare the analysis and evaluation of the Intellectual Capital Statements in regard to product and process innovation and their relation to other standard factors a few principal terms shall be defined in the next paragraphs. The basics of intellectual capital management and in particular the Intellectual Capital Statement (ICS) are followed by a description of product, process and organizational innovation.

2.1 Intellectual Capital Management

In order to bridge the gap between the requirements for internal management purposes and external reporting, InCaS developed instruments to systematically assess, develop and report an organisation's IC. As a main project result, the "European Guideline for Intellectual Capital Statements (ICS)" has been published. The guideline describes in detail each single step of the ICS implementation and provides templates, checklist supplements and the ICS toolbox in order to support this process (EU Commission 2008).

The InCaS project consists of 50 pilot implementations in SMEs from 5 different EU countries (Germany, France, Poland, Slovenia and Spain). Indeed, it represents the extension of a methodology previously implemented with great success in 50 German SMEs (Mertins et al. 2009). Today there are known approximately 1.000 ICS implementations and the German guideline and toolbox have been downloaded from the internet more than 100.000 times (Herrmann 2013).

The ICS approach consists of two models to guide and to enable the ICS implementation process: firstly, the Structural Model aims at defining the "language" (i.e. the vocabulary) to be used when dealing with IC and secondly, the Procedural Model leads the organisation through the ICS process and defines five implementation steps: (1) Define Business Model, (2) IC Analysis, (3) Measurement, (4) Strategy Refinement & Measures and finally (5) prepare the Final ICS Document.

ICS Structural Model

The structural model of the ICS approach – a result of the consolidation process of international approaches on IC management and reporting – describes the main elements

of the ICS as well as their interrelations. The model is a holistic and systemic representation of the way the organisation has structured its business processes to deliver value to the customers. Starting point is the vision and strategy of the organisation with a view to the possibilities and risks encountered in the external business environment. Following the most frequently used structure to describe intangible resources, the ICS framework divides intellectual capital into three dimensions: human, structural and relational capital (Figure):

- Human Capital (HC) includes the staff’s competencies, skills, attitudes and the employee’s motivation. Human Capital is owned by the employee and can be taken home or onto the next employer.
- Structural Capital (SC) comprises all structures and processes needed by the employee in order to be productive and innovative. It “consists of those intangible structures which remain with the organisation when the employee leaves” (Edvinsson, Malone 1997).
- Relational Capital (RC) sums up all relationships to external groups and persons established by the organisation, e.g. customers, suppliers, partners and the public.

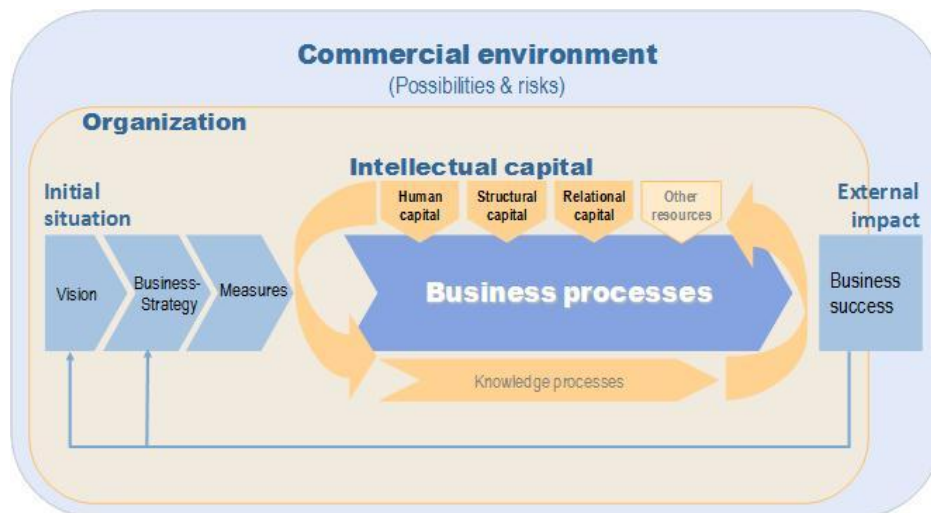

Figure 1: ICS Structural Model (Mertins et al. 2009).

IC Standard Factors: A decisive step towards the harmonisation of international approaches in the field of IC measurement and reporting has been taken by the initiatives

mentioned above. They established a concept on how to harmonise the huge variety of intangible elements which build the basis for superior business performance in order to bridge the gap between individuality and comparability of IC-related information (Mertins et al. 2009).

Using the IC categorisation as mentioned above the harmonisation of ICS content was started on basis of the empirical results collected in more than 50 pilot implementations. The results from practice showed, that approx. 80-90% of individual IC elements could be harmonised on an aggregated level, while the remaining 10-20% are individual respectively organisational specific (Mertins, Will 2008). The table below shows those factors of Intellectual Capital, which could be harmonised across all participating companies and have been empirically identified as a standard set of so called "IC factors".

2.2 Product, Process and Organisational Innovation

Innovations are of substantial significance for the effective economic and technological development of economies and enterprises. Innovations replace existing products, processes or organizational structures and have the capability to change the persisting technological, economical systems or even organizational and social structures. In this contribution product and process innovation are perceived as the main categories, while the strategic organizational – or business model innovation - is subject to an evaluation regarding the adaptability.

According to the definition of the standard success factors of IC, that cover 80 % of all intellectual capital factors (Mertins, Will, Wuscher 2007), product innovations are defined as innovations of great importance for the future of the organization. The development, testing, production and introduction to the market of new or improved products or services or the adaption of functionality to other uses is considered product innovation. Incremental changes to products e.g. the change of specifications, materials or addition of functionality is also comprised in the general definition.

The optimization and improvement of existing procedures as well as the development and implementation of new processes is defined as the process optimisation and innovation standard success factor of intellectual capital. Inefficient procedures within an organization or in regard to the interfaces and interaction with suppliers, partners or customers are often regarded as a cause for low or decreased competitiveness and economic losses. Therefore, the continuous improvement of procedures, striving to

increase the effectiveness and efficiency, is a corner stone of the definition of the standard success factor for intellectual capital. Utilizing systems such as idea management to constantly map and evaluate potential improvements and implementing new procedures or incremental process innovations can help to overcome the inefficiencies.

The business model – the means and methods employed by organisations to create, deliver and capture value (Osterwalder, Pigneur 2010) – is usually subject to innovation, when new markets are developed or penetrated by an organisation or through the structural change in existing markets (Zott, Amit 2007). Thus, both product and process innovation may render the inherent business model obsolete or inadequate. Organisational innovation is herein defined as the adaptation of new organisational structures or procedures within the business model, structural organization or external relations.

3 Analysis and Evaluation of Intellectual Capital Statements

The analysis and evaluation of previously created Intellectual Capital Statements of 38 German enterprises is separated herein into the description of the data and the analysis and evaluation in regard to the relations between the standard success factors of intellectual capital (see *Figure 2 - Figure 4*) with a special focus on product and process innovation.

	Standard Success Factors	Description
HC-1	Professional Competence	Human Capital includes the staff's competencies, skills, attitudes and the employee's motivation. Human Capital is owned by the employee and can be taken home or onto the next employer.
HC-2	Social Competence	
HC-3	Employee Motivation	
HC-4	Leadership Ability	

Figure 2: Standard Success Factors for Human Capital

	Standard Success Factors	Description
SC-1	Internal Co-operation and Knowledge Transfer	Structural Capital comprises all structures and processes needed by the employee in order to be productive and innovative. It “consists of those intangible structures which remain with the organisation when the employee leaves” (Edvinsson, Malone 1997).
SC-2	Management Instruments	
SC-3	Information Technology and Explicit Knowledge	
SC-4	Product Innovation	
SC-5	Process Optimisation and Innovation	
SC-6	Corporate Culture	

Figure 3: Standard Success Factors for Structural Capital

	Standard Success Factors	Description
RC-1	Customer Relationships	Relational Capital sums up all relationships to external groups and persons established by the organization, e.g. customers, suppliers, partners and the public.
RC-2	Supplier Relationships	
RC-3	Public Relationships	
RC-4	Investor Relationships	
RC-5	Relation to Co-operation Partners	

Figure 4: Standard Success Factors for Relational Capital

3.1 Data-basis

In this contribution the Analysis of 38 consolidated Intellectual Capital Statements of German enterprises of both the production and service domains are evaluated regarding the interdependencies of the inherent standard success factors for intellectual capital concerning product innovation as well as process optimization and innovation in particular. Of the 38 ICS 25 are service enterprises, while 13 are associated with the production domain. The interrelations between the standard success factors of intellectual capital are shown in the table below as aggregated averages. The table is structured in such a way, that the influence evaluation numbers correspond influence the standard success factors in the rows have on the factors in the columns. As an example the number “2” in row 1 and column 8 is an assessment of the influence HC-1 has on SC-4. The scale for the interrelation assessment is structured as follows: factor (row) has (0 = no, 1 = a weak, 2 = strong, 3 = very strong) influence on factor (column).

Table 1: Aggregated average interrelations (From Mertins, Wuscher, Will 2012)

	HC-1	HC-2	HC-3	HC-4	SC-1	SC-2	SC-3	SC-4	SC-5	SC-6	RC-1	RC-2	RC-3	RC-4	RC-5	AS
HC-1	x	1	2	1	2	1	1	2	2	1	2	2	1	1	2	21
HC-2	1	x	2	2	2	1	1	1	1	2	2	1	1	1	2	20
HC-3	2	2	x	1	2	1	1	2	2	2	2	1	1	1	2	22
HC-4	2	2	3	x	2	2	1	2	2	2	1	1	1	2	1	24
SC-1	2	2	2	1	x	1	1	2	2	1	2	1	1	1	1	20
SC-2	1	1	2	2	2	x	1	2	2	2	1	1	1	1	1	20
SC-3	2	0	2	1	2	1	x	1	2	1	1	1	1	1	1	17
SC-4	2	0	2	0	1	1	2	x	2	2	2	2	2	2	2	22
SC-5	2	1	2	1	2	1	2	2	x	1	2	1	1	1	1	20
SC-6	1	2	2	1	2	1	1	2	1	x	2	1	1	1	1	19
RC-1	1	1	2	1	1	1	1	2	1	1	x	1	2	1	1	17
RC-2	1	0	1	0	1	1	1	2	1	0	1	x	1	1	1	12
RC-3	0	0	1	0	0	0	1	1	1	1	2	1	x	2	1	11
RC-4	0	0	1	1	0	0	0	1	0	0	1	1	1	x	1	7
RC-5	2	1	1	1	1	0	1	2	1	1	2	1	2	1	x	17
PS	19	13	25	13	20	12	15	24	20	17	23	16	17	17	18	269

AS = Active sum

PS = Passive sum

Considering the active sums (AS), it is visible that product innovation as well as process optimization and innovation have a strong influence on the other standard success factors for intellectual capital. In a first step of the analysis, the active and passive sums of the interrelations of the factors product as well as process optimization and innovation are considered. Both innovation factors show a relatively high influence on all other factors, where product innovation shows a slightly higher aggregated average influence of 22 in contrast to the value of 20 of process optimization and innovation. Considering the influence of other factors on the innovation factors SC-4 and SC-5, the same observation is made.

For an in-depth analysis, the data basis is separated into the data regarding the service and production enterprises. The following tables show the aggregated average interrelations of the service and production enterprises. The passive data indicates the influence of the factors in the columns onto the innovation factors. The active data indicates the influence taken by the innovation factor onto the other factors.

Table 2: Aggregated average interrelations of production enterprises

Passive	HC-1	HC-2	HC-3	HC-4	SC-1	SC-2	SC-3	SC-4	SC-5	SC-6	RC-1	RC-2	RC-3	RC-4	RC-5	
SC-4	3	2	2	2	3	1	2	x	1	2	2	2	0	1	2	25
SC-5	2	1	2	2	2	1	2	2	x	1	1	1	0	0	1	18
Active																
SC-4	2	1	2	1	2	1	2	x	2	2	3	2	2	2	2	26
SC-5	2	1	2	1	1	1	2	1	x	1	2	1	0	1	1	17

The sample of the production enterprises allows a closer look at the assessed influences between the standard success factors of intellectual capital. In comparison to

the service enterprises (see Table below) the influences on product innovation are assessed as stronger on average. The active and passive influence of process optimisation and innovation is slightly higher rated by service enterprises.

Table 3: Aggregated average interrelations of service enterprises

Passive	HC-1	HC-2	HC-3	HC-4	SC-1	SC-2	SC-3	SC-4	SC-5	SC-6	RC-1	RC-2	RC-3	RC-4	RC-5	
SC-4	2	1	2	2	2	2	1	x	2	1	2	1	1	2	1	22
SC-5	2	1	2	2	2	2	2	1	x	1	1	1	1	0	1	19
Active																
SC-4	1	0	2	0	1	1	2	x	1	2	2	1	2	2	2	19
SC-5	2	0	2	1	2	1	2	2	x	1	2	1	1	1	1	19

In the inspection of this data, the larger sample size of the service enterprises needs to be considered, as it provides a solid basis for general assumption, while compensating for major exceptions.

4 Intellectual Capital and Innovation

As described, the close relation between innovation capabilities and the intellectual capital is manifested in the definition of process and product innovation as standard success factors of the structural capital. Moreover, the influence of intellectual capital and the strategic management thereof to increase the innovation capabilities of enterprises can be assessed as a crucial effort to maintain the organisations' competitiveness. The following descriptions of interrelations are limited to those that show a strong or very strong influence on the innovation standard factors. The inherent definitions of the standard success factors are based on the European ICS Guideline (European Commission 2008). First, this assessment is conducted for the production enterprises, followed by a comparative assessment of the service enterprise. In these, generic improvement methods are described and other drivers as well as innovation inhibitors (Wulfen 2011 / Trías de Bes, Kotler 2011) are addressed.

4.1 Human Capital and Innovation

The capabilities that are brought into the value adding process of an organisation, the human capital, is a basic prerequisite for product innovation as well as process optimisation and innovation. The standard success factors of human capital have an overall strong influence on the product innovation. First of all, the professional competence has a very strong influence on the product innovation and a strong influence

on the process optimisation and innovation, as the collective expertise and experience is a prerequisite to develop technical enhancements or new technical solutions. Generally, the competence management should therefore target the recruitment of highly competent employees and their further professional development to increase the innovation capability. This competence however, needs to be balanced across the knowledge domains of the operation and organisation and should include the competence to implement and adapt solution-oriented innovation systems and methodologies.

The social competence and especially the communication aspect are essential for the product innovation activities as it includes the employee's creativity and flexibility. Moreover, the communication of ideas and the nurturing trust-enhancing behaviour foster the generation of ideas and innovations through constructive discussions and co-operation. The specific training of communication and co-operation competences of the employees and the inherent prevention of fear-inducing environments (Trías de Bes, Kotler 2011) can improve the idea generation and communication. This is important in order to align the technological and product strategies with the idea evaluation. The social competence has only a weak influence on the process optimisation and innovation, a fact that can be explained, as the general value adding processes of an organisation are set within the business model and it is the human capital that determines the quality and efficiency with which these are executed.

The employee's motivation to play a part in the organisation and in particular the sub areas of identification with the organisation and the sense of participation in achievements has a strong influence on product innovation. In general the individual employee's motivation influences the performance in terms of quality and efficiency. Findings by SAUERMAN and COHEN suggest that the employee's motivation (to innovate) is influenced by extrinsic and intrinsic factors that have an impact on the individual effort in idea generation and implementation (Sauer mann, Cohen 2008 / Tyrone, Simpson, Dehlin 2012).

Equally strong as the latter, the influence by the leadership ability concentrates around the ability to administrate and motivate people, showing a close connection to the other human capital factors. Therefore, the utilization of methodologies to develop and communicate strategies, visions as well as their empathic implementation should foster the intrinsic factors for motivation to innovate.

4.2 Structural Capital and Innovation

The organisational structures and processes that determine the employees' interaction and their overall productivity have a weaker influence on product innovation and process optimisation and innovation, where these are part of the structural capital. The internal co-operation and knowledge transfer stands out with a very strong influence on product innovation. Here the ability to co-operate, as included in the social competence, is applied across the different hierarchy levels. The focused internal knowledge transfer builds professional competencies and retains knowledge within the organisation, thus building the innovation capabilities regarding products and processes between generations.

The management tools have a weak impact on both innovation factors. This is mostly due to the fact that tools and instruments are utilized to support the leadership ability, which might not directly be perceived by all employees in the participative assessment of the success factors.

The information technology and explicit knowledge is assessed to have a strong impact on both innovation factors. Information and communication systems are a significant part of today's working environment and implicitly influence the acquisition, processing and utilization of knowledge. State of the practice information and communication systems help to effectively and efficiently perform given tasks, and assist the employees to operate and control integrated production systems. Moreover, the fast and convenient access to information, design and simulation systems may optimise products or processes and generate innovative ideas.

The influence of SC-5 on SC-4 was assessed as weak, while on average a strong average influence was calculated vice-versa. As most process innovation in the production domain is of technical nature it may induce product innovation due to new possibilities, but is mostly concerned with existing products or procedures. Product innovation entails a certain change in processes, of which some may not exist and require optimisation or innovation.

The corporate culture, comprising all values and norms, influencing joint interaction, knowledge transfer and the working manner, has a strong impact on product innovation. Compliance to rules, good manners, "Do's and Don'ts" and the handling of failures are important aspects of this factor. While in product innovation the risk of failure induces a natural fear of failure and their consequences (Trías de Bes, Kotler 2011), the process optimisation or innovation is regarded as being influenced weaker as such conditions are

less evident. Moreover, the economic impact of process optimisation is measurable directly, whereas the economic impact of product innovation remains relatively uncertain, thus.

4.1 Relational Capital and Innovation

The relational capital, comprising all relationships to external groups or individuals established by the organisation, e.g. customers, suppliers, partners and the public, overall has a weak impact on product and process innovation. Public and investor relationships are in part even assessed as having no impact on the innovation factors.

Relationships to customers, whether former, current or potential customers have a strong influence on product innovation, which is evident, as the innovative solution generation is at least in part based on the customer's demand. The management of these relations, beyond the classical understanding of Customer Relationship Management (CRM), allows deeper insight to the customer's demand for innovative solutions, whereas the internal procedures are an underlying factor that are not influenced by these relationships as much.

Basically the same assessment was made regarding the relationships to suppliers. Product innovation is influenced strongly by the purchasing and cultivation of suppliers, whereas the internal procedures and their optimisation are only influenced in a weaker manner. It is noteworthy, that the relationships to the public on average have no influence on the innovation factors and the investor relationships play only a minor role for the product innovation.

The relations to professional co-operation partners, where joint activities in customer, supplier or investor acquisition and the networking knowledge transfer activities influences the product innovation more than it does the process optimisation and innovation. The transfer of knowledge and best practices in research and development partnerships has evidently a higher impact on the innovation activities regarding products than on the internal processes. Based on experiences in the analysis and transfer of best practice (processes) the sharing of internal process-related information is often associated with greater impediments due to the sensitivity or confidentiality.

4.1 Comparative Evaluation of Interrelations in the Service Domain

The assessment of influences between the standard success factors of intellectual capital of the enterprises within service domain shows a similar pattern to that of production enterprises. However, the passive and active influence of product innovation is evidently higher in the production domain, while the same counts for process optimisation and innovation in the service domain.

The influence of the relational capital is more or less equal in sum to that of the production enterprises, though it is apparent, that in service enterprises the strength of these influences is distributed more even amongst the factors. Although in the average there are no interrelations assessed as very strong by the service enterprises, due to aggregation - only two were assessed as very strong – within the human capital, the passive interrelation is evenly distributed. The influence of the innovation factors on human capital is non-existent regarding the social competence and weak or non-existent regarding the leadership ability.

5 Conclusion

The ability to manage the organizational performance with regard to standard success factors such as the price-performance ratio, production cost and quality is perceived as a standard part of any operation. However, in order to achieve and maintain a competitive advantage, enterprises need to progress their internal procedures and products according to the customer demand (Stern, Jaberg 2010). This contribution analysed the interrelation of the standard success factors of intellectual capital with a special focus on product and process innovation in order to derive an insight to the possibility to generate good practices to increase the innovation capabilities. Although the definition of success factors for organizational innovation is to be perceived with caution, as the applicability is questionable (Lager 2010) for each individual enterprise, a set of good or best practices can be identified along the interrelations of the standard success factors for intellectual capital. However, the generic definition of standards or good practices should be performed separately regarding the type of organisation that is considered.

The increasing normative pressure to increase the sustainability performance of the organisational operation is manifested in legislative requirements to limit the environmental, social and economic impact. This regulatory-push is not evident in this research. Equally, the increasing requirement of investors to gain insight into the

sustainability of their investments and a certain demand in economic and socially sustainable investments, as evaluated in social responsible investment (SRI) indices and others (OECD 2009). While the potential contribution to the sustainability performance by eco-innovation and process optimisation in the production domain is unquestionable (Forschungsstelle für Energiewirtschaft e.V. 2009), this interrelation is not accounted for in the inherent data of this research.

The research and development co-operation in competitive situations (Stern, Jaberg 2010) and increasingly in innovative co-operation networks is proving to become an effective opportunity for SMEs to systematically encounter the increasing performance pressure of changing framework conditions. These networks comprise suppliers and customers as well as competitors, therefore distinguished from the standard success factor of relationships to co-operation partners. In this contribution this holds true for product innovation, while the influence of relationships to customers and suppliers on the process optimization and innovation were assessed as weak. A closer look into the structure of the inherent enterprises as well as the evaluation of intellectual capital statements of enterprises that are active in such networks shall provide a more in-depth insight. The organisational innovation as a result of the innovation activities could be analysed, when considering the new forms of collaboration such as open innovation, collaborative innovation and design thinking in enterprises of this sort. Furthermore, the derivation of good practices regarding the management of intellectual capital will be further developed with a supplementary evaluation of the interrelations, taking the secondary influences into account.

Structured Abstract

Purpose – Customer Knowledge Management (CKM) has been recognized within marketing as a significant resource that can be managed to improve innovation, to facilitate sensing of emerging market opportunities and to support long-term customer relationships management. Specifically, the aim of this paper is to test a model in order to examine the impact of customer collaboration as an antecedent of CKM, and the influence of both variables on innovation capacity and marketing results, in order to better understand the customer's potential role on innovation.

Design/methodology/approach – The conceptual model and the hypotheses are tested using PLS (Partial Least Squares) approach to Structural Equation Models (SEM) with survey data from 210 companies in Valencia (Spain). Using as key informants the owners of the company, data was collected using a random stratified probability sampling procedure with proportional allocation to the economic sectors. Personal interviews were developed using a structured questionnaire

Originality/value – The value of this study appears as a result of combining the three theories in the field of innovation, not previously tested together - the Resource-Based theory, the Service Dominant Logic (SDL) and the Organizational Learning theory- for proposing model that allows better understanding of the role of CKM and customer collaboration in marketing results and innovation capacity. Moreover this paper provides a comprehensive approach working on all types of innovation (product/service, production processes, management and marketing). It also generates knowledge to empirically test the proposition nº 2 of the theoretical work of Lush et al. (2007) based on the contribution of customer in the innovation co-creation process.

Practical implications – The results of this study hold important implications for business management and policy management. The study shows the CKM importance on

¹ *This research has been financed by the Cátedra Ciudad de Valencia 2013, Inndea Foundation of Valencian Local Government and University of Valencia.*

organizations innovation capacity and marketing results. Furthermore, it contributes to highlight the importance of customer collaboration in the innovation process. Recognizing CKM as an important variable that influences directly and indirectly innovation capacity and marketing results should encourage managers pay attention to their CKM processes.

Keywords – Customer knowledge management, customer collaboration, marketing results, innovation capacity.

Paper type – Academic Research Paper

1 Introduction

Due to the financial crisis and the subsequent difficulties being experienced by companies, now more than ever, they need to survive and succeed through finding a competitive advantage. Companies that work in managing its knowledge and innovation will survive in the market and will improve its performance while maintaining its competitive advantage (Nonaka and Takeuchi, 1995; Pil and Holwelg, 2003; Ribeiro, 2003). Some authors point out Knowledge as the most important strategic resource to build a sustainable competitive advantage (Zack, 1999; Eisenhardt and Martín, 2000). This approach is in line with the Service Dominant Logic (SDL) one, where Lush et al. (2007) propose that knowledge represents the only true basis for the sustainable development of a competitive advantage, given that it is an operant resource that enhances the service, and it is a primary requirement for innovation and competitiveness of the company (Nonaka, 1994; Nonaka and Takeuchi, 1995; De Clercq and Arenius, 2006).

In this way, knowledge and innovation are inseparable concepts, and have become the dominant topics for managers (Prahalad et al., 2004). Innovation is the application of knowledge, and sharing knowledge through collaborative innovation is becoming increasingly important. Much research shows direct evidence of knowledge management implementation on innovative works (Nesta and Saviotti, 2005; Alegre et al., 2011).

Innovation has been studied throughout the literature with a resource-based theory approach (Subramanian and Nilakanta, 1996; Menguc and Auh, 2006; Tajeddini, 2011; O'Cass and Sock, 2013), from the SDL perspective (Flint, 2006; Lush et al., 2007; Vargo and Lush, 2008; Michel et al., 2008), and also from the organizational learning theory (Cavusgil et al., 2003; Lin et al., 2008; Tarí and García-Fernández, 2011), but to our knowledge never from a perspective that approaches the three theories overall.

In this way, findings from this study pretend to provide several contributions in four directions. Firstly, this study works with a new organizational perspective approximating the various theories mentioned previously for the study of knowledge management on the customer in the field of innovation. Secondly, results highlight the critical role of knowledge management and the role of customer as collaborator in the innovation process in its different types (product / service, in production processes, management and marketing). Thirdly, countering evidence from the SDL approach on customer collaboration in the innovation process. specifically about the proposition n° 2 "collaborative competence is a primary determinant of knowledge acquisition in the company to obtain the competitive advantage", of the theoretical work of Lush et al. (2007) based on the role of the customer, not having found empirical study to date contrasting the relationship between customer collaboration in the innovation process and CKM. And finally, this study helps managers and researchers to clarify the relationships between the concepts studied (CKM, customer collaboration, innovation capacity and marketing results) following the new organizational perspective proposed.

2 Conceptual model and hypotheses

2.1 Customer knowledge management

In the emphasis on knowledge as a key competitive factor in the global economy, corporations may be overlooking a major element –customer knowledge. Customer Knowledge Management (CKM) is about gaining, sharing and expanding the knowledge residing on customers, to both customer and organization benefit. It can take the form of prosumerism, mutual innovation, team-based co-learning, communities of practice and joint intellectual property management (Gibbert et al., 2002).

Referring to the origins of knowledge management, there are precursor theories of this variable such as the resource-based theory with its extension to the approach of dynamic capabilities and organizational learning theory. The resource-based theory shows the relationship between profitability and allocation of resources so that companies must identify what the most valuable resources are , and if they have not achieved them, then should seek to acquire these resources in the strategic factors market (Barney, 1991). Based on this theory, Spender (1996) considers knowledge management based on the creation and application of knowledge as a resource.

The dynamic capabilities approach emerges as an improvement of this theory initiated by Penrose (1962) and expanded by Wernerfelt (1984) and Barney (1991) in the sense of giving a dynamic view of organizational behavior (and not static as provided by this theory) in order to explain the success of companies operating in environments with high levels of dynamism and complexity. It is based on this approach that several authors consider dynamic capabilities such a composition of knowledge management activities taking place in the company (Benner and Tushman, 2003; Zahra et al., 2006; Nielsen, 2006). Considering all of this, the knowledge can be conceived as a strategic resource, that is acquired through learning and experience, and whose management generates dynamic capabilities. So knowledge as a resource focuses on the role of dynamic capabilities (Helfat, 1997; Teece et al., 1997; López and Sabater, 2002), understood these such as the ability of the organization to integrate, build and reconfigure their set of resources and capabilities to respond quickly to changes in the environment (Teece et al., 1997). As a result, this study adopts the definition of knowledge management proposed by Alegre et al. (2011) as the set of organizational practices and dynamic capabilities in relation to (respectively) the creation, preservation and transfer of knowledge. Moreover, the purpose of knowledge management is to improve the output to the customer (Darling, 1996).

2.2 Customer collaboration in the innovation process

For innovation to occur, knowledge is best created and transferred in an organizational culture which encourages collaboration and facilitates learning networks (eg. through communities of practice, use of experts and shared social activities). Several studies support the idea of considering the consumers collaboration in the innovation process, arguing that a company should interact with customers because it is a basis for successful innovation (McKenna, 1995; Wind and Mahajan, 1997).

From the Service Dominant Logic (SDL) perspective, the capacity to collaborate with customers during the development of a service, transforms customer into an operant resource, through which the company can encourage innovation and competitiveness (Vargo and Lusch, 2004; Ordanini and Parasuraman, 2011). According to Cheng et al. (2012), customers are considered as important resources for the development of new products and they can serve as a key source of competitive advantage. Also the customer

participation in the initial phase of new products has been recognized as a key factor for manufacturers in the launch of successful new products (Dow et al., 1999).

Customer collaboration in the innovation process has been studied from several perspectives throughout the academic literature according to Alam (2006): from the market orientation perspective (Hurley and Hult, 1998; Jaworski and Kohli, 1993; Slater and Narver, 1994); from the perspective of relationship between companies (Bendapudi and Leona, 2002; Bolton et al., 2003), as a network perspective (Achrol, 1997; Biemans, 1991; Comer and Zirger, 1997) and from competition and market knowledge perspective (Griffin and Hauser, 1993; Li and Calontone, 1998; Moorman, 1995).

This research will adopt the concept of customer collaboration in the innovation process from the perspective of the SDL according to the definition presented by Vargo and Lush (2008), which considers collaboration as a process in which the company interacts and negotiates with customers to develop a value proposition, where collaboration becomes a part of the co-creation of value in which the company can participate and where the customer has an active role as a co-creator. The SDL approach has proved successful in approaching in the conceptualization of relevant topics in marketing (Vargo and Lusch, 2004; Michel et al., 2008; Ordanini and Parasuraman, 2011).

2.3 Innovation capacity

Innovation capacity is a key competitive tool for business long-term success and for survival, being this a widely recognized idea (Deshpandé et al., 1993). It is considered a mechanism through which organizations adapt to the dynamic environment through continuous innovation, providing a response to changes in the environment.

According to different authors the research focused on innovation processes distinguishes two stages (initiation and implementation) (Zaltman et al., 1973; Rogers, 1983; Van de Ven, 1986; Hurley and Hunt, 1998), allowing to identify the terms innovation orientation and innovation capacity. Innovation orientation refers to an aspect of the corporate culture that seeking openness to innovation among its members actively encouraging them to create, contribute and experiment new ideas at work (Hurley and Hunt, 1998). So it is in the implementation stage where the variable innovation capacity appears, where all events and actions occur (related to changes in an organizational

innovation, initial use and continued of it and the time when it becomes a routine feature of the organization) (Damanpour, 1991).

As a result, this study adopts the definition by Hurley and Hunt (1998), who define innovation capacity as the ability of the organization to adopt and implement new ideas, processes or products successfully. This variable reflects whether the organization supports the development and/or adoption of innovations or, by contrast, resists this process.

2.4 Marketing results

It is in the 90's when the revolution of performance measurement begins to occur, appearing a large number of people interested in marketing results (Neely, 1999). A wider conceptualization of business performance would emphasize operational performance indicators (i.e. non-financial) as well as financial performance indicators, so that it would be logical to use measures such as market share, the introduction of a new product, product quality, marketing effectiveness, value added, and other measures of technological efficiency (Venkatraman and Ramanujam, 1986).

This approach follows the more general rational theory of the company that says the purpose of an organization is to achieve a set of objectives (Cyert and March, 1963). Besides, marketing managers feel more and more pressure to measure the impact and value of marketing in their companies (Clark, 1999; Kokkinaki and Ambler, 1999; Marketing Week, 2001) due to high competition, among other factors. This competition forces companies to be increasingly market-oriented and to use marketing metrics - internal and external measures related to marketing and market position that are believed to be linked to the financial performance in the short and long term-, (Ambler et al. 2003; Barwise and Farley, 2004).

2.5 Hypotheses and Theoretical Model

Fang et al. (2008) propose that customer participation in the development process of a new product increases the level of information shared during the process. According to Lush et al. (2007), the SDL recognizes the competence of collaboration as a key for any business aiming a competitive advantage because it helps in the development of two additional meta-competencies -absorption and adaptation-, created from knowledge management, that the authors argue that are critical in the complex, dynamic and

turbulent environment. Lush et al. (2007) state in their proposal 2, that collaborative competence is a primary determinant of knowledge acquisition in the company to obtain the competitive advantage, we can infer that collaboration is a key to acquire knowledge within the firm. In addition, customers provide a broad base of skills that often represent an untapped source of knowledge. Companies that are based on knowledge on a customer base can capitalize them during the course of their innovation activities (Blazevic and Lievens, 2008). This knowledge is not created by an individual mind but rather through activities and interactions between companies and customers - co-produced knowledge- (Blazevic and Lievens, 2008). So that we can say that collaborations with customers generate knowledge creation or, more specifically, the co-production of this knowledge, which is one of the activities of knowledge management process and contributes to such management.

As a result of this discussion, we can infer that customer collaboration in the innovation process improves knowledge about the customer (the level, intensity, frequency and amplitude) and consequently in its knowledge management generation. This allows us propose the following hypothesis:

***H1:** Customer collaboration in the innovation process is directly and positively related to customer knowledge management.*

Knowledge management is an important tool to manage innovation activities and represents a routine element of the innovation process. These knowledge management activities make the innovation process seem less uncertain and more specific (Cantner et al., 2009).

According to the study of Tarí and García-Fernández (2011), innovations come from the creation of knowledge, such as incubator projects, the application of this knowledge through teamwork, empowerment and engagement with knowledge. And that knowledge creation has positive effects on innovation performance (Kessler et al., 2000).

Implicit knowledge resources and knowledge capabilities positively influence in company innovation capacity (Subramaniam and Youndt, 2005; Urgal et al., 2011). Systems of knowledge and learning contribute positively to innovation process (Wheelwright and Clark, 1992), to improve the performance of innovation activities and innovation results (Sánchez and Mahoney, 1996; Helfat and Raubitschek, 2000).

Also, several authors have analyzed the influence of knowledge and their characteristics in the innovative capacity of the company, concluding that knowledge

positively influences the probability of business innovation (Duguet, 2000; Gopalakrishnan and Bierly, 2001; Rao and Drazin, 2002). Knowledge management has a positive effect on innovation (Forcadell and Guadañillas, 2002; Andreou et al., 2007) given that the capture, store, share and distribute knowledge allow innovation (Baptista et al., 2006). In addition, this knowledge management facilitates the creation of new products or new methods of production, because it develops scenarios for the introduction and improvement process design.

Focusing on knowledge management dimensions, the adoption of knowledge management practices is positively correlated with innovative performance according the study of Alegre and Lapiedra (2005) who understand this performance as the union of the effectiveness of innovation (including measures of innovation capacity) and efficiency, and Alegre et al. (2011) authors show that both knowledge management practices and dynamic capabilities are valuable to the company because it contribute to innovation performance.

As a result of all this, we propose customer knowledge management as an antecedent to innovation capacity and we pose our following hypothesis:

H2: *Customer knowledge management affects directly and positively the innovation capacity of the company.*

Knowledge management and innovation produce a significant impact on performance given that these are deliberately aligned with the strategic objectives and this strategic orientation allows the organization to anticipate and respond to changing market conditions (Ferraresi et al, 2013).

According to Tarí and García-Fernández (2011), there are theoretical studies that confirm how knowledge management practices have a positive influence on the operating results of the companies (Davenport and Prusack, 1998; Massey et al., 2002) considering marketing results as part of them. This influence has also been empirically validated in other studies (Schulz and Jobe, 2001; Choi and Lee, 2003; Darroch and McNaughton, 2003; Tanriverdi, 2005; Lloch et al., 2007; Zack et al., 2009). Particularly, a positive influence of knowledge management on marketing results -such as sales and market share- has been approached (Darroch and McNaughton, 2003; Chadam and Pastuzak, 2005; Tanriverdi, 2005; Huang and Shih, 2009). This allows us to propose the following hypothesis:

***H3:** Customer knowledge management is directly and positively related to marketing results.*

Several studies (Matthing et al., 2004; Alam, 2006; Carbonell et al., 2009) conclude that company-consumer interactions are positive for the following reasons: it provides a more complete idea on consumer needs, it reduces the development time of a new service and it generates an improvement in the economic and financial performance of the new service. In addition, when the customer collaboration in the innovation process is being carried out, the co-creation of the product/service and this is what will cause a positive impact on business results (Vargo and Lusch, 2004; Ballantyne et al., 2008).

García et al. (2011) contrast empirically that customer participation impacts favourably on customer results -such as loyalty, customer satisfaction and value added or marketing results.

Other studies show empirically that the customers' involvement in service innovation improves sales performance. In this way, Martin and Horne (1993) show the positive link between customer participation in the development process in a service and the success in its commercialization process. Gales and Mansour-Cole (1995) demonstrate how customer participation is positively related to the success in the sale of the new technology. Therefore:

***H4:** Customer collaboration in the innovation process is directly and positively related to marketing results.*

Through the use of customer participation techniques -focus groups, surveys, interviews and others-, companies can achieve a better understanding of customer needs and innovation opportunities that the market offers (Hennestad, 1999). This interaction with the customer is very useful in the initial and final stages in the innovation process (Gruner and Homburg, 2000; Alam, 2002; Alam, 2006) because these require more amounts of information (Zahay, et al., 2004).

Furthermore, this customer collaboration in new product development activities can provide the innovation capacity to develop more differentiated products and services for certain target markets (Lagrosen, 2005); having a positive effect on the innovation capacity and more specifically in products innovation (Lin et al., 2010), in process innovation (Slater y Narver, 1995), in services innovation (Lin et al., 2010) and in marketing innovation (Dean and Evan, 1994; Lin et al., 2010). Therefore, we propose our last hypothesis:

H5: Customer collaboration in the innovation process is directly and positively related to company innovation capacity.

In Figure 1 we can see the theoretical model proposed in this research.

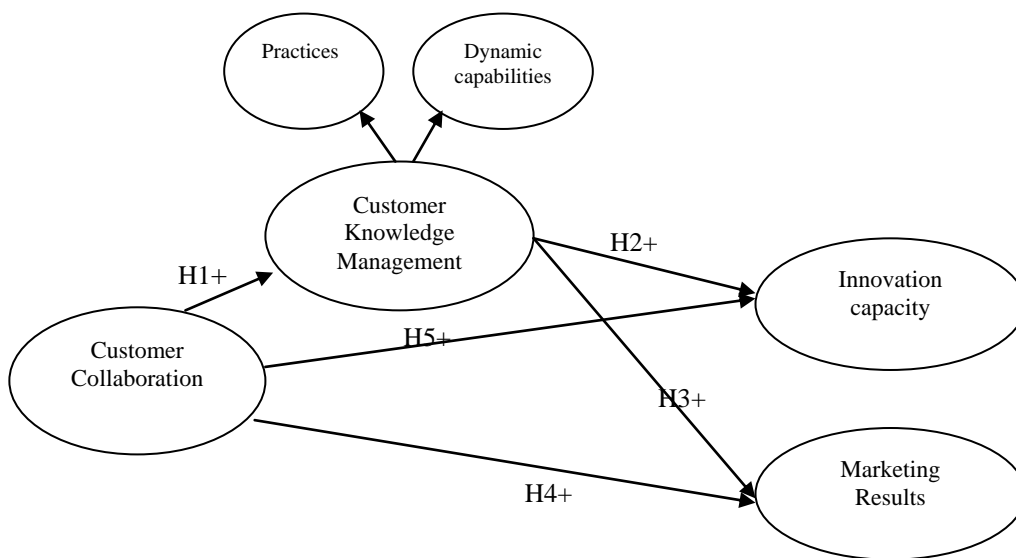

Figure 1. Proposed Model

3 Methodology

In order to better understand Valencian Companies Innovation processes, the city of Valencia local government innovation area (Inndea) financed this research. It would constitute the first step to better design policies directed to innovation improvement.

Firstly, a qualitative study was conducted through a focus group with eight representatives of major business associations in Valencia and its metropolitan Area in order to have a better approach to the innovation concept and improve the quality of the questionnaire.

Then, obtaining data was conducted using a personal structured questionnaire directed to directors/managers of the companies.

Valencia and its metropolitan area constitute the third largest city in Spain, after Madrid and Barcelona. The city hosts 47.222 companies, basically SMEs and in the area of services. This study was conducted with a random sample of 210 companies of

Valencia and its metropolitan area, which were chosen according to a random stratified probability sampling with proportional allocation to the economic sectors (agriculture, industry, construction and services).

Most of companies included in the sample have less than 20 employees (96%), the 60% are companies with antique of more than 6 years and whose managers/entrepreneurs are more than 35 years old (81.5 %), with a training level between basic and intermediate (69.5%). This profile represents the Valencian business framework, constituted by family owned small companies. We worked with a confidence level of 95.45% and an error estimate of +/- 7%. Fieldwork was conducted during the month of July 2013.

The instruments used for the measurement of the variables were adapted from the literature employing 5-point Likert scales. CKM was measured adapting the scale of Alegre et al. (2011), considering it as a second-order construct with two dimensions: knowledge management practices on customers (knowledge storage and dissemination of knowledge) and dynamic capabilities of knowledge management (composed of the internal and external learning competences). Customer collaboration in the innovation process was measured using the 4-item scale by Ordanini and Parasuraman (2011). Innovation capacity was adapted from Santos et al. (2013) 4-item scale. Lastly, marketing results was measured using the scale 4-item scale by Vorhies and Morgan (2005) (Table 2) which was measuring marketing results in relation to their competitors.

4 Results

Data was analyzed in two stages, first we validate the measuring instrument and secondly we proceed with the estimation of the structural model (Barclay et al., 1995). For this analysis, the partial least squares regression (PLS) technique data analysis was used (Smart PLS software, 2.0). This technique was used as recommended by the work of Barroso et al. (2005), for predictive purposes These authors confirm in their study that the PLS technique is mainly oriented to the causal predictive analysis in situations of high complexity (i.e. models with large number of variables, indicators and relationships) but with a theoretical knowledge little developed (Wold, 1979; Barclay et al., 1995).

4.1 The measuring instrument validation

The evaluation of the measurement model implies the individual item reliability analysis, internal consistency or reliability of a scale, convergent validity and discriminant

validity (Barclay et al. 1995; Cepeda and Roldán, 2005). Regarding the item individual reliability, it can be affirmed that loads of all items have a value higher than 0.7 for the corresponding factors.

The reliability of the constructs was analyzed based on the criteria of α Cronbach and composite reliability index (CRI) giving values above 0.7 in all cases, which is the recommended value (Churchill, 1979). AVE values were higher than 0.6 in all cases. This shows that over 60% of the variance of each construct is due to their indicators (Cepeda and Roldán, 2004). The results of these tests can be seen in Table 2.

Table 2. Reliability and Convergent Validity

Factor	Ítem	Load	Cronbach's α	CR	AVE	
F1.Customer collaboration (CC)	CC1	Interact with customers to obtain useful information for the process	0,918*	0,966	0,975	0,908
	CC2	The intensity with which we interact with customers is high	0,967*			
	CC3	The frequency of meetings with customers is high	0,959*			
	CC4	The number of customers with whom we interact is high	0,966*			
F2.Dynamic capabilities of customer knowledge management (DCCKM)	DCCKM 1	(I'm better than my competitors) on my ability to obtain information about customers and their needs (in fairs, events, industry news, expert reviews, newsletters ...).	0,850*	0,842	0,893	0,679
	DCCKM 2	(...) in my effective and updated collection of customer information	0,761*			
	DCCKM 6	(...) in my ability to put myself in front line of innovation (such as ability to generate new processes, new products, new markets, etc.)	0,895*			
	DCCKM 7	(...) in my ability to manage the effort we make in innovation (such as information search effort, monetary resources, training, etc.)	0,781*			
F3. Customer knowledge management practices (CKMP)	CKMP1	We use coding systems of knowledge/information that have about our customers (in databases, software, etc.)	0,794*	0,915	0,933	0,667
	CKMP2	We use internal mechanisms to promote exchange of information on customers	0,782*			
	CKMP3	We use participatory techniques among our employees and customers (such as client meetings, client interviews for improvements, etc.)	0,732*			
	CKMP4	We use tools to customer information reaches everyone in the company	0,754*			
	CKMP5	We have information processing systems about customers	0,881*			
	CKMP6	We use control systems and review of existing information on the company on customers	0,871*			
	CKMP7	We use systems that allow the customer information that was used in previous innovation tasks to be used in innovative new tasks	0,885*			
F4. Innovation Capacity (IC)	IC1	The company has introduced innovative products and/or services in the last 3 years	0,788*	0,854	0,899	0,690

	IC2	The company has innovated in production processes (adoption of new technologies, improved processes) in the last 3 years	0,832*			
	IC3	The company has innovated in management processes (administrative area, human resources, new departments, project management) in the last 3 years	0,829*			
	IC4	The company has innovated in marketing aspects (commercialization, penetrate in new markets and/or segments, new distribution channels, new forms of communication with customers and/or suppliers, new methods or pricing strategies) in last 3 years	0,870*			
F5. Marketing results (MR)	MR1	The growth of our market share is higher than our main competitor	0,881*	0,919	0,943	0,805
	MR 2	The growth of our sales revenue is higher than our main competitor	0,912*			
	MR 3	The acquisition of new customers is higher than our main competitor	0,894*			
	MR 4	Increased sales to existing customers is superior to our main competitor	0,900*			

*All loads are significant $p < 0,001$

Discriminant validity was evaluated by comparing the square root of the average variance extracted (AVE) with the correlations between the factors. It can be confirmed that the correlations were lower than all square roots of AVE and therefore, discriminant validity is achieved.

4.2 Structural model estimation

Once the psychometric properties of the instruments have been evaluated, we proceed to analyze the structural model using PLS. To assess the predictive capacity of the structural model, we begin by evaluating the R^2 . According to Falk and Miller (1992), these values must exceed the value of 0.1: lower values, even being significant, would not be acceptable. Table 4 shows that R^2 of all dependent factors is higher than 0.1 (the critical level mentioned).

We continue then to evaluate the predictability of the model by applying the Stone-Geisser test (Q^2) for each dependent construct through the blindfolding procedure. It was tested that Q^2 revealed an acceptable model predictive capacity, due that all values exceeded 0 (Table 3).

Table 3. Hypotheses testing

Causal relationship	Hypotheses	β	Value T
		standardized	bootstrap
H1: Customer collaboration \rightarrow CKM	Accepted	0,362*	7,234
H2: CKM \rightarrow Innovation capacity	Accepted	0,316*	7,756
H3: CKM \rightarrow Marketing results	Accepted	0,384*	7,289

H4: Customer collaboration → Marketing results	Accepted	0,113**	2,282
H5: Customer collaboration → Innovation capacity	Accepted	0,230*	4,882
*p< 0,001; **p< 0,05			
R ² (CK)= 0,130 ; R ² (marketing results)= 0,191; R ² (innovation capacity)= 0,205			
Q ² (CKM)= 0,0833 ; Q ² (marketing results)= 0,0279; Q ² (innovation capacity)= 0,0646			

The results presented at Table 3 allow confirm the five hypotheses proposed, which means that CKM affects directly, positively and significantly to innovation capacity and marketing results, being promoted directly by customer collaboration in the innovation process. Likewise this study demonstrates how the customer collaboration has a direct and positive impact on marketing results and innovation capacity.

5 Conclusions

This study proposes a promising approach by connecting three key theories accepted in the literature: the resource-based theory, SDL and organizational learning) to better understand the variable CKM and its behavior in the area of innovation.

The results show how customer knowledge is a key strategic resource for companies as it positively contributes in improving organizations' innovation capacity (innovation in products/services, in production processes, in management and in marketing) and marketing results, increasing market share, sales revenue or the acquisition of new customers.

We also provide evidence on the importance of customer collaboration in the innovation process and its influence on CKM, confirming that customer collaboration is an antecedent of CKM. Also, the direct influence of this collaboration in innovation capacity and marketing results is proved.

Furthermore these empirical results show that CKM and customer collaboration in the innovation process allow the company improve results in relation to its immediate competitors (sales, market share, new customers acquisition) in a sustainable way, which can be interpreted as the achievement of competitive advantage.

The results involve a number of implications for business management and policy makers. First, this study helps managers to realize the importance of CKM given its positive influence on organizations innovation capacity and marketing results. Firms managing CKM are more likely to detect emerging market opportunities before their competitors and also to more rapidly create economic value for the corporation, its

shareholders, and its customers. Second, results obtained show the relevance of collaborating with customers in the innovation process as a key input given its effects both on innovation capacity and marketing results. In conclusion, this paper provides better bases for managers to encourage innovation in their companies and how to improve marketing performance.

In consequence, companies should implement CKM practices, such as the use of mechanisms for sharing information -databases, computer programs- and techniques for employees-customers participation.

In the area of public management, findings suggest that governments should better help companies develop CKM activities by creating programs that would enable companies develop an organizational culture more customer-oriented.

Limitations in this research pose areas for further research. First, note that it has been used the same source of information (the director / manager) to measure all model variables (antecedent and consequences) and collect information on the same moment of time, which could generate common variance bias. Although this is a common practice, it would be appropriate to conduct the survey at different key informants of the company and in different times. Another aspect to consider is that this study was conducted in one city and its metropolitan area. It would be interesting to evaluate the model in other geographical areas and/or other countries. Finally, it would be of interest to introduce other variables in the model that can act as consequences of CKM, such as financial performance (profitability, ROI) or customer outcomes (customer satisfaction, customer loyalty). Likewise, other antecedent variables of CKM as innovation culture (Davenport et al., 1998; Lloria, 2004), or customer orientation (Narver and Slater, 1990; Cantner et al., 2009) could be approached.

Structured Abstract

Purpose – The body of research about knowledge management in SMEs is rather scarce. Nevertheless, scholars that have investigated the peculiarities of KM processes in SMEs have found that SMEs do not manage knowledge the same way as large firms. Particularly, even though SMEs seem to be aware of the value of their knowledge assets, they generally have an unplanned and unsystematic approach to KM. In light of this, the paper intends to deepen our understanding about the way SMEs plan, implement and use KM. Specifically, it aims at identifying the nature (deliberate or emergent) of this process, the involved actors, and the relevant influencing factors.

Design/methodology/approach – The paper examines the KM experience of Infonet Solutions, a small Italian ICT services company. It adopts the case study approach, given the descriptive and exploratory nature of the research. The unit of analysis is represented by the KM system implemented by the company in the last decade. The background conditions, the history of the system, its features and drawbacks are deeply analysed. The company was selected for two main reasons. First, it is a typical Knowledge-Intensive Business Service company, where knowledge is the key competitive resource. The second is a question of opportunity: it was possible to have direct access to relevant information thanks to the participation of a company executive to the research.

Originality/value – The paper contributes to improve understanding of KM approaches by SMEs. Given that this is a single case-study, the idea is not to draw conclusions of

general validity, but rather to derive some implications concerning the implementation of KM practices and tools by SMEs, possible warnings for both researchers and executives, and suggestions for the formulation of new hypotheses on KM abilities of SMEs, to test by means of other research methods.

Practical implications – The outcomes are significant for both research and practice. As regards research, it is argued that the adoption of KM practices in small businesses can be seen as an “emergent strategy”, in other words it is strongly affected by the specific situation in which the individual firm operates. This leads to conclude that a single “best-way” KM approach, based on a rational planning method, is almost impossible to define in SMEs. As concerns the practice, the study reveals the key adoption patterns of KM by SMEs, and provides suggestions on how to manage the factors that influence these patterns in a context that will be called “emergent KM”.

Keywords – Knowledge Management, Emergent KM, SMEs, KIBS, Case-study

Paper type – Academic Research Paper

1 Introduction

It is widely acknowledged that the body of research about knowledge management (KM) in SMEs is rather scarce (Durst and Edvardsson, 2012; Dwivedi et al. 2011), especially when compared with the large number of studies concerning big companies. The relatively few existing contributions, however, seem to agree on the fact that SMEs do not manage knowledge the same way as large firms (Chan and Chao, 2008; Wee and Chua, 2013). Consequently, their KM initiatives cannot simply be seen as a scaled-down reproduction of large company practices (Desouza and Awazu, 2006). In fact, SMEs, even when they are aware of the importance of their knowledge, usually follow an unplanned, unsystematic and informal approach to KM (Edvardsson, 2006, 2009; Hutchinson and Quintas, 2008). In light of this, the paper aims to deepen our understanding about the way SMEs plan, implement and use KM practices and systems. Specifically, it aims at identifying the nature (deliberate or emergent) of the implementation process, the main involved actors, and the relevant influencing factors.

The paper illustrates and discusses the KM experience of Infonet Solution, a small Italian ICT services company. The unit of analysis is represented by the set of KM systems and practices that the company has implemented in the last decade.

The study covers two research areas regarding KM in SME that, according to Durst and Edvardsson (2013), need more attention and development, i.e., longitudinal studies (namely, studies that analyse the dynamics of a phenomenon over long periods of time)

and realistic lens (namely, studies that explicitly focus on the peculiar characteristics of SMEs). As regards the first point, the case study covers a time span of about a decade, during which the KM approach of the company has changed and intensified, since it has modified its business, has faced new challenges, and new tools for managing knowledge became available. Concerning the second point, the analysis has adopted a realistic view of the company under investigation by taking into account the limited resources it has and the specific business environment where it competes.

Since this is a single case study, the idea is not to draw conclusions of general validity, but rather to derive some implications concerning the implementation of KM systems by SMEs, possible suggestions for both researchers and executives, and ideas for new hypotheses about the peculiarities of KM in SMEs to be tested in future research.

The paper articulates as follows. The next section proposes a brief review of the literature on KM in SMEs, and clarifies the conceptual framework of the study. The third section illustrates the research methodology adopted. Section four describes the case of the company and its path towards KM. The fifth section discusses what emerged from the study, while the last makes some conclusive comments, illustrates the limitations of the study, and suggests some possible research directions.

2 KM in SMEs

As well documented by recent reviews (Durst and Edvardsson, 2012; Dwivedi et al., 2011; Ribière and Christian, 2013), the literature that examines KM in the context of SMEs is still scarce. Nevertheless, there are some interesting contributions that deserve to be mentioned here in order to frame and describe the rationale of this study.

It is first necessary to step back and discuss the meaning of the term KM and its nature, in order to avoid confusion and to clarify its possible use in the case of SMEs. Although there is no commonly shared definition on what KM is or should be, several authors focus on its deliberate and planned nature. Otherwise, there is the risk that any activity of an enterprise that deals with knowledge directly or indirectly can be called “a KM practice”: in other words, everything. Therefore, these scholars assume that only systematic practices directly and evidently targeted to managing knowledge (in one of its manifestations) should be intended as KM.

For instance, Wong and Aspinwall (2004) define KM as the systematic management of knowledge-related activities and processes (i.e., creating, organizing, sharing and using knowledge) in order to create value for an organisation. Daft (2007) refers to the efforts to systematically find, organise and make a company's intellectual capital available, and to foster a culture of knowledge sharing so that the organizational activities built on what is already known. Under this perspective, it is possible to speak about KM initiatives when they refer to a deliberate action intended to enhance the distinctive capability of the organisation through a systematic approach to generating, capturing, disseminating and exploiting knowledge (Chua and Goh, 2008). Such actions can involve managerial practices, organisational solutions, human resources, technological tools and so on.

The above definitions emphasises the purposive nature of KM, and consequently they fit the context of large organizations and multinationals, characterised by a formal and systematic planning of all the activities including KM. Therefore, this way of conceiving KM may tend to deny, for small businesses, the possibility or even the capability to implement KM.

However, it is clear that KM practices are not limited to large companies (Wei et al., 2011), but they are adopted by SMEs as well. In particular, KM can give to SMEs the same benefits as large organizations, such as better communication, improved customer knowledge, faster response times, greater efficiency in processes and procedures, and reduced risks from the loss of critical knowledge. According to Dotsika and Patrick (2013) implementing KM initiatives in SMEs may be even more crucial, as knowledge can be their single key resource. The problem is that KM is not so popular in SMEs, due to some factors such as inadequate awareness of managers, high costs and budget issues, as well as poor resources and insufficient technical expertise.

The empirical research about KM in SMEs provides fragmented insights (Edvardsson and Durst, 2012). Nevertheless, all the authors seem to agree on a point, and specifically on the fact that it would be wrong to assume that SMEs can practice KM in similar ways as large organisations (Desouza and Awazu, 2006): KM in small businesses can't simply be reduced to scale-down versions of the large companies' experience (Wong and Aspinwall, 2004). Hence a key question is: to analyse KM practices in small businesses, do we need a new concept of KM and new interpretive frameworks that are different from those normally used to analyse the case of large firms?

A possible answer to this question can be found in the recent literature. In this regard Hutchinson and Quintas (2008) affirm that, to understand the management of knowledge in SMEs, it is necessary to look beyond the introduction and practice of formal or nominal KM initiatives. SMEs, in fact, without “being fluent” in the language of KM, or even recognizing their behaviours as KM, are often proactively engaged in what are called “informal KM practices”. In a previous paper, Edvardsson (2006) had already noted that explicit KM policies in SMEs are lacking, but many small companies treat KM on an operational level, i.e. at the level of systems and tools.

According to Edvardsson and Durst (2013), compared to larger firms, SMEs tend to be more oriented towards the management of tacit knowledge, and their communication flows often involve other companies. They are also less successful in sharing knowledge by means of formal systematic approaches than large companies. In short, small businesses manifest an “informal short-term approach” towards organizational learning and KM. In SMEs, KM processes occur naturally regardless a formal charter has been set in place (Wee and Chua, 2013): in these organizations, KM is often practised but may be not recognized as such.

This unstructured and not-formalised approach to KM by SMEs poses significant challenges to both scholars and practitioners, and hence it deserves to be analysed more carefully. So far, the literature has especially investigated the peculiarities of KM processes in SMEs, and the relevant enablers and barriers (Desouza and Awazu, 2006; Nunes et al., 2006; Wee and Chua, 2013; Wong and Aspinwall, 2005). Less attention, instead, has been deserved to the pathways that small companies follow when they implement KM. In particular, little is known about the real nature (deliberate or emergent) of KM processes, and the relevant managerial implications. In order to help fill this gap, present study aims to investigate the ways with which KM initiatives emerge and are implemented by SMEs and the involved actors, and to identify opportunities and risks, as well as enablers, and constraints.

Some clarifications are needed about the terms that appear in the rest of the paper. The term “deliberate” will be used to indicate a planned process, i.e. a process that is precise and articulated, and directs the organisation towards goals that have been established in advance. Conversely, the term “emergent” will indicate an unplanned process, whose goals (and how to achieve them) constantly change, depending on the evolution of the circumstances. The previous words were preferred to the use of “formal” and “informal”:

particularly, the adjective “informal” does not clarify the evolutionary nature of an emergent KM. Instead, the term “formal” is reserved to practices that are applied with the idea of implementing KM, while “informal” to practices that are concerned with knowledge processes, but are not labelled or constituted as KM. Finally, we won’t equate deliberate (formal) KM with the management of codified knowledge, or emergent (informal) KM with the management of tacit knowledge. For instance, the unplanned adoption of a CRM system to manage relationships with customers is exactly the case of emergent introduction of a KM system that deals with explicit knowledge.

3 Research method and research questions

This paper draws its insights from the experience of Infonet Solutions. We used the case study approach given the descriptive and exploratory nature of the research, and the complexity of the investigated issue (Leedy and Omrod, 2005). In particular it can be seen as a revelatory case in Yin’s terminology (Yin, 2003) since it offers the opportunity for an in-depth analysis of internal features that are generally less accessible to outside researchers. The purpose of the case study is a combination of a “how” and a “why” questions concerning the management of cognitive assets by small companies. The case has been elaborated by using information provided by various people in the company, and from documental sources that have been collected over several years. As regards the generalization of the findings, the idea is not to draw conclusions of general validity, but rather to derive some implications concerning the approach followed by SMEs in the adoption of knowledge management practices and systems, as well as to provide suggestions for further analysis or for implementation in similar situations.

The unit of analysis is represented by the practices and projects to introduce and use KM that the company has carried out in the last decade to support its business activities. The company was selected for two main reasons. First, it is a typical Knowledge-Intensive Business Service company, where knowledge is the key competitive resource and, as such, it requires to be carefully managed. The second important reason is a question of opportunity: it was possible to have direct access to relevant information especially thanks to the participation of a company executive to the study. The direct contact with people involved in the project allowed to reveal aspects that are often difficult to discover by an external observer. The potential bias in the analysis (due to the

fact that one of the authors is a company's employee) was mitigated by separating the "collection" phase from the "analysis" (which was mainly conducted by the other two authors).

Research questions are as follows:

- Does this small business follow a deliberate or an emergent approach to KM?
- If an emergent approach (as suggested by the literature) is followed, which are the relevant opportunities and risks? Which are the main enablers and obstacles?

The assumption here is that even an emergent approach has to (and can) be adequately managed, which means creating the conditions for the organization for adopting KM practices and systems that make its business processes more efficient and effective.

4 The case study

4.1 The company

Infonet Solutions is a small ICT company located in the North East of Italy with 30 employees and 5 external collaborators; the annual turnover is about 5 billion Euros. Infonet provides high-level custom-made solutions to optimize the IT platforms of the clients, which are mostly medium-sized organizations belonging to different sectors, from manufacturing and service industries to healthcare centres, public agencies and no-profit organizations. Customers are all located in Northern Italy, especially in the eastern part. The main services include: cloud computing, data centres, virtualization, and business continuity. The company, founded as a reseller of telecommunications components, was taken over about 20 years ago by three young computer technicians who have progressively turned it into what it is today. Currently, it is organized into five main Departments: Management, Accounting, Sales/Marketing, Support and Delivery. The last two are the technical heart of the company: the first one deals with the design, development and implementation of new brand solutions, while the second manages the technical assistance and maintenance of the installed systems. Being an ICT company, Infonet Solutions can be deemed to have the peculiar features of a knowledge-intensive business service company as described by Muller and Doloreux (2009), i.e. a firm where knowledge is the main competitive asset that must be strategically managed. This makes the company under examination particularly interesting with regard to issues related to KM.

The story of Infonet is that of a dynamic company that has undergone a huge evolution in the last decade. Until 2003 it was a typical small private company run by the owners, who had no managerial competencies. It worked only on a job-order basis, and provided installation services of computer infrastructures. At that time, the company counted 12 people including the owners. These, being aware that the firm would not have been able to grow without taking on more managerial characteristics, decided to hire an outside manager and to entrust him the role of Chief Executive Officer. Since then, the company has begun to focus on support services that consist of managing systems installed at the customer site for the years of operation. At the same time, the company also started doing marketing, an activity hitherto neglected. Recently, Infonet opened a branch in Milan, with two new employees that have the mission to expand the market in North-western Italy.

4.2 Cognitive content of the service delivery process

To better understand the KM needs of Infonet it is useful to recall its nature of KIBS company. As well underlined by the literature, very often KIBS firms act as innovator brokers or “bridge for innovation” (Leiponen, 2006; Muller and Zenker, 2001) when they occupy an intermediate position between external sources of knowledge and local recipients (Figure 1). In cognitive terms, this means operating as interfaces and mediators between the more tacit and specific knowledge buried in the daily practice of client firms, and the more generic knowledge which is available in the economic environment as a whole (Bolisani and Scarso, 2009; Bolisani et al., 2011; Scarso and Bolisani, 2012). As brokers, KIBS companies are containers and dynamic sources of “quasi-generic knowledge” extracted from repeated interactions with customers and other actors, including the producers of new scientific knowledge. Hence, the management of external knowledge is a particularly crucial issue for a company of this kind especially that required to manage the business relationships with the customers.

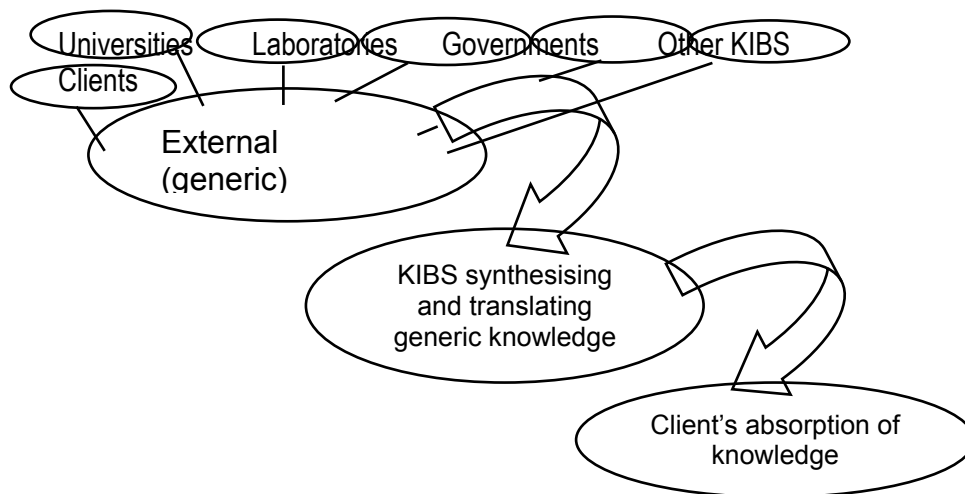

Figure 1: The intermediating role of KIBS

To better understand the knowledge flows that characterize the business of Infonet, the activities that denote the typical service delivery process of the company are now illustrated and discussed. As any firm that delivers project-based technical solutions, it usually resorts to a sequenced project activity that, in the case of a completely new client, involves the following steps:

- first contacts with the customer;
- preliminary analysis, requirement identification;
- feasibility study, formulation of an offer;
- negotiation, contract;
- technical development;
- release, test, and implementation;
- post-sale assistance.

Three issues should be underlined here. First, the whole process can last a long time. Commonly, in fact, the lifecycle of an ICT infrastructure is several years, and it ends with the development of a new project aimed at substituting or completely renovating the installed solution. During this period, the provider ensures the proper operation of the infrastructure. Second, as clearly illustrated in Figure 2, the different phases involve different people, with different capabilities and skills, and belonging to different departments. Third, the successful delivery of the service requires a deep involvement of the customer during the different phases. To sum up, the entire process calls for an

appropriate management of the knowledge exchanges both with the client, and inside the company.

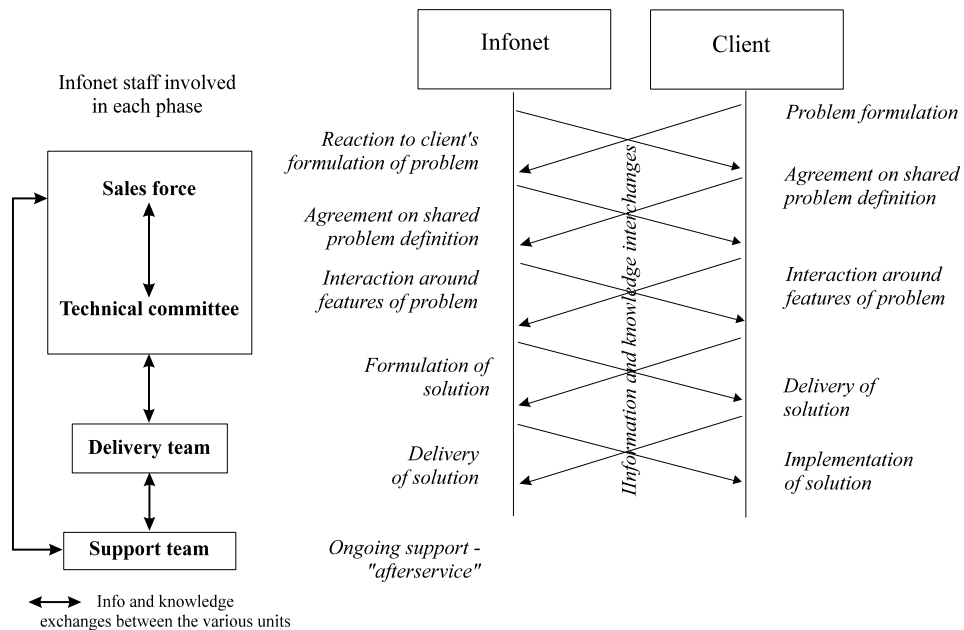

Figure 2: The different phases of service delivery and post-sale assistance at Infonet

In particular, a successful delivery and a post-sale assistance that can solve the clients' problems effectively, require that all the involved employees have a quick and good understanding of the system that is installed at the customer's site. This is not as simple as it may seem, given the long duration of the project and the variety of the involved players. For instance, an employee that is called to assist the customer (e.g., in case of system breakdown or other maintenance tasks) needs to handle both explicit components of knowledge (system configurations, network structures, functioning details) and tacit components (specific explanations of the reasons for some particular configuration). This situation is particularly interesting because the employee that carries on post-sale assistance is generally not the one that designed or installed the system. Therefore, there is a need to perform a complex and deferred transfer of knowledge between different employees. Similarly, the sales agents who want to offer a new solution to old or new clients may need to exploit the knowledge of previous projects and their characteristics. Such knowledge consists of explicit components (i.e., technical data) and tacit ones

(perceptions of user needs, possible market value of a particular system, etc.): also in this case it has to be transferred between different people in different times.

4.3 Infonet path towards KM

As said in the previous section, the knowledge required to effectively manage the business relationships with the customers is particular crucial at Infonet, and hence it deserves to be managed in the best way. The company is fully aware of this, as evidenced by the fact that the first efforts to manage it date back to more than ten years ago, when it introduced the “libretto di impianto” (see below). It should be noted that such knowledge is a mix of technical knowledge (concerning various technical aspects of the installed solutions) and commercial knowledge (concerning the business requirements and other features of the individual clients), which complicates its management.

In the following pages, two paths towards the adoption of KM practices and systems by Infonet will be illustrated. The first path led to the successful introduction and use of a wiki system, and the second path to a delayed and marginal adoption of a CRM application.

4.3.1 The wiki project

In the first years of its business activity, Infonet mainly sold TLC products. Since the clients generally didn't know how to install them, the company started to offer installation services. At that time, there was no need of documenting the work. The company had no necessity of keeping track of the work they were doing: the information coming from the products' catalogue was sufficient. This phase lasted about 5 - 6 years. Later, the company slowly began to move its business toward the design, delivery and maintenance of ICT solutions. It was a real leap, given that the business radically changed from spot commercial transactions to partnership relationships with customers. Such relations began with a consulting activity, continued with the delivery of the solutions, and then with customer support for helping the client use and develop the system. So, at Infonet, executives realized that it was important to start to store pieces of information and knowledge about the installed systems. Especially, this was important to help the effective exchange of knowledge between the delivery people (those that design the systems and install them at the customer site) and the support people (who perform the post sales activity). In particular, the company started to collect information about every

installation of a new system, and to compile a written report for each system. The resulting document (called “libretto di impianto” - book of the system) was intended to support that knowledge exchange between the different parts of the company. Originally, this problem of KM was not intended nor solved in a structured way, but by means of a simple and intuitive paper archive. This situation continued for some time.

The first important step towards a real KM system to improve the management of all the technical knowledge about delivered installations dates back to around 2003, when Infonet started to use Microsoft Exchange Server to share public folders and emails about new installations. This tool had some limits: especially, it was difficult to classify, locate and understand a specific piece of knowledge. Actually, the tool was very flexible, but this ended with increasing confusion among users. The problem is that when people make big efforts to store information and knowledge, but such efforts turn out to be useless because they can't easily retrieve the stored information, the risk is that the instrument is quickly abandoned. The public folders of Microsoft Exchange were a simple way to store emails in a shared ways, and some minimal ability to search by text, date, sender, subject, and the like were offered. But since everyone was free to write and manage his/her own e-mails as he/she preferred, it was practically impossible to locate the needed information. The company tried to give some rules concerning, e.g., the way of writing the object of an e-mail, or the kind of content to include in specific circumstances, but with no significant results. After the abandonment of Microsoft Exchange, public folders were not moved but kept in order to not miss past knowledge and possibly migrate it in a new storage. This never occurred since, in the end, Infonet realised that such migration was an even bigger problem, especially because there was little time to do that.

To overcome the limitations of Microsoft Exchange, the company adopted another software (Owl Intranet Engine), a very simple Content Management Systems with an internal database. This tool was chosen by considering that the actual owners of the useful knowledge were not the “internal” staff (i.e., people that work in the company offices) but the technicians who carried out the installations materially, at the client's site. In point of fact, most of the critical information is collected on the ground, by those who do the work. Owl was a web-based tool that allowed to get the information at any time, and in a shared way. However, given the huge amount of stored data, the tool soon began to cause problems. To simplify the use of Owl, initially a taxonomy to classify documents was created. There was a classification tree divided in two parts: one for “the products” (i.e.,

ICT components) and the other for “the customer installations”. The idea was that technicians could keep a record of the intervention they had made for a customer in a free format; later, the information had to be reworked and stored in the second area of the tree, in a more structured format. Hence, the company identified two stages in the process: a first phase of knowledge collection, where people wrote notes in the way they preferred, and a second of elaboration of the collected knowledge, in order to make it usable by others. This was however complicated by the way Owl indexed topics: searches, in fact, yielded “false positives” or unsatisfactory results. In addition, documents could be of different kinds: texts, files, configuration plans, datasheets, images, zip files, pdf files, links to web pages, and some more. This made it difficult to integrate all them in a common classification framework.

These first experiments showed that developing a KM system that focuses on a particular technology and then fitting it to the flows of knowledge in the organizational processes may result in ineffective use. In view of these unsatisfactory results, the company began to consider other approaches and tools. To facilitate the flexibility of KM, it was decided to focus on systems that allowed dynamic templates for uploading information contents, document revisions, process workflows, and so on. Firstly, a specialized software for KM, Knowledge Tree, was taken into account. This is a complete Enterprise Content Management system with a workflow engine, indexing, metadata management, logical access control system with high security, etc. However, after several reflections and some tests, the company eventually decided to adopt a wiki system, that has the same features of Knowledge Tree, but is a more free and user friendly platform. The decision was based also on the fact that wikis retain all the information that is uploaded, even in case it is unstructured, but they still preserve some logical order so that contents are retrievable and usable for the daily work. Furthermore, with a wiki, the logics of operation and content management can be decided in a shared manner, and is modifiable dynamically.

The present version of the wiki used at Infonet is based on MediaWiki, the free software open source wiki package which is also used by Wikipedia. It was introduced in the company in 2009, by the Support Department, and was implemented thanks to the collaborative efforts of two members of this Department: its head (who is also one of the founding shareholders of the company) and a young new employee. It was configured by reflecting on the knowledge contents that are “really” needed by the different people that

collaborate in a project with a client, and on its usability. The first version was totally devoted to technical people, and focused on technical contents. Later on, in 2013, it was extended to the commercial staff. At present, the introduction of the wiki is apparently a success, as confirmed by a recent survey among the employees of the company, who have indicated this instrument as the main source of knowledge they employ. By the way, the tool has raised the interest of administrative staff who recently asked to have a section dedicated to their activities. Since there is no space here to dwell on the technical characteristics of the system, nor this is the goal of the study, only a few lines will suffice to describe it.

Infonet's wiki portal is split into two different "sub-portals": one for the technical staff (delivery, technical committee, and support) and the other for the commercial staff (sales force). The "technical" part has, mainly, knowledge contents related to the existing applications by customers and past installations. The "commercial" part contains log-in data for accessing vendors' websites and for processing requests for offer. Both portals are, however, accessible by all company users. The wiki is flexible and allows to upload different kinds of content. This turns out to be crucial, because the users need to transfer and retrieve knowledge that can have different forms: technical data, but also pictures, explanations, codes, and so on. It is therefore difficult to use a pre-defined format for all the potential contents that must be uploaded. However, the company decided to pre-define some templates that people use to upload new contents. This allows some flexibility in the way people insert their contents, as well as a quicker retrieval. A pre-defined classification of the contents in different sections is also used. All this derives from the experience of the company, and is specific to that particular way of working. Another important feature of the wiki is that it allows to edit the contents inserted by others, and to track all the changes that have been made. Lastly, to simplify its use, some functionalities were added, such as word-like editor, and a printing feature that allows to create booklets and print them in a pre-defined format.

Having described, although in brief, the road that led to the current situation, now some remarks on its main actors, and on the factors that have shaped it, are needed. Concerning the actors, a key role was played by two members of the Support Department that were the actual promoters of the introduction of the various KM tools that have been adopted and tested. In this regard, it should be recalled that the need to collect and store the information about the client installations originated from this Department, because

they are its members that must resolve maintenance requests, and hence they need knowledge about the systems that other people have formerly installed. It certainly proved to be decisive the fact that one of the members of this Department was also one of the owners of the company: otherwise, probably, the development would have been much slower. Also, the propensity of the CEO towards experimentations – at least in a controlled way (i.e., with a certain degree of freedom but avoiding to make big mistakes) – has given a positive impulse to the process.

The two promoters of the KM systems were also those who have technically implemented and configured the various KM tools: they configured the software, provided the taxonomies, created the templates, added the needed functionalities, and so on. In doing this, they were helped by their competencies in Computer Science, but also by the fact that they are involved in the daily work of the company and, therefore, they have the sensibility to capture the essential requirements and problems of the KM processes. Despite their direct actions in KM, the two promoters continue to carry out their daily work. This means that there is no one who is formally in charge of the KM system: there is no knowledge manager, no chief knowledge officer, etc. There isn't even a "supervisors" that controls those that upload new contents: the control of the pieces of knowledge that are inserted in the wiki are left to the normal "communitarian control" as is usual of wiki systems. However, a person is responsible for a technical check of what technicians upload: this is important to give consistency and fairness to the content. The employee who performs this activity is, however, not an "expert": his task is just to read the documentation and assess if it is understandable from any other person.

Another important aspect, which is probably very important for a small company, is the availability of open source software like in the case of MediaWiki. Costs of implementation of a complex software would be probably detrimental to the development of the project. An additional factor that has undoubtedly affected the development, use and abandonment of the various systems was their respective usability and user-friendliness, and their full integration with daily activities. As we have seen, some KM systems proved to be user-friendly, others didn't. However, it was just the experimentation that made it possible, for the company, to finally select the appropriate solution.

In using the system, the technical people are advantaged, not only due to their familiarity with ICT applications, but especially because the use of the instruments did

not affect the way they worked and therefore didn't imply special changes in internal processes. Quite different is the situation in the case of the sales staff that was not accustomed to document their daily activities in a systematic way. This is the main reason why the commercial employees were involved in the KM project only four years later. It should be noted that to induce the commercial staff to use the wiki, the promoters had to introduce some initial contents that could be useful to them.

4.3.2 The CRM project

Completely different, in both the path followed and the final outcomes, was the introduction in the company of a CRM software: differently from the previous case, this was a planned activity that, however, didn't produce the expected results. After hiring a new employee to follow the marketing efforts of the company, it was felt that a new tool was necessary to help her in this job. It was then decided to implement a Customer Relationship Management (CRM) software. Accordingly, on initiative of the CEO, a preliminary study was made in collaboration with the local University, to understand what information flows of the Sales Department were significant, what relevant information it needs, and how a CRM software could meet these needs.

The company finally bought a CRM software (SugarCRM), that was the specular equivalent of the KM software "Knowledge Tree" but targeted to the commercial area: each customer, phone call, commercial visit (either they result in an order or not) had to be classified and stored in the CRM together with any relevant information that would have been retrievable and used in the future. However, the software was judged very cumbersome by those who had to use it. And this happened even though it had been previously examined and approved by the sales staff. In other words, despite the careful planning, once the system was put into operation, none of the commercial Department practically used it. An internal analysis was conducted to understand the reasons of this scarce use, but the answer given by the commercial people was always the same: "the system is a difficult tool to use", at least in comparison to the way the people were accustomed to work or the expectations they had about it. Almost certainly, the main reason of the failure of the instrument was that the sales staff had to bear the burden of introducing information without obtaining direct benefits.

But surprisingly, at the beginning of 2013, the same commercial staff that previously rejected the CRM system SugarCRM, later asked to use another system – Salesforce –

which has exactly the same logic of an “old” and traditional CRM. The reason was simple: Salesforce is a software that is currently used by the majority of the company suppliers (e.g. HP, Citrix), and hence it allows to share sales leads and other information with them. This software is unfortunately highly structured, so it would be very hard to integrate it with the Wiki system which is used by the technical staff. This means that the sales people have to use the two tools but can’t integrate the information from one to another; this can cause duplication of information, loss of efficiency, and risks of inconsistency.

To summarise, the factors that seem to have hindered the introduction of a CRM software at Infonet can be listed as follows:

- a “top down” approach to the adoption of the system. Actually, the idea of trying to use a CRM software came from the CEO and was probably inspired by the marketing director; while the potential users (i.e., the commercial staff) were involved only in a second time;
- a preference of key persons of the Company for the use non-procedural approaches to sales management;
- a poor alignment between the tool and the current sales processes. In particular, the use of the CRM required additional work in entering information and data that previously were not gathered;
- some technical deficiencies of the systems concerning its integration with the tools generally used by the sales people, in particular mobile phone and e-mail;
- the perception of the sales force that they wouldn’t gain direct advantages for their daily work.

5 Discussion

The history of the introduction of the KM systems at Infonet highlights some interesting points that deserve to be discussed. First of all, the pathways followed in the two cases are significantly different. In the case of the wiki, its adoption is not the consequence of a planned strategy but is a solution that has emerged along the way. Actually, over time the objectives and recipients of the project have gradually but significantly changed. From a system that was conceived to be used mainly by the technical area, the company passed to one targeted to the commercial staff too, and may

be extended to the administrative employees in the near future. As well underlined by one of the promoters of its introduction, the approach followed in the development of the system “*was contingent and closely tied to the tools available*”. On the contrary, the adoption of the CRM was the result of a deliberate strategy, and hence its introduction had been planned directly. For this reason, the CEO considered it appropriate to perform a preliminary study on the information needs of the Sales Department. Anyhow, in both cases there wasn’t a specific reference to the concepts and models of KM – for instance, an analysis of KM processes, of categories of knowledge, of learning processes, etc. Infonet executives had heard of KM, but they had never considered KM approaches explicitly. This confirms the findings of previous studies, namely that small businesses typically adopt and use practices and tools of KM without recognizing them as such.

The two systems also differ as regards the kind of knowledge which they deal with. In point of fact, the CRM system contains only explicit knowledge (i.e., data and information about the clients), while the wiki system stores both explicit and tacit knowledge: ideas, experience, opinions, and so on, expressed in various forms and formats. Moreover, the introduction of information in the CRM system occurs in a highly structured manner, while in the wiki the contributors are allowed greater freedom. In this regard, it is interesting to note that the examined company makes use of both tacit and explicit knowledge, and both are relevant for its business.

In both situations, the characteristics of the technology have played a decisive role. The availability of new tools has led the company to experiment their use. In this regard, one might say that, at Infonet, the management of knowledge has been strongly mediated by the availability of appropriate instruments. In doing this, the company has benefited from the fact that its people work in the ICT field and have, therefore, good competence of Computer Science. The advent of Web 2.0 technologies, as well as the availability of open source software, has acted as a catalyst for the introduction of KM systems.

6 Conclusion

The present study aimed at addressing the question whether small businesses adopt a deliberate or an emergent approach to KM, and in the second case, which are the relevant opportunities and risks, and the main enablers and obstacles to the adoption of KM practices.

The lesson that emerges from the experience of Infonet is that in small enterprises, the introduction of KM practices and tools can follow both deliberate and emergent approaches. As the case study shows, it is not necessarily true that the first approach is more effective than the second.

Also, the empirical evidence confirms that, in small companies, the development of KM can occur with no direct reference to the concepts of KM as a “scientific discipline” as scholars can call it. And even when, in the end, the company recognizes that there are some activities that can or should be called KM, the approach remains strictly “anchored” to the requirements of day-by-day activities. This leads to conclude that a single “best-way” KM approach, based on a rational planning method, is almost impossible to define in SMEs. Nevertheless, the experience of Infonet suggests that there are some conditions that can affect or hinder the successful adoption of KM practices by SMEs, and in particular:

- a bottom-up approach, that is the involvement of operational users from the early stages of the project;
- demonstrating the actual usefulness of the KM systems and practices in the real life of the company;
- integration of KM with the current working practices and technological tools, and alignment with the internal business processes;
- sponsorship of owners, especially when, as it usually occurs, they carry out operational activities that involve the use of the wiki. In this case, the owner must be the first to be convinced of its usefulness;
- propensity to experimentation and tolerance to mistakes. This is crucial because it favours a proactive and well-disposed attitude towards the introduction and use of new managerial methods;
- familiarity with IT technologies, since they can play as catalyst of the adoption of KM practices.

This study has some clear limitations that should be also highlighted. Especially, as any single case-study, generalizations are risky. However, the study can at least represent a starting point for a fresh approach to studying KM implementations in small companies based on a principle of emergent strategies.

In light of this, further research is needed both to confirm the findings of the present analysis, and to investigate in greater depth the factors that can influence the introduction and use of KM in the case of “emergent KM”.

Structured Abstract

Purpose – This study aims to analyse the use of various forms of „knowledge utilization“ (Zhang et al., 2009), especially the role of knowledge management (Rode, 2001; Lichtenthaler, 2005; Wamae, 2009), as a means to integrate strategic customer knowledge in order to be one step ahead of the market and competitors. For this purpose, premises, processes, and factors are highlighted, which are essential to incorporate the knowledge of strategic customers into the knowledge base of knowledge-intensive SMEs (Spithoven and Teirlinck, 2010) and therefore contribute to the commercialization of knowledge intensive products as well as services (Lichtenthaler, 2005; Chen et al., 2010).

Design/Methodology/Approach – Several factors which are relevant for the integration of strategic customer knowledge have been extracted from knowledge utilization literature. Establishing relations (Teece, 1998; Clarke and Rollo, 2001), solving customer problems (Backer, 1993), and SMEs capacity to absorb knowledge (Teigland and Wasko, 2003) are crucial for the integration of strategic customer knowledge. Since research and literature in the field of “knowledge marketing” (especially in knowledge-intensive SMEs) is still scarce, the authors regard a qualitative research approach as appropriate. The empirical data were not obtained in an artificial way, but in a natural one. The general case study according to Yin (2009) could include both qualitative and quantitative research. However, the following case study primarily focuses on the qualitative research method (Lamnek, 2008; Mayring, 2010; Merriam, 1988).

Originality/Value – The knowledge base – internally or externally acquired – which constitutes the basis of a unique competitive advantage of enterprises in the software and other knowledge-intensive industries, can be expanded and utilized in a better way through “commercialisation of knowledge” (Lichtenthaler, 2005; Chen et al., 2010). Particularly customers and the integration of their knowledge are relevant to knowledge-intensive firms, because these factors allow enterprises to acquire additional know how that supplements the limited resource base and which can be utilized for product development, innovations, and other customers.

Theoretical Implication – This research paper aims to contribute to “knowledge utilization” as well as SME literature since the empirical data collection was exclusively limited to SMEs. Hence, three necessary processes have been identified: (1) Developing

communities of practise or knowledge networks, (2) solving customer problems, and (3) possessing the absorptive capacity to understand and integrate customer knowledge.

Practical Implications – In terms of practical contributions, this paper intends to clarify the utilization of strategic customer knowledge as well as its relevance in product development in knowledge-intensive industries. Additionally, customer knowledge is also crucial in terms of commercialising the predominant resource of such enterprises – knowledge-intensive products and services. Here, three factors are decisive: Establishing relations, solving customer problems, and the capacity to absorb knowledge. Emphasising on these particular factors of marketing activities, might influence the success of knowledge-intensive SMEs in comparison to competitors. Marketing activities carried out by knowledge-intensive SMEs should therefore clearly differ from other industries. The consideration of these factors enables top level management to differentiate themselves by utilizing knowledge marketing.

Paper type – Research Paper

1 Introduction

The globalization of markets, the convergence of previously distinct industries, and the fact that markets become even more unpredictable are challenges for firms (Day and Montgomery, 1999). The increasing speed of information transmission, the increasing amount of information that can be transmitted and processed, is leading to the creation of new types or patterns of information firms (Glazer, 1991). In general, these so called knowledge intensive firms are operating in knowledge markets with aims of generating revenues, gaining knowledge access, setting industry standards, profiting from infringements, realizing learning effects, and guaranteeing freedom to operate (Lichtenthaler, 2005). In the 21st century, the era of communication and information technology, resources responsible for the emergence of intangible assets are becoming more and more important. The resource “knowledge” is seen as a strategic resource as well as a central challenge in the business environment of this century (Spender, 1996; Boisot, 1998). The significant components for a sustainable competitive advantage represent the knowledge lead of the company (Teece, 2001). The goal is to bundle knowledge in a way that enables firms to offer added value to their customers. Problems, experiences, and suggestions for improvements of customers should be identified and

passed on to the company (Handlbauer, 2000). The way firms go about handling knowledge as an ever more important resource and influential factor with regards to long-term business success has become an essential part of business administration. The systematical handling of company knowledge places the company in a position to differentiate itself from the competition (Wiig, 1997).

Zack *et al.* (2009) showed that existing internal knowledge resources are utilized for strategic planning and that the customer is unfortunately neglected as a strategic knowledge partner. The "customer" is placed in the center of attention when it comes to an adequate utilization of knowledge in knowledge intensive firms. The associated knowledge and skills that reflect customer knowledge should be integrated in the value creating activities of the company through experiences, problems and suggestions for improvement (Handlbauer and Renzl, 2009; Gibbert *et al.*, 2002). Several studies show that, especially in small- to medium-sized enterprises, resources are limited (Desouza and Awazu, 2006; Boisot, 1998; Jarillo, 1989; Aragón-Correa *et al.*, 2008; Coviello and Martin, 1999). As Zack *et al.* (2009) and Zack (1999) describes in the area of strategic management, knowledge gaps can come about in order to reach a future strategy. As one approach, it is possible that the customer could fill these knowledge gaps in the form of a value creating complementary resource. We define these customers as "strategic". The „strategic customer“ in a knowledge based sense is seen as, in this context, a sustainable and value creating knowledge cooperation partner rather than a passive product receiver. The goal of the following paper is to clarify processes and factors, which support the utilization of the knowledge of strategic customers, who are involved in value creation activities.

2 Theoretical Background

2.1 Strategic Knowledge Management

Probst *et al.* (2002) define knowledge as it refers to all the knowledge and skills individuals use for the solution of problems. In literature, the resource knowledge is summarized as intellectual capital of the company, which generates value (Zabala *et al.*, 2005). Knowledge involves company's processes, people, values, culture, intuitions, and opinions (Zabala *et al.*, 2005). Nonaka and Takeuchi (1995) distinguish tacit and explicit forms of knowledge. Both forms are described with different attributes, like intangibility,

uniqueness, concurrent usability, value uncertainty, and publicity (Nonaka and Takeuchi, 1995; Chen et al., 2010). Knowledge can refer to an object or a capability and it may reside in individuals, groups, documents, processes, or repositories (Alavi and Leidner, 2001). Nevertheless, or exactly for this reason, tacit knowledge which lies in the minds of employees (Zack, 1999), and that of the customer is regarded as significant. It is therefore indispensable, at the strategy development level, to embed an enterprise-wide and cross-functional knowledge orientation within company principles (Albrecht, 1993). A company provides the physical, social, and resource allocation structure, so knowledge can be shaped into competences (Teece, 1998).

Strategic knowledge management focuses on the core competences of the company, which mirrors knowledge that is critical for success. Core competences can be described as a collection of resources, capabilities, knowledge, as well as technological characteristics of the company. In combination they can create added value for the customer base (Barney, 1991; Prahalad and Hamel, 1990, 1999). Competitive advantages can be generated and protected owing to the fact that strategic components of “knowledge goals” are focused on the core competences (expansion of internal company strengths) in this century. As a result, generated knowledge can be employed higher customer usage. In order to reach this goal, Zack (1999) believes that firms must be able to describe the relationship between strategy and knowledge. The type of knowledge is of significance for the strategic direction and needs to be identified. Subsequently, this knowledge should be compared with the current knowledge in the company to identify any possible knowledge gaps. The existing internal knowledge assets are predominantly used for strategic planning. Involving the customer as a strategic knowledge partner in strategic matters is, however, hardly done in most firms (Zack *et al.*, 2009). For this very reason - that knowledge goals can concentrate on the core competences of the company - we can speak of customer orientation.

2.2 Customer Oriented Focus

The concept of customer oriented knowledge management is becoming increasingly important. The CKM approach represents an embellishment of traditional knowledge management with a special focus on customer knowledge as a resource. This stems from the fact that not only the "internal (employee)", but also "external (customer)" knowledge flows should be recorded (Gibbert *et al.*, 2002). The concept has the aim to support

corporate strategy with customer insights, offer an ideal basis for the optimization of strategy and innovation processes (Smith and McKeen, 2005), and facilitate internal improvements. The terminology of CKM has been seen in the relevant literature as the management of customer knowledge. The application should serve to expand the organizational knowledge base with the customer perspective. The focus lies on the internal company view within the classical knowledge management model and should make more effective and efficient work possible, which should then optimize costs (Probst et al., 2002; Nohr and Roos, 2003; Ostertag, 2003; Garcia-Murillo and Annabi, 2002). In contrast, the strategic focus of CKM rather concentrates on growth and innovation through the incorporation of customers and shows that customer knowledge represents a part of the organizational knowledge, which can generate competitive advantage (Gibbert *et al.*, 2002; Smith and McKeen, 2005). It could be characterized as knowledge management with a special focus on customer knowledge (Handlbauer and Renzl, 2009), which Gibbert *et al.* (2002, p. 459) describes in the following way:

„In the emphasis on knowledge as a key competitive factor in the global economy, corporations may overlook a major element – customer knowledge.“

As already mentioned, the customer holds a central position in place. However, there are varying customer types in the corporate environment. Grönroos (2000) distinguishes different customer categories. On the one hand, the “transactional approach” states that customers are not interested in building a sustainable and intensive partnership with the company. On the other hand, there are customers that wish to have a relationship with the company. This concept is entitled the “relational approach”. The relational approach is divided into both active and passive partnerships. Passive-oriented customers are content when they have the possibility to contact the company when the need arises. Active-oriented customers, in contrast, search for contact with the company and want to actively participate in corporate affairs. These customers can be used for various value creation activities as long as they are motivated to be involved for this purpose. It is therefore possible, for example, that these individual customers act as their own marketing department and evaluate the products or services which they have most experience with.

They could then also share their experiences with other customers (Bowers and Martin, 2007; Bettencourt, 1997; Berthon *et al.*, 1999; Hood, 1998; Parasuraman *et al.*, 1985).

Customers can also be integrated into the innovation phase as they possess knowledge concerning new market trends and needs of other customers as well as their expectations (Kelley *et al.*, 1990; Kelley *et al.*, 1992). The customer further possesses optimal prerequisites in order to advise the company both internally and externally if improvements and complaints are received. As a result, additional value creation activities can be improved (Bettencourt, 1997). Ultimately, their knowledge should support both the existing and newly acquired customers in terms of their purchasing processes when not only present knowledge but also latent knowledge influences their decision and purchasing behavior (Davenport and Klahr, 1998; Garcia-Murillo and Annabi, 2002; Schaschke, 2007). Another approach concerning how value can be generated with customers is referred to as client co-production in the “service literature”. This infers that such customers are seen as “partial employees” and can be implemented anywhere from marketing to engineering services. The model of co-production focusses on complex multidimensional structures and is rather oriented towards short-term partnerships (only a few months) (Bettencourt *et al.*, 2002). Additionally the customer could play a strategic role, which can be defined as a trustful partnership where the customer is intrinsically motivated and represents a marginal percentage of the entire customer base (Wilhelm *et al.*, 2013).

2.3 Knowledge Markets and Participants

Another key term in this article is the knowledge market, where intangible goods are traded (Kafentzis *et al.*, 2004; Jeong *et al.*, 2013). In general, the market transparency in these knowledge markets is very low and high risks or uncertainties concerning knowledge asset quality and value may occur on both sides (firms and clients) (Desouza and Awazu, 2004). Because of these uncertainties, for example, clients often hesitate to change their knowledge provider (Greenwood *et al.*, 2005). Following activities are described within these markets: comparison of available products and services, acquisition of knowledge of providers, exchanging of tacit or explicit knowledge forms, competition, and cooperation of firms for knowledge resources (Probst *et al.*, 2002; Desouza and Awazu, 2004; Kafentzis *et al.*, 2004; Grover *et al.*, 2009).

Following participants and factors characterize these knowledge markets: market makers, buyers, sellers, brokers, market rules, and the market space (Desouza and Awazu, 2004). Kafentzis *et al.* (2004) and Chen *et al.* (2010) additionally highlight different roles

in the market for knowledge: the knowledge supplier and requester, third parties, knowledge processor, and the knowledge service provider. For participants with current technologies for distributing information in knowledge markets, it is easy to explore market segments that were not reachable before (Shapiro and Varian, 1998). Here, the so called imperfections of knowledge markets (Teece, 1998) lead to different challenges for participants: the identification of knowledge clients, absorptive capacity, intellectual property rights, adequate compensation for knowledge transfers, assessing the value of intellectual assets, or the nature of knowledge (Lichtenthaler, 2005).

In general, human and social factors appear in many areas of trading and exchanging knowledge (Kafentzis et al., 2004). The sharing of knowledge is a social process (Rodger, 2012). Here, the “social exchange theory” plays an important role for all participants of the market, which describes that people share information or knowledge with the expectation of reciprocity (Kankanhalli et al., 2005; Rodger, 2012). Additionally, in these markets for knowledge, a high variety of knowledge intensive services and corresponding skill requirements exist (Consoli and Elche-Hortelano, 2010). In other words, the level of education of knowledge employees is quite important to identify appropriate cooperation partners and to access and assimilate the relevant knowledge (Spithoven and Teirlinck, 2010).

2.4 Special Role of Knowledge-Intensive SMEs (KISMEs)

Today, the processing of information in firms is regarded as the critical task and the ability to do so as the critical competition requirement (Greenwood et al., 2005). Here, firms, which clearly differ from industrial firms in terms of value creation and the level of information asymmetry between the company and its clients, are in the focus of interest (Sheehan and Stabell, 2010). In general, knowledge intensive firms are defined as organizations within a knowledge economy (Drucker, 1999), that create market value through the application of knowledge to client demands (Swart and Kinnie, 2003). Starbuck (1992) characterizes them when at least on third of the personnel are experts. Their output must be of an exceptional expertise, which makes an important contribution (Starbuck, 1992). Therefore they rely mainly on human and organizational resources, like experts, which are highly educated individuals, and the application of expertise to deliver their services (Swart and Kinnie, 2003; Greenwood et al., 2005; Sheehan and Stabell, 2010; Leon, 2011; Abecassis-Moedas et al., 2012). The human resources are also called

knowledge workers, which predominantly use cognitive skills (Leon, 2011). These employee skills are essential to the creation of competitive advantage for these kind of firms (Swart and Kinnie, 2003). Also known as expertise, these skills are the very core of the KISMEs offerings (Sheehan and Stabell, 2010). Not only the personnel is the most important resource, because of the intensive interaction with clients, but also clients are essential (Alvesson, 2000). In general, the human capital dominates products, services, and innovations (Starbuck, 1992). KISMEs often have the problem of retaining key personnel, which emphasizes the significance of factors like commitment and loyalty (Alvesson, 2000). In general, enhancing knowledge sharing capabilities by strengthening employee trust depends on employee commitment and, furthermore, on a corporate environment of collaborative teamwork (Tongo, 2013). Nevertheless, a certain style of working and organizational culture implies additional organization-specific knowledge (Alvesson, 2000). Other individual factors like intrinsic motivation, norms, reciprocity, and identity are enhancing for an effective knowledge sharing environment (Alvesson, 2000). Here, so called community-based organizations building long lasting and trusting relationships with all employees (Tongo, 2013).

The literature analysis has shown that distinct characteristics are: the type of input or capital, the type of work, and industry characteristics (Swart and Kinnie, 2003). Within KISMEs you can additionally differentiate between: the knowledge intensity, the low capital intensity, and a professionalized workforce (von Nordenflycht, 2010). These firms are mostly born out of an innovative idea, as a directly employed workforce will not always grow quickly and supply services just to a few clients (Swart and Kinnie, 2003). They mainly sell problem-solving services, which are based on feedback from clients (Sheehan and Stabell, 2010). Generally, problem-solving strategies are constrained by the capabilities of both employees and clients (Consoli and Elche-Hortelano, 2010). The strategic customer can serve as a complementary resource given that this type of firm displays a limited resource base (lacking knowledge, marketing and finance). Furthermore, firms strive to recognize new and additional opportunities through their clients. Customer orientation, therefore, encompasses that companies orientate themselves towards their customers and should manage to get a hold of useful knowledge concerning current products (Handlbauer, 2000).

The products and services are often called knowledge intensive business services, which are innovative activities, sources of innovation, and carriers of innovation (Hertog,

2000; Mas-Verdu and Alba, 2011). These are carried out through a strong interaction between customer and the corporate knowledge base (Hertog, 2000; Mas-Verdu and Alba, 2011). The main goal is to transfer tacit knowledge and experiences in order to become useful and effective in delivering services to new clients (Abecassis-Moedas et al., 2012). The tacit nature of knowledge makes its exchange more difficult, while simultaneously making its reuse by clients and competitors more difficult (Laundry et al. 2012). In general, work processes in KISMEs are always novel, complex, and involve problem solution (Swart and Kinnie, 2003). Hereby, tacit knowledge or experiences of the employees are repeatedly enacted in novel circumstances (Swart and Kinnie, 2003). Especially combining various types of highly specialized knowledge to develop problem-specific solutions is the main process of them (Laundry et al. 2012). Hence, these firms heavily rely on self-determination, one-dimensional hierarchies, and the need for extensive communication for coordination (Alvesson, 2000).

2.5 Processes and Factors of Knowledge Utilization

First, the identification of knowledge assets a company possesses or needs, their possible knowledge clients as well as the knowledge product or service these clients need (Teece, 1998; von Krogh et al., 2001) are prerequisites for the utilization of knowledge. Furthermore, the identification process plays a major role, because of the imperfections of the knowledge markets, like the lack of market transparency (Lichtenthaler, 2005). Here knowledge exchanging relationships are essential for knowledge utilization, which is described, for example, by an external growth by means of takeovers, mergers and acquisitions (Antonelli, 2006). A company by itself seldom possesses the complete set of resources required to commercialize its knowledge stocks effectively, because new knowledge usually emerges from beyond a company's boundary (Lin and Wu, 2010). Here, firms need to pay attention to cultural and organizational contexts, in which their stakeholders most effectively are encouraged to utilize knowledge (Clarke and Rollo, 2001). Therefore, it is crucial to develop an organizational culture that reflects the willingness of members to seek others' disparate knowledge and share their own (Hargadon, 1998; Thite, 2004). Additionally, the KISMEs reputation increases the value of knowledge for buyers (Zhuge and Guo, 2007; Weiss et al., 2008; Greenstein and Markovich, 2012). Acquiring a reputation as an innovator may facilitate firms' access to

financing, may make it easier to get contracts, grants and subsidies, or hire the best researchers (Muller and Pénin, 2006; Rodger, 2012).

Another main process of knowledge utilization described by authors is a coordination and governance process of knowledge assets in firms. The heterogeneity of knowledge and participants who possess knowledge require coordination in order for firms to succeed (Antonelli, 2006). Here, the governance of knowledge includes coordinated transactions, quasi-hierarchies, and constructed interactions (Antonelli, 2006). In general, the coordination and governance of knowledge is dominated by different factors like identifying the appropriate knowledge and the intended application (Hicks et al., 2002), finding knowledge providers and recipients, evaluating knowledge assets, or determining the knowledge value (Chen et al., 2010). In doing so, electronic knowledge repositories enable employees to leverage and reuse existing knowledge, share knowledge with others, and stimulate the development of new knowledge and ideas (Lin and Fan, 2011). An effective knowledge system involves an adequate knowledge transfer (Mudambi et al., 2009) and the company needs to be able to identify experts on recurring problems (Lee and van den Steen, 2010). Garavelli et al. (2004) explain that when firms are organized as knowledge communities, knowledge emerges through the organization actions. The objective of these communities is to connect people in various forums in order to reduce capital and operating costs, increase utilization, and improve the firm's market positioning (Mital et al., 2010; Ramanigopal, 2013). The existence of social networks and social ties enhanced by group dynamics, knowledge activists, knowledge sharing culture (Ramanigopal, 2013), environment of mutual respect and trust, a shared purpose, a shared context, and managerial belief (Moitra and Kumar, 2007) are characteristics of knowledge networks. Today, the electronic connectivity of relevant knowledge producers can combine internal knowledge of a firm and external pieces of knowledge (Patrucco, 2005).

An important factor for the utilization of knowledge is described as the focus of solving problems of customers. Here, firms leverage their intellectual capital and package it into high value-added knowledge based products and differentiated services, which are capable of solving customer problems (Chen et al., 2010). Especially relevant for problem-solving services is task specific information which is collected from the company's customers (Verona et al., 2006; Consoli and Elche-Hortelano, 2010). The focus of the problem-solving capability lies in the interactions between customers and firms. It is a knowledge based process, which consequently requires flexibly customized

services and products in order to respond to customer feedback (Massey et al., 2001). With technological tools of customer relationship management (Massey et al., 2001), the development of customized services and products is supported and the ability of firms to expand their knowledge is maintained (Verona et al., 2006).

One additional factor of knowledge utilization is the capability of firms to absorb knowledge or to innovate from their current knowledge assets (Chen et al., 2010). In general the absorptive capacity is the ability of a firm to recognize the value of new, external information, assimilate it, and apply it (Cohen and Levinthal, 1990). Teigland and Wasko (2003) explain the absorptive capacity as combining existing internal knowledge with novel external knowledge to develop creative solutions and improve performance. The decisions relating to knowledge innovations are ultimately based on three main questions: who (people), what (knowledge assets), and why (business objectives) (Goh, 2005). Innovation is usually perceived as a group of activities involving interaction and knowledge exchanges between people and organizations (Muller and Pénin, 2006). Here, the absorptive capacity embodied in people is the key element for the organizational integration of external knowledge (Spithoven and Teirlinck, 2010). Especially the function or skills of the company's employees become a qualitative aspect of absorptive capacity (Spithoven and Teirlinck, 2010).

3 Research Methodology

The first step refers to a case study (in accordance with Vaus (2001)) and possesses an explorative character. Yin (2009) describes a case study as follows:

„Case Study is an empirical enquiry that investigates a contemporary phenomenon in-depth and within its real-life context, especially when the boundaries between the phenomenon and context are not clearly evident” (p. 18).

According to the definition of Yin (2009), the case study method focuses on the meaning of the research design. Evidently, the qualitative social research within the case study problem takes on a meaningful determinant. When choosing a research design, case studies are applicable when many variables need to be elicited which limit themselves to a small number of research units (Vaus, 2001). Choosing a case study as research object

is especially interesting in a context where the research design focuses on new or scarcely researched problems (Eisenhardt, 1989).

3.1 Unit of Analysis

The present paper analyzes a single case study. The following criteria were specifically necessary for the choice of the company:

- Company operates using a relatively flat hierarchy system (hardly any bureaucracy)
- Company was created and follows a customer orientation towards a problem-solution strategy
- Most work in the company is based on intellectual nature and well-educated, qualified employees form the major workforce
- Flexibility and open knowledge disclosure are integrated into the company culture

The selected company for our single case study is a small software company located in the Principality of Liechtenstein. The firm meets all the requirements for the choice of our single case study. This company can be seen as a knowledge intensive company and is described shortly in the following section. Furthermore, the approach and selection of the interviewees will be described.

Medical Company

The examined company considers itself an innovative software developer that is clearly in alignment with the customer needs of modern ENT-clinics. The company's headquarter is located in the Principality of Liechtenstein (Rhine valley). The company also has an office in Riga (Latvia) which was established in the course of the firm's expansion strategy. Currently, the company has 18 employees, whereas most of them are graduates who have obtained a university degree. The company develops and sells various databases which enable clinics, researching doctors in the ENT-field, and the pharmaceutical industry to record their therapies and perform statistical evaluations. Individual customer projects are conducted for clinics and various pharmaceutical firms. The company perceives itself as an individual customer software partner in the medicinal field. Naturally, this field of medicine must follow strict guidelines and heavy regulations steadily rising qualitative and legal requirements. Field analyses show that the medical technology field will have a strong growth tendency in the future. Consequently, the

importance of research and quality assurance in the medicinal field will continue to grow. Because of the specific application of individual programs as well as the database that is seen as a complementary product to the clinic information system, the company effectively operates in a niche market. This implies that the demand is relatively small and there are only few directly competitive products in the market. Despite its activity in a niche market, the company serves international customers in over 20 countries.

3.2 Level of Analysis (Approach and Selection of Interviewees)

The selected company provides an excellent research unit based on the chosen focus of KISMEs. Access to the interviewees was facilitated owing to the fact that one of authors is in contact with the company. Retrospectively, the authors put strong emphasis on integrating various perspectives concerning the selection of interviewees such as different departments and positions within the company, as well as distributors and strategic customers. In doing so, much broader data could be acquired, which should consequently reveal more meaningful findings. The selection of the individual interviewees was conducted in consultation with the owner of the business. In conclusion, nine individuals were chosen and interviewed in this study.

The authors' intentions were to ask open questions using an interview guide based on the explorative character of the following paper. A pilot study was conducted after the successful construction of the interview guide. This allowed the authors to make further, small adjustments to the interview guide. The duration of the interview depended on the individual and lasted between 30 and 90 minutes. The individual interviews were recorded and subsequently transcribed in the time frame from January 2012 until February 2014. The characteristics of the interviewees are summarized in Table 1.

Interviewee	Position
A	CEO / Owner
B	Marketing & Sales (M&S)
C	Research and Development (R&D)
D	Supervisory Board
E	Strategic Consultant
F	Research and Development (R&D)
G	Research and Development (R&D)
H	Strategic Customer
I	Strategic Customer

Table 1: Interviewees

3.3 Data Analysis

The information gathered from the data collection will be analyzed in six steps (Bogner, Littig and Menz, 2009). For this purpose, the interviews need to be transcribed beforehand (Saunders and Lewis, 2012). Generally, there are two different approaches: on the one hand, a complete transcription in which word for word is transcribed; on the other hand, a partial transcription in which only a certain degree of detail is transcribed (King and Florrocks, 2010). However, it is necessary to proceed carefully in order to lose or distort as little information as possible. Hence, the single interviews were recorded allowing the authors to completely transcribe them. Subsequently, the content of the nine interview protocols were structured according to topics. This process is called coding. For this purpose, the authors created a matrix to visualize the thematic analysis. The answers of the interviewees were processed according to their content and then entered into the corresponding fields of the matrix. Here, the wording of the answers should be maintained, but, at the same time, not too many quotations should be incorporated (Bryman, 2008). The objective of this method is the thematic classification of the interviewees' original statements.

Subsequently, the statements of the interviewees will be summarized according to their affiliation of the examined department. As a consequence, a new matrix, divided into the departments management, sales, and R&D, is developed and displays the core statements from the strategic customer's view on the particular sections of questions. Through this technique, a comparison of the respective contents is possible. The next step contains the evaluation, in which the authors strive for a conceptualization of the contents. The evaluation of data followed after the qualitative analysis of contents according to Mayring (2010). Mayring (2010) distinguishes four different techniques of qualitative analysis. The evaluation of the interviews is based on the technique of "summarization." Here, the first step includes the selection of the representative partial quantity that relates to the research question and, subsequently, its categorization. The structure of the interview guide served as a starting point for the categorization. After the categorization, the contents of the interview protocols were assigned to the predefined categories. Afterwards, the data could be examined and analyzed. Also, the result were discussed and theory was compared to practice (Flick, 2011; Gläser and Laudel, 2008; Mayring, 2010). The evaluation of data ends with a theoretical generalization. In this step, the specific

themes are abstracted and compared to theory. The assessment of available business records, which are relevant to the examined process, support the data analysis.

4 Presentation of Findings

The strategy of the studied firm emphasizes that the needs of the customers are satisfied to the highest degree and the end customers of the firm's customers can be given medical treatment of highest quality. Based on this strategic thinking, the products must be ideally customized to the customers' needs, which is why the firm constantly advances their products by integrating customer feedback originating in problems customers have experienced in the industry.

4.1 Developing Communities of Practice or Knowledge Networks

The identification of different knowledge sources to generate or adapt products or services of the company stands at the very beginning of the process and represents much more than a routine. In this case, the importance of finding adequate employees of the firm or external partners to further develop the company's main outcomes is highlighted by the limited available resources of the unit of analysis and its reliance on additional knowledge of their customers. Due to the limited resources of the observed firm, it is dependent on additional external sources of knowledge. The firm not only struggles with finding adequate resources such as strategic customers or partners, it also needs to have a workforce and a capable system to implement this external knowledge. Therefore, the company employs more than 15 workers with academic degrees. Due to special terms and conditions in the firm knowledge is maintained by different teams. The general structure of the firm and its flat hierarchy enable the employees to exchange internal knowledge more easily and without formal barriers. A technology-based system of knowledge storage (Intranet) helps to connect different employees in project-based processes. Here, team meetings on a regular basis support the internal sharing knowledge acquired from customers. According to the statement of the interviewees, the external knowledge perspective plays a crucial role; especially the category of strategic customers – who are active participants and value-adding to the firm.

The relationship building process is an important step after the firm has identified the relevant strategic customers. Establishing trustworthy relationships with these customers

constitutes an inevitable prerequisite for the transfer of knowledge. Once more, the integration of knowledge of strategic customers depends on the firm, their employees' willingness to receive knowledge, and the customers' willingness to provide information. Here, the degree of openness for knowledge exchange is influenced by people, knowledge assets, and business objectives of the firm. In the analyzed case, the strategic customer and the firm both seek to develop a sustainable and value-adding relationship. The work processes and styles also represent substantial knowledge from the relationship with customers and their generative feedback on products and services. Since they have a major impact on developed innovations, customers embody a vital factor in the process:

“it does not work without cooperating with the customer, to add value to the programs, because otherwise we would develop things that are not needed [Interviewee A (CEO) & G (R&D)].”

The process of relationship building is not only a necessity for the success of the analyzed firm, but is also an important factor when it comes to the adequate utilization of knowledge. Especially social determinants like trust, reputation, rewards, and motivational factors are essential for establishing potent economic relations. We recognized these items of relationship building in different activities and situations inside and outside of the firm, for example, when employees were collaborating with other colleagues or when employees were contacting potential customers for the first time with the goal of establishing a more intense relationship. The studied firm's customers particularly consider reputation and trust (word-of-mouth) when deciding for a firm and its products. Nevertheless, relationships and cooperation of employees within firm boundaries are also very important for the adequate usage of knowledge. Here a system of rewarding for knowledge exchange and other motivation factors, like trust could be acknowledged in the studied firm. This indicates that the incentives are not based on an extrinsic, but rather on an intrinsic level. This statement was supported by the thoughts of Interviewee I (strategic customer):

„The motivation is that the product can be further developed through ideas, and if you are active, you have to be challenged and encouraged. Challenged means that ideas are contributed and encouraged means that the firm then really tries to implement these ideas and in a short period of time.”

During the exhibitions, it could be observed that knowledge exchange occurred on an implicit knowledge level. The concrete acknowledgements between strategic customers

and the observed company could be elicited and discussed. The empirical analysis showed that the communication channel only occurred directly and was based on concrete experiences. The strategic customer (Interviewee H) described this as follows,

„that occurs by telephone. I sit down and concretely bring my ideas together.”

So, together, strategic customers and the firm form a “community of practice“. The communication within the internal and external knowledge exchange constitutes the knowledge network. Factors such as the choice of the communication channel, experiences, and trust are crucial for the establishment of a knowledge network.

4.2 Solving Customer Problems (Coordination & Governance of Knowledge)

The coordination and governance of knowledge transactions between the analyzed firm and the strategic customers serves and seeks to assure the protection of intellectual capital of the firm and correspondence to customer needs. In this context, we have to take into consideration that, in the medical industry, it is highly important to handle patient-information confidentially and to locate further data of strategic customer correctly, since other customers are competitors and, therefore, it would be counterproductive. The CEO (Interviewee A) of the firm mentions that sometimes both parties are bound to confidentiality agreements, since some customers insist on such a contract, because generally sensitive data is revealed and shared. In further interviews, it was determined that the internal firm knowledge is “hardly” shared with customers. More commonly, new databases are created based on customer input and example criteria. In reference to the IT department, employees share only very little information with customers [Interviewee B (M&S)]. Interviewee C (R&D) explains this fact as follows,

„From the view of the firm, we share relatively little with customers, I mean technically. The customer simply knows how the system functions but only in the meaning of who can use it. What and how the method of programming occurs is not shared with the customer.”

However, when creating customer oriented software products, it is inevitable to integrate the customer into all phases of development. Therefore, flexibility, experiences, and problem-solving competences of employees are essential. Employees, who are directly in contact with customers, must know about the firm’s own competences and the customers’ needs in order to connect these two components. Technology, such as a CRM system, enables employees to oversee internal and external knowledge resources.

However, generally it depends on the frequency and intensity of conversations between customers and employees.

The value creation activities of strategic customers should be seen as honest and constructive feedback in the innovation phase as well as in marketing and sales according to interviewee H (strategic customer). This should happen if they can be seen as active reference contact partners for other customers. Interviewee I (strategic customer) perceives strategic customers as value creating partners in all phases of innovation generation as well as being involved in voluntary marketing activities.

„Development and marketing both demand a high involvement. I conduct a lot of marketing on a voluntary basis because I believe in the product idea and of course support the company. As far as marketing is concerned, the booth that is used at conferences and trade fairs is not enough. Strategic customers have to convince their colleagues of the products in a believable way.” [Interviewee I (strategic customer)].

The studied firm must identify, fulfill, and share customer needs. Furthermore it is important for the firm that the organizational knowledge base is protected. The question of “how much knowledge should a business give away” does hence not arise, since the strategic customers does not reveal any competition-relevant information of the firm is stated by Interviewee C (R&D).

4.3 Possessing the Absorptive Capacity to understand and integrate Customer Knowledge

The capacity of absorbing knowledge from external sources is enabled by the whole workforce and is not dependent on only one person or team. Information, even from other departments of the firm, becomes highly crucial. In the studied firm, this varies from R&D up to the Marketing department in different parts of the value chain, as Interviewee B (Marketing & Sales) argues:

„The employees are not medics, in fact they are specialists in the field of software development, but in order to fill the software with medical knowledge, develop new products, and facilitate growth customer knowledge is certainly necessary.”

Due to the fact that knowledge as well as absorptive capacity can be regarded as intangible assets of a firm, it is very difficult to delineate the decisive conditions and

factors for optimally integrating customer knowledge. One possible approach to integrate customer knowledge into a firm's knowledge base would be the structured documentation and management of knowledge with the help of information technology. Nevertheless, most of the knowledge exists in the minds of the individual employees. The analysis revealed that the documentation and management of such explications was facing obvious limits in terms of time and extent, as Interviewee A (CEO) described:

„we don't have time to sit down and record all thoughts about the customers in detail and then codify them. But if I am totally convinced then I would note a key word or two somewhere in a document.“

The knowledge base of the studied firm is strongly based on the knowledge and experience of employees of this industry. Since customer knowledge, which should be integrated, is firmly related to the core business of the firm, the absorptive capacity simultaneously grows and allows the employee to understand and implement more and more customer needs. Additionally, through the active participation of the strategic customer, the implementation of the customer's ideas leads to a better product, this again serves as a key motivational factor for him. Customer motivation can also be evoked due to additional factors such as customers who are able to increase their own reputation in expert circles by integrating themselves into value creating processes. Documentation analysis shows that the company published multiple statements from strategic customers, since strategic customers seem to feel content and proud when the firm uses their quote in publications. This occurs, for example, if a customer's portrait is published with an existing product and thus strengthens the firm's own marketing (image and look) according to Interviewee B (M&S).

The ability to generate value in cooperation with the customers, or absorptive capacity, depends on the level (intensity) of collaboration and is further used for different value-creating activities. The strategic customer's motivation to share his or her knowledge and the shared information's relevance for product development play decisive roles.

5 Conclusions

The present is targeting the question of "How can strategic customers are utilized for knowledge marketing activities"? We point out, empirically, that three necessary

processes have been identified: (1) Developing communities of practice or knowledge networks, (2) solving customer problems, and (3) possessing the absorptive capacity to understand and integrate customer knowledge. Based on the collected data, by use of interviews, these three processes could be confirmed.

It became clear that firms, which have the opportunity to exchange knowledge internally more easily and without formal barriers, could be referred to as “Management by Corridor” (Durst and Wilhelm, 2011). This pragmatic approach outlines an important factor in order to absorb customer knowledge. The capacity of absorbing knowledge from external sources is enabled by the whole workforce and is not dependent on one single person or team and is distributed in different value creating activities, as described by Cohen and Levinthal (1990). As soon as the customer knowledge and strategic customer are integrated into the organizational knowledge base, the basic requirements for successful knowledge marketing according to Rode (2001) are fulfilled, such as knowledge, experiences, customer, or business relations. Knowledge marketing is a good specific form of marketing (Rode, 2001). According to Lichtenthaler (2005), firms can commercialize their own knowledge assets or knowledge gained by strategic customers by turning it into sales, licensing, joint ventures, strategic alliances, mergers, or even internal use. Another important key element for the commercialization of the strategic customer’s knowledge is his or her motivation to collaborate with the firm and act as an active knowledge partner. As seen in Gibbert et al. (2002), the empirical results suggest that valuable customers feels valued through their integration in the value creation process and thereby could pave the way for sales activities (customer profiling). Based on these factors, it is only possible to conduct “knowledge marketing” after a successful identification.

To summarize, particularly KISMEs, which have to deal with limited resources (Jarillo, 1989; Pelham and Wilson, 1996), can additionally benefit by carrying out Knowledge Marketing. Through the integration of strategic customers, the knowledge base can be expanded, customers and reputation can be increased, and therefore Knowledge Marketing can be carried out.

The case illustrates that the cultural and organizational context (Clarke and Rollo, 2001) are of great importance in order to utilize knowledge correctly. A knowledge sharing culture as a social network (Ramanigopal, 2013) is a necessary requirement to build valuable relations within the firm as well as outside the firm (with customers). To

gain knowledge outside the firm's boundaries, employees must act customer-oriented and solving customer problems must be main priority. Here, task specific information is collected from the company's customers (Verona et al., 2006; Consoli and Elche-Hortelano, 2010). In order to integrate this information, the absorptive capacity embodied in people is the key element (Spithoven and Teirlinck, 2010). The case shows that employees can only utilize customer knowledge for innovations, if they have the required skills to understand relevant information and utilize this knowledge for the product (Teigland and Wasko, 2003). In their works, Lichtenthaler (2005) and Chen et al. (2010) argue that the commercialization of knowledge supports the firm's ability to exactly satisfy customer needs and impart the characteristics of the products/services to customers. The empirical results of this study can only confirm this topic and additionally recommend an integrated knowledge marketing approach, in which we determined that the integration of strategic customers, including the developmental phase, facilitates problem-solving by means of feedback loops.

6 Implications and Limitations

6.1 Research Implications

Due to the novelty of the topic, in regards to knowledge marketing, first empirical analyses could contribute to broaden the field in terms of literature. As shown in Figure 1, three processes (1) developing knowledge networks, (2) solving customer problems, and (3) maintaining absorptive capacity could be proven empirically by the conducted analysis. The current literature could be enriched through this study.

Especially in KISMEs, which highlight the resource knowledge, the results represent an enhancement of literature. In addition, the field of knowledge utilization gained another perspective by deepening the integrated knowledge marketing approach and therefore could be summarized into different processes and factors.

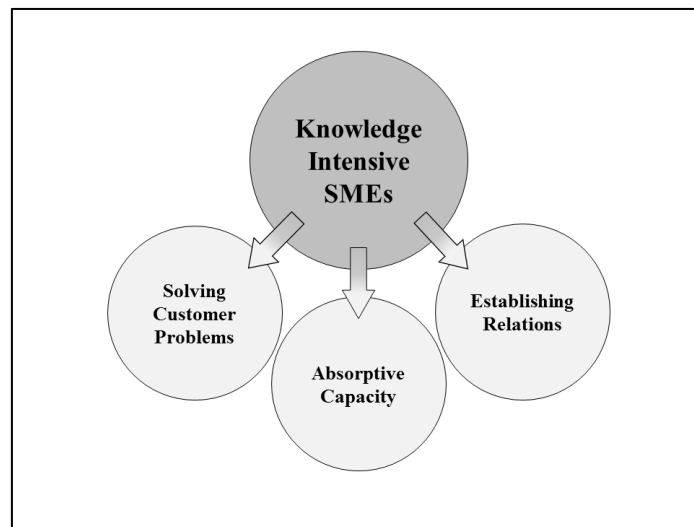

Figure 1: Processes and factors of KISMEs

6.2 Managerial implications

Through an integrated knowledge marketing approach, as described in the case, managers can identify their strategic customers/partners more easily and utilize their knowledge. The establishment of relations and integration of important customers can now be executed in a more focused way and, thus, more efficient solutions for customers can be found. All of these processes serve the management in order to sell knowledge intensive products/services more easily. Especially KISMEs, which only possess a limited resource base, can sell their products more easily with the help of these processes as well as the integrated knowledge marketing approach. By integrating important customer knowledge, they are able to continuously refine their products and are not solely dependent on their own internal resources.

With the present single case study, awareness in regards to the topic “knowledge marketing” in KISMEs could be increased. Managers of such firms should concern themselves with this topic in order to generate competitive advantage and be ahead of competitors. The consideration of these three processes enables top management to strategically orientate them on a systematic basis and implement all three processes.

6.3 Limitations

The following single-case-study includes multiple limitations. This paper can only offer a first confirmation. However, in order to further confirm the result, additional empirical works must be conducted. This study cannot be generalized for all knowledge intensive firms due to the fact that only one single company was analyzed in form of an empirical case study. The empirical results of this case study cannot be transferred to other business fields because the researched field consists of special characteristics and the customer holds a particularly important role. As a suggestion, future researchers in this field should embellish the single-case-study with additional case studies. These measures are described as “exemplary generalization” in qualitative research.

The present single case study has already integrated a multitude of stakeholders, e.g. the owner, supervisory board, employees, consultants, and customers. The research could be applied to a more specific data basis by, for example, conducting market research were possible, by possibly analyzing objectively which customers could be able to fill the knowledge gap.

Structured Abstract

Purpose - The main purpose of this paper is to investigate the role of knowledge management in the development of virtual networks participated by small firms.

Design/methodology/approach - The paper reviews two streams of literature focused on knowledge management in small firms and virtual enterprise. This allows to define an appropriate research question that has been addressed by a questionnaire survey conducted in network of small firms operating in a high-tech sector. This network of firms acts as a virtual enterprise.

Originality/value - The main value of the paper is to explore two main gaps emerging from the extant literature on knowledge management in small firms and virtual enterprise. In addition, it provides empirical evidences of knowledge management practices adopted in a virtual network populated by small firms.

Practical implications – From the practical point of view, the paper suggests that to fully exploit the potential of virtualisation, small firms need to implement new technological solutions. This means that small businesses need to sustain their virtualisation process through the adoption of technological platforms that allow managing and sharing knowledge more effectively.

Keywords - Knowledge management, Virtual enterprise, small and medium sized enterprises, literature review, questionnaire survey

Paper type - Academic Research Paper

1 Introduction

The important role that small and medium sized enterprises (SMEs) are playing in modern industrial environment has been analysed by a large number of scholars (Al-Mutawah et al., 2009; Dyer, Hatch, 2006; Esper et al. 2010; Esposito, Passaro 1994; Esposito, Raffa, 2007; Genovese et al., 2013; Gunasekaran, Ngai, 2007; Lakshman, Parente, 2008; Lee et al, 2010; Samuel, 2011, Iandoli et al. 2012). Nevertheless, the reasons why small firms show poor usage of KM tools are still unclear and benefits of KM adoption are not fully exploited by these firms (Alavi, Leidner, 2001; Durst, Edvardsson, 2012; Marra, Ho, Edwards, 2012; Thorpe et al., 2005, Esposito et al., 2009).

Several researches show that the factors preventing the adoption of practices and strategies of knowledge management by SMEs are connected to three main aspects: the nature of knowledge is mainly human embedded; there is a sort of common knowledge, that is a knowledge known to all members of the organization; the scarcity of resources pushes SMEs towards the exploitation of external knowledge resources (Esposito, Raffa, 1994; Desouza and Awazu, 2006; Egbu et al., 2005; Frey, 2001; McAdam and Reid, 2001; Pillania, 2006, 2008a; 2008b; Sparrow, 2001; Wong, 2005; Wong and Aspinwall, 2005).

Even though these aspects seem to explain the factors hindering the adoption of KM formal practices in SMEs, it should be emphasized that the Information and Communication Technology (ICT) is increasingly reducing their weight by offering new tools that are low cost, ease-to-use, and more effective (Antonelli, et al., 2000; Esposito, Mastroianni, 2001; Garrigos-Simon, et al., 2012; Matlay, Westhead, 2005).

In summary, on the one hand, the literature highlights the factors preventing SMEs from adopting KMSs. On the other, new technologies are having the effect of reduce the human and financial barriers hindering the adoption of KMSs, are facilitating the process of socialization of the knowledge that is crucial for SMES, and are offering new systems supporting KM practices.

This dichotomy emphasizes that, although the number of papers regarding the knowledge management in SMEs is increasing, the body of knowledge remains still limited and further research efforts are needed (Durst, Edvardsson, 2012).

This is particularly true in the context of networks populated by SMEs. In fact, one of the main gaps in the literature on KM in SMEs concerns the role of KM in the development of the SME networks. In such networks, relationships and exchange of

knowledge between focal firms (namely large companies acting as a product/service developers/integrators and maintaining relationships with customers) and small suppliers firms are critical to ensure the competitiveness of this network. For this reason, it is important to investigate the ways through which knowledge is spread across networks populated by small enterprises. The virtual enterprise (VE) offer an interesting perspective in this context as it is a new organisational model connecting firms (and then small firms also) for limited period of time through a strong technological support (namely ICT tools) and for achieving fast-changing market opportunities in partnership with other firms belonging to the network.

The main aim of this paper is explore the role of KM in the development of virtual networks participated by small firms.

A systematic literature review on VE has been carried out and a research question has been identified. Such research question has been addressed through a questionnaire survey conducted in a network populated by small firms operating in high-tech industries.

The paper is organised into six sections. Following this introduction, the second section describes the results obtained from the systematic review on virtual enterprise. This allows to identify an appropriate research question. The third section provides detail about the research context in which the empirical survey has been conducted, while the fourth section outlines the survey methodology. The main findings emerging from the survey are presented and discussed in the fifth section. Conclusions and implications are outlined in sixth section.

2 Conceptual framework

This section provides the conceptual foundations of this paper. The following subsection is devoted to explore the literature on virtual enterprise (VE). The comparative analysis of the literature allows to identify the research objective of this paper that has been addressed through a questionnaire survey. The methodology and results of the empirical investigation have been detailed in further sections of the paper.

2.1 Virtual enterprise and small firm networks

The radical changes that have occurred in the competitive scenario in recent years have driven SME networks to seek new ways to cope with the growing complexity of the

business environment in order to secure the access to new sources of competitive advantage (Guerrieri and Pietrobelli, 2004).

The recent literature and business practice have shown that SME networks are seeking new forms of collaborative relationships with a high degree of decisional and operational flexibility in order to satisfy the customer demand faster and at lower cost (Chiarvesio et al., 2004). One of these emerging organisational forms is the Virtual Enterprise (VE). The virtual enterprise model has been indicated as suitable for addressing changing market conditions through flexibility, extensive ICT usage and KM (Blecker and Neuman, 2000; Choi et al., 2008; Pollalis and Dimitriou, 2008).

Despite scholars and practitioners devoted an increasing interest towards this organisational form, the literature on this topic appears quite fragmented and a number of issues needs to be further investigated.

Starting from this scenario, a comprehensive and systematic bibliographic survey has been carried out by Esposito and Evangelista (2014).

The objective of this subsection is to analyse the literature on VE in order to explore the potential role of KM in when this organisational form is populated by small firms.

This was achieved primarily by a systematic analysis of journal articles contained in the Web of Science Academic database. A keyword search using the terms “virtual enterprise” was performed and the search process was limited to peer-reviewed publications alone (e.g. ISI journal articles). The final sample consisted of 41 articles (Table 1).

Table 1 - VE: sample articles by macro-areas

Macro-areas	Papers	%
Operations Research & Business Science	21	51,3%
Engineering	6	14,6%
Information Systems & Computer Science	14	34,1%
Total	41	100,0%

They have been grouped in the following three macro-areas: 21 articles from the Operations Research and Business science area, six articles from the Engineering area, 14 articles from the Information Systems and Computer Science area. The 41 articles were studied in detail and the results of the content analysis are described below.

Summarising results of the content analysis it emerges that a number of shared and non-shared viewpoints may be identified in the existing literature on VE (Table 2).

Table 2 - Overview of literature review: shared issues

Issues	Shared literature evidence
Main aims	- <i>Exploit fast-changing market opportunities</i> (Jagdev and Browne, 1998; Park and Favrel, 1999; Mezgar et al., 2000; Zhang et al., 2000; Presley et al., 2001; Jagdev and Thoben 2001; Khalil and Wang, 2002; Mikhailov, 2002; Wu and Sun 2002; Lefebvre and Lefebvre, 2002; Gou, 2003; Kim et al., 2006; Cunha and Putnik, 2006; Dowlatshahi and Cao, 2006; Corvello and Migliarese, 2007; Huang, et al., 2008; Sari et al., 2008; Wang and Chan, 2009; Rosu, and Dragoi, 2011)
Partnership objectives	- <i>Share costs, skills, and core competencies</i> (Jagdev and Browne, 1998, Tuma, 1998; Park and Favrel, 1999; Zhang et al., 2000, Camarinha-Matos et al., 2001; Martinez et al., 2001; Presley et al., 2001; Weisenfeld, et al., 2001; Mikhailov, 2002; Wu and Sun 2002; Gou, 2003; Manthou et al., 2004; Feng and Yamashiro, 2006; Dowlatshahi and Cao, 2006; Sari, et al., 2007; Corvello and Migliarese, 2007; Chen, et al., 2007; D'Atri and Motro, 2008; Gunasekaran et al., 2008; Sari et al., 2008; Rosu, and Dragoi, 2011)
Network characteristics	- <i>Flexible, rapid, dynamic and reactive network</i> (Park and Favrel, 1999; Tuma, 1998; Mezgar et al., 2000; Zhang et al., 2000; Camarinha-Matos et al., 2001; Martinez et al., 2001; Khalil and Wang, 2002; Lefebvre and Lefebvre, 2002; Beckett, 2003; Davidrajuh, 2003; Huang, et al., 2004; Kim et al., 2006; Cunha and Putnik, 2006; Corvello and Migliarese, 2007; Gunasekaran et al., 2008; Wang and Chan, 2009)
Nature of organisation	- <i>Partnership among independent companies</i> (Jagdev and Browne, 1998; Mezgar et al., 2000; Jagdev and Thoben 2001; Lefebvre and Lefebvre, 2002; Khalil and Wang, 2002; Mikhailov, 2002; Davidrajuh, 2003; Manthou et al., 2004; Huang, et al., 2004; Sari, et al., 2007; Corvello and Migliarese, 2007; Chen, et al., 2007; Huang, et al., 2008; Wang and Chan, 2009)
Partnership characteristics	- <i>Temporary relationships</i> (Jagdev and Browne, 1998; Zhang et al., 2000; Camarinha-Matos et al., 2001; Jagdev and Thoben 2001; Weisenfeld, et al., 2001; Khalil and Wang, 2002; Wu and Sun 2002; Lefebvre and Lefebvre, 2002; Tatsiopoulos, et al., 2002; Huang, et al., 2002; Mikhailov, 2002; Beckett, 2003; Gou, 2003; Huang, et al., 2004; Feng and Yamashiro, 2006; Kim et al., 2006; Dowlatshahi and Cao, 2006; Corvello and Migliarese, 2007; Sari, et al., 2007; Gunasekaran et al., 2008; Huang, et al., 2008; Sari et al., 2008; Huang, et al., 2011; Rosu, and Dragoi, 2011) - <i>Collaborative/cooperative relationships</i> (Jagdev and Browne, 1998; Tuma, 1998; Zhang et al., 2000; Jagdev and Thoben 2001; ; Mikhailov, 2002; Yoo and Kim, 2002; Huang, et al., 2002; Davidrajuh, 2003; Manthou et al., 2004; Feng and Yamashiro, 2006; Kim et al., 2006; Chen, et al., 2008; D'Atri and

	Motro, 2008; Gunasekaran et al., 2008; Wang and Chan, 2009; Sari et al., 2008; Huang, et al., 2011)
Coordination and communication tools	- <i>Extensive use of ICT and computer networks</i> (Jagdev and Browne, 1998; Tuma, 1998; Park and Favrel, 1999; Mezgar et al., 2000; Zhang et al., 2000; Camarinha-Matos et al., 2001; Weisenfeld, et al., 2001; Jagdev and Thoben 2001; Martinez et al., 2001; Khalil and Wang, 2002; Mikhailov, 2002; Wu and Sun 2002; Lefebvre and Lefebvre, 2002; Yoo and Kim, 2002; Manthou et al., 2004; Huang, et al., 2004; Corvello and Migliarese, 2007; Gunasekaran et al., 2008; D'Atri and Motro, 2008; Chen, et al., 2008; Huang, et al., 2008; Wang and Chan, 2009; Rosu, and Dragoi, 2011)

In particular, the authors that shared the following features of the VE (Table 2):

1. the *main aim* of VE is to exploit fast-changing market opportunities;
2. sharing of risks, costs and competencies is the main *partnership objective*;
3. the virtual enterprise is characterised by a dynamic and flexible *network*;
4. the *organisation* is typified by relationships involving independent companies;
5. *the partnership* is typically temporary and based on a collaborative approach;
6. *coordination* and *communication* tools used are based on ICT.

Beside these shared issues, a number of important non-shared issues, have been identified in the research works analysed as illustrated by Table 3. In this case, a VE characteristic cited by one or few authors only has been considered as a non-shared issue. The description of each of them is given below.

Even if all the authors agree on the existence of an agent that acts as a coordination unit, there is no common viewpoint on its nature and role. While some stress that the coordination unit may be both internal and external to VE (Jagdev and Browne, 1998), others stress the crucial role of the leader firm (Tuma, 1998; Camarinha-Matos, 2001), or the importance of a small headquarter staff to deal with administrative and management details (Presley et al., 2001), or the function of the product integrator which distributes the manufacturing tasks and manages in parallel the product's physical and virtual value chains (Lefebvre and Lefebvre, 2002; Feng and Yamashiro, 2006).

Table 3 - Evidence from the literature review: non-shared issues

Issues	Non-shared literature evidence
Coordination unit	<ul style="list-style-type: none"> - <i>Coordination agent may be both internal and external to the VE</i> (Jagdev and Browne, 1998) - <i>Small headquarters staff dealing with administrative and management details</i> (Presley et al., 2001) - <i>The product integrator distributes the manufacturing tasks and manages in parallel the product's physical and virtual value chains</i> (Lefebvre and Lefebvre, 2002; Feng and Yamashiro, 2006) - <i>The participants are coordinated by a leadership team that understands who can help get things done</i> (Beckett, 2003)
Organisational structure	<ul style="list-style-type: none"> - <i>VE members self-organise their activities</i> (Mezgar et al., 2000) - <i>The relationship in a VE is mostly non-hierarchical in nature</i> (Jagdev and Thoben, 2001) - <i>The VE organisational structure is mostly hierarchical</i> (Feng and Yamashiro, 2006) - <i>A VE replaces hierarchy with incentives and formal and procedural coordination with communication systems</i> (Corvello and Migliarese, 2007)
Firm size	<ul style="list-style-type: none"> - <i>VE model bridges the gap between large and small firms</i> (Park and Favrel, 1999) - <i>VE is especially suitable for small and medium-size enterprises</i> (Wu and Sun 2002) - <i>VE appears as a business strategy for small and medium-sized enterprises</i> (Hsu and Hsu, 2008) - <i>There is a lack of e-commerce tools supporting the formation of VE among SMEs</i> (Davidrajuh, 2003)
Knowledge management	<ul style="list-style-type: none"> - <i>KM critical resource to achieve competitive advantage in VEs</i> (Pollalis and Dimitriou, 2008; Choi et al., 2008) - <i>KM support systems can provide the management of virtual organizations with effective means of meta-management</i> (Khalil and Wang, 2002) - <i>KM systems supported by web-based technology improve competitiveness of VEs</i> (Yoo and Kim, 2002) - <i>to establish common business processes that support a virtual enterprise physical, information and decision subsystems need to be integrated in an overarching KM framework</i> (Beckett, 2003)
Market relationships	<ul style="list-style-type: none"> - <i>Customer deals directly with the product integrator during product design or may interface with him/her through business platforms</i> (Lefebvre and Lefebvre, 2002) - <i>The manufacturer manages relationships with customers</i> (Jagdev and Browne, 1998) - <i>The agent will validate the identity of every member, manage service requests of every partner, reasonably distribute resources, and implement communication between customer and the cooperative object</i> (Huang et al., 2004)

Also with respect to organisational structure the literature offers no prevailing point of view. For Feng and Yamashiro (2006), VE organisational structure is mostly hierarchical and a leading company needs to create feasible process plans and select suitable partners,

based on product features and candidate partners' capabilities. Gunasekaran et al. (2008) also consider the VE as the integration of participating firms at different levels of cooperation. By contrast, Jagdev and Thoben (2001) consider that relationships in a VE are mostly non-hierarchical in nature. Also for Tuma (1998) one of the interesting features of virtual enterprises is the required lack of hierarchies. Further, Corvello and Migliarese (2007) stress that the VE replaces hierarchy with incentives and formal and procedural coordination with communication systems, whereas according to Mezgar et al. (2000) VE members self-organise their activities.

The role of firm size in the VE context generally appears underestimated. We believe that this shortcoming needs to be addressed as many industrial systems in more developed countries are populated by a large number of small company aggregations, as in the case of industrial districts. Few papers stress that virtualisation is particularly suitable for SMEs (Thompson, 2008; Wu and Sun, 2002); others consider the VE as a network that includes both large enterprises and SMEs (Martinez et al., 2001; Park and Favrel, 1999). For Katzy and Dissel, (2001) the partners potentially participating in the network are in most cases related parties; independent companies, but also decentralized profit centres or strategic business units of a global holding company.

Moreover, the literature seldom refers to the increasingly important role of knowledge and knowledge management systems in the context of VEs. Exceptions are Pollalis and Dimitriou (2008), Blecker and Neuman (2000), and Choi et al. (2008) who consider KM a critical resource to achieve competitive advantage in VEs; Khalil and Wang (2002) according to whom KM support systems can provide the management of virtual organizations with effective means of meta-management; Yoo and Kim (2002) who find that KM systems supported by web-based technology improve competitiveness of VEs; and Beckett (2003) who argue that the form of subsystem reference architecture may help defining the business processes needed by a virtual enterprise, considering the blend of tacit knowledge, codified knowledge and facilitating ICT tools used.

Finally, although the literature shows that the virtual enterprise is designed to create value from a business opportunity, it is not clear which specific participating company manages the relationship with the final user of the product/service. According with Lefebvre and Lefebvre (2002) the customer deals directly with the product integrator during product design or may interface with him/her through business platforms. In the view of Jagdev and Browne (1998) the manufacturer manages the relationships with

customers, while Huang et al. (2004) argued that an external security-based agent manages relationships among the VE partners and the customer (the product integrator).

2.2 Assessment of literature review and research questions

This section summarises the above literature review in order to identify gaps and define an appropriate research question. Considering the aspects of KM in SMEs, one of the main gaps that may be identified concerns the role of KM in the development of the SME networks. In such networks relationships and exchange of knowledge between focal firms (namely large companies acting as a product/service developers/integrators and maintaining relationships with customers) and small suppliers firms are critical to ensure the competitiveness of the entire network. For this reason, it is important to investigate the ways through which knowledge is spread across networks populated by small enterprises. The virtual enterprise offer an interesting perspective in this context as it is this new organisational model connecting firms (and then also small firms) for limited period of time through a strong technological support (namely ICT tools) and for achieving fast-changing market opportunities in partnership with of other firms of the network. As shown in table 3, firm size and the role of knowledge management are both important non-shared issues and need additional investigation.

Considering the above gaps, it is possible to define the main research question to be explored in this paper: what is the role of KM in the development of virtual networks participated by small firms?

In order to address the above research question, a questionnaire survey has been conducted in a high-tech SME network (ENTech hereafter) located in the eastern area of Naples city (Italy). The following sections describe the context of investigation, the methodology and the main results of the survey.

3 The context of investigation

The East Naples high tech network is an association of 25 SMEs founded in March 2007. The main objective of this association is to integrate resources and competences of the firms to seize the opportunities of the local market. The total number of employees is about 3,000 people and the total turnover is about 400 million Euros. The ENTech mainly consists of SMEs as shown in Table 4. In the table, the latest EU definition of SMEs proposed by the EU Commission has been used (European Commission, 2005).

Table 4 - The ENTech firms' breakdown by employees

Employees bands	N.	%
0-9	3	12
10-49	10	40
50-249	11	44
≥250	1	4
Total	25	100

Network firms operate in different high-technology manufacturing and service sectors as shown in Figure 1.

Figure 1 - ENTech high tech network: company sectors

Manufacturing companies	Aerospace	1	Aermec Sud
		2	ARM
		3	ASTRO Ind.
		4	Fox-Bit
		5	K4A
		6	Magnaghi Aeronautica
		7	Vulcan Air
	Engineering	8	Farina Impianti
		9	Mecfond
	Transport (lines, infrastructures and equipments)	10	AET
Service companies	Aerospace (Research & Development)	11	MARS
	ICT	12	Euro.Soft
		13	Intecs
		14	ITS
		15	Kell
		16	Naosys
		17	Null Pointer
		18	SRSe
	Management training and consulting services	19	Form & ATP
		20	Mater
		21	Protom
		22	Tecno-In
	Transport (system and service)	23	Ansaldo Segnalamento Ferroviario
		24	Lead Tech
	TLC	25	Canale Otto S.p.A.

The most part of companies are involved in aerospace and ICT sector. The total turnover increased by 28% in the period 2004-2007 and this led to a growth in investment by 21% in the same period. These investments are mainly aimed at developing new products/services or new professional skills as shown in Figure 2. Other relevant investment objectives consist of replacing obsolete technology, while increasing production capacity and performance improvement play a limited role in motivating company investment.

The ENTech network was chosen as an appropriate case for our investigation for four main reasons.

First, ENTech is one the most important networks of firms in the Campania region operating in high technology manufacturing and service sectors. Therefore, it has a critical impact on the economy of the entire region. The Campania region (and the Naples area in particular) is a long-established leader in producing complex components for the aerospace industry.

Figure 2 - ENTech main investment objectives

Secondly, most of the ENTech firms are integral parts of international manufacturing and technology supply networks especially with reference to the aerospace and railway industry. More specifically, some of the firms are first tier suppliers of the Alenia Aermacchi company (one of main partners of the Airbus consortium), EADS, Boeing, Bombardier and other domestic and international companies. Some others are main

suppliers of leading railways and defence companies such as Ansaldo Breda, Alstom, and Selex ES.

Thirdly, as with the Virtuelle Fabrik model proposed by Katzy and Crowston (2008), the ENTech network uses trust as internal governance mechanisms which are the basis for setting up virtual collaborative deals. Technology cooperation is complemented by the capability to identify market opportunities to be exploited through new project development.

Finally, the companies operating in the ENTech network are continuously involved in short-term technological innovation projects based on the integration and sharing of their own competencies. Projects are set up between the companies participating in the network and they dissolve once project objectives have been achieved (a sample of relevant projects examples are reported in Table 5). These virtual enterprises are generally aimed at engineering and manufacturing innovative products collaboratively.

4 Questionnaire survey methodology

After reviewing the tow streams of literature a questionnaire survey has been conducted. The survey methodology has been organised into the following five steps:

- a) Definition of basic survey objectives and preparation of the draft questionnaire.* In this phase a draft version of the questionnaire has been prepared together with the basic survey objectives.
- b) Establishment of focus groups.* In order to test the suitability of the basic survey objectives and the comprehensibility of the draft questionnaire a focus group involving 8 experts with different competences and professional background was established. The focus group has been developed in three different phases. Firstly, the topic investigated has been presented in order to make focus group participants familiar with it. Secondly, the draft questionnaire has been submitted to the panellists in order to get their useful feedback and comments. Finally, panellists' remarks have been discussed in a plenary session.
- c) Re-focussing of survey objectives and questionnaire.* On the basis of feedback received during the focus group discussion, the questionnaire has been finalised. Most of the questions included in the questionnaire are based on a Likert scale ranging from 1 to 9. Some other questions allow more qualitative answer in order to allow respondents to express their own personal opinion.

d) *Test of the questionnaire.* In this step, the final version of the questionnaire has been tested through 3 pilot interviews carried out in ENTech network.

e) *Survey implementation.* The survey has been conducted in spring 2008. The total number of respondents is 18 out of 25 companies with a response rate of 72%. The questionnaire has been submitted during face-to-face interviews involving at least two managers with different skills and role (e.g. a manager involved in the strategic firm decisions making process and a manager involved in the operation management). This allowed obtaining both strategic and operational perspectives.

In order to have a more comprehensive picture of the ENTech network, information from complementary sources (e.g. company websites, company reports and industry magazines) have been collected and analysed.

5 Survey findings

This section presents findings emerging from the empirical survey. In particular, the findings presented here are related to the questionnaire sections analysing firm relationships and knowledge management practices.

5.1 Firm relationships

In this section the relationships among the firms are analysed. Such relationships have a dynamic nature due to the collaborative projects undertaken by ENTech network firms. The survey investigated the nature of relationships among firms belong to the network. Findings are shown in Figure 3 where each bar represents the number of firms out of the 18 respondents that are engaged in a particular type of collaboration.

Figure 3 - Nature of relationships

Relationships in the production, design and development phase account for only a limited percentage. The most important forms of relationships are the involvement in common shared new product development (NPD) programmes and the exchange of technical information.

In order to provide a more detailed picture of collaboration within the ENTech network, a sample of projects currently undertaken is shown in table 5. In such projects, the proposer not always assumes the role of coordinator. Sometimes the coordination of the project is committed to another firm involved in the partnership.

Table 5 - ENTech collaborative projects as potential VEs

Project name	Project Description
Electric aircraft	Mixed electric propulsion aircraft
KA-2H	Innovative helicopter
SAC	Composite anti-crash system for helicopters
SAEG	Steering electric innovative system
RTA	Advanced coverings for aircraft industry
IRENE	Space capsule for picking up cosmic dust
SPA	Advanced system for satellite antennas polymerisation
HM&M	Health monitoring and management system for space aircraft
FSL-EC	Study of human - computer interaction systems
Liquid bag buffers	Development of liquid bag buffers systems for innovative bearing
HPF	Heat pipes for spatial vehicle control
3D Modelling	Real time capture system of 3D models
Tele-medicine	System for the application of telemedicine and remote-medicine using satellite system
SIGRI	Information system for monitoring and control of forest fires

According to the competencies required, each project listed in Table 5 may be a potential VE involving ENTech network firms. The development of collaborative projects is the main objective of the partnerships in the VE model. This makes the ENTech network a context for the creation and implementation of VEs.

5.2 Knowledge management practices

In order to develop collaborative projects, companies generally tend to adopt knowledge and information management tools (Figure 4).

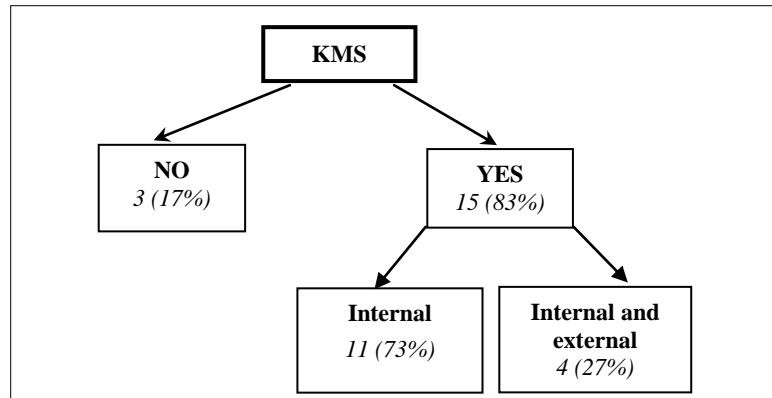

Figure 4 - KMS adoption in ENTech

For this reason, the usage of Knowledge Management System (KMS) has been explored. Firstly, the survey indicated that 83% (15 firms) of the sample firm have a KMS in place 73% of these companies (11) adopt an internal KMS. The most widespread tools of internal KMS implementation (Figure 5) are the Internet website (87%), work teams (87%) and intranet (67%).

Figure 5 - Internal KMS implementation tools

The high importance attached to work teams demonstrates that, in high technology sectors, interactions and interpersonal relationships are a fundamental tool for problem solving. In this context, it is worth to distinguish between service and manufacturing firms. On the one hand, service firms operating in the telecommunications, ICT, and aerospace sectors generally tend to use advanced and structured KMS equipped with a document management system, data mining, decision support systems, and dedicated

work team. On the other hand, manufacturing firms working in the aerospace sector as sub-suppliers, use a less structured KMS finalised to management control and business resource management.

Although only 4 firms use internal and external KMS, each single firm investigated claimed for wider KMS embracing the entire East Naples high tech network. For this reason, the benefits of a KMS serving the entire firm network have been analysed (Figure 6). In the figure the average value of answers for each expected benefit is reported.

The figure interestingly shows that a KMS serving the entire East Naples high tech network may have a positive impact not only on the innovation and the operational management, but also to better understanding of the marketplace. This feature further clarifies the potential support that a KMS can provide to VEs. In fact, the main aim of a VE is to exploit market opportunities using the competencies of member companies.

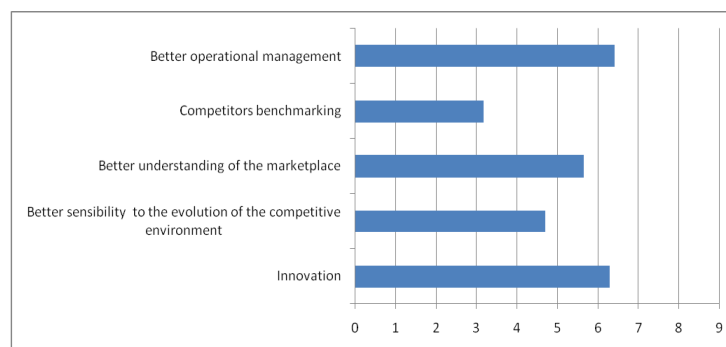

Figure 6 - Expected benefits of the KMS

However, there are a number of barriers to implement KMS in the ENTech network (Figure 7). The unavailability of partner to share critical information, the safeguard against competitors and the need to protect critical information are the most relevant barriers. This suggests that companies seem oriented to preserve their own intellectual assets from the opportunist behaviour of potential partners. Such obstacles may be overcome through increasing mutual trust. This objective may be achieved stimulating the collaboration among firms.

Another aspect investigated relates to information that firms are willing to share (Figure 8) and obtaining (see figure 9) through the use of a KMS platform serving the East Naples high tech network. In both figures the average value of answers for each item is reported.

Figure 7 - Knowledge-sharing barriers

Simultaneously analysing figures 8 and 9, it emerges that firms show a strong appreciation about the implementation of a KMS platform to facilitate the diffusion of information on products/services. Other relevant information that firms are willing to share and obtain from a KMS concern market features and market opportunities. It is worth noting that firms show a special interest in sharing information on market opportunities.

Figure 8 - Information which firms are willing to share through a KMS platform

This is a common VE feature that literature has put in evidence (see table 3). The most relevant difference in the two figures above relates to information on relationships with institutions and funding opportunities. In fact, considering these two items it emerges

that firms view the KMS of the East Naples high tech network as a platform for mainly obtaining information.

Figure 9 - Information which firms need to obtain from a KMS platform

6 Conclusions

The main aim of this paper is to address the following research question: what is the role of KM in the development of virtual networks participated by small firms?

In order to address the above research question, a questionnaire survey has been conducted in a high-tech SME network. The ENTech network was chosen as an appropriate case for our investigation for four main reasons. First, ENTech is an important network of firms operating in high technology manufacturing and service sectors with a critical impact on the local economy of the entire region. Secondly, most of the ENTech firms are integral parts of international manufacturing and technology supply networks especially with reference to the aerospace and railway industry. Thirdly the ENTech network uses trust as internal governance mechanisms, which are the basis for setting up virtual collaborative deals. Finally, the companies operating in the ENTech network are continuously involved in short-term technological innovation projects based on the integration and sharing of their own competencies.

The survey results show that the companies investigated have perceived the strategic value of managing knowledge processes and consequently adopt a variety of KMSs. In particular it emerges that:

1 - 83% (15 firms) of the sample firm have a KMS in place, 73% of these companies (11) adopt an internal KMS. The most widespread tools of internal KMS implementation are the Internet website (87%), work teams (87%) and intranet (67%).

2- service firms operating generally tend to use advanced and structured KMS equipped with a document management system, data mining, decision support systems, and dedicated work team.

3- manufacturing firms use a less structured KMS finalised to management control and business resource management.

4- each single firm investigated claimed for wider KMS embracing the entire network.

5- KMSs serving the entire network may have a positive impact not only on the innovation and the operational management, but also to better understanding of the marketplace. This feature further clarifies the potential support that a KMS can provide to VEs.

6- the unavailability of partner to share critical information, the safeguard against competitors and the need to protect critical information are the most relevant barriers. This suggests that companies seem oriented to preserve their own intellectual assets from the opportunist behaviour of potential partners.

7- firms are willing to share and obtaining through the use of a KMS platform serving the East Naples high tech network.

8- it emerges that firms show a strong appreciation about the implementation of a KMS platform to facilitate the diffusion of information on products/services.

9- firms are willing to share and obtain from a KMS concern market features and market opportunities.

The survey results allow the identification of a number of potential avenues for further research. The first research implication derives from the fact that SMEs generally use not updated KMSs instead of the newer ones. This issue requires further and in-depth analysis concerning the degree of alignment between KMSs used by SMEs and the nature of knowledge from both the ontological and epistemological perspectives.

Secondly, the literature review indicates that the vast majority of papers analysed have used quantitative or qualitative methodologies (with a prevalence of quantitative

methods). Considering that the KM phenomenon is characterised by both quantitative and qualitative elements, further research in this field should be based on multiple research methods used in combination (e.g. a triangulation approach).

Structured Abstract

Purpose – The range and configuration of public services depend on needs expressed by society, and the responsibility for the implementation of these needs within a given territory lies with basic public administration bodies. The provision of public services within the idea of sustainable local governance is possible as a result of cooperation between the public and private partners, business environment institutions and society. In this paper, we adopted definition of sustainable local governance as a process run by local governmental bodies within inter-organizational collaborative networks aimed to socially and economically boost a specific region, while respecting environmental protection and land development.

Design/methodology/approach – An approach based on both in-depth literature studies and empirical research was proposed. Two main types of public services were analysed: social (health care, education, culture, recreation, social care, housing, public safety) and technical (public transport, waste management, water management, recreation areas). The research was conducted from 2011 to 2013 in Poland, among privately-owned and state-owned enterprises in the range of the research project, entitled “Technological Foresight of Public Service Sector Development within the Silesian Metropolis”. After the project had been completed, these analyses were complemented as a result of in-depth literature studies and direct structured interviews with experts.

Originality/value - The study was conducted from the perspective of local authorities, of experts operating within the public sector, and finally from the perspective of enterprises. The use of studied mechanisms was identified, and the needs in terms of their development were analysed. In addition, the solutions for the elimination of restrictions concerning the cooperation between public administration and enterprises in the provision of public services were proposed. An innovative methodology, which includes opinions from the perspective of public administration, representatives of enterprises, and is additionally supplemented by the interviews with experts, enabled the analysis of the issue in a comprehensive manner.

Practical implications – Public administration needs information regarding the possibilities of involving enterprises in the process of providing public services within the idea of sustainable development. These analyzes enabled us to achieve the following results:

1. We identified the mechanisms motivating enterprises to participate in the public services provision.
2. We estimated scope of using and utility of enterprises' participation mechanisms.
3. We analysed the needs and methods of increasing enterprises' participation mechanisms in the public services provision.

These results were based on the statistical analysis.

Keywords – Sustainable local governance, Public services, Participation mechanisms, Collaboration, Public management.

Paper type – Academic Research Paper.

1 Introduction

The organization and course of social life depend on many functional factors. These include, among others, the supply of necessities, the movement of persons and goods, health care, water management, waste management, administration, culture and education. These factors are elements of public services, which cover all goods meeting the needs of and services provided to the general public. The range and configuration of public services depend on needs expressed by society, and the responsibility for the implementation of these needs within a given territory lies with basic public administration bodies. However, the development of social and economic life runs increasingly ahead of the authorities' ability to meet citizens' expectations as for the type and quality of public tasks, especially taking into account the principles of sustainable development. In addition, the experience of developed countries shows that only knowledge-based economy leads to the sustainable development of local government. This approach enables the growth of comprehensive actions that create new products and services. This is due to the specific nature of innovation processes which take place in the context of inter-organizational and inter-sectoral collaboration centred around a given issue (Peled, 2001; Sienkiewicz-Małyjurek, 2013).

Due to these conditions, the public sector should become interested in engaging the private sector in the provision of public services. However, the private sector has no obligation to participate in these tasks. Private sector entities might participate on a

voluntary basis, if such a move appears to them as a beneficial and desirable one. Therefore, the following questions arise:

1. What mechanisms are used to motivate the private sector to participate in public service provision?
2. How useful are the enterprise participation mechanisms in public service provision?
3. What factors and to what extent affect the use of the enterprise participation mechanisms in public service provision?

The aim of this article is to answer these questions.

2 Research methodology

In the article, the subject of the study are the mechanisms of collaboration of enterprises in the provision of public services. The time range covers the period from 2011 to 2013 and the spatial area of the Silesian Metropolis, formerly known as Metropolitan Association of Upper Silesia (Polish: *Górnośląski Związek Metropolitalny*), which includes 14 large cities with county rights (Provincial Spatial Development Plan of Silesia, Silesian Marshal's Office, 2004). The choice was determined by the possibilities of conducting the research, and by development dynamics of the region. The amount of GDP and investment outlays gives the Silesian Metropolis the second place in the regional division of Poland (Strategy for the Development of Upper Silesia..., 2010). In addition, considerable industrial potential of the country is focused in this area. The dominant industry sectors here are coal mining and metallurgy. Changes connected with the restructuring of the economy of the region caused modern branches, such as electronics, automotive and food processing, to develop here more and more rapidly (Strategy for the Development of Upper Silesia..., 2010). At the same time, the Silesian Metropolis and Ostrava Agglomeration are seen in Europe as the so called Moravian-Silesian Metropolitan Group, representing the core area of the cross-border region of Upper Silesia and Northern Moravia. It is, moreover, the sixth-largest urban-industrial concentration of the United Europe.

A part of the analyses was conducted within the research project entitled “Technological Foresight of the Development of Public Service Sector within the Silesian Metropolis”, and after the project had been completed, these analyses were supplemented with interviews with experts. Screening performed in the initial phase of the project

indicated that thematic panels should focus on the following issues relating to the various categories of public services (Bondaruk et al., 2009; Karbownik, Dohn, Sienkiewicz-Małyjurek, 2012a; Karbownik, Dohn, Sienkiewicz-Małyjurek, 2012b):

- culture: culture, physical culture and recreation, education;
- environment: water management - water supply and sewerage, waste management, keeping the environment clean and orderly, energy supply, public green;
- transport: services and infrastructure;
- health: health care, public safety, welfare services.

The study also includes services that are not covered by the above classification, and which link those areas (such as administrative and information services etc.). This classification is not a finite set, but is composed for the research purposes. Test procedure used here is based on both the in-depth study of literature, and empirical research. The latter is qualitative and quantitative, and uses the following methods: desk research, survey research and interviews with experts. The research was conducted in three stages:

1. Identification of enterprise participation mechanisms in public service provision.
2. Assessment of the scope of use and usability of the enterprise participation mechanisms in public service provision.
3. Analysis of factors affecting the use of the enterprise participation mechanisms in public service provision.

The research regarding the identification of the mechanisms of enterprise participation in public service provision was based on an analysis of industry documents, legislation and the available scientific literature. These sources depict the principles of efficient collaboration aimed at the provision of public services, without taking into account the scope of this collaboration. In fact, this constitutes the objective of further research - the analysis of the scope of use and usability of participation mechanisms. This research project was conducted in May 2011, using a questionnaire. Senior managers from 14 municipalities forming the Silesian Metropolis participated in it. Due to the fact that the project was originally meant to improve the transfer of research results to the realm of business, and to cause its actual spread there, the research encompassed also senior managers from 200 randomly selected companies of the areas of transportation, health, culture and environmental protection (with 50 companies from each area). The research process was concluded by interviews with experts, conducted at the turn of 2012 and

2013 among 15 people. The expert group comprised of specialists from government bodies, academics and entrepreneurs operating in selected areas: transportation, health, culture and environment protection.

3 Theoretical background

3.1 Collaboration of sustainable local governance

Sustainable development is nowadays a priority in the policy of many countries and international organizations, such as United Nations or the European Union. Contemporarily, the fundamental importance in this area is attributed to the regional development factors. This is due to the fact that the existing legislative measures give local governments independence and autonomy of decision in terms of their actions, so that they can directly shape the sustainable development in the area administered (Kozuch, Sienkiewicz-Małyjurek, 2013).

Local governance is the process, in which basic research consideration is given to the efficiency of the network of public entities linked by the power of local authorities or under the control of these authorities. Its specificity lies in the fact that it is performed by proper authorities, while ensuring the departure from caring for individual interests for the sake of common good of stakeholders of the local government, aimed at local development (Kozuch, 2012). Local development is understood as harmonized and systematic activities of both public authorities and all other entities within a given unit of local government. Such activities aim to create new and improve existing usability, form favourable conditions for the economy, and provide spatial and environmental order, in accordance with the principles of sustainable development.

However, local development consistent with the principles of sustainable development is not possible within merely individual actions of local governments (Mah, Hills, 2012; Agranoff, 2006, Lee, Feiock, Lee, 2012). This requires sustainable local governance, conducted by local authorities in inter-organizational collaboration networks. It aims at socio-economic development of the region, with respect to the environment and spatial planning, focused on the sustainable management of resources, and using modern instruments of public management (Kozuch, Sienkiewicz-Małyjurek, 2013). What forms the basis for the sustainable development of local government is inter-organizational

collaboration (Lozano, 2007). It stimulates collective action, enables responding to changes in local conditions flexibly, and also lowers the costs of action (Sullivan, Skelcher, 2002; Considine, 2013; Torfing, 2005). It serves to strengthen the relationships between local investors and social administration, the creation of networks and regional identification (Came'n, Gottfridsson, Rundh, 2011). Cooperation is also an essential element of knowledge management in the public sector (Wiig, 2002). This is due to its focus on the fulfilment of tasks and organizational learning, with the support of advanced technologies.

Terms and conditions of cooperation are determined by a set of values, beliefs, opinions and experiences of individual organizations and their members (van Winkelen, 2010; Rhodes et al., 2012). Past experience affects the perception and evaluation of partners, as well as shapes opinions and expectations. These factors are reflected in the level of trust and commitment to collaboration (Tubin Levin-Rozalis, 2008; Moynihan, 2009; Ryu., So, Koo, 2009; Caceres, Paparoidamis, 2007). Trust emerges as the result of the certainty and predictability of expectations towards other people, having faith in their good will, believing in usefulness of common interests and projects, even in an emergency situation (Tubin, Levin-Rozalis, 2008). Commitment, in turn, is the desire to use skills to their fullest, together with the willingness to effectively operate in the organization. In addition, commitment fosters collaboration through voluntary participation in the projects, despite the existing norms, obligations or beliefs. Moreover, inter-organizational collaboration is dynamic and subject to risk (Veal, Mouzas, 2010; Ehrengren, Hörnsten, 2011). The changing conditions have a critical impact on its course. Changing conditions might result from both the turbulence and uncertainty of the environment, and from the course of managing the process of interaction. These factors may reduce the level of trust and commitment towards joint undertakings, and thus may limit the level of collaboration.

Collaboration in public service provision requires certain outlays, but it might bring much more benefits. The private sector, while participating in the implementation of public service, engages primarily its financial resources, but it also make its systems, technologies or distribution channels available. In return, stable contracts, an opportunity to achieve high profits, technical knowledge, better branding, social legitimacy and influence are achieved. On the other hand, the state sector, while risking credibility as well as social support and influence, might achieve such benefits as: more innovative

services of increased quality, efficient use of public funds, increased investment opportunities, increased income, increased competitiveness, and increased social support. The benefits of collaboration in the provision of public services might greatly exceed outlays. First of all, as a result of revenues from services, acceleration occurs in the area of R&D, in particular in, for example, infrastructure, which is of benefit to all actors in the territorial system, including society, public administration, entrepreneurs, customers, etc. As a result of the involvement of the private sector, the efficiency of the investment might be increased, encompassing, among others, shortened time of preparation and implementation of projects, or increased innovation and quality of services offered.

The legitimacy of cooperation in the sustainable local governance is supported by local experiences from around the world. These include, among others, increased use of public transport and reduced car traffic in Edmonton, Canada (Khare, Beckman, Crouse, 2011), the formation of the Regional Centre of Expertise in Hamburg, Germany (Filho, Schwarz, 2008), and the limitation of greenhouse gases in Sao Paulo and Rio de Janeiro, Brazil (Martins, Ferreira, 2011). It may therefore be concluded that collaboration in the provision of public services favours the creation of new knowledge about this process, which affects the growth of innovation, entrepreneurship and effectiveness of sustainable operations of local governments. As a result, the competitiveness of a region increases, while maintaining the required standards of environmental quality.

2.1 Creating knowledge in sustainable local governance

Theoretical and practical interest in knowledge management in organizations gained importance in the last 20 years. Initially, knowledge management focused mainly around quite narrowly shaped possibility of converting tacit knowledge to explicit knowledge, in the context of its distribution by means of more or less complex systems (Lundvall, Nielsen, 2007). This approach allowed to comprehend the “nature” of knowledge in an organization, as created in two dimensions: epistemological (affecting sources of knowledge – explicit/ formal knowledge and tacit/ silent knowledge) and ontological (the relationship between individual, group, organizational, and inter-organizational knowledge (Rasmussen, Nielsen, 2011)). Undoubtedly, one might claim that the above-mentioned statements, in the context of knowledge management, cannot be directly mapped in relation to public administration. Numerous studies indicate that knowledge management in public administration comes down to the management of information

resources. The transition from information resources management in public administration to knowledge management generally boils down to transforming the data in hand-held archives into the data in the form of digital recordings and tools for selecting, updating and retrieving information. Management systems designed for individual resources are autonomous, since they were created solely for the use of certain services, with virtually no access for others. Current information management systems in public administration seem like “an overlay” on historically traditional solutions. A visible effect here is acceleration and simplification of the tasks previously performed manually. According to I. Maj (Maj, 2004), impediments connected with the transition from information resources management to forms of knowledge management might be of the following nature:

- the methodology of the approach to organization (enterprise) knowledge management is different among the theorists and practitioners of enterprise management, and different among the theorists and practitioners in the management of information resources in public administration;
- lack of funds or high costs of transition to integral solutions, which are usually not standardized, both with regard to IT tools, and system solutions;
- lack of knowledge about new solutions among public administration employees;
- lack of motivation among public administration employees.

The greatest potential for the creation of knowledge lies in the context of the implementation of the tasks entrusted to local governments, mainly regarding the provision of public services. In innovative processes, the participation of enterprises in the provision of public services favors bilateral absorption and transfer of knowledge related to both the technological, or organizational aspects, and the conditions of external environment. In addition, there are interdependencies between the level of development of the public sector and innovation of the private sector.

2.2 Mechanisms of enterprises' participation in sustainable local governance in Poland

Participation is the process by which stakeholders can influence the priorities for action, policy, resource allocation, and access to public goods and services (World Bank Group, 2014.03.15). It is based on the commitment of individuals and groups to the implementation of projects, and it helps to improve decision-making processes, activities,

and stimulate creativity and innovation. In public service provision, in order to ensure high quality of these services, it is necessary to act jointly. However, before it can happen, initiatives aimed at strengthening the relationship between public and private entities are requisite. Appropriate mechanisms of collaboration are introduced for this purpose.

In European countries, in order to increase private sector involvement in the provision of public services, a number of initiatives are introduced (e.g. specific tax incentives, pre-commercial procurement (Amanatidou, 2008; Cec', 2007; Vigoda-Gadot, 2004; Carruthers, Ashill, Rod, 2006; Arlbjörn, Freytag, 2012), but the dominant role in this area is played by public-private partnerships (Jamali, 2004; Cheung, Chan, LAM, Chan, Ke, 2012; Sjölander, 2007; Nisar, 2007; Jamali, 2007). In Poland, the array of tools that might be applied is as wide, and in the course of the conducted research and analyses, 10 basic mechanisms of engaging private enterprises in the delivery of public services were identified. The characteristics of these mechanisms are shown in Table 1.

Table 1. Collaboration mechanisms in public services provision in Poland

MECHANISM	DESCRIPTION
Public Procurement	contracts for pecuniary interest concluded between the contracting authority and the contractor, the subject of which are services, supplies or construction works
Public-Private Partnership	joint implementation of projects, based on the division of tasks and risks between the public entity and the private partner; in the contract for public-private partnership, the private partner is obliged to complete the project in return for remuneration, and to incur, fully or partly, the expenditure on the project's completion implementation, or to pass it to third party, whereas the public entity is obliged to cooperate in achieving the project, in particular by bringing own contribution
Legal instruments	contracts concerning entrusting the private sector with fulfilling a part of the public functions: contracts for services, service and management contracts, leasing agreement, concession agreement, other legally binding agreements
Financial Instruments	subsidies, subventions, grants - the state budget expenditure subject to special accounting rules, passed in order to fill in the missing funds for financing or co-financing of activities important to the public interest, in a strictly defined, unilaterally determined amount, non-repayable, free of charge and interest-free
Privatization	acquiring shares in the increased initial capital of sole-shareholder Treasury company created as a result of commercialization (transformation of a state-owned company into a privately-owned company) by entities other than the Treasury or non-state legal entities; selling state-owned shares in companies; disposing of all tangible and intangible assets of state-owned enterprise or company resulting from commercialization under the terms of legal acts by means of: selling the enterprise, bringing the enterprise to a company, leasing the enterprise for use against payment
Outsourcing	undertaking consisting of separating certain functions performed by the parent company from its organizational structure, and transferring these functions to other economic entities to be performed by them

Digitization	implementation of solutions for the transmission of data in digital form (personal computers, Internet, mobile phones), which poses increasingly better opportunities of remote communication and reception of information
Clusters	spatial and sectoral concentration of entities acting for the purpose of economic development or entities acting for innovation, research units and enterprises engaged in an economic activity [...], competing and cooperating in the same or related industries, and linked by a cooperation network
Activities of innovation support institutions	government institutions (Polish Agency for Enterprise Development, Industrial Development Agency, Regional Industrial Parks), regional organizations (technology parks, business incubators, technology transfer centres, centres of excellence, special economic zones), business environment institutions (both for -profit economic entities and non-profit organizations), training and consulting centres, special economic zones
Territorial Marketing	all strategic and technical approaches that are used by organizations (associations, units, public institutions, enterprises) in order to gain new resources and improve the efficiency and quality of completing projects set to meet the specific public needs, while maintaining the principles of ethics, leading to the fulfilment of certain missions

Source: own work based on: Dz. U. 2004 Nr 19 poz. 177; Dz. U. z 2010 r. Nr 113, poz. 759, Nr 161, poz. 1078, Nr 182, poz. 1228 – art. 2; Dz. U. z 2009 r. Nr 19, poz. 100, z 2010 r. Nr 106, poz. 675 – art. 1 i 7; Dz. U. 1996 Nr 118 poz. 561 – art. 1; Dz. U. 2009 nr 61 poz. 503 - §2 pkt. 8; Zarządzanie publiczne – elementy teorii i praktyki, pod red. A. Frączkiewicz-Wronki, AE, Katowice 2009; Sosnowska A., Poznańska K., Łobejko S., Brudlak J., Chinowska K.: Systemy wspierania innowacji i transferu technologii w krajach Unii Europejskiej i w Polsce, PARP, Warszawa 2003; Trocki M: Outsourcing: metoda restrukturyzacji działalności gospodarczej, PWE, Warszawa 2001; Polska 2030. Wyzwania rozwojowe, Zespół Doradców Strategicznych Prezesa Rady Ministrów, Kancelaria Prezesa Rady Ministrów, Warszawa 2009; Szromnik A., Marketing terytorialny, Wolters Kluwer, Warszawa 2010.

The identified mechanisms are present in Poland both independently, and simultaneously with other ones. They may also complement each other. Frequently, within a single mechanism several others are used, e.g. a public-private partnership uses legal and financial mechanisms that might successfully operate separately. A similar situation may occur in the case of territorial marketing, or innovation support institutions. The mechanisms presented in Table 1 were used in the research concerning the scope of participation of enterprises in the provision of public services.

4. Empirical data analysis

4.1 Mechanisms of enterprises' participation assessment in sustainable local governance

In order to determine the usability of the various mechanisms of enterprises' participation in sustainable local governance, an analysis of the level of their use was

conducted. The results of these analyzes allow one to conclude that both the public sector and the private sector possess experience necessary to assess the identified mechanisms.

The analysis of the level of use of enterprises' participation in sustainable local governance indicates that all of these mechanisms are implemented in practice. The mechanisms utilized to the greatest extent are: procurement (66.1% of total responses), territorial marketing (40.5%) and financial instruments (34.5%). The least frequently pointed out to are: digitization (11.9%) and clusters (15.5%). The results of research carried out in enterprises is somewhat different, with - after the dominant role of public procurement (89.7% of responses) - digitization and activities of innovation support institutions considered to be the most frequently used tools of participation in the creation of public services. In turn, the least frequently pointed out to are: privatization (16.3%), public-private partnerships (28.2%), and - as in the case of local governments - clusters (28.6%).

The level of mechanisms of enterprises' participation in sustainable local governance is largely determined by their usability, understood as the ability to meet existing needs. The research taking the opinions of local governments, enterprises, and experts into account found that the highest rated mechanisms are financial instruments. Legal instruments and digitization were also highly rated. Clusters, privatization and outsourcing were perceived as the least useful. The distribution of ratings, accounting for the average values for the confidence interval $\alpha = 0.05$, is illustrated in Figure 2.

Fig. 1. Assessment of the usability of the instruments of enterprise participation in social services provision

Source: own work

Moreover, the analysis of the observations and comments revealed that the main limitations in the provision of public services on the basis of the relationship between public and private entities are: operations taking more time than when performed separately, the lack of agreement, the risks associated with the functioning of partnerships (e.g. infringement of the rules), bureaucracy, or loss of control of the expansion of networks. These factors may discourage companies from collaborating in the provision of public services. It also unveils the need to improve the undertakings motivating companies to participate actively in this area. In order to eliminate the impediments of cooperation in the provision of public services, the respondents propose the use of the following solutions:

- Laws stabilization;
- Pilot Project;
- Sureties, cancellation of taxes;
- Shortening the way of legal decision to implement;
- A coherent and well thought out policy of public service delivery arising from the verification of social needs, compatible with the national programs;
- Handing over a wider range of tasks from local governments to the non-profit sector;
- Joint planning of public infrastructure development.

4.2 The analysis of the factors motivating enterprises to participation in sustainable local governance

The analysis of the factors that motivate enterprises to participate in sustainable local governance was based on interviews with the experts. On the basis of the analysis of descriptive statistics, it was found that the experts see the need to increase the use of most of the mechanisms of participation, but to a different extent, depending on a given mechanism (cf. Table 2). The needs to increase the investment in innovation support institutions, territorial marketing and digitization are perceived as the greatest ones. Moreover, the experts believe that, in the studied area, it is not expedient to increase the use of privatization and public procurement.

Table 2. Descriptive statistics in the study of the need to increase the use of the mechanisms of enterprises' participation in sustainable local governance

The study also allows one to state that, according to the experts, the increase in participation of enterprises in the provision of public services is to the greatest extent influenced by legislation and the involvement of local governments. These factors, on a scale of 1 to 5, received respectively 4.67 and 4.2 points. Such factors as engagement on the part of businesses and initiatives of local governments were also highly rated. According to experts, among the identified factors influencing the increased use of mechanisms of enterprises' participation in sustainable local governance, interaction risk is the least important. These results are illustrated in Figure 2.

To assess the internal reliability of the items, Cronbach's alpha was used. Assuming the threshold of 0.7 as satisfactory (Cronbach, 1951), it was found that all the obtained results are reliable. The results of performed tests are shown in Table 3.

Tab. 3. Statistics of reliability in the study of mechanisms of enterprises' participation in sustainable local governance

The results of this research clearly indicate that the implementation of public tasks in Poland must frequently cope with excessive formalization, bureaucratization and administrative “proceduralization” of support mechanisms. As a consequence, the effects of collaboration between the public and private sectors are of an unsatisfactory level,

since it is based mostly on the mechanism of procurement. In the field of public procurement, in over 90% of cases, the only criterion for the selection of the tenderer is the price, despite the fact that the legislature provides the contracting party with many opportunities of the evaluation of products and services. This allows one to not only choose the products best suited to the needs, but also take into account the social and environmental criteria - socially useful ones. Unfortunately, setting the price as the sole criterion in selecting the contractor is theoretically the simplest and leaves the least room for malpractices. In turn, using the support of so few instruments in the provision of public services leads to avoiding innovative and risky development projects, for the sake of safe and routine activities, which might consequently curb self-sustainability.

5 Conclusions

The partnership of local governments and private entities interested in cooperation is increasingly important in the provision of public services. This process undoubtedly increases the transfer of knowledge through mutual acquisition of experience.

Given the emergent importance of knowledge management in the public sector, particularly on stakeholder partnerships to assist public policy developments, it is regrettable that there still is limited guidance in the knowledge management literature on how governments can develop more effective partnerships (Riege, Lindsay, 2006).

The conducted research clearly indicates the need to involve more mechanisms to support the provision of public services. These actions will ensure a coherent and well thought out policy of public services provision, resulting from the verification of social needs, and based on joint planning of public infrastructure development. This is directly related to the fulfilment of the main priorities of sustainable development

Corporate Governance and Technological Knowledge Development: A Configurational Approach

Subba Moorthy

Department of Management
Herberger Business School, St. Cloud State University
720 Fourth Avenue S, St. Cloud, MN 56301, USA

Structured Abstract

Purpose - Explore how corporate governance affects development of firm technological knowledge.

Design/Methodology/Approach - I conducted canonical correlation analysis on a large sample of US manufacturing firms. Five dependent variables, measured using firms' patent data, capture five dimensions of technological knowledge - breadth, depth, enhanced, new, and stagnant knowledge. Independent variables cover three dimensions of corporate governance – ownership concentration, managerial stake, and board composition. In addition, I included both industry and firm contextual variables, to increase the study's reliability.

Findings - Results indicate two types of firms. One group consisting of 'cautious generalists', wherein high breadth and depth of technological knowledge and a strong emphasis on enhancement is linked to concentrated shareholdings, increasing top management's stake in the firm by offering stock options, and a board low in accounting experience. In contrast, the second group's technology profile de-emphasizes breadth and focuses on deepening existing knowledge stock. This group has a relatively weaker emphasis on stock options to reward top management and a board with strong financial background.

Originality/Value - This study furthers our understanding of strategic management of technological knowledge in three ways: by developing theoretically meaningful components of a firm's aggregate stock of technology; constructing ratio-scale measures of those components - breadth, depth, enhanced, new, and stagnant technological knowledge; using canonical correlation analysis which, rather than multiple regression analysis, is the more appropriate technique to derive meaningful implications for managers.

Keywords: Technological knowledge, Corporate governance, Ownership, Board of Directors, R&D.

Paper type – Academic Research Paper

1. Introduction

Superior firm performance depends on effective corporate governance. All three ‘corporate governors’ – i.e., shareholders, managers, and board of directors – play important roles in their firm’s strategic management. As technology is strategically important for firm performance, it is well recognized that developing and maintaining the firm’s technological knowledge assets is a corporate governance responsibility (Baysinger et. al., 1991; David et. al., 2006; Hansen and Hill, 1991; Hermann et. al., 2010; Lhuillery, 2011; Premuroso and Bhattacharya, 2007). Most investigations, including those cited above, have almost exclusively focused on firms’ total stock of technological knowledge (measured using R&D expenses or patent counts). But studies on technology strategy clearly indicate that total stock is too aggregate a variable to yield useful results, and suggest taking a more fine-grained approach (e.g., Diaz-Diaz et al., 2008; Hall et al., 2005; Hall et al., 2007; Leiponen and Helfat, 2010; Moorthy and Polley, 2010). Responding to that suggestion, I argue for and develop five dimensions of – breadth, depth, enhanced, new, and stagnant knowledge – as being more relevant for studying firm technological assets.

We face a similar situation in studying corporate governance. It is a multidimensional construct, and inclusion of all three governance dimensions – ownership structure, managerial stake, and board composition – would yield richer dividends. The large number of independent and dependent variables that would be involved in such studies causes analytical challenges, which has been handled by statistically studying effects of one governance factor while holding the other two constant. Conceptually, such ‘divide and conquer’ approach does not make much sense. This is one reason for the ‘mixed and inconclusive’ results observed from studies on the performance effects of one or other of the governance variables (Bell et. al., 2013: 162).

So, it does not look promising to theorize and develop hypotheses on the independent effects of one governance variable on one technological knowledge dimension, or, at most, the combined effects of two governance dimensions on one knowledge component. The point is that any observed combination of breadth, depth, new, enhanced and stagnant technological knowledge is a result of complex interactions between owners, managers, and the board. Whether the technological knowledge profile of a firm is affected by differing corporate governance structures is, therefore, an interesting question to look into. As such, I report here on the empirical study I

undertook to explore the relationship between a firm's corporate governance and its technological knowledge development. In the section that follows I draw on knowledge management and agency theory literatures to explicate the five dimensions of technological knowledge and three dimensions of corporate governance meaningful for this study. The methods section that follows details how patent data can be used to construct meaningful measures of firm technological knowledge, and explains why canonical correlation rather than multiple regression is appropriate for analyzing the corporate governance – technological knowledge relation. After presenting results of the analysis, the paper concludes with a discussion of 'where we should go from here'.

2. Theoretical Arguments

2.1 Dimensionality of Firm Technological Knowledge

Organizations can develop knowledge in a variety of technological domains. Because of their limited resources, organizations are forced to make choices. By choosing to develop knowledge in one domain, they give up their option to develop expertise in other areas. Thus, an increase in knowledge in one technological field implies a lack of knowledge in another field. Such choices profoundly influence an organization's ability to be successful in the long run (Leiponen and Helfat, 2010; Moorthy and Polley, 2010; Subbanarasimha et al., 2003). Hence, decisions regarding the breadth and depth that firms want in their stocks of knowledge become important. It also immediately follows that the kinds of changes to be made in the existing stock to achieve a targeted breadth and depth are important as well. Thus, there are two aspects in capturing firm technological knowledge: the first is the stock aspect which captures the breadth and depth of technological knowledge a firm possesses, and the second is the flow aspect capturing changes in the firm's knowledge over time. Three types of changes can be made to a stock of knowledge. Some portions may be kept unchanged and other portions built upon. Further, technological knowledge in areas completely new to the firm can be added to the existing stock. These dimensions have been observed to affect firm performance (Moorthy, 2012). Thus, the three dimensions that capture the flow aspect of a stock of knowledge are stagnant, enhanced, and new technological knowledge.

Regarding the combinations of breadth and depth of technological knowledge that firms ought to develop, theories of expert learning and performance inform that depth of knowledge is important (Bower and Hilgard, 1981; Day and Lord, 1992). Depth of

knowledge permits firms to have a better and more complete understanding of any one area. In contrast, the technological imperative that firms face points to the need for maintaining some degree of breadth in their stock of knowledge. The imperative arises from the fact that most technologies are faced with the existence of competing technologies. Often, a desired outcome can be achieved using more than one technological method (Arthur, 1989). Hence, there is usually a need for maintaining a certain breadth of technological knowledge.

2.2 Corporate Governance: Factors Influencing Development of Technological Knowledge

Both organizational and environmental factors influence the development of technological knowledge. Organizationally, the players involved in a firm's corporate governance have the greatest impact on decisions about knowledge development. Typically, this happens to be the owner/manager, whose values and beliefs determine both types of knowledge a firm develops as well as the way it goes about their development. If the owner/manager happens to be the same person(s), then one set of values and beliefs affect knowledge development. However, in the case of publicly held corporations, ownership and managerial control do not rest in the same person(s). Three distinct social actors, consisting of owners, managers, and boards of directors are involved in the firm's corporate governance. As the goals of these three groups of claimants differ, and indeed often conflict, technological knowledge development becomes highly problematic.

Corporate governance is concerned with the mechanisms set up to reconcile the conflicting interests of shareholders and managers in publicly held corporations. Shareholders (i.e., owners) desire steady income from dividends and gradual appreciation in the market price of their stock. They have the flexibility of reducing their risk by holding a diversified portfolio of securities (Fama, 1980). In contrast, managers act 'so as to maximize their own lifetime incomes' (Monsen and Downs, 1965: 225). They rent their human capital (knowledge and competence), are dependent on the firm's success for their livelihood, and hence, desire security (Marris, 1963). While both shareholders and managers wish to maximize incomes, the difference is that managerial income consists of both monetary and non-monetary elements (Monsen and Downs, 1965). As shareholding disperses, firm operations may be conducted more to advance managerial interests than to fulfill owner goals (Berle and Means, 1968). There is, thus, a need for some sort of control to align the conflicting interests of owners and managers. This is achieved

through the establishment of a board of directors. The board, by virtue of its legal mandate to hire, fire, and establish compensation schemes for managers, safeguards shareholder interests.

Conflicting goals of owners and managers affect the strategic actions firms take in their search for long-term success. As an intermediary between shareholders and managers, board behavior also affects long-term performance. Thus, all three social actors play a role in corporate strategy, and therefore, in technological knowledge development. Evidence indicates that ownership concentration, managerial stockholdings, and diversification are related to R&D intensity (Hill and Snell, 1988; McEachern and Romeo, 1978). The present study adds to this research stream by investigating whether the same three factors, along with board composition and managerial option values, are related to distinct configurations of the stock and flow dimensions of technological knowledge -- i.e., to breadth, depth, stagnant, enhanced, and new technological knowledge.

2.2.1 Ownership Concentration and Technological Knowledge

Ownership concentration affects development of technological knowledge by affecting owners' coordination ability. If the firm's stock holdings are highly dispersed, then shareholder co-ordination becomes difficult, compromising their ability to affect the firm's strategy. Thus, to the extent that shareholdings are concentrated, owners' technological strategy will be elaborated in such a manner that the five dimensions of technological knowledge will enable the achievement of owners' values and goals.

2.2.2 Managerial Stockholdings, Rewards, and Technological Knowledge.

In the case of managers, the nature of their stockholding and rewards affects the technological knowledge that is developed. There is a fundamental asymmetry in the differential rewards facing managers. As returns to a successful innovation increase, the manager's take does not increase proportionately. But commercially disastrous innovations pose serious threats to a manager's position. Both aspects will act to increase a manager's risk-aversion (Monsen and Downs, 1965). A second risk-aversion source is managerial compensation. To decrease agency problems, owners provide compensation in the form of stockholdings and stock options. While such compensation schemes may decrease agency problems, they also decrease risk-taking by managers. As managers' stock holdings increase, their fortunes become more strongly tied to those of the firm. They are not as willing as owners to take chances on the uncertain payoffs of unknown

technologies. Consequently, we can expect managers to concentrate on exploiting the innovation potential of existing knowledge instead of developing new technological knowledge.

2.2.3 Board Composition, Background and Technological Knowledge

Evidence shows that firms include their boards in determination of corporate strategy (Andrews, 1981; Judge and Zeithaml, 1992), and often down to the functional level (Henke, 1986). Therefore, we can expect boards to participate in decisions regarding technological knowledge development.

When looking at board effects, theories inform us that an effective board should be composed of both insiders and outsiders. Though agency theory and stewardship theory differ about the primary role of a corporate board, with the former emphasizing the vigilance role of a board and the latter focusing on knowledge and social capital that boards bring to the firm, both agree that effective boards need both inside and outside directors (Carpenter and Westphal, 2001; Davis et al., 1997; Hillman and Dalziel, 2003; Kroll et al., 2008; Short et al., 2001). The empirical question is about the ratio of outside to inside directors that an effective board would have. To the extent that insiders -- i.e. members of the firm's management team -- dominate a board we would expect to see the managerial view of technological knowledge to dominate. In contrast, when the board is dominated by outsiders, and is a "participative board" then shareholder's interests will be served. A second property of the board that has a bearing on corporate technological knowledge is its members' functional and educational backgrounds. Backgrounds of board members will influence their understanding and appreciation of science and technology, and hence, the opinion about the role technology should play in the firm's long-term success. Professions have distinctive cultures and uncertainty avoidance is an important dimension along which any culture differs (Hofstede, 1980). Membership in professional bodies leads to socialization of the members into adopting particular values and beliefs. An individual member's attitude toward risk falls in line with that of the professional society's norms. This is particularly the case with accounting, financial, and scientific and engineering personnel, whose respective professional bodies tend to have strong norms.

2.3 Industry and Firm Contextual Factors

While a corporation's owners, top management team, and board of directors affect its knowledge development strategy, the technological knowledge ultimately developed is affected by both industry and firm contextual factors. The rate of technological change affects the breadth and depth of technological knowledge. With increasing change, firms may decide to keep pace with that change by constantly updating, and thus, enhancing knowledge in existing technological competencies. In contrast, it is equally possible that firms may decide to gain knowledge in areas of technology new to them because the nature of products and process requires this. Similarly, industry concentration and market growth affect the nature of technological knowledge that firms develop. The positive economic profits and market power possessed by firms in concentrated industries encourage them to take more risks. Therefore, firms may allocate resources to develop technological knowledge in a variety of technological fields resulting in greater breadth of technological knowledge. Alternatively, market power may result in complacency. Firms may not make concerted efforts to either maintain existing competencies or develop new technological competencies. The same arguments hold for firm-level contextual factors of profitability and product/market diversity. If profitability is high, the firm will have a higher level of slack. R&D is one area on which the firm may expend this slack -- on expanding either breadth or depth of technological knowledge.

In summary, we expect the five dimensions of technological knowledge to be affected by (1) ownership concentration, (2) managerial shareholdings and rewards, (3) board composition and background, (4) industry conditions of concentration and technological change rate, and (5) firm profitability and diversity.

3. Method

3.1 Sample

Data for this study are from six sources. US Patent Office data helped to calculate the technological knowledge variables. Ownership concentration data were obtained from the 1976 and 1977 issues of CDE Stock Ownership Directory published by Corporate Data Exchange, Inc. Mueller (Mueller, 1986) provided managerial shareholdings and option values information. Profitability data were obtained from the National Bureau of Economic Research R&D Master Data Tape (Cummins et al., 1985). Firm diversity was

measured using data from the EIS/TRINET database. The technological change variable was constructed using data from the Yale Industrial R&D Study (Yale Survey, 1983).

Availability of data dictated the use of variables in the statistical analysis. Obtaining patent statistics for firms by the technology classes was the most difficult. As these data were available for just the 1967-72 and 1973-79 periods, all other information had to be collected for one of these periods. Given the difficulty of obtaining past data, it was decided to collect data on the independent variables only for the second (1973-79) period -- the more recent of the two periods. When data from all sources were merged, the sample size containing no missing values turned out to be very small -- a total of 32 cases. It was therefore decided to conduct two separate analyses with different sets of independent variables chosen to obtain a sample size adequate for conducting statistical analyses. This resulted in one subsample of 57 cases consisting of ownership dispersion variables, and a second subsample of 81 cases consisting of managerial shareholding and board composition variables. The context variables were present in both the subsamples.

3.2 Measures

3.2.1 Technological knowledge variables

Measuring the stock (i.e., breadth and depth of knowledge) and flow (i.e., changes in knowledge) dimensions of technological knowledge required information on the nature of technologies for which patents were issued. This information was obtained from the U.S. Patent Office files. To facilitate patent examiners' search of existing patents, the Patent and Trademark Office has constructed an elaborate classification scheme consisting of 352 different classes of technology (the detailed names and titles can be found in the US Patent and Trademark Office Manual of Classification, 1983). When a patent is granted, the technology class to which it belongs is noted on the patent document. The technology class information can be used to construct measures of the stock and flow dimensions of a firm's technological knowledge as described below.

3.2.1.1 Technological Knowledge (Stock)

Suppose a firm's total number of patents is distributed over n patent classes. Let p_i be the fraction of patents that are in patent class i . Then a measure of technological knowledge is:

$$\text{Technological Knowledge} = 1 - \sum p_i^2 \quad (1)$$

This Herfindahl-type index ranges from 0 at the lower end (implying technological knowledge in a single class) to a theoretical maximum of 1 (implying technological knowledge spread over a wide range of classes). One shortcoming of the measure is that it does not provide any indication of the spread of patents across patent classes. The measure can be modified to overcome this lacuna. Adding and subtracting $1/n$ in equation 1 yields:

$$\text{Technological Knowledge} = (1 - 1/n) - \sum [p_i^2 - (1/n^2)] \quad (2)$$

i.e., $\text{Technological Knowledge} = \text{Tech Knowledge-Breadth} - \text{Tech Knowledge-Depth}$

These measures of breadth and depth of technological knowledge were calculated for the sample firms. Information on the technology classes to which a firm's patents belong was available only in an aggregate form for two periods -- 1967-72 and 1973-79, and not on a yearly basis. Thus, the technological stock variables were calculated for the 1973-79 period and the flow variables were calculated for changes in knowledge between 67-72 and 73-79 periods.

3.2.1.2 Technological Knowledge (Flow)

Three measures capture changes in knowledge between the two periods. If TPAT is the total number of patents the firm applied for and was granted during both period one and two - i.e. during the years 1967-79, then the three measures are calculated as follows.

- i. **Tech Knowledge - Stagnant** measures stagnant technological knowledge - i.e. technology classes in which expertise created in period one was not developed further in period two. This is calculated as $\sum \text{pat}_i / \text{TPAT}$, where pat_i = number of patents in technology class i in period one, in which class no additional patents were obtained in period two.
- ii. **Tech Knowledge – Enhanced** captures knowledge possessed by the firm in various technological fields in period one that was enhanced in period two. It is calculated as $\sum \text{pat}_i / \text{TPAT}$, where pat_i = number of patents in period two that are in technology class i , in which class the firm already had patents in period one.
- iii. **Tech Knowledge - New** measures knowledge in those technology fields the firm possessed no knowledge in period one but developed in period two. It is

calculated as $\sum \text{pat}_i / \text{TPAT}$, where pat_i =number of patents in period two in technology class i , in which class the firm had no patents in period one.

3.2.2 Corporate governance variables

Three categories of governance variables are used in this study: (1) ownership concentration, (2) managerial stake, and (3) board composition.

3.2.2.1 Ownership concentration. Three measures index ownership concentration.

- i. **Ownership - # with 2%** is the number of shareholders having two (or more) percent of total stock. Higher values indicate greater dispersion of ownership.
- ii. **Ownership - % with 2%** captures percentage of total stock held in fractions of two (or more) percent.
- iii. **Ownership - % of top 5** being percentage of total stock held by the top five shareholders.

3.2.2.2 Managerial stake is captured with two measures.

- i. **Executive ownership** is measured by looking at the percentage of total stock held by the top five managers.
- ii. **Executive options value** is the dollar value of stock options granted to the top five managers calculated as a percent of their salary and bonus.

3.2.2.3 Board composition. Three measures capture this dimension of corporate governance.

- i. **Board outsider ratio** being the ratio of outside to inside directors.
- ii. **Board acting experience** measured as the percentage of directors with a functional background in accounting.
- iii. **Board finance experience** measured as the percentage of directors with functional background in finance.

3.2.3 Contextual Factors

3.2.3.1 Environmental factors. Three industry-level variables are used to capture the firm's environment.

- i. **Industry rivalry** measured using the industry's four-firm concentration ratio in 1972. For diversified firms in the sample, a weighted average was calculated where the percentage of total firm sales accounted for by each line of business was used as a weight.
- ii. **Industry growth** measured as average annual growth rate in value of industry

shipments between 1968 and 1978. Again, for diversified firms, a weighted average measure was calculated using percentage of firm sales in the particular industry as the weight.

- iii. **Industry technological change** was calculated using data from Yale R&D Survey (Yale Survey, 1983). Researchers at Yale University gathered data on technological change for each industry by surveying R&D managers. Using this data, a weighted average technological change rate was calculated for each firm in the sample. Weights were determined by calculating proportion of firm sales accounted by each industry in which it operated.

3.2.3.2 Firm contextual factors. Two firm contextual variables are used in the study.

- i. **Product diversity** was calculated using an entropy measure (Jacquemin and Berry, 1979). Suppose a firm is active in n 2-digit SIC industries. Then,

$$\text{Product diversity} = \sum_{i=1}^n p_i \cdot \log_n(1/p_i)$$

where p_i = share of firm's total sales accounted for by the i^{th} 2-digit industry segment. 1978 data were used to calculate diversity. 1972 data were used when 1978 numbers were unavailable. (Firm sales data by industry were available for just those two years.)

- ii. **Return on Capital** was measured as the average of yearly return on invested capital for the period 1973-79.

Three steps were taken to increase reliability of the results. One, all financial numbers were adjusted for inflation. Two, return on capital, had to be available for at least five of the study's seven-year period - 1973-79. Three, for a diversified firm to be included in the sample, industry technological change data had to be available for industries accounting for at least 80 percent of a firm's total sales.

3.3 Analyses

Canonical correlation. This study's focus is on exploring how configurations of a firm's technological knowledge are related to its governance structure as well as firm and industry contextual factors. Multivariate regression would have been an appropriate statistical tool if there were just one dependent variable – i.e., if firm technological knowledge were uni-dimensional. Given that we have five distinct dimensions of

knowledge, the analytical technique must be capable of handling five dependent variables. Separately regressing each of the five technological knowledge variables on the governance and context variables does not help determine whether there exists systematic relationships between specific combinations of dependent variables and independent variables. Canonical correlation analysis is the appropriate statistical technique for such a situation. It forms linear combinations of two sets of variables – one set for the dependent variables and the other for the independent variables. The combinations, termed canonical functions, are formed so as to maximize the between-set correlations. Because of multiple variables in each set, rarely does one canonical function account for all of the original variables' variance. After the first canonical function, the technique proceeds to form a second function with the variance that was not captured by the first function. The process continues until all the variance in the set with the smaller number of variables is captured – the dependent variable set in the present case as it has five variables compared to the independent variable set, which consists of either eight or eleven variables. As explained earlier (section 3.1), missing values necessitated splitting the sample into two subsamples. Industry and firm contextual variables are common to both subsamples. The first subsample contains only ownership concentration variables while the second includes managerial ownership and board variables.

3.4 Results

The sample covers a wide variety of manufacturing industries. Average annual sales vary from a minimum of \$27 million to a maximum of \$24 billion with a median value of \$554 million. Average annual R&D expenditures varied from \$6,000 to \$762 million with a median value of \$7 million. Total patents for the 1973-79 period varied from one to 4,309 with a median value of 46, and the number of technology classes over which the patents are spread ranged from one to 208.

Table 1 provides summary statistics and Pearson correlation coefficients for the ownership concentration subsample, and Table 3 for the managerial ownership and board subsample. For both subsamples, canonical analysis provides five canonical functions. The first function was significant for ownership subsample, and the first two functions for the second subsample. Canonical correlation results are presented below for only these statistically significant functions.

3.4.1 Canonical Correlation Analysis with Ownership Concentration Variables. Table 2

In this subsample, the predictor set consists of the three ownership concentration variables, and the three industry and two firm context variables. Wilk's λ for the full model – i.e., with inclusion of all five canonical functions – is 0.29, and statistically significant; $F(40, 140.94) = 1.60, p < .02$. With the first canonical function removed, $F(28) = .97, p < .52$. Hence, Table 2 shows results for only the first function. Redundancy for the function is .24. Thus, 24 percent of the total variance of the dependent variable set is accounted for by the predictor variable set.

The table also helps answer two additional questions about the dependent variables. One, which of the five technology variables are important in the technological knowledge variate extracted by the first canonical function? All five are important based on using a cutoff point of .30 for interpretation of the structure correlations (column 1), as suggested by Tabachnick and Fidell (1983). As the signs indicate, breadth, depth, and enhanced technological knowledge load in one direction whereas stagnant and new technological knowledge load in the opposite direction. Second, how much of the five variables' variance is captured the variate? 48 percent according to Table 1.

The predictor variate is composed of four independent variables with industry rivalry, firm return on capital, and number of influential owners (Ownership - # with 2%) being positively related to each other. In contrast, stock held by influential owners (Ownership - % with 5%) has a negative sign indicating that it is inversely related to the other three. This variate captures 16 percent of the total variance (of the eight independent variables).

3.4.2 Canonical Correlation Analysis with Managerial and Board Variables. Table 4

In this analysis, the first two canonical functions are statistically significant. (For the full model, approximate $F(55, 304.46) = 1.81, p < .001$. With the first canonical correlation removed, approximate $F(40, 252.12) = 1.53, p < .03$, and with the first two canonical correlations removed $F(27, 196.32) = 1.13, p < .30$.)

Redundancy numbers show that the first canonical function accounts for 18 percent of the total variance of the dependent variable set. The dependent variate accounts for 47 percent of the raw variance of the five technology variables, with breadth and enhanced knowledge being positively related to each other but inversely to new and stagnant knowledge. Depth of knowledge makes no significant contribution to this variate. Only technological change (structure coefficient value of .33, in column 1 of table 4) contributes to the predictor variate. If we relax the .30 cutoff value, industry rivalry and

accounting experience of board members are the next two important contributors.

The second canonical function accounts for an additional 4 percent. The dependent variate here (column 3 of Table 4) shows heavy contributions of depth and enhanced knowledge (structure coefficients values of .87 and .54 respectively). This emphasis on depth is reinforced by the high value of stagnant knowledge but with an inverse relationship (structure coefficient = -.54). In the independent variate, market growth and profitability are the strongest influencers with supporting contribution by financial knowledge of the board (structure coefficients = .47, .53, .32 respectively, in column 3 of Table 4).

A surprising result is the role played by technological experience of board members. In the first variate, it does not play any role, and in the second it plays a negative role (structure coefficient = .17 and -.28, in columns 1 and 3 respectively).

4. Discussion

Two aspects will be highlighted in this section. The first subsection below will describe in more detail the two main patterns of governance-knowledge relationships implied by the canonical correlation analysis. This is followed, in the subsequent subsection, by a discussion of limitations to generalizability that is imposed by data as well as by using canonical correlation as the main analytical tool.

4.1 Corporate Governance-Technological Knowledge relationships: Cautious Generalists versus Focused Exploiters

Canonical correlation analyses point to two distinct configurations. The first configuration, to be found in the first canonical function in both Tables 2 and 4, and termed the cautious generalists, points to a situation where both breadth and depth of technological knowledge are important. However, while breadth is important, it is not attained at the expense of ignoring enhancement of knowledge in areas in which the firm currently has knowledge. The negative coefficient of new knowledge reiterates the point that firms do not go about obtaining breadth of knowledge by haphazardly developing knowledge in new areas of technology. This configuration of stock and flow variables is positively associated with rivalry and firm profitability. Surprisingly, technological change is not an important factor in this scenario. Of the governance variables, number of owners possessing two or more percent of total stock has a positive relationship, and

percentage of total stock owned by the five largest shareholders shows a negative relationship to the criterion variate, supporting our expectations.

With respect to managerial and board influences among the cautious generalists, the first canonical function in Table 4 shows that technological knowledge development is not related to the relative importance of outside directors. Instead, professional background of board members does matter - boards with high ratios of accounting professionals seem to frown upon high breadth of technological knowledge and upon enhancing existing knowledge. Concurrently, such boards appear to encourage rather than discourage development of knowledge in technological areas new to the firm. One explanation for this can be found in the contextual situation facing the cautious generalists. The positive coefficients of technological change and profitability in the predictor variate indicate that as these contextual factors grow stronger, accounting-dominated boards and concentrated ownerships de-emphasize enhancement of existing knowledge and push for developing knowledge in technological areas new to the firm.

The second distinct configuration of technological knowledge, termed focused exploiters, is profiled by the second canonical function of Table 2. Firms in this category prefer a technological strategy of focus -- concentrating on a few areas of technology and giving importance to keeping the firm's knowledge in the areas updated. The predictor variate associated with this technology strategy presents a situation where market growth, firm profitability and diversity, and board financial background are important. A strategy of focused technological knowledge is associated with an industry environment of high market growth and by firm conditions of low diversity and high profitability. Again, type of managerial reward is not related to technology strategy. Such a strategy seems to be influenced by boards having a high percentage of directors with experience in finance (or who represent financial institutions).

4.2 Limitations

This study is subject to limitations associated with use of canonical correlational analysis and content-based empirical studies. To increase reliability, canonical loadings rather than canonical weights have been used to decide the contribution that each variable makes to its canonical variate. However, loadings are also not stable across samples. Thus the specific combination of the technological knowledge variables making up the variates in this study may not be replicated in another sample. The specific configuration

of the five technological knowledge dimensions observed in this sample may not be found in other samples. However, it is encouraging to find that the knowledge variables have shown a tendency to fall into meaningful combinations. Future studies can, therefore, expect to find a firm's technological knowledge profiles to be systematically related to its governance structures.

Content studies, such as the one reported, have the advantage that they provide evidence of the consequences of managerial actions. Secondary data help measure and study the technological footprints left behind by the complex and interacting actions of shareholders, managers, and board directors. What is observed are the end results. What remains unanswered is how those results came to be – i.e., how the particular technological profile happened to get formed. To answer the question of 'how', one needs to capture and document the processes of interaction between owners, managers, and the firm's board of directors. This will no doubt be of practical utility to people involved in corporate governance. Apart from being time consuming, conducting such research is difficult because of the challenge of gaining access to observe top management and board meetings.

5. Conclusions

Results of this exploratory study are encouraging, and suggest that follow-up investigations would be useful. The current study contains a wide diversity of firms spanning many industries and of disparate sizes. This is useful in the sense that its results have greater generalizability. A negative consequence is that only simplistic prescriptions can be offered, if at all. To provide meaningful prescriptions we need increased accuracy. One way to achieve accuracy is to study the governance-knowledge relationships in narrow context. An obvious way to narrow the context is to choose specific industries where technological competence is crucial, such as in the pharmaceutical, telecommunication, and semiconductor industries.

This study used patent data from the 60s and 70s. While technological knowledge was important for competitive advantage even then, two significant changes have occurred. One, there has been a tremendous increase in the importance of software-based knowledge, relative to electro-mechanical technological knowledge, for achieving sustained competitive advantage. Thus, studies of the governance-knowledge relationships in software-based industries will be a useful contribution. Secondly, institutional investors have become an increasingly important type of shareholder, and

shareholder activism has increased. Their objectives and time horizons are rather different from non-institutional investors, and can affect decisions regarding importance of technological knowledge development. Preliminary studies indicate that family and institutional owners differential impact on R&D investments (David et al., 2006; Hansen and Hill, 1991; Kim et al., 2008). Follow-up studies on impact of owner type on technological knowledge development would be useful additions in this stream of work.

Knowledge co-creation for urban services innovation

Emma Puerari *, Grazia Concilio, Antonio Longo

Dipartimento di Architettura e Studi Urbani
Politecnico di Milano
Via Golgi 39, 20134 Milano

** Corresponding author*

Structured Abstract

Purpose – More and more cities are challenged by the general ineffectiveness of the public spending programme management and by the economic crisis. This affects the quality of urban services and the quality of urban lives. Coherently with this trend an international discussion started on the governance model behind urban service production: a model shift from public-private partnership (3P model) towards public-private-people partnership (4P model) is observed which is not yet analysed in depth (Majamaa et al., 2008; Zhang and Kumaraswamy, 2012). New urban initiatives are growing in number, which consider people relevant actors of the service ideation and creation aiming at developing effective environment for urban service co-creation (Sibukele et al., 2012).

Within the perspective above, the main purpose of the paper is to highlight the role of co-creation in urban service provision (Jégou, 2011; Manzini et al. 2008; Manzini and Rizzo, 2011). The paper wants to demonstrate how the 4P model represents a possibility to foster and drive large-scale changes in which different stakeholders can play meaningful role (Concilio, 2010; Fischer, 2006; Kernaghan, 2009). In particular it analyses what is the role of knowledge creation in idea generation for innovating urban public services.

Design/methodology/approach – Considering the main scope of the paper, the authors carry out a case-based analysis and report the results of a long process in the urban environment of the Milan municipality experience in rethinking urban green areas growth and management. The co-creation process is described considering its bottom-up nature and its interaction with the local administration when moving from deliberation to decision making. In particular it is analysed in order to envision how some small (self-organized) criticalities/opportunities (Puerari et al., 2013) emerged in the city of Milan can be captured, coordinated and amplified to play a meaningful role in defining/envisioning possible futures that can enhance larger changes. Hence, some specific co-creation sessions are described (with the use of cognitive mapping tools) and analysed in terms of knowledge contents and dynamics relevant for the shift from deliberation to decision making and the kind of governance models arising from the co-creation process.

Originality/value – The originality of the paper stays, first, in focussing on the role played by co-creation in the creation of knowledge and in the generation of ideas for the innovation of urban public services. Second, the methodological aim of the paper is

exploring the potentials arising when integrating co-design tools and methodology with knowledge mapping tools.

Practical implications – Cities are looking for new ways to create and produce urban services that can respond to citizens needs in a more effective way. Practical implication of the proposed paper are specifically related to the lessons learnt from the described experience and analysis of the Milano case within the framework of urban green areas development and management.

Keywords – urban services, innovation, private-public partnership, urban governance models.

Paper type – Academic Research Paper

1 Public Service Innovation

1.1 Why?

The general topic of innovation has inspired a vast amount of research, theorizing, speculation and wishful thinking (Kimberly, 1981), it has become one of the key “buzzwords” beloved by policy makers and practitioners around the world (Borins, 2001; Eshima et al., 2001; Albury, 2005). Innovation is different from changes that are gradual improvements and developments of existing services, provided by a public service organization, and/or their organizational context. Changes represent continuity with the past, whereas innovation represents a specific form of change: the introduction of new elements into public service, like new knowledge, new organization and/or new management or procedural skills; it represents discontinuity with the past. When the change represents a discontinuity, the supply of public service requires new structure, new skills and competence, it might involve the creation of a new organization and the meeting of a new need. Unfortunately, it is not possible to predict changes, assess their impact upon organization and service and develop adequate change and innovation; therefore producers, managers and suppliers of public services need to be able to deal with emergence, which is a phenomenon that can not be foreseen; changes and innovation in public services are transformational and evolving entities influenced by the context, composed by different layers as institutional, global, national and local arena (Osborne, 2005). Indeed, innovation is a very attractive concept that combines a determination to reform and improve public services (Osborne & Brown, 2013), with a perspective that

aims to a sustainable public service implementation and delivery.

Starting from this assumption, the White Paper *Innovation Nation* argues that innovation in public services “will be the essential to meet the economic and social challenges of the 21 century” (Department of Innovation, Universities and Skills (DIUS) 2008, p.8; see also Audit Commission, 2007), as increasing growth, performance, employment, knowledge and skills (Stephen & Lush, 2008; Tether, 2003). In fact, services are the fundamental tools for value creation and exchange, as well as their considerable implications for research, practice, societal well-being, public policy and new governance framework.

It is worthwhile to explore possible renewal of urban services within urban environments, due to the fact that cities and urban areas offer a critical mass experimentation in a large-scale open and citizens driven innovation environments; in fact cities are considered as innovation drivers in areas such as health, environment, inclusion and business (European Urban Agenda of the European Commission, 2010) and have to be considered as true containers of flows and exchanges among residents and other stakeholder attending the urban system itself (Dvir, 2005).

Cities are facing challenges to maintain and upgrade urban infrastructures and establish efficient, effective, open and participative innovation processes to jointly create the innovative applications and services able to respond to citizens’ needs. In particular in this time of growing complexity, due to the crisis of representative democracy, the globalization of culture and the economy, the rising cost of energy, the financial crisis and the subsequent economic crisis, the problem of fragmentation (diversity), the ageing of the population, the increasing interest (at all scales from local to global) in environmental issues (Albrechts, 2013).

1.2 What governance model? From 3P to 4P model

Traditionally, the supply of public services is associated with two types of agents: public or private. On one end the *bureaucratic Leviathan* (Hardin 1978) and the welfare state, on the other the contractual governance (Foldvary, 1994).

In the last decades it has been suggested that it is possible to establish *public-private partnerships* (PPPs) for services supply so integrating the potentials of both the sides of traditional services supply, imagining a situation in which the different parts are combined each time in different ways, according to the context (Ostrom, 1990). It is

possible to consider that “the concept of partnerships is generally described as a ‘mechanism allowing the mobilisation and co-operation of a great number of actors in order to mould the necessary political and operational consensus to affect directly the everyday life of all members of society’” (Paskhaleva, 2001, p.7), partnerships are believed to embody many advantages which are coincident with the presently acknowledged main criteria for sustainability – it requires consideration of multiple stakeholders’ interests, it implies a long term perspective based on common goals, and can accommodate a wide range of conflicting perspectives. Moreover, in order to define and classify the different type of PPPs it is necessary to understand (1) what they are seeking to do, what is their purpose and what are their focuses; (2) who is involved in this relationship, what are the key actors and how is their relationship defined; (3) the timing or stage of development of this process and the changing relationships and activities over time; (4) where this relationship has been built, considering the national and the policy context for each partnership (Osborne, 2000).

Therefore, the PPPs have been addressed as a key tool of policy across the world (Osborne, 2000; UNECE, 2008; Osborne & Brown 2011). Not only they have been seen as a cost-efficient and effective mechanism for the implementation of public policy across a range of policy agendas, also they have been articulated as bringing significant benefits in their own right, particularly in terms of developing socially inclusive communities. The main arguments that sustains PPPs are mainly three:

1. The withdrawal of the welfare state, which reduces the resources allocated for public services (social services, health, education, infrastructure, etc.) (Taylor et al. 1999; Avi-Yonah & Reuven S., 2000; Blomberg et al. 2000).
2. The ineffectiveness of public sector that are delivering low quality services, whereas private sector or private-public partnerships could be able to deliver better services at the lower cost (Dunleavy & Hood, C., 1994).
3. The bureaucratization of the public sector, which are undermine by a certain inertia due and its inability to innovate and to address new needs (Thiel & Leeuw, 2002).

Likewise, more recently many criticisms have been raised against PPPs that are charged to not be a real occasion of cooperation aimed to add value and share risk of public service provision, but rather to be a way to revert to traditional forms by contracting out and by separating responsibilities (Klijn & Teisman, 2003; Miraftab,

2004). The main critics to PPPs can be described along with five concepts:

- a) Accountability: some scholars pointed out some shortcomings in the accountability of many PPPs. (Willems & Van Dooren, 2011; Swingendouw, 2010).
- b) Autonomy and capacity: other problems could be related to the loss of autonomy and capacity of both stakeholders. There could be the risk of a loss of responsiveness to citizens needs instead of a marketization (Andrews & Van de Walle, 2013) and, on the other end, the risk for private actors of a loss of ability for independent public action and difficulties in the implementation of the partnership itself (Batley & Rose, 2011).
- c) Trust: there could be a need of rules and regulation mechanism aimed to maintain trust, due to the fact that synergy requires partners willing to look for new solutions for joint ambitions and for the exchange of information and ideas (Entwistle & Martin, 2005).
- d) Efficiency: it could occur a loss of capacity in responding to people needs and an inability to produce and deliver efficient public services (Börzel & Thomas, 2005; Hodge & Greve, 2007).
- e) Legal basis of the modern state: another important risk could be the blurring of the demarcation between public and private law (Osborne, 2000).

2 The 4P model

Developing from the criticism arose against the PPPs, and shortly described above, the most recent research begins to consider the possibility of potential new partnerships, stressing the need to improve the value of people in the implementation of urban services (Denhardt & Denhardt, 2011, p.42) through a vision of governance that includes the three main sectors (government, the private sector and civil society) and emphasizes process between many actors with different and sometimes conflicting priorities. People are not only recognized as drivers for shortening the distance between one problem and the way the service response to it is conceived and implemented; they are also viewed as creative communities that can activate processes of radical innovation in services conception and production (Alam, 2004; Boyle & Harris, 2010; see the idea of participatory and collaborative service systems by Manzini et al., 2008 or Baek et al., 2010). A reformulation of existing models is actually founded on the participatory governance

principles (Fischer, 2006) and, when dealing with participatory governance, partnerships are the fundamental structures to consider; therefore, it is necessary to investigate the possibility to reshape the existing types of partnerships. Following this vision, the literature is trying 1) to show how PPP projects have failed to produce certain characteristics, expressed in purchasing processes, which instead appear desirable, and 2) how it is possible to develop a new partnership involving the public and the private sector and people (Private, Public, People partnerships, the 4P model).

In fact, it is necessary that public purchasers and private providers understand the limitations of current practices in order to develop PPP in the future production of services geared more to the needs of users (Ahmed, 2006; Bovaird, 2007; Majamaa, 2008; Majamaa et al., 2008; Kernhagan, 2009; Zhang & Kumaraswamy, 2012). The *4P model* can represent an opportunity for innovation in the practices of urban services production and delivering, within an urban innovation engine (Dvir, 2005; De Witte & Geys, 2013). The public administrations should be able to take advantage of the ability of people to self-organize (Puerari et al., 2013) also using the technologies¹, capturing their needs to foster sustainable communities. They should take advantage from events of collaboration between citizens and institutions, using them as opportunities for a long-term local change, reaching common goals through dialogue, knowledge and resources sharing. The public administration, within these arenas (Denhardt & Denhardt, 2011), which represent the places (physical or not) where the exchange and the interaction between the different actors in the process of supplying urban services can occur, no longer represent the producer or the user; they can rather be, for example, simply the facilitators of the service creation and production, or the actors involved in the service management. The role of the different actors within these processes is flexible, fluid; it may have temporary value, it is determined by the specific context and time in which these innovation engines develop (Periphèria 2013).

Therefore, there is not an optimal model, in which public and private actors together with citizens can be combined to activate and maintain innovation engines, rather there is an infinite set of possible solutions established and defined by the context in which the innovation processes develop. The innovation itself becomes the continuous interaction between the different actors who collaborate in the production of urban services. The

¹*It is interesting to note how the available, accessible and collaborative technologies web 2.0, as blogs, Wikipedia, social-networks, can represent not only different ways for social interactions, but also a new type of citizen involvement in urban life, in the community and in the space of the city itself (Foth et al., 2011).*

stakeholders' engagement strategy has to follow different approaches in every city, defined by the specific context of services production. This includes both the number of additional stakeholders to be engaged and their specific power or ability to involve others that are strictly related to their institutional profile and cultural context.

3 Rethinking urban green areas: the case of Milan

3.1 The case of Milan

The reason for considering the “green areas” case of the Milan Municipality is threefold: 1) “green areas” represent a very traditional urban public service that a municipality is asked to supply and maintain to assure a high quality of life in the city, a good quality of the urban environment, sports, and *loisir* but also good urban ecosystem; 2) in many cities green areas maintenance is challenged by the economic crises so asking for innovation not only in the way maintenance is carried out but also in the service conceptual framework; 3) the whole Parks and green open spaces structure of Milan is currently under discussion and the deliberation process is highly participatory.

Moreover an on-going European project (<http://my-neighbourhood.eu>; <https://www.facebook.com/MyNeighbourhood.eu?fref=ts>), aimed at service co-design in neighbourhood environments, has recently conceived a support for citizens who want to take care of collective (even public) green open spaces; Quarto Gardening is the name of this initiative. In order to guarantee the public and collective value of the Quarto Gardening initiative a long interaction with the public administration has been activated that is producing new hypotheses about the way green public areas can be managed and maintained.

Finally inside the city of Milan many initiatives are emerging that show a increasing civic engagement of the citizens towards whatever has a public value: many social streets are being activated, many public areas are re-qualified by autonomous initiatives of the citizens. Citizens in Milan are showing their will of becoming operational owners of public spaces and start initiatives that are even challenging regulations and praxis of public spaces uses and transformations.

3.2 The material welfare of parks and green open spaces of Milan

The material welfare of Parks and green open spaces in Milan is characterized by the absence of a system that structures both the public and the protected areas, although the presence of rich facilities, that can be effectively used and maintained, and the variety of initiatives aimed at the care of green areas of the city.

Hence, the picture that composes the green open spaces of Milan is hardly to be recognized due to its fragmentation (Balducci et al., 2011). The city is confined in the administrative borders, but the associated social and economic dynamics belong to a mega-city-region of five million inhabitants, extended between Po River and Switzerland. This situation creates an overlapping of powers and the presence of peripheral conditions regardless of the distance from the centre of the city, with a state of multiple identities and centralities, expression of many new forms of citizenship of urban populations. The green open spaces swing between over-use, care without full recognition, abandonment and decay. For example there are overcrowded and over-exposed historical spaces interested to an excess of multitude uses and pressures as the historical parks, able to host the multiple needs of free and organized expressions of public life, as sports and music events and seasonal festivals, intensive use by old and new citizens, foreign population (as *Sempione Park*, *Porta Venezia public garden*, *Ravizza Park*, *Solari Park*, *Forlanini Park and Lambro Park*). On the other end there are wide areas of public properties or public entities or subsidiaries by the public bodies, often situated in the periphery of the city, free of projects that provide a future availability by the use of citizens that are in a state of decay or, in the best cases, assigned to the care of third parties, as farmers. They are considered as 'no men's land', not equipped and not inserted in the lists of project of the public administration. Furthermore, there are some areas, treated outside the ordinary structured management and administrative practices. These are large and very minute areas, built through different processes and often with the 'distraction of the institutions' (see *Giambellgarden*, *viapadovaseminaviapadova*, *Isola pepe verde*, etc.).

Observing the green spaces of Milan it is possible to recognize the structure of a parallel city through the trigger of technical and cultural engagement process aimed to realize the objectives through a designed project, but, also, through partial initiatives that are part of an ecology, where each person or institutions (City Council, parks administrations, committees, associations and people) can give the best contribution of ideas and actions.

Moreover, in Milan recently revealed in his evidence, but actually matured in very different forms over at least 40 years a new idea of collaboration between citizens, associations, committees and the public administration is being developed, which is strictly related to the need of people/association/public entities for better green public spaces. It is an element of great interest since it seems to represent a way not usual and not strictly institutional to activate a process of construction and reform of public spaces equipment that integrates aspects of tangible and intangible welfare, which mobilizes multiple energies and civic resources (Munarin & Tosi, 2012). This active and prolific environment, as a primordial soup, could become an urban innovation engine (Dvir, 2003, 2005) and trigger, generate and catalyse innovation that could restore Milan Green Areas.

In particular, many initiatives aimed to the green areas management, are proliferating in the Milan territory. This complex constellation of urban innovation epiphanies (Puerari et al., 2013), composed by a rich environment of initiatives and associations, each of them characterized by a different management model, different level of institutionalization and maturity (i.e. *Cura e Adotta il verde pubblico*, *viapadovaseminaviapadova*, *isola pepe verde*, *Quarto Gardening*, see Table 01, but also some institutional entities as the representatives of *Parco Nord*, *Parco delle Cave*, *Parco Sud*, *Media Valle Lambro*, etc.), is becoming a viral trigger for the public administration for rethinking new possible modes to provide the management of the public green areas.

Table 01. Some of the initiatives aimed to the green areas management that operates in the Milan territory

Name	What	References
Cura e adotta il verde pubblico	It is an initiative promoted by the public administration that gives the possibility to private enterprises and citizens to participate in the maintenance of green areas of the city. It provides different ways for the care of the green areas (the technical sponsorship, the financial sponsorship, agreement of technical cooperation, etc.). Each care action is allowed by official contracts between the adopter and the public administration.	http://bit.ly/1bff55k https://maps.google.it/maps/ms?msid=209401580085820538987.0004e36cc28727f0fc930&msa=0&dg=feature
viapadovaseminaviapadova	It is a grassroots initiative promoted directly by the citizens of a specific neighbourhood situated in the North East of Milan. They decided to join the “environmental committees for Milan”, aimed to the environmental rehabilitation of the green areas.	https://www.facebook.com/viapadovaseminaviapadova?ref=ts
Isola pepe verde	It is an initiative promoted by a group of citizens living in the neighbourhood “Isola” that decided to found an Association in 2011. Their motivations	https://www.facebook.com/pages/Isola-Pepe-

	come from the lack of green spaces of the neighbourhood, a situation stressed by the closure of a near garden in 2007. The association aims to maintain a small area, mostly fenced, owned by the City Council, which includes a green area and a parking area. In May 2012 the public administration provided the regulation related to the “shared garden initiative” aimed to regulate situation like this one and in May 2013 the area became an official “shared garden”.	Verde/125389367522362?fref=ts https://isolapepeverde.wordpress.com/
Giambellgarden	It is a grassroots initiative, located in the south west of Milan, which was born thanks to the help of a specific project aimed to the creation of new urban gardens around the city, thanks to the help of a foundation. It is aimed to maintain some orchard and a small green area around them. This project represents a possibility of socialization for foreigners and people with low income that lives the near neighbourhood.	http://www.progettopuntoelina.it/giambellino/index.php/laboratorio-di-quartiere/81-giambellgarden.html
Quarto Gardening	It is a service aimed to the care of public and collective green open spaces of the Quarto Oggiaro neighbourhood. It is the result of an on-going EU-Project (my-neighbourhood) that involves the public administration and citizens, searching for a new solution for the maintenance of the green areas.	http://my-neighbourhood.eu/c/contacts/ https://www.facebook.com/MyNeighbourhood.eu?fref=ts

3.3 The “Green Table” initiative

In this active environment, another important collective actor was born in 2011, within the “*ChiamaMilano*” initiative, which aims to provide communication tools for the citizens of Milan, to discuss various topic of interest for the city and to promote citizens participation and access to the decision taken by the local institutions in order to improve their quality of life, the “*Green Table*”. Its main goal is to improve the maintenance of the green areas of Milan and it has the important role of catalysing needs, suggestions and priorities of some association and other important actors that operate for the maintenance of the green areas with regard to innovate their management. This peculiar actor has activated a process of civic activism and awareness aimed to a structural change and innovation of the structural vision and management of the green areas.

At the current stage, it is possible to identify four different steps in the development of this long and complex process (see Table 02).

Table 02. Key Actors and related cognitive roles

	What	Actors	What Knowledge
Step 01	Physical and structural vision	Activist joining the “Green table“	<ul style="list-style-type: none"> • Spatial Planning • Landscape Design
		Representatives of the associations joining the “Green table“	<ul style="list-style-type: none"> • Experiential on park management. • Ecology • Agriculture
		Coordinator of the “Green table”	<ul style="list-style-type: none"> • Coordination • Participation processes
Step 02	New vision for a green Milan	Counsellor (Milan environmental system)	<ul style="list-style-type: none"> • Administrative
		Academic consultant of the Counsellor	<ul style="list-style-type: none"> • Spatial Planning • Landscape Design
		Officers of the (Milan environmental system council)	<ul style="list-style-type: none"> • Spatial planning • Administrative
Step 03	Strategic Document of “Green Table”	Representative of the associations joining the “Green table“ (1)	<ul style="list-style-type: none"> • Experiential on park management • Territorial Development • Ecology
		Representatives of the associations joining the “Green table“ (2)	<ul style="list-style-type: none"> • Experiential on park management • Agriculture
		Academic consultant of the “Green Table” (1)	<ul style="list-style-type: none"> • Spatial Planning • Geographic Information System
		Academic consultant of the “Green Table” (2)	<ul style="list-style-type: none"> • Spatial Planning • Territorial Development
Step 04 (on going)	Map	Academic consultant of the Counsellor	<ul style="list-style-type: none"> • Spatial Planning • Landscape Design
		Academic consultant of the “Green Table” (1)	<ul style="list-style-type: none"> • Spatial Planning • Geographic Information System
		Representatives of the associations joining the “Green table“	<ul style="list-style-type: none"> • Experiential on park management. • Ecology • Agriculture

The first step is characterized by a totally grassroots character, during which the representatives of the associations, an activist joining the “Green table“ and its coordinator have collaborated to define a new Physical and Structural Vision, justified by the environmental system of Milan. At first, this Vision consisted of the Environmental System in Milan, which at this time included all the green areas existing in the mega-city region and which was twofold: the *ecological system of Milan* that including the *shape and measures dimension* (dimension, shape and location), influenced by the *management dimension* that comprising the *management actors* (institutions, municipality, private actors) (see Figure 01).

Figure 01. Step 01. Physical and Structural Vision

This step was necessary because the previous existing plan of the Milan green areas (Annex of the PGT 2010 of Milan), which was meant to foresee the creation of a green belt around the city and eight green beams that were supposed to connect the periphery to the centre. This plan was restricted to the administrative boundaries of the municipality of Milan, without taking into account the metropolitan dimension of the Milan environmental system. The final stage of this first period was the presentation of this vision to the citizens and to the public administration, in particular to the Counsellor of Milan environmental system and to the Counsellor of Milan Urban Planning, during an official event that took place in the City Council on April 20th 2013. This was the occasion for the Public Administration to recognize the role of the “Green Table” as the link between the public administration and the citizens, useful to capture contributions and suggestions in order to learn from people and organizations that operate onto the environmental system of Milan.

Triggered by this event, the process went on with the Counsellor of Milan environmental system assuming the responsibility, with the help of an academic consultant and of the officers of the Milan environmental system, to elaborate a document, which showed the changes and the enrichment of the perspective (see Table 02, Step 02). A document was elaborated (“The new vision for a green Milan”) and presented to the “Green Table” (October 10th 2013) during an official meeting, held at the Urban Center of Milan and also attended by the Counsellor of Milan Urban Planning, and then approved by the Milan City Council (November 29th 2013) (Deliberazione della Giunta Comunale n.2400 del 29/11/2013).

This new document extended the perspective and enhanced the process toward the metropolitan area: the environmental system of Milan matches with a vision for the whole

city (see Figure 02). The *management* of the green areas was based not only on the recognition of a plurality of subjects and actors, but also on the *management praxis* (agronomic principles, landscape conservation, care techniques, ecological principles, reduction of financial costs) that were influenced by the *property regime of the areas*. This structure of the management dimension was based on a continuous process of sharing between these areas under the regulatory role of a vision coordination played by the municipality. This process would be facilitated by the assumption by the Counsellor of Milan Environmental System of various positions within the City Council (Territorial Welfare Policies, Policies for Human Resources, Promotion of Sports and Sport Associations, Development of events, General Services, Protection of Animals, Relations with Local Institutions).

Moreover, this document underlined how the relation between the *management dimension* and the *ecological system* was no longer univocal, but mutual: the two dimensions are interrelated and affect each other. The ecological system included not only the *shape and measures dimension*, but also the *components of the ecological network* (simple green areas, gardens, agricultural areas, parks, water network). This vision assumed the landscape as a fundamental element that influences the Milan ecological system through a unitary vision. Similarly, the accessibility and usability of the existing areas influenced and were influenced by the ecological system, aiming at the reconnection of the existing heritage that only need to be visible and connected with the all green areas.

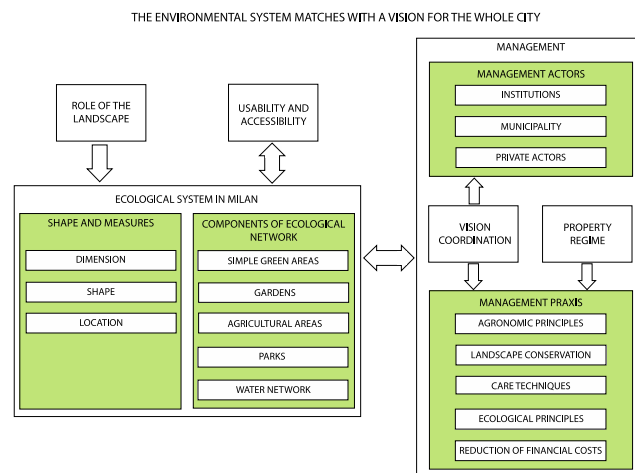

Figure 02. Step 02. New Vision for a Green Milan

Starting from this vision, the Counsellor, recognizing its bonding nature between the municipality and the citizens that operate in the green areas, invited the “Green Table” to continue its work in the offices of the Milan City Council to enforce the relation and to elaborate a strategic document that would be useful for the public administration to better know and understand the wills and the necessity of these various stakeholders (see Table 02, Step 03). This third step started in January 2014 and, within the action of the whole “Green Table”, involved four fundamental actors: two representatives of the association that operates in the green areas and two academic consultants. This process ended in the first days of March 2014 and pushed further the vision proposed by the public administration. The delivered document stressed in particular the idea that it would be the citizen’s participation that helps in build the environmental system of Milan, assuming that the green areas are a constrain for the city growth: in fact not only the existing green heritage of the city has to be part of the environmental system, but also the missing links between the existing green areas have to be recognized and protected as fundamental elements together with the necessary reuse of the abandoned areas (see Figure 03).

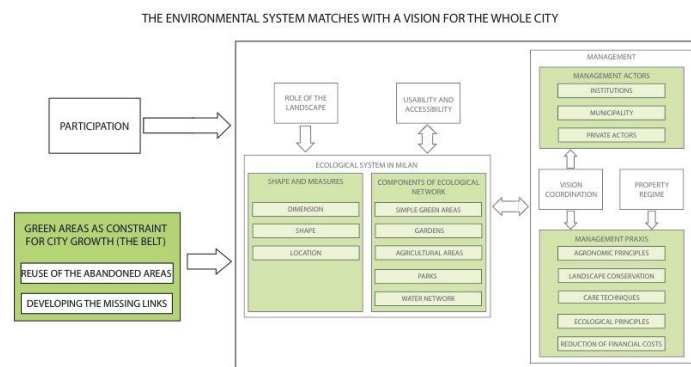

Figure 03. Step 02. Strategic Document of “Green Table

The strategic document of the “Green Table” shows how a mapping activity is required to drive the process further to identify other associations and movements that are working and experimenting new ways of managing green areas in Milan to increase the participation and the awareness of the public administration about these topics, but also to identify the existing abandoned areas useful for a reuse and the areas where there are missing links between the existing and already recognized green areas. The map will

show what are the current uses of the different green areas, the use recognized by the existing plan, but also what are the dimensions and the actual management activity and the rules provided for each area. This fourth step is still in progress and is involving the representatives of the association joining the green table, the academic consultant of the Counsellor and an academic consultant that is participating at the “Green Table” (see Table 02, Step 04).

4 Conclusions

The case analysed in this paper allows some considerations that may have a general value considering that many cities are nowadays rethinking their modes to provide public services. The maps developed in the previous paragraphs represent the evolution of the Milan “green infrastructure” concept and show how the concept enriched throughout the interaction process in a way that moved from considering the simple shape and extension dimension up to including procedural, maintenance and governance elements. It moved from the spatial quality of the green areas system to the whole public service conception; from a simple list of the green areas to the mapping of a complex service system including spatial, actors and procedural resources and the way these can become a value for a territorial system that is even larger than the Milan municipality.

The governance model that emerges from the analysis is not simply a PPPP one; it is not simply considering the diversity of the actors involved and their possible roles. The governance model is based on the 4P model but it is richer than that: it shows that the governance is the result of a learning process that involves knowledge in action, or better action as knowledge. Many of the actors involved in the making of the governance are transforming their own experiences into a cognitive infrastructure of the emerging governance.

While the service is innovated, its governance is reshaped, thus showing this is not a simple change in the service production and supply, it is rather a significant innovation process able to reframe the whole vision, urban vision, behind the service and the way it is created and produced.

Many innovation forces are active in urban environments; such forces are often aligned with the most recent concepts of innovation and suggest very far looking modes for service supply which involve citizens in the activation of changes, sometimes also radical changes, asking for public administrations to act as enabling, legitimation, and

supportive agents. Within these changes, new and original forms of government and governance are suggested which an innovation oriented urban administration has to “sense” and “capture” to capitalize their innovative cognitive capital into the innovation of public services. In the Milan case the “sensing” was effective and transformed a bottom-up initiative into a innovation process that is affecting the way the public administration is conceiving the green areas and also the whole urban system of public spaces.

Note: This paper is the result of a collaborative work. Nevertheless paragraphs 1, 2 are by Emma Puerari; paragraph 4 is by Grazia Concilio; paragraph 3 is the result of a collaborative writing by Puerari and Concilio. Antonio Longo contributed to the article with his knowledge and information about the case study

Corporate governance and economic sustainability: some thoughts based on the Albanian case

Structured Abstract

Purpose – Corporate Governance (CG) is considered an important element in improving firms’ long-term financial performance, increasing their asset values and, as such, it can be of benefit to society at large. This paper aims to analyze CG within the Albanian context. Given its importance, Albanian companies face an urgent need to assess CG standards and promote CG reforms in order to improve their performance and become able to attract foreign direct investment. This paper explores the specific transformations that Albanian managers face in the current dynamic and complex business environment, and the need for sustainability based on “good” CG practices.

Design/methodology/approach – The Delphi technique is adopted. This technique is based on the rational principle that ‘n’ human minds are better than one when confronting lack of precise knowledge about a certain problem/research question (*cf.* Ferreira and Monteiro Barata, 2011). In this approach, a sequence of successive individual questions is asked and then supplemented with information and advice, to correct the first stages of the process and, under certain parameters, generate consensus. The overall characteristics of the Delphi process are anonymity, controlled feedback, and statistical treatment of the group responses. The Delphi technique is typically applied in situations where the problem under discussion cannot be resolved by precise analytical techniques, because there are no historical data or relevant information available (*cf.* Ferreira and Monteiro Barata, 2011; Çipi *et al.*, 2014).

Originality/value –This paper delves into the relatively unexplored topic of CG practices in Albania, regarding which there is currently very little research or information. Furthermore, it does so by studying the application of a methodology (the Delphi technique) which has not, to the best of our knowledge, been applied to such a context before. Empirically, our investigation involves a panel of CEOs from Joint Stock Companies’ (JSCs) from the most representative cities in Albania.

Practical implications – The outcomes of our study should serve as reference for further efforts aimed at enhancing CG in Albanian companies. They should also serve as catalyst for international comparisons and, from a benchmarking perspective, for the adoption of internationally recognized CG best practices by Albanian companies. This can be seen as a “key to sustainability”, meaning that a broader perspective should be adopted in future CG reforms in Albania to support sustainable economic development. Indeed, a better awareness of the long-term benefits of CG best practices can help Albanian JSCs attract powerful foreign investors and, thereby, boost the country’s development.

Keywords – Corporate Governance, Development Prospects, Sustainable Growth, Albania, Joint Stock Companies.

Paper type – Academic Research Paper.

1. Introduction

The implementation of good Corporate Governance (CG) has been argued to generate numerous positive consequences for the company and society as a whole. Good governance has been shown to contribute to: i) improved performance and operational efficiency; ii) better access to capital markets (as investors are typically more willing to invest in firms with effective governance); iii) lower costs of capital; iv) increased asset values; and v) positive image and reputation effects among both internal and external stakeholders (Çipi *et al.*, 2014). Empirical evidence shows that CG even matters for achieving sustainable economic growth. Good CG in large companies can further serve as an example and standard for Small and Medium Enterprises (SMEs), thus leading to a more favorable business environment overall. It has a long-term influence on the development of financial markets, economic risk and tends to lower the degree of corruption and mismanagement in businesses and political circles, thus influencing sustainable economic growth.

This suggests that CG is not only important in developed markets but also in transition economies such as Albania. The challenge of CG in Albania is to generate a
