FOREWORD

A very warm welcome to the 9th edition of the International Forum on Knowledge Asset Dynamics (IFKAD2014). In the last nine years since we held our first conference in Matera, the IFKAD community has tremendously increased transforming IFKAD in one of the major and renowned international events focused on knowledge-based development.

Over the years the Forum, which has been attended by many of the world's leading experts in the Knowledge and Intellectual Capital Management, has been documented in conference proceedings and several special issues of high-quality journals.

This year the IFKAD conference brings together academicians, policy makers, practitioners and young researchers from different fields to provide an opportunity for discussion and debate regarding “Knowledge and management models for sustainable growth” from a wide range of perspectives – economic, social, environmental and cultural.

The aim is to explore the relevance of Knowledge and Intellectual Capital management for supporting organizations as well as regional and urban systems in their value creation dynamics according to a sustainable growth perspective. This involves the understanding and development of approaches, models and tools for effectively managing key-knowledge value drivers to support the sustainable growth of organizations and communities. Particular attention is paid on the role of the knowledge assets dynamics on the design and development of innovative models and interventions in order to provide solutions to problems at organizational, social and urban scale exploiting intangibles, skilled workforce, relationships, and advanced technologies.

The programme of this year's conference is just as rich and enlightening as previous conferences. We have an exceptional line of keynote speakers who will share their research and practical insights as well as inspire new reflections and research paths. We have over 200 speakers and 40 countries are represented at the conference. This is further characterised by an excellent combination of papers from academia and practice. Presentations will be on issues as wide ranging as Knowledge management models and strategies for sustainable growth of organizations and communities; Knowledge resources management for sustainable innovation; Models, approaches, methods and tools to support sharing, creation and exploitation of knowledge for sustainable value creation dynamics; Knowledge value drivers and sustainable health systems; Knowledge and social innovation models for sustainable development; Performance measurement and sustainable growth of organizations and communities as well as Arts-based initiatives and creativity as a resource for sustainability.

The IFKAD conference has made excellent progress. Behind this success there is the work and support of numerous people. In this regard, we would like to thank all the authors, chairs and reviewers for their valuable cooperation in building IFKAD 2014. A special thank to the organising committee that passionately has worked to make another excellent and memorable event.

We are really honoured for your participation and we look forward to meet you in occasion of IFKAD 2015.

Conference co-chairs

Daniela Carlucci, Giovanni Schiuma, JC Spender

Structured Abstract

Purpose – Due to the small size and to the high level of labour division, small firms in Industrial Districts need to establish horizontal and vertical cooperative relationships (Camuffo and Grandinetti, 2011; Malberg and Maskell, 1999) in order to share and combine complementary knowledge assets. Whilst the network approach (Granovetter 1985; Powell, 1991) has greatly contributed to the understanding of knowledge exchange processes in IDs and of their influence on performances, research on small firms' networks has mostly assumed the network structure as a given. According to this gap, the purpose of the paper is to answer to the following research questions: is knowledge complementariness among firms in an industrial district a sufficient condition to let supply networks to emerge? What is the effect of relational embeddedness in determining the structural properties of these networks?

Design/methodology/approach – We adopt an approach grounded on complexity science and consider the Industrial District as a Complex Adaptive System (Holland, 2002). The methodology used in the research is the agent-based simulation. We present an agent-based model of a stylized ID and build on it a virtual laboratory in which we perform generative experiments (Epstein and Axtell, 1996), in order to answer to the above research questions.

Originality/value – In the literature on firms' networks, *topological works* study how specific network structure influence the intensity of knowledge flows among a network's firms. Our perspective is dual to the topological one: by not assuming that links among firms are pre-existent our objective is to generate the network topology with the help of an agent-based computational laboratory.

Our contribution would be on different aspects: 1) we would explore how knowledge exchange processes can generate the emergence of network structures; 2) we analyse this topic in the context of small firms' clusters, taking into account the crucial role that social

characteristics of these systems play in shaping the phenomenon of network emergence; 3) the paper aims at contributing to the literature stream of dynamic emergence and evolution of supply networks, with a specific focus on the impact of collaborative strategies of agents on the emergent structures of networks.

Practical implications - Main results of simulation experiments show that for every experimental set a stable network of links emerges among firms of the simulated ID. In addition, through the generative experiments we are able to identify certain conditions under which the emerged networks exhibit a hub&spoke structure. The model here proposed is not a case-based model, but an ideal-typical computational model, aimed at exploring and identifying a micro-macro relationship that could be applied to a class of empirical cases. As a consequence, the present research does not request, at this stage, a strict relation between the model and the empirical reality. The simulation is devoted to produce research hypotheses to be tested further using traditional methodologies. As this empirical validation process will be completed, the computational laboratory that has been presented in this paper could be used as a tool to support policy analysis e policy making decision processes.

Keywords – knowledge exchange, supply networks, industrial cluster, agent-based modelling.

Paper type – Academic Research Paper

1 Introduction: supply networks in flexible specialized industrial districts

In the last fifteen years a new stream of research (Choi et al., 2001; Li et al., 2010; Pathak et al., 2007; Surana et al., 2005) in supply chain management literature has emerged that frame supply chains and networks as Complex Adaptive Systems (CAS).

A CAS is a system characterized by a large number of autonomous and heterogeneous agents, that interact locally and simultaneously according to some simple behavioural rules (Holland, 1992). Agents learn and adapt to both the environment and to the other entities populating the system. Non-linearity, emergence and self-organization are the most relevant properties of a CAS and all are related to the huge amount of parallel interactions among the agents of the system. CASs are systems in which new patterns, structures, and aggregate behaviours or properties *emerge* from the bottom-up (Epstein and Axtell, 1996) as “nonlinear and dynamic function of the large number of activities made in parallel by interacting entities” (Pathak et al., 2007). The non-linearity implies that the collective behaviour of the system cannot be reduced to the sum of the local behaviours of its components. Emergence and self-organization refer to the emergence

from the bottom-up of an order that is not imposed by a central controller (Holland, 1992). Examples of CASs can be identified in several fields of natural, human and social life: the ant colony system, the human immune system, trade markets, industrial clusters and supply networks represent only a limited group of systems recognized as Complex Adaptive Systems.

In their seminal paper, Choi et al. (2001) define the supply network as “a network of firms that exist upstream to any one firm in the whole value system” and suggest that the networks refer not only to the materials flow but also to the knowledge flow.

Furthermore, they argue the claim that supply networks cannot be simply recognized as “systems”: supply networks are Complex Adaptive Systems.

Recognizing supply networks as CAS implies a new approach to the topic of supply chain management: from a deterministic approach focused on deliberative and control aspects to a new perspective based on the concepts of emergence and self-organization.

Starting from this seminal work, additional papers (Surana, 2005; Pathak et al., 2007; Nair et al., 2009; Li et al., 2010) have further developed the conceptualization proposed by Choi et al. (2001). All these studies are mainly devoted to suggest the need of changing the perspective in supply chain management, by considering the self-organization, the non linear dynamics and the emergence as fundamental properties to be taken into account by decision makers and to be better explored and understood at the research level.

The contribution of this paper would be in this direction, by adding new elements or steps in the process of understanding of supply networks as emergent patterns. In particular, we focus on how local interactions among small firms of a value chain exchanging knowledge assets (Esposito and Raffa, 1994) can let the emergence of a supply network structure.

The spontaneous emergence of structures and the self-organization of supply networks are particularly evident in the context of flexible specialized Industrial Districts (IDs). IDs are geographically localized production systems characterized by a large number of small and medium sized firms that are involved in various phases of the production of a homogeneous product family (Becattini, 1989)

These firms are highly specialized in a few phases of the production process and join up in supply chains in a flexible and dynamic way depending on market opportunities. Thus, within IDs a spatial labour division is accomplished (Piore and Sabel, 1984).

In particular, two forms of labour division characterize the IDs production model: vertical and horizontal division of labour. Vertical division of labour takes place among ID firms involved in different phases of the production process. Each phase represents a stage of the supply chain. Horizontal division of labour occurs among ID firms involved in the same phase of the production process. These firms may act with different degrees of specialization in the same production phase. For example, if a firm is specialized in a single product it establishes inter-firm relationships with other companies operating in the same production phase to acquire additional labour capacity. Both types of labour division favor the formation of a dense network of inter-firm relationships in which cooperation and competition coexist. In particular, inter-firm cooperation within neo-marshallian IDs has been traditionally developed to a greater extent vertically rather than horizontally (Albino et al., 2007).

By adopting a theoretical perspective influenced by social network theory and complexity science, a stream of literature, mostly developed in the '80s and '90s, attributed IDs' effectiveness to the richness of IDs' underlying relational systems (Aydalot, 1986; Becattini, 1989; Brusco, 1982; Camagni, 1989; Rullani, 1992).

The network perspective (Granovetter, 1985; Powell, 1991), though acknowledging the relevance of transaction cost economics, emphasizes the social and cultural determinants of inter-firm relationships, like the role of informal transactions (Uzzi, 1997), the sharing of norms and culture, reciprocity and trust (Jones et al., 1997). A key characteristic of social networks is that they allow efficient access to knowledge resources for members of the network (Podolny and Page, 1998) as well as the creation of idiosyncratic and valuable knowledge resources thanks to the sharing and integration of individual knowledge. Furthermore, thanks to geographic proximity and the availability of social capital, IDs are privileged loci for tacit knowledge diffusion (Inkpen and Tsang, 2005).

Whilst the network approach has greatly contributed to the understanding of the complexity of knowledge exchange in IDs and its influence on IDs performances, research on small firms' supply networks has mostly assumed the network as a given.

The aim of this paper is to fill this gap in the literature by implementing an agent-based model that simulates the mechanisms of interaction and exchange of complementary knowledge between the firms of an ID in order to predict the structural

properties of the supply networks that emerge from these interactions and to identify those that can guarantee the best innovative performance at the system level.

In particular, we are interested in exploring: i) if the firms' need to exchange complementary knowledge is a sufficient condition for the emergence of stable supply network structures; ii) if so, what are the structural properties of the networks that emerge as a result of the mechanisms of interaction and exchange of knowledge; iii) whether and how different behaviours undertaken by the district firms, in order to maximize their knowledge endowment, can affect the characteristics of the networks emerging from the interaction of actors at the local level.

2 Background: network structures and knowledge flows

The literature on firms' networks (Dyer and Singh, 1998; Dyer and Nobeoka, 2000; Human and Provan, 1997; Levinson and Asahi, 1996) has widely recognized networks of firms as loci for innovation, knowledge creation and inter-organizational learning (Podolny and Page, 2000).

A firms' network consists of a collection of (often small) autonomous actors that pursue repeated and enduring reciprocal exchanges aimed at creating products or services for final markets. Examples of firms' networks are R&D consortia, trade associations, strategic alliances and also Industrial Districts (Inkpen and Tsang, 2005).

Repeated, enduring and structured relationships are the main rationale behind the capability of networks to spread and diffuse knowledge among their members (Inkpen and Tsang, 2005). The literature on firms' networks proposes different approaches to the analysis of knowledge exchange/transfer phenomenon.

Topological works study how specific network architectures and related structural properties influence the intensity of knowledge flows among a network's firms and the knowledge accumulation performances at the firm and at the network level. The research in this stream refers, from the theoretical point of view, to social network theory and, from the methodological point of view, to social network analysis. Furthermore, the focus is on different kinds of networks, such as strategic alliances, intra-corporate networks, lead firm-networks or supply networks. Structural properties of networks that have been proven to influence network performance (e.g. knowledge diffusion, learning, innovation, etc.) are density, centrality and the existence of cliques (Provan et al., 2007). The stream

of research on the *management of innovation* is aimed at identifying key characteristics of successful learning and diffusion of innovation in networks. Papers in this stream are mainly focused on strategic alliances or productive networks, such as supply networks (Dyer and Nobeoka, 2000; Lorenzoni and Lipparini, 1999), and adopt qualitative research methodologies such as single or multiple case studies (Esposito et al., 1997) . These studies provide interesting narratives to analyze specific knowledge sharing routines in order to gather insights and lessons learned for the development of governance and management guidelines to support efficient learning dynamics in networks.

Both the *topological* and the *management of innovation* approaches assume network architecture as given and neglect the problem of how specific structural arrangements can emerge and dynamically evolve from bottom-up interactions among agents exchanging and sharing knowledge.

There are important researches on networks' formation and on their dynamic evolution (Gulati, 1999; Gulati and Gargiulo, 1999). These studies are almost exclusively focused on the firm or on the dyads level and mostly analyse the specific context of strategic alliances. Finally, in this field there is yet a lack of works that approach the problem of network structures formation from the bottom-up using a simulation approach, with few exceptions.

Ozman (2007), for example, uses a simulation model to explore whether knowledge tacitness and environmental turbulence affect the emergent structure of firms networks built up to exploit-explore external knowledge sources. The proposed simulation model is an agent-based model in which firms construct external linkages for the purpose of learning via exploitation or exploration. Ozman's model shows that stable environments and codified knowledge result in the emergence of local star firms. When knowledge tacitness and environment turbulence increase, local stars become global stars.

Cowan, Jonard and Zimmermann's paper (2007) on networks as emergent structures from bilateral links is another important exception to the most common approach to the problem of knowledge exchange in firms' networks. This work explores which kind of networks emerge from bilateral collaborations between firms aimed at exchanging knowledge. Two elements influence alliances and network formation: the way in which agents pool their knowledge resources and the way in which they select and choose partners. Repeated bilateral partnerships result in the emergence of innovation networks

and in certain parts of the parameter space these networks have properties of small worlds.

This last paper provides a number of points of reference which we build upon: our theoretical perspective and methodological approach are very similar to those of Cowan et al. research (2007). Our perspective can be considered dual to the topological one: by not assuming that links among firms are pre-existent our objective is to generate the network topology with the help of a computer model by making minimal assumptions about the rules governing the exchange mechanism. In particular, we are interested in exploring structural properties of supply networks emerging from links among small firms in an Industrial District, assuming that these links are created out of need to exchange complementary knowledge assets and that the choice of partners is influenced by relational embeddedness.

The contribution of this paper would be on different aspects: first of all, we would explore in general the topic of how knowledge exchange processes among heterogeneous agents can generate the emergence of network structures; secondly, we are interested in exploring the interplay between knowledge exchanges and network architecture in the context of small firms' clusters, taking into account the crucial role that particular social characteristics of these systems play in shaping the phenomenon of network emergence; thirdly, the paper aims at contributing to the literature stream of dynamic emergence and evolution of supply networks, with a specific focus on the impact of collaborative strategies of agents on the emergent structures of networks.

3 Methodological approach

The methodology adopted in this research is the Agent-Based Modelling (ABM). ABM is recognized as one of the most proper tools of complexity science (OECD Global Science Forum, 2009), in particular for policy advice and decision making concerns.

ABM is a computational method to model and simulate complex systems made by several agents that interact to each other and with the environment (Gilbert, 2007). Modeling and simulating complex agent-based systems could have different, not alternative, functions: exploring in a virtual laboratory the dynamic behavior of a system or a phenomenon that could be difficult to investigate through the observation in the real world; performing generative experiments (Epstein and Axtell, 1996) in order to establish

if a set of micro-specifications is able to determine the emergence of observed, plausible or eventually unexpected macroscopic regularities and growing new theories from the bottom-up; solving formal problems that are not analytically tractable (Gilbert and Terna, 2000). Furthermore, agent-based models can be classified with respect to their target according to a taxonomy proposed by Boero and Squazzoni (2005) for models used in social science. They classify agent-based models in: 1) case-based models; 2) ideal-typical models; 3) abstract models. Case-based models are those strictly related to the empirical world, aimed at finding a micro-macro relationship to better understand a circumscribed empirical case. Ideal-typical models are “theoretical constructs” (Boero and Squazzoni, 2005) used to explore mechanisms that apply to a specific class of empirical phenomena. In this case, the full correspondence between the model and the empirical reality is not a requisite of this class of models. Finally, abstract models aim at representing in a simple way general social phenomena (Carley, 2002). The above categories differ for their diverse targets and, as consequence, for their relationship with empirical reality.

In this research, the ABM is used to identify a possible micro-macro (knowledge exchange mechanisms – network structures) relationship that could apply in a specific class of phenomena (flows of complementary-specialist knowledge assets among small subcontracting firms in flexible specialized industrial districts). The proposed model is, thus, a “typification” that does not refer to a well defined empirical case (a specific industrial district), but relate to some stylized facts concerning the empirical reality of traditional industrial districts.

In the following section the proposed model is described.

3.1 The model

The model represents a canonical Industrial District (ID) (Becattini, 1989; Markusen, 1996). According to Becattini (1990), the canonical neo-marshallian district is “a socio-territorial entity which is characterized by the active presence of both a community of people and a population of firms in one naturally and historically bounded area.”

The main characteristics of the canonical neo-marshallian ID are (Becattini, 1990, Markusen, 1996; Paniccchia, 1998): a business structure dominated by small firms, substantial intra-district trade among buyers and suppliers, low-level cooperation with firms external to the district, vertical cooperation prevailing over horizontal cooperation,

strong labor division according to the flexible specialization model (Piore and Sabel, 1984), geographical proximity among firms facilitating the emergence of a common culture and of reciprocity and trust.

As said before, the construction of the model is based on some stylized facts reported in theoretical and empirical literature on IDs. In particular, the model: i) reproduces the business structure of traditional IDs characterized by small firms (limited relational capability, specialization of each firm in one phase of the productive process); ii) assumes the geographic proximity among firms. The physical proximity among agents of the model is taken for granted in the sense that the typology of social relations among district's firms and the typology of their transactions are typical of co-location (Albino et al., 2000; Albino et al., 2007; Brusco, 1990). Only links internal to the district are considered and, as a consequence, the specific measure of distance among agents does not matter in the model; iii) represents the high level of labor division typical in canonical districts; iv) allows for vertical cooperation; v) reproduces some socially-determined mechanisms regarding partners choice.

A major simplification in the model is that the cluster is a closed system into which external firms cannot enter. Although this restriction certainly represents a limitation of the model, in stable phases of their existence, neo-marshallian IDs can be assumed to be very similar to closed systems because they tend to exhibit low entrance rate and high level of embeddedness of existing links (Markusen, 1996).

In the followings, the building blocks of the model are illustrated in depth.

3.1.1 The agents

The agents of the model represent the firms of an ID. According to the flexible specialization model, firms are specialized in different phases of the production process and the corresponding agents are divided into three different classes.

Figure 1 - Graphical representation of the firms in the ID through NetLogo interface

As shown in Figure 1, blue nodes represent the “contractors”, green nodes represent the “first-tier sub-contractors” and the yellow nodes represent the “second-tier sub-contractors”. The contractors directly interact with the enterprise customer, represented by a red node on the top in the grid-space; the first-tier sub-contractors can exchange goods and information with the contractors and with the second-tier sub-contractors; the second-tier sub-contractors receive raw materials and resources from the raw materials suppliers, represented by the red node on the bottom in the grid-space.

The firms are arranged in the grid-space of the simulation environment on five different levels, in relation to the different stages that comprise the supply chain.

The formation of the supply chain has been assumed to proceed from the top down. In fact, when a contractor receives an order from an enterprise customer, to be able to cope with the request it must necessarily rely on the cooperation of the firms at the level immediately below. In other words, in the model is not simulated the market demand or the awarding of an order to the contractors. What is simulated is a part of the response mechanism.

To each agent of the model a knowledge assets vector is associated:

$$K_j = [c_{j1}, c_{j2}, \dots, c_{jn}] \quad (1)$$

Each dimension c_{ij} represents the knowledge level achieved by the firm j -th in the i -th asset. In the proposed model n is settled equal to 3. Consequently, to each agent a three-dimensional knowledge vector is associated:

$$K = [c_1, c_2, c_3] \quad (2)$$

whose elements represent the knowledge level achieved by the agent in three different categories of knowledge and that evolve over time through a knowledge exchange. Knowledge levels are measured through real positive numbers in the interval $[0, \text{knowledge_limit}]$, where the “knowledge_limit” is a parameter introduced in the model and set equal to 100. In the simulation model there are 90 firms of which 20 are the contractors specialized in c_1 , 30 are first-tier subcontractors specialized in c_2 and 40 are second-tier subcontractors specialized in c_3 .

At the beginning of simulation each agent is supplied with a certain knowledge level depending on its specialization. In particular, in order to parameterize the knowledge level possessed by the firms in each category, the variable $k = (\text{knowledge_limit} / 10) / 2$ is created. In this way, to each firm is assigned a random value in $[k, k + \text{random } k]$ for the knowledge category in which is specialized and the value k in the other two categories. For example, if knowledge_limit is set equal to 100, the value of knowledge level in which each type of firm is specialized is randomly chosen in $[5, 10]$, while in the other two knowledge categories is equal to 5.

Consequently knowledge vectors are defined as follows:

$$\begin{aligned} K_{\text{contractors}} &= [c_1, c_2, c_3] = [5 + \text{random } 5, 5, 5] \\ K_{\text{first-tiers subcontractors}} &= [c_1, c_2, c_3] = [5, 5 + \text{random } 5, 5] \\ K_{\text{second-tiers subcontractors}} &= [c_1, c_2, c_3] = [5, 5, 5 + \text{random } 5] \end{aligned} \quad (3)$$

The knowledge level of the enterprise customers and raw materials suppliers is set equal to:

$$K = c_r = 5 \quad (4)$$

In addition, every agent has its own Absorptive Capacity (AC). The AC is a construct used to measure a firm’s ability to value, assimilate, and apply new knowledge (Cohen and Levinthal, 1989). The principal element to determine a firm’s AC is represented by its available knowledge. To each firm is associated a three-dimensional vector:

$$A_C = [a_{c_1}, a_{c_2}, a_{c_3}] \quad (5)$$

whose components indicate the AC level in each knowledge category.

The AC is a function of the knowledge level that a firm already has. A simple way to model the dependency of (a_{ci}) on existing knowledge is to assume a direct proportionality as follows:

$$\begin{aligned} a_{c_1} &= c_1/100 \\ a_{c_2} &= c_2/100 \\ a_{c_3} &= c_3/100 \end{aligned} \tag{6}$$

In the course of simulation, the set of competencies, and therefore the AC, is subject to continuous changes, due to two conflicting processes: learning and obsolescence.

3.1.2 Interactions

During the simulation, firms interact with each other, creating a network of relationships that evolve dynamically due to the continuous creation of new links, removing others and exit from the market of all inefficient firms. The interactions mechanisms modelled in the proposed agent-based system are learning mechanisms and the construction of networks.

In particular, two types of learning mechanisms are considered: the internal learning and the external learning (or relational).

Internal learning considers that the firm produces the knowledge by itself through the skills of individuals who work in it and, therefore, without any interaction with other firms. In the proposed model, the internal learning process has been implemented through the introduction of the “sigmoid function”.

Formally, let $c_i(t)$ and $(a_{ci})(t)$ respectively the knowledge level in which a firm is specialized and the AC in that specific knowledge, at the time $(t + 1)$ each firm will increase that knowledge level by an amount equal to:

$$C_i(t + 1) = c_i(t) + \frac{1}{1 + \exp^{[-(a_{ci})(t) \cdot c_i(t)]}} \tag{7}$$

while the knowledge levels in which a firm is not specialized remain unchanged.

External learning is a process of learning by interacting. This process involves the continuous exchange of knowledge between two firms A and B. The external learning occurs only if the condition of complementariness is satisfied, namely if there is at least one category of knowledge in which A dominates B and, at the same time, there is at least one other type of knowledge where B dominates A. As long as there is one category in

which agent A dominates agent B and one in which B dominates A, both agents perceive trade as mutually advantageous and a connection between them is activated.

As reported by Cowan and Jonard (2004), thanks to the external learning process, at every cycle each agent increases the knowledge level in which it is not specialized by an amount proportional to the AC in that knowledge.

Formally, assuming that at time t the firm B dominates the firm A in the category of knowledge c_i , the knowledge level that the firm A may reach at time $(t + 1)$ in the category c_i , after interacting with the firm B, is expressed by the following relation (symmetric for firm B):

$$c_{A,i}(t + 1) = c_{A,i}(t) + (a_{c_{A,i}}) \cdot [c_{B,i}(t) - c_{A,i}(t)] \quad (8)$$

Instead, as regards the agents representing the contractors and the raw materials suppliers, the increase of knowledge is done through the following relation:

$$c_r(t) = [(t/100)^2] \cdot 100 + 5 \quad (9)$$

Another force affecting firms' knowledge endowment is represented by the obsolescence. In fact, if on one hand every firm keeps on learning during the simulation, on the other hand knowledge levels decrease progressively at each cycle by an amount equal to the obsolescence rate. This latter, modelled through the parameter "obs", is equal for all firms and is variable in $[0, 1]$.

This phenomenon affects the firms' survival, causing their death and the exit from the market if they cannot counterbalance this effect through internal or external learning processes.

In order to avoid the exit from the market, each firm searches one or more partners with which create a link and exchange knowledge, in order to maximize its knowledge endowment. Another parameter introduced in the model is the maximum number of interactions that any agent can activate at each cycle. This latter, modeled through the parameter "L", represents the maximum allowed number of outgoing links. This modelling choice is a reasonable assumption since interaction involves transaction costs; in particular, small firms can manage only a limited number of partners at the same time, though they can build relations with many partners during their life. By limiting the number of simultaneous partners we also force firms to choose among possible partnership alternatives. It is not imposed, however, any constraint on the number of input

links. In the model, the parameter L has been settled equal to 3, as in previous steps of this research (Iandoli et al., 2012) it has been verified that the variation of this parameter in a predefined set of values does not significantly affect the results of simulations.

Figure 2 shows a simplified flow chart describing how firms make decisions about building or breaking links.

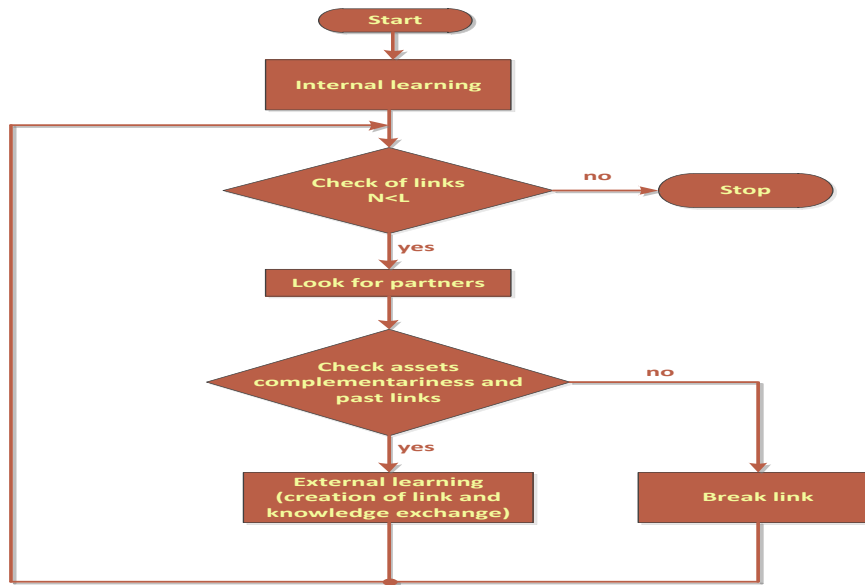

Figure 2 – Network building flow-chart

The probability of creating a link is dependent on two elements. The first element is the level of reciprocal complementariness between agents’ knowledge endowment, measured by the following relation:

$$p = 1 - \left| \frac{c_i - c_j}{\max(c_i, c_j)} \right| \quad (10)$$

where $(c_i - c_j)$ represents the “cognitive distance” between different specialist skills, while $\max(c_i, c_j)$ is the normalization factor. The second element influencing the probability of link establishment between two firms is the (normalized) number of links that they have already established in the past. In fact, one of our objective has been to introduce a mechanism of selection that takes into account whether and how the “embeddedness” of the firms in the social system can influence their behavior and, ultimately, as the latter may reflect on the network characteristics. In this regard, when a firm chooses to develop cooperative relationships with other entities, it selects its partners

based on reputations, recommendations or relying on previous experiences were successful.

Firms that prefer previous partners are driven by a sort of “inertial rationality”. However, the embeddedness in the social system does not prevent the actors in the system to make decisions based solely on an “utilitarian rationality”, mainly in order to complement their knowledge endowment and thus enable collaboration, even sporadic, with entities other than the partner usually involved in exchange relationships.

More in depth, we have modelled the probability for a firm to establish a link with a potential partner (when the complementariness condition is satisfied) in the following way:

$$f = T \cdot x + (1 - T) \cdot y \quad (11)$$

where x represents the number of links established in the past between the two firms, y represents the knowledge gap between different specialist skills, while the T parameter measures the relative weight of these two variables and can assume values in the range $[0,1]$. From this relation we deduce that for high values of T , the probability that two firms establish a link depends more on the number of relationships that they have already established in the past, while for low values of T such probability depends to greater extent from their cognitive gap.

4 Experimental sets and simulation analysis

In order to develop the interpretive hypotheses about the phenomena under investigation, the behaviour of the model has been analyzed through simulations under different parameters configurations.

More in detail, set $L = 3$ and $\text{knowledge_limit} = 100$, three different experimental sets have been analyzed each of which corresponding to a different value of the parameter T : $T = 0.10$, $T = 0.50$ and $T = 0.90$. Fixed T , it has been analyzed the behaviour of the system for three different values of the parameter obs ,: $\text{obs} = 0.50$, $\text{obs} = 0.60$, $\text{obs} = 0.65$.

As shown in table 1, 9 different scenarios have been considered, for each of which 100 simulation runs have been performed.

Table 1 – Experimental sets

Set	T	Obsolescence		
I experimental set	0.10	0.50	0.60	0.65
II experimental set	0.50	0.50	0.60	0.65
III experimental set	0.90	0.50	0.60	0.65

In the first setting the parameter T is equal to 0.10. This means that the probability that two agents establish a link to exchange knowledge is almost totally dependent on the level of knowledge gaps between them. The probability will decrease as this gap increases. In the second experiment the value of T is equal to 0.50. This implies that the number of past links and the level of knowledge complementariness have the same weight in defining the probability of establishing a link. In the third experiment, T is equal to 0.90. This means that the probability of a link being created between two agents depends much more on the number of past links between them than on their level of knowledge complementariness. The probability of establishing a link increases according to the level of relational embeddedness of the two firms.

For each experimental set, different variables have been analyzed in order to describe with sufficient precision any emerging scenario. Specifically, the number of surviving nodes at the end of the simulation (a sort of stable equilibrium is reached) and the number of links for each type of firms.

The choice to investigate these variables is mainly due to the fact that is not meaningful in this case to use other classical metrics of Network Analysis, such as the centrality or the characteristic path length, since they always return the same values. The model simulates the vertical relationships between firms in an industrial district, then the measure that allows to obtain unequivocally information about the output of the simulations is the degree of connectivity of the network and of its nodes. This information can be easily obtained right through the above-mentioned parameters.

Furthermore, social simulation models are usually not deterministic and our model is not an exception. In our case this implies that if one runs a simulation with identical parameters setting twice, different nodes will survive, different relationships among them will be established and therefore different link distributions will be produced in each run. Since one of our aims has been to look for statistical regularities of the network generated by the model in different iterations within a same experimental set, it has been necessary

to adopt a method to objectively classify the network structures produced by the simulation in each run. Specifically, The statistical distribution of the links has been identified as a way to describe and classify the output of the simulations. Therefore, we chose an appropriate method to cumulate the set of distributions obtained in each run and to establish whether there was a recurring network structure for a given experimental set.

In order to achieve those aims we have used the Kolmogorov-Smirnov (K-S) test (Chakravati et al, 1967). Without being exhaustive, the K-S test can be thought of as goodness of fit test. It computes an estimation of the distance between two samples and tells us whether those two samples can come from the same distribution. So, we compared our simulation outputs with a Gamma distribution with a significance level equal to 0.05. The Gamma distribution is useful for this purpose because it can describe a wide range of distributions with just two parameters: shape and scale. For each simulation output we performed the K-S test with a shape between 1 and 9 with step 1, and a scale ranging between 1 and 4 with step 0.5, then we chose the pair with the lowest p-value. All the chosen p-values are smaller than the 0.05 significance level.

4.1 Results

Experimental results are reported in bar plots for the K-S test, where each bar represents the relative frequency with which a Gamma distribution with a given shape and scale has been produced in the total sample of iterations generated in each experimental set.

In order to read the bar plots presented, a clarification of the meaning of the shape-scale couple is needed. The first value gives an idea of the extent to which a link distribution is positive skewed; the smaller is the shape, the more positively skewed the distribution is. So, for instance, a link distribution where the shape equals 1 represents a scale-free network. The second value provides information about the mean of the link distribution: the greater the scale, the greater the mean of the link distribution. One way to read these bar plots, with respect to network structures, is to identify shape-scale couples on the left hand side as scale-free networks, and the ones on the right hand side as random networks. Those couples located between the left and the right hand side of the bar plot represent link distributions characterized by a rounded pick and a moderate right tail.

A first interesting conclusion that has been reached by performing the simulations, is that after a certain number of cycles the system reaches an equilibrium state that presents constant values of the output variables of the. In particular, whatever the value of the

parameter T , when the obsolescence is equal to 0.50, the number of cycles in which the network reaches stability is about 260, when the obsolescence is equal to 0.60 and 0.65 the number of cycles in which the network reaches stability is about 340. After this interval of time, the variables that measure the structural characteristics of networks are characterized by a constant value. Thus, the value of the number of cycles depends on the value of the parameter *obs*.

Also the trend of the population seems to be influenced by this parameter. In fact, it has been observed that, whatever the value of the parameter T , the number of firms that survive decreases as the value of obsolescence increases. This result seems to confirm the fact that in the traditional districts the survival of firms is due to the presence of a poorly innovative environment, unlike the high-tech districts that are characterized by environments more dynamic and therefore more selective.

With respect to the distribution of the number links, in all the experimental sets each firm has on average a number of links equal to 4. In particular, there is greater similarity between the sets where $T = 0.10$, and $T = 0.50$, while for the set in which $T = 0.90$ the values are significantly different. So, it is possible to say that the number of links of the firms and how they are distributed strongly depends on the way in which firms choose their partners, but also on the obsolescence, since it affects directly the population of surviving firms.

It may still be noted that, whatever the value of the obsolescence, the system reaches an equilibrium state characterized by high values of the average knowledge level. In fact, when the cognitive pauperisation takes place with a high speed, and therefore for high values of obsolescence, the competition between the firms significantly increases, the market becomes more selective and only those firms with high knowledge and absorptive capacity are able to survive. In this context, there is an heterogeneous distribution of knowledge which will tend to comply with the exit from the market of those firms with a low level of knowledge endowment. Instead, low values of obsolescence create an uncompetitive environment, where even the firms with limited knowledge endowment are able to survive by improving their knowledge assets and by determining, also in this case, an homogeneous distribution of knowledge.

This behaviour can be interpreted, generally, as a tendency of the system to reorganize and rebalance itself in a completely autonomous way, by eliminating the firms less efficient in terms of learning as a result of the changes induced by the external

environment. The ability to react to changes by reconfiguring the network of internal relations is one of the main features of industrial districts.

At the equilibrium is also possible to observe the presence of one or more hub, namely firms characterized by a number of connections slightly higher than the average value in the system and which play the role of leading enterprises..

In particular, the analysis of the simulations shows that the evolution of the network toward characteristics of a scale-free network is mainly influenced by the parameter T .

Figure 3 shows the bar diagrams of the K-S test performed relatively to the experimental set in which $T = 0.10$.

In this scenario, firms select potential partners mainly according to an “utilitarian” criterion. In particular, the networks emerging from the interaction between firms have structural features typical of a scale-free network. This property is emphasized as the obsolescence parameters increases.

This scenario is characterized by the presence of hubs, that are mainly represented by first-tiers-subcontractors.

Figure 3 - Experimental results obtained for $T=0.10$ and for different values of the obsolescence: (a) $obs=0.50$; (b) $obs=0.60$; (c) $obs=0.65$.

Figure 4 shows the bar diagrams of the K-S test performed relatively to the experimental set where $T = 0.50$.

In this second scenario, the situation is substantially similar to the first scenario, but with a less pronounced tendency toward scale-free networks.

Figure 4 - Experimental results obtained for $T=0.50$ and for different values of the obsolescence: (a) $obs=0.50$; (b) $obs=0.60$; (c) $obs=0.65$.

Figure 5 shows the bar diagrams of the K-S test performed relatively to the experimental set where $T = 0.90$.

The third scenario corresponds to the situation in which the behaviour of firms is “inertial”, with a tendency to give greater weight to past relationships. In particular, by increasing obsolescence, the networks that emerge from the interaction between firms have on average structural features typical of a random networks. In this scenario, the first-tier-subcontractors present a number of links moderately higher than the other firms.

Figure 5 - Experimental results obtained for $T=0.90$ and for different values of the obsolescence: (a) $obs=0.50$; (b) $obs=0.60$; (c) $obs=0.65$.

In summary, the analysis carried out through generative experiments shows that: 1) the complementariness of specialized knowledge among small firms in a ID is a sufficient condition for the emergence of stable transaction networks; 2) the level of knowledge obsolescence (parameter obs) affects the survival of the population of firms at the equilibrium, but not significantly the average level of knowledge acquired by agents; 3) the logic (utilitarian vs. inertial, parameter T) driving the selection of potential partners and the establishment of cooperative relationships affects the structure of above networks. In particular, the emergence of hub&spoke networks is driven by the prevalence of an utilitarian criterion used by firms in choosing partners. In this scenario, the frequency of occurrence of hub&spoke structures increases according to the level of obsolescence.

Starting from these results it can be concluded that most selective environments (in particular with respect to the internal district environment) are more conducive of hub&spoke structures, that, in turns, are recognized by literature as best performing in innovation, diversification and knowledge diffusion (Guerrieri and Pietrobelli, 2004; Phelps et al., 2012)

5 Conclusions

The main objective of this paper was to investigate the topological properties of the supply networks emerging as a result of selective choices made by small firms of a flexible-specialized Industrial District in exchanging complementary knowledge assets.

Contrary to the many works that have used social network analysis to investigate the properties of clusters of small firms, we did not assume the network as given. Our aim was to improve our understanding of the transactional mechanisms that favor the emergence of network structures from stable and recurring patterns of interactions among autonomous firms provided with bounded rationality. In particular, we focused on knowledge exchange happening among firms in a closed cluster, and we modelled the partnership mechanism based on competencies' complementariness that is typical in the formation of supply chains in IDs with flexible specialization through a simple barter of non-rival assets among agents. Furthermore, we modelled the impact of relational embeddedness on the choice of possible partners and, by doing that, we were able to investigate the role played by various social mechanisms characterizing canonical IDs in shaping the general behavior of the system. Our simulation results show that, our assumption on knowledge complementariness is sufficient to generate stable networks and that the logic driving the choice of partners is able to affect the structure of these networks. In fact, when the logic inspiring firms in choosing potential partners is mostly "utilitarian" the distribution of links among surviving agents is power law like, determining the emergence of hub&spoke structures that are recognized as more conducive to growth and evolution of the system. A similar result is obtained in a scenario in which the "utilitarian" logic is perfectly balanced by an "inertial" logic, represented by a choice criterion driven by the history of past links between the firms involved in the relationship. This result can be interpreted as the presence of a relational embeddedness threshold affecting the structure of nodes connections in emerging supply networks. This hypothesis is, at this stage of the research, the first output of the simulation analysis and has to be further verified by means of empirical validation.

Given the current state of development in agent-based technology, we do not consider it mature enough to identify straightforward applications for practitioners. So we see it primarily as a tool through which social scientists can improve their understanding of the phenomena object of their investigation, especially when these involve heterogeneous

agents, lack of centralization and complex co-evolutionary or path-dependent development trajectories.

However, some lessons learned, confirmed by subsequent empirical testing, could lead to novel insights for policy makers or trigger new directions for policies experimentation and design.

Agent-based modeling's promise is not in the development of tools to map reality and make predictions, but in the potential to help policy-makers to simulate possible consequences of certain choices. To allow them to examine potentially unexpected impacts as well as to support sense-making and creative thinking thanks to a deeper analytical understanding of problems.

In addition to the general remarks and criticisms advanced to the agent-based modeling approach as a whole, our study suffers from other more specific limitations that we intend to address in future work.

First, we have not yet validated our model using evidence from empirical studies on real IDs, so the next step will be to complement our present work with field work to gather the necessary data. Unfortunately this kind of empirical work is usually hard and time-consuming, because companies are often unwilling to disclose information on their partnerships or because they do not have a reliable longitudinal information database to build the map of their interactions. Consequently, the relational system and its evolution through time has to be reconstructed from scratch and then subjected to cross-validation because of the multiplicity of different sources from which information has to be obtained and verified.

Second, we have not included horizontal relationships in our model. Whilst, at least in vertical IDs, they are of secondary importance compared to the vertical, supply chain-driven partnerships, we have no clues on how much they can contribute to shape the structure of the network and explain its performances in terms of knowledge creation/sharing and diffusion. A first step will be to compare our model with similar ones developed to explain innovation performances in other kinds of firms clusters characterized by a higher importance of horizontal collaboration (Cowan, 2005) and a flatter organizational structure, as in certain kind of hi-tech clusters. The comparison of different ways of organizing collaboration and their impact on innovation in different models of industrial organization could be a fruitful angle for the identification of

suggestions for policy makers on how to increase the innovation potential of small firms networks.

Structured Abstract

Purpose – To sustain growth in turbulent environments SMEs face major challenges due to their limited human, organizational and financial resources and capabilities. How to reconcile learning and growth to sustain competitive advantage of SMEs in turbulent environments is a vital but widely unsolved question in theory and practice .

Design/methodology/approach – Based on a three year action research project with 124 SMEs in Germany drivers and obstacles of growth have been identified and the methodology “Learning to grow” has been developed and successfully applied in further learning networks of SMEs in Germany, Spain , Argentina, Brazil and Peru.

Originality/value – This methodology puts in evidence the effectiveness of project based learning to sustain and develop growth capabilities of SMEs. Aligning learning of teams with business challenges creates measurable short or mid-term results as well enhances organizational capabilities to sustain growth.

Practical implications – Evaluations carried-out demonstrate that the learning projects let to significant business results (for example conquering new markets, adding new services to products, improving processes, productivity and quality) as well as enhancing organisational capabilities amongst which are improved team work, better problem solving, enhanced communication , freeing of owners or managers from daily routine tasks, development of leadership capabilities of middle managers, entrepreneurial thinking of employees.

Keywords – SMEs, growth, turbulent environment, project learning, dynamic capabilities

Paper type – Practical Paper & Academic Research Paper (both aspects are developed)

1 Introduction

To sustain growth in turbulent environments SMEs face major challenges due to their limited human, organizational and financial resources and capabilities. Owner/managers are overloaded by daily business and are pressed to delegate and integrate new employees (Van Bruystegem et al 2008). While striving to cope with current business SMEs tend to lose grip on future development and thus deplete resources while growing in an often uncoordinated manner. On the other hand periods of growth can be quickly followed by periods of decline. Hence the need to adapt to turbulent environments (Detarsio, North, Ormaetxea 2013, see also www.dynamic-sme.org)

How to reconcile learning and growth (Holt and Mcpherson 2006) in order to sustain competitive advantage (Barney 1991) of SMEs in turbulent environments is a vital but widely unsolved question in theory and practice. Wiklund et al (2009 p.351) argue that “despite substantial increase in research volume, recent reviews of the literature on small firm growth suggest that little is still known about the phenomenon, and conceptual development has been limited.” Macpherson and Holt’s (2007) literature review on knowledge, learning and small firm growth also reveals deficits in research on the concrete mechanisms of learning and their relation to growth of SMEs.

To deepen our understanding of learning and growth of SMEs and subsequently develop and test learning formats to support growth of SMES a three year action research project was carried between 2009 and 2011 in three German regions (Baden-Württemberg, Sachsen and Berlin-Brandenburg) with 124 SME which had above average growth rates. Out of these 26 SMES were selected to develop the “*Learning to grow*” methodology ” (Hardwig, Bergstermann, North 2011). In the action research Wiesbaden Business School cooperated with “RKW” the German government supported consulting service for SMEs.

Following a review of our empirical results on learning and growth of SMEs the main focus of this paper is to present the “*Learning to grow*” methodology which draws on deliberate learning as a means of developing dynamic capabilities (Zollo and Winter 2002) and applies project-based learning (Scarbrough et al. 2004) closely linked to business challenges.

2 Obstacles and drivers for growth of innovative SMEs

2.1 Survey of growing SMEs

To learn more about the real obstacles and what drives company growth, above average growing and innovative SME's were examined. In three German regions companies known to the RKW advisors were selected that had a) a growth rate above average of their sector and b) had a high innovation capacity as demonstrated by product and process innovations in the previous three years as well as maintained regular research and development activities. Two thirds of the selected firms realized a growth in sales of more than 10 % per annum in the years 2005 to 2007.

In the 124 SMEs a survey (Bergstermann et al. 2009) was carried out during a two hours consultation– mostly with the owner or a top manager of the enterprise. A three-part instrument was used. It contained a standardized questionnaire about the conditions of growth, an interview about the situation of growth and perspectives of development of the company as well as a self-assessment of the management quality.

During the sifting of the empirical data it became obvious, that enterprises in growing markets, achieve higher growth-rates than enterprises in stagnating or shrinking markets. 17% of surveyed SMEs, however, were able to achieve an increase in turnover of more than 20% annually, although they acted in stagnating markets. This supports our assumption that rather than unfavorable environmental conditions the quality of the management impacts the success of an enterprise, which is consistent with Macpherson and Holt's (2007) literature review.

Manager/owners of the surveyed companies were further asked to give explanations for several factors contributing to growth as well as gauge their relative importance. The three factors "competence of the employees", "sound business strategy" and a "strong leadership" marked in Figure 1 were not only relevant in the subjective assessment of the company decision-makers, but also had a statistically high impact on the strength of an enterprises' growth.

What Contributes Most to the Growth of Your Firm?

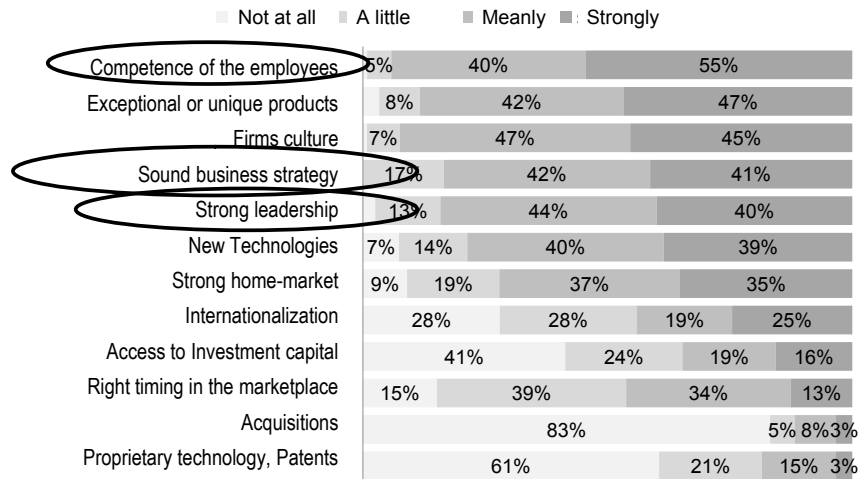

Fig. 1: Contributions to growth from the owner/manager's point of view (base: 124 SME owner/managers interviewed in 2008)

Those three factors are closely linked. Owner/managers who cited leadership as a relevant contribution to growth also mentioned strategy and competence of the employees as highly related to growth. We will call this connection of a strong leadership and a sound business strategy valuing the contribution of competence of the employees "competence-based management".

To test the hypothesis, if competence-based management is a decisive factor to explain growth of SMEs we realized a factor analysis (Oneway ANOVA). The independent variable was growth of turnover in the years 2005 to 2007 (compound annual growth rate)¹. As dependent variables we took variables relating to the structure of the enterprise², its situation of competition³, its growth strategy⁴ as well as its innovativeness⁵ - all these factors are possible sources of growth.

¹ Growth of turnover is highly correlated with the growth of the number of employees.

² Industry, size (employees), age of the enterprise, grade of independency, the relations of property, and the structure of the staff's qualification.

³ Porter's five forces: Supplier power, threat of substitutes, buyer power, barriers to entry, degree of rivalry.

⁴ The product / market orientation and the regions of market activity.

⁵ Intensity of product and process innovations, expenditure of research and development.

The analysis shows that apart from “competence-based management” only 2 of the 16 variables checked were in statistically significant correlation with the strength of growth in turnover of these enterprises. The two other factors are “threat of substitutes” (highly significant) and intensity of “process innovation” (weakly significant). Both factors have like competence-based management, an impact on the strength of growth, whereas all the other factors could not be cleared up.

This supports the hypothesis that the quality of the management to a large extent explains the strength of growth in our sample. This result is consistent with newer research on determinants and dimensions of firm growth (cf. Zhou / deWit, 2009) where mostly internal factors are held accountable for growth.

2.2 Higher performance by activating the employees.

The results of the survey also show that those SMEs, whose representatives named competence-based management as a strong contribution to growth (Fig. 1) showed higher growth than the other SMEs or our sample. At the same time, there are further indicators showing a better economic performance of those enterprises:

- They have a better profitability (improvement in the last three years and in self estimated comparison to competitors),
- They articulated less problems with the staff (motivation and willingness for accomplishment of the staff; conflicts within the staff and conflicts within the company management) and
- They have stronger innovation activities (more process innovations in the last three years; more social innovations within the company; fewer problems within the organization while realizing innovations).

Higher performance could be a result of a stronger activation of the employees. Owner/managers following a competence-based management agreed more often to the statements displayed in Fig. 2 describing a stronger engagement of the employees for company goals than leaders of SMEs not explicitly practicing a competence-based management (see Fig.2).

Activating Employees through Competence-based Management

Independent Variable: „Competence-based Management“ - (Factor analysis, Oneway ANOVA)

Statement	Significance	
„Our employees show in their daily activities, that they support firm's aims of growth and innovation.“	0,000	Highly
„Our firm is characterized by the ambition to continuous improvement and looking for new solutions“	0,001	Highly
„The relations between the members of our firm are characterized by mutual respect and trust.“	0,001	Highly
"Our employees share the firm's visions."	0,009	Highly
„Our employees engage strongly for the needs of our customers“	0,018	
„Employees in our firm are strongly success- and achievement-orientated.“	0,028	
„We realize improvement based on ideas of our employees all the time.“	0,039	Weakly
"Transfer and sharing of knowledge goes well even between departments and different professions."	0,054	Weakly
„Our firm is characterized by entrepreneurial thinking and action of employees.“	0,078	Weakly

Fig. 2: Owner/managers who practice a competence-based management confirm statements describing the activation of employees to a greater extent than those not explicitly practicing this management approach.

The results of our investigations point to the fact that a competence-based management leads to a higher performance by activating the competences of the employees. Essential features of SMEs practicing a competence-based management approach are more encouraged and empowered employees acting with responsibility, the ability to exchange knowledge and to learn as well as realizing changes within the organization. Thus responsiveness to external changes and dynamics in society, including technology or markets is increased. In this respect a competence-based management approach contributes the development of “dynamic capabilities” (Teece 2007). Several empirical studies showed that dynamic capabilities contribute to performance and growth of SMEs (He/Wong 2004; Lubatkin et al. 2006; Protogerou et al. 2008). They have an indirect impact on performance by adjusting the company’s core competences: “Dynamic capabilities seem to support and enhance the reconfiguration and development of new

marketing and technological competences which in turn lead to higher competitive performance in terms of market share and profitability.” (Protogerou et al. 2008, p.27).

What are the implications of the survey results for the development of a learning format to enhance growth of SMEs? The approach to be developed has to closely link business challenges and learning, it should activate potentials of employees and enable them to take up responsibilities within a framework of strong leadership. In operational terms the empowerment of employees should free the manager/owner from day-today business in order to devote more time to strategic issues. In addition only a minimum of external assistance (consultancy/coaching) should be needed by the companies to implement the learning format.

3 The “Learning to grow” methodology

3.1 Key features

Following the survey phase a first group of 13 SMEs distributed over the three regions representing different sizes and sectors (particularly manufacturing and services) and willing to join an action research “experiment” to develop a learning format to enhance growth capabilities were selected. This first group served over around 9 months to develop the methodology. In a subsequent second consortium of 13 firms the methodology was further matured. In the mean time “*Learning to grow*” has been applied in learning networks of SMEs in Germany, Spain (UGGASA 2013); Brazil (North et al. 2013), projects in Peru and Argentina are under way (cf. Dynamic SME project). Up to now approximately 70 SMEs have made their learning journey to enhance growth capabilities using the methodology

In a nutshell “*Learning to grow*” consists of the following steps: Based on a structured analysis of growth capabilities and deficits by means of a “wheel of growth” the owner/manager supported by a “growth coach” defines a strategic growth project that has a short to medium term impact on business performance and in parallel serves to develop/sustain growth capabilities. To this effect the project is delegated by the owner/manager to a team of employees who define their learning objectives to be accomplished and carry-out the project conceived as a learning journey over a period of 6 to 9 months. The whole process is supported by a coach (approx. 12 half days of intervention) who has been trained in the methodology. Normally the “*Learning to grow*” methodology is used in a network of about 10 SMEs whose teams meet to exchange

experiences and run joint learning sessions. In the following the methodology will be explained in more detail.

3.2 The wheel of growth: diagnosing growth challenges and capabilities

To develop the “*Learning to grow*” methodology we classified interview results and thus identified four typical challenges of SME growth. Nearly all the 127 SME’s involved could be assigned to one of the four challenges (98%):

- Many firms were in a situation demanding them to sense new growth potentials, (19% of the SME’s).
- For others the challenge was defining a growth strategy to orientate the enterprise towards capturing market potentials (22%).
- Further enterprises discussed seizing growth potentials by motivating and empowering their employees to exploit available possibilities for growth by consequent action (20%).
- The strongest group of the survey (36%) included enterprises which had grown successfully over a period of time and were now challenged to cope with the effects of growth: such organizations had to be adjusted to the situation or there were problems with the supply with the most important resources (e.g. the lack of qualified employees, and the bottleneck of financing).

Linking these survey results to theory it became evident that the challenges named by owner/managers matched quite well with Teece’s (2007) “Sensing”, “seizing” and “transforming” trilogy of dynamic capability development: "For analytical purposes, dynamic capabilities can be disaggregated into the capacity (1) to sense and shape opportunities and threats, (2) to seize opportunities, and (3) to maintain competitiveness through enhancing, combining, protecting and, when necessary, reconfiguring the business enterprise’s intangible and tangible assets. Dynamic capabilities include difficult-to-replicate enterprise capabilities required to adapt to changing customer and technological opportunities." (Teece 2007, 1319).

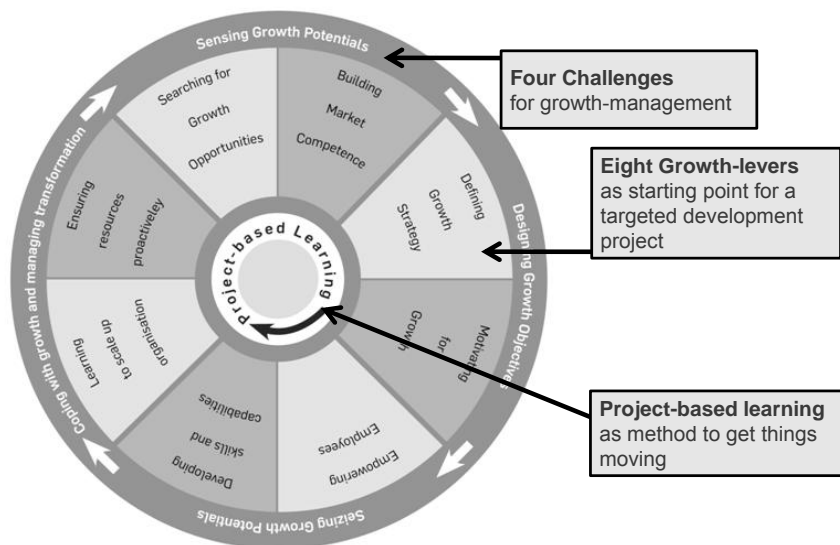

Fig. 3: The Wheel of growth

Merging theory and practice we constructed a *Wheel of Growth* to analyse growth capabilities. It comprises the four central challenges and two “growth levers” for each challenge:

1. Sensing growth potentials (Searching for growth opportunities, Building market competence);
2. Designing growth objectives (Defining growth strategy, Motivating employees for growth);
3. Seizing growth potentials (Empowering employees, Developing skills and capabilities);
4. Coping with growth and managing transformation (up-scaling the organization, Ensuring resources proactively).

The two “growth levers” defined for each challenge constitute fields of action to leverage growth capabilities of the firm. The growth levers were derived from our analysis of 124 SMEs based on the interviews with owner/managers.

To use the wheel of growth as self-analysis tool for each lever two key statements have been formulated. They are rated according to the capability level reached (using a three-point traffic light scaling) and in a second rating the relative importance for sustaining competitiveness is assessed in order to derive priority areas of action.

Statements for the lever “searching for growth opportunities” for example are “Our company observes and recognizes systematically new possibilities and trends in relevant markets and learns from competitors, clients, suppliers, partners” and “Our company encourages and effectively uses the ideas of the employees” .¹

The self-analysis is usually carried-out in a dialogue between owners and managers of an SME and the external coach and takes about two hours. The 4 challenges, 8 levers, and 16 key questions are the starting point of targeted innovation and learning projects.

3.3 A learning Project impacting on business performance.

Based on the wheel of growth the external coach assists the owner/manager to define a learning project which on the one hand will have a measurable short to medium term business impact and on the other hand is well suited to improve growth capabilities.

Past projects have focussed for example on such topics such as improving competitor analysis, implementing an idea competition for new products and services, expanding to new markets, improving internal organisation, creating a continuous improvement process, developing a participative strategy process, establishing a second management level etc.

The development of growth capabilities starts with the identification of the actual relevant challenges faced by an enterprise during the process of growth. In practical terms, the coach assists the manager/owner to define a learning project. The manager/owner selects members of a project team considering in particular competence development potentials and needs (e.g. preparing staff for middle management position, learning cooperation across units, preparing technical staff for sales support). In a briefing session the project is handed over to the team. Subsequently the owner/manager acts as client of the team. This requires the owner/manager to trust in the team and not to interfere (which is also a learning process for the owner/manager).

The team supported by the coach develops a project plan containing not only the business objectives but also detailed learning objectives for the team as a whole and for individual members. Often a competence matrix (cf. North and Kumta 2014) is used to visualise current and desired competence distribution of the team. After approval by the manager owner the project is carried-out step by step which is supported by the coach.

¹ *The wheel of growth with the 16 questions can be downloaded from www.dynamic-sme.org*

There are regular meetings scheduled with the “client”, the team organises its self-learning and, if necessary, task related training is provided by the coach.

The “growth coach” acts as process consultant following Schein’s (1999) concept of building a helping relationship. By understanding that the consultant/coach can only help the clients to solve their problems consultation becomes a matter of establishing a supportive relationship in which the client is guided to understand the need and opportunities for change. The growth coach is to facilitate the project and the learning process, ensure communication between project team and manager/owner and periodically reflect with team and manager/owner on the process.

Many owners/managers of SMEs have mixed feelings of employing external consultants and normally would expect an expert consultant to solve their “technical” problems. Therefore the growth coach has often to overcome resistance to process coaching in SMEs and cautiously support a cultural change. In order to train “growth coaches” a 20 hour training course is offered for participants with consultancy and coaching experience. In order to qualify for a certificate as growth coach candidates have to successfully accompany a “*Learning to grow*” project and submit a report to the originators of the methodology. Coaches are invited to participate in a supervision process.

Experience exchange and peer pressure in a SME network is integral part of the Learning to Grow methodology. Usually a “*Learning to grow*” network consists of 7-10 SMEs in a region who are not competitors. One rationale of the network is to act as a pacemaker to ensure that projects at firm level keep track. Furthermore the network agrees on training needs and runs joint training sessions (p.e. on topics such as project management, internal organisation, effective team work, active sales management). During the usually 6 months project duration three “Learning to grow” workshops are carried-out, where SMEs share their project advances and difficulties and in each session focus on a relevant topic from the wheel of growth (p.e. delegation and empowerment of employees). There is always time for networking between project teams which in some cases leads to intensive bilateral interaction.

4 Triple value: Results of *Learning to grow* projects

This methodology puts in evidence the effectiveness of project based learning to sustain and develop growth capabilities of SMEs. Aligning learning of teams with

business challenges creates measurable short or mid-term results as well enhances organizational capabilities to sustain growth.

During the development process of the methodology periodic interviews and reflection sessions were carried-out by the researchers with manger/owners, project teams and consultants acting as growth coaches. A number of case studies were written to document the project process at firm level (RKW Deutschland 2012). In the Basque (Spanish) SME *Learning to grow* network storytelling was used to create evidence on results achieved UGGASA (2013). In the mean time a standard questionnaire is in place, one for manager/owners and another for project teams to evaluate results of the project, which has been applied in two *Learning to grow* networks so far.

These evaluations demonstrate that there is a triple benefit of the learning projects.

Firstly, projects let to significant business results (e.g. conquering new markets, adding new services to products, improving processes, productivity and quality). This is relatively easy to measure related to the “business objectives” of the project.

Secondly, learning projects have contributed to enhance organisational capabilities amongst which are improved team work, better problem solving, enhanced communication, freeing of owner-manager from daily routine tasks, development of leadership capabilities of middle managers as well as entrepreneurial thinking of employees. The learning projects have also raised the awareness about the unused potentials of employees. While at the beginning of the project some manager/owners stated “*I doubt that my people are able and qualified to carry-out such a project*”, in the reflection session at the end of the project the same managers/owners stated: “*I was not aware what my people are able to do*” or “*I have learned to trust in the capabilities of my people*”. The demonstration what teams are able to achieve let also to a different communication and delegation behaviour. Asked about the effects of the project team performance at the end of a 6months learning journey the 9 owner/managers of the Basque *Learning to grow* consortium (UGGASA 2013) particularly valued the increased capacity to reflect, self-organise and orientation towards firm objectives. The perception of project results by 46 members of 7 projects teams of SMEs in lower Saxonia (Hardwig 2012) is shown in figure 4. More than fifty percent of the respondents agreed that there had been a substantial improvement of internal communication and that new processes, procedures, structures had been introduced ensuring a better use of employee potentials thus rendering the organization more flexible and adaptable to change.

A third benefit of the *Learning to grow* methodology is derived by creating a network of participating firms allowing exchange of experiences with the methodology, for discussing solutions to similar problems (for example internal communication, delegation of responsibilities, improving sales) and pooling resources for training on topics of mutual interest. The joint workshops were seen as an important pacemaker and exerted peer pressure to advance in the in-company projects.

As the workshops usually are hosted by one of the participating enterprises this gives also a chance to get to know the host and establish business links. While in Germany there is a long tradition of SME cooperation, in Spain or Latin America SMEs tend not to cooperate. Therefore in these countries the barrier to open itself and share insights with other SMEs still needs to be overcome.

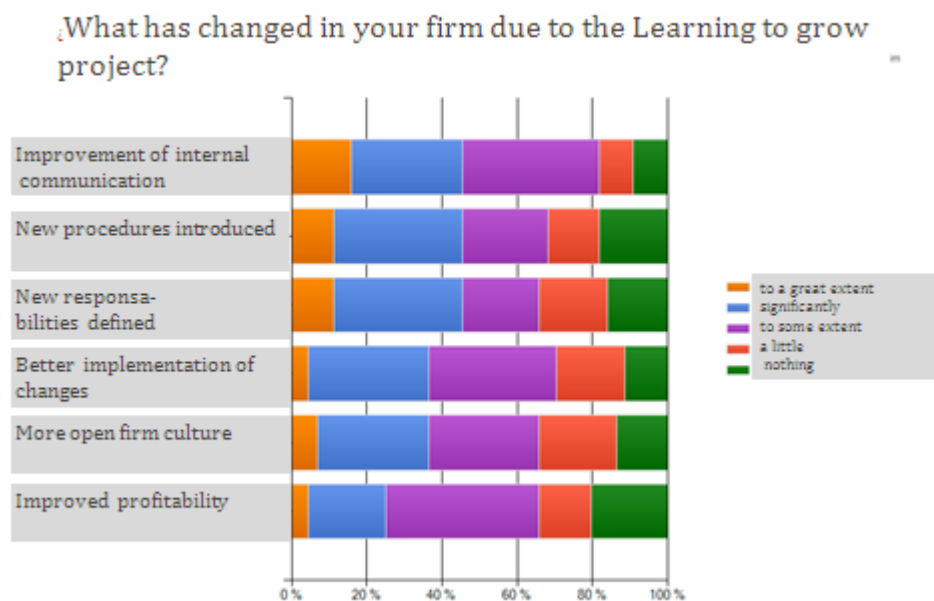

Figure 4: Perceived changes by project team members (basis: 46 members of 7 projects teams of SMEs in lower Saxonia, 100% = 46 answers, Hardwig 2012)

5 Conclusions

There is an abundance of programmes worldwide aiming at an improvement of SME performance by providing external advice. Programmes vary widely in their approaches and effectiveness. The experience with currently about 70 projects demonstrates that the

Learning to grow methodology is an effective way of developing capabilities relevant to sustain growth in SMEs. Combining business objectives with a learning journey addresses the desire of owner/managers for measurable short or midterm business results and introducing changes of attitudes and behaviours towards a more participative management. Employees gain confidence in their capabilities and learn how to evaluate and develop their competencies.

The mayor challenge resides in ensuring continuity after the end of the first *Learning to grow project* in the firm. Usually the cost of the external coach is funded by a regional development agency or other SME assistance programme. Once the first project is over SMEs would need to continue either by themselves or pay for the coach and organize between themselves to continue the *Learning to grow* network. While a significant number of SMEs continued work with their coach to support implementation of the first project or start a second one, the majority of firms who participated in a funded *Learning to grow* initiative have not continued with an external coach even though they expressed their satisfaction with project results. This is a common phenomenon of SME assistance programmes.

Therefore, in recent *Learning to grow initiatives* emphasis is put on the training of internal coaches who will execute a first project with an external coach and then should be able to run a second project without or only a minimum of external assistance.

Furthermore, an evaluation is planned to assess if changes initiated in a *Learning to grow* project have taken root in the participating SMEs. Based on occasional contacts we know that instruments like the project charter or the competence matrix are used on a regular basis in a number of firms.

Our vision is that *Learning to grow* projects become a routine exercise to sustain change in turbulent environments.

Small Business Issues: Impact of Canada's Global Competitiveness and Recommendations for Sustainable Growth

Mark Kam-Loon Loo

Concordia University College of Alberta
7128 Ada Boulevard, Edmonton, Alberta,
Canada T5B 4E4

Structured Abstract

Purpose – Identify barriers to small business in Canada and propose policies to sustain growth due to three key reasons: (a) small businesses are the driver of economic growth, forming 87% of Canada's total businesses and 25% of total value of export goods worth \$68 billion, (b) they sustain the Canadian economy with the highest growth in export value by 20% in the last decade when big firms declined by 20%, and (c) their growth is impeded by Canada's slipping rank in global competitiveness from top 10 to 14th in the last two years.

Design/methodology/approach – As the performance of small firms is influenced by the nation's global competitiveness, the author proposes an approach to identifying the barriers by replicating and validating the World Economic Forum's (WEF) annual survey of 16 business barriers in over 140 nations, reported in the WEF's global competitiveness reports. The WEF's sample comprises an average of 98 firms per nation of unspecified firm size. This research samples 316 small firms to identify the rankings and relevance of the 16 barriers and match them against Canada's 12 pillars of global competitiveness to develop policies that promote small business growth and sustainability.

Originality/value – This methodology puts in evidence for the first time the validation of the WEF's 16 barriers to business, not tested anywhere previously but critically important among small firms, the economic spine of a nation. The top five barriers were found uniquely different from WEF's rankings: tax rates, tax regulations, access to financing, Poor Work Ethic and restrictive labour regulations. Chi-square and independent sample tests found respective significant associations and differences between barriers and business categories, provinces and data collection methods, which further help highlight the respective barriers specific to each demographic variable.

Practical implications – The outcomes of the research provide implications for focusing resources in dismantling barriers by type of business, employee size and province, and strengthening weak pillars in global competitiveness to sustain long-term growth for small firms. Abiding by the United Nation's Principles for Responsible Management, this research helps build a model of knowledge management for decision makers to monitor and analyse relevant data sources, design and implement policies to promote

small business sustainability. This research will provide the stimulus among academic scholars, industry captains and government leaders to collaborate for a better economic future and a more globally competitive nation.

Keywords – small business, barriers, sustainability, knowledge management, policies.

Paper type – Academic Research Paper with Practical Implications

1 Introduction

A small firm, commonly known as small business, is a business with less than 100 employees (Longenecker, Donlevy, Champion, Petty, Palich & Moore, 2013) or has 1 to 99 paid employees (Industry Canada, 2014). As of December 2012, there were 1,107,540 employer businesses in Canada, of which 1,087,803 were small. Small businesses make up 98.2% of employer businesses, medium-sized businesses make up 1.6% and large businesses at 0.1 % (Industry Canada, 2014). This demonstrates the critical role small businesses play in providing employment.

Small firms are the driver of economic growth, forming 87% of Canada's total businesses and 25% of total value of export goods worth \$68 billion in 2009 (Canadian Small Business Exporters, June 2011). In terms of export value, they have helped sustain Canada's economy over the last decade growing by 20% in export value when big firms declined by 20% (Canadian Small Business Exporters, 2011).

However, the growth of small business is impeded by various factors. Financiers are reluctant to fund small firms with innovative products due to the difficulty with evaluating the risk of such ventures (Craig, Jackson and Thomson, 2006 p. 346). Small firms are one of the largest customers of commercial banks but the loans are often limited to very short periods, ruling out financing any considerable investments and export activities (Lloyd, 2009).

There is little factual knowledge of the state of small business apart from the reports from the Canadian government. An online review of the Small Business Association of Canada (2014) found networking activities but lacked statistical information on small business issues. National and international bodies such as the Canadian Chamber of Commerce and the World Economic Forum present annual reports that cover the business scenario of the nation but they do not devote a section to study in-depth small business issues.

Canada's slipping rank in global competitiveness from top 10 to a weaker 14th position in the last two years has become a growing concern. This signals rising threats from other nations who are strengthening their pillars of competitiveness to help small firms succeed and new entrepreneurs flourish. Even Qatar, once a distant 27th has surged past Canada to 13th position.

The barriers faced by small business deserve attention and assistance to enhance their growth and sustainability which in turn strengthen Canada's global competitiveness. The attention is increasingly critical considering more and more organisations accredit their competitiveness to knowledge assets and value knowledge as the differentiating competitive lever (Nonaka and Takeuchi, 1995; Robbins, Coultier, Leach and Kilfoil, 2012).

1.1 Objective

This central objective of this research is to investigate the key research problem:

What are the significant barriers to small business in Canada?

There are five research issues and related objectives to investigate this key research problem as described in Table 1 below.

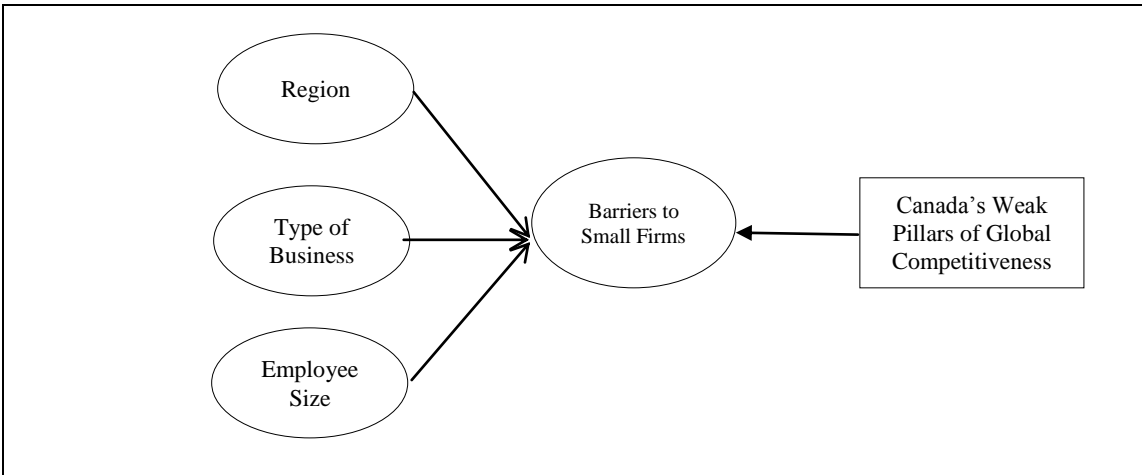

Table 1: Five Research Issues and Objectives

<p>Research Issue 1 What are the barriers faced by small firms in Canada and are they different from bigger firms?</p>	<p>Research Objective 1 Identify the significant barriers to small firms in Canada and investigate any differences with bigger firms.</p>
<p>Research Issue 2 Is there a difference in the barriers faced by small firms between Western and Eastern Canada?</p>	<p>Research Objective 2 Investigate the significant differences in barriers to small firms between Western and Eastern Canada.</p>
<p>Research Issue 3 Is there a difference in the barriers faced by small firms among different types of business in Canada?</p>	<p>Research Objective 3 Investigate the significant differences in barriers to small firms between types of business in Canada?</p>
<p>Research Issue 4 Is there a difference in the barriers faced by small firms of differing employee size in Canada?</p>	<p>Research Objective 4 Investigate the significant differences in barriers to small firms by employee size in Canada.</p>

<p>Research Issue 5 What are the areas of Canada’s global competitiveness affecting the sustainability of small firms?</p>	<p>Research Objective 5 Investigate the performance of Canada’s global competitiveness to determine the weak pillars that affect the sustainability of small firms.</p>

Figure 1 shows the theoretical framework to facilitate the discussion of the five research objectives.

Source: Developed by author for this research.

Figure 1: Theoretical Framework

Referring to Figure 1, the key primary objective related to the theoretical framework and as stated in Research Objective 1 is to identify significant barriers to small firms.

The three related objectives are to investigate the differences in barriers to small firms among regions, types of business and employee sizes as stated in Research Objectives 2 to 4. Together they contribute to the significant barriers to small firms.

The final objective as stated in Research Objective 5 is to identify the weak pillars of Canada’s global competitiveness that affect the sustainability of small firms.

Following the investigations, this paper will present implications for policies to improve the sustainability of small firms and stimulate entrepreneurship, which in turn enhance Canada’s global competitiveness.

The relevance of knowledge assets as fundamental strategic factors of business success has been widely recognised in today’s competitive scenario (Barney, 1991;

Drucker, 1993). In this regard, this research will also propose a framework that captures and utilizes relevant knowledge to plan and implement policies that sustain the growth of small firms and enhance the nation's global competitiveness.

Knowledge management is cultivating a learning culture in which an organization's members systematically gather knowledge and share it with others in the organization to achieve better performance (Robbins et al., 2012). In the context of this paper, the organization is the nation and the need for knowledge management pertains to the barriers faced by small business.

1.2 Contributions of this Study

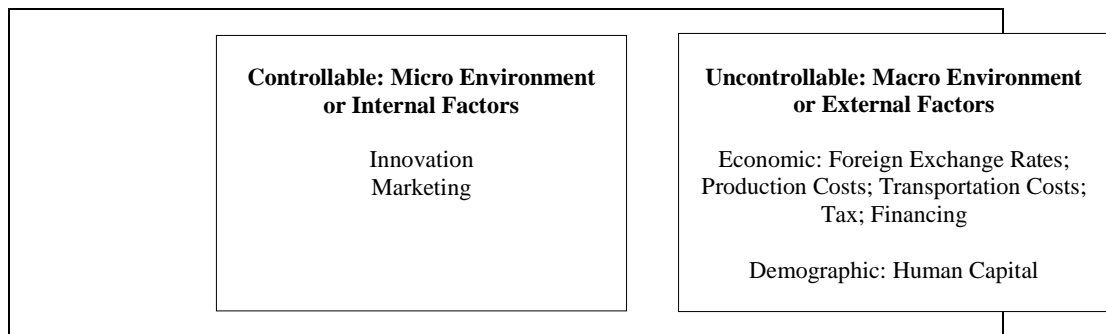

Canada's small businesses are engines for job creation that boost economic growth. In 2012, over 7.7 million employees, or 69.7 % of the total private labour force, worked for small businesses (Industry Canada, 2014). Despite recognition as the biggest employer, there is a lack of literature that identifies a comprehensive range of barriers to small firms, or studies the relationship between the barriers and the nation's global competitiveness, to provide a holistic approach to sustaining small business growth.

Canada is richly endowed with natural resources and its physical and cultural proximity with the biggest market in the world, the United States (US), has enabled the development of manufacturing and export industries. Canada's policy of cultural diversity has encouraged international trade and high educational attainments provided the intellectual capital to fuel economic progress. Despite all these favourable indicators, Canada still slips from 10th to 14th position in the global competitiveness rankings among 140 plus nations by the World Economic Forum. This study is timely to identify the weak pillars of competitiveness that hinder the growth of small business.

2. Literature Review

What are the barriers to small business? Are the barriers to small business the same or different from bigger businesses?

The first question can be answered by literature that studied specific issues to small business. These issues can be attributed to controllable and uncontrollable factors as shown in Figure 2.

Source: Developed by the author for this study.

Figure 2: Controllable and Uncontrollable Factors faced by Small Firms

The controllable issues are related to the micro environment or internal factors. Small firms can determine the kind of innovative products and/or services they can offer to local and international markets (Aschalek, 2011; Hunter, 2002; Withers, Drnevich and Marion, 2011). Canadian television shows such as Dragons Den feature entrepreneurs seeking funding to market their innovations. Small firm entrepreneurs work for themselves and thus, have the flexibility to create products and services that they deem marketable, unlike corporate employees who are subject to investment priorities (Burgess, 2002; McMillan, 2009; Sharma, Greg and Sharma, 2011; Spence, 2003). They generally have funds in the initial stage of research and development but they would eventually need help to market their innovations (Duan, Yangins, Mullins & Hamblin, 2002; Elsen, 2011; Hannel, 2003).

Small firms can control the variables in their marketing strategy – target market, product, price, distribution channels, promotion and customer service. They can decide which markets to target, evaluate emerging markets and adapt responsively to customer needs (Chadwick, Moore and Polushin, 2008; Ghafoo, Fukaikha, Khan and Hassan, 2011; Craig et al., 2006; Reuber and Fisher, 2012; Rowden, 2001). Geographical proximity such as domestic markets and export destinations closer to Canada will help lower transportation costs (Kohli, 1994; Lawless, 2010; Lee and Swagel, 1997; Partridge and Futan, 2008) while cultural and language proximities will ease trade with international markets (Easton and Kortum, 2002; Hutchinson, 2005; Lawless, 2010; Lloyd, 2008).

However, there are uncontrollable variables that affect small firms negatively, known as the macro environmental or external factors. The economic environment is largely influenced by local and global political developments. Firms are subject to increase in cost in transportation and raw materials for production (Lai and Chun, 2004; Carrere and Schiff, 2004; Clausing, 2001) as well as fluctuations in foreign exchange rates (Carrere and Schiff, 2004; Kohli, 1994).

While some entrepreneurs are able to initiate innovations with their own funds, others need financing to get started. However, small firms will ultimately need financing to commercialize innovations to reach a wider market and achieve economies of scale (Craig et al., 2006; Duan et al., 2002; Kalantaridis and Vassilev, 2011; Miocevik and Crjnak Karanovic, 2011). The issue is access to financing. Investments in start-ups have declined from \$5.9 billion with 1,007 ventures in 2000 to \$1.5 billion with 444 ventures in 2011 (Canadian Chamber of Commerce, 2013), which means the dollar investment and number of new ventures financed had shrunk respectively to 25% and 44% of the start-ups a decade ago.

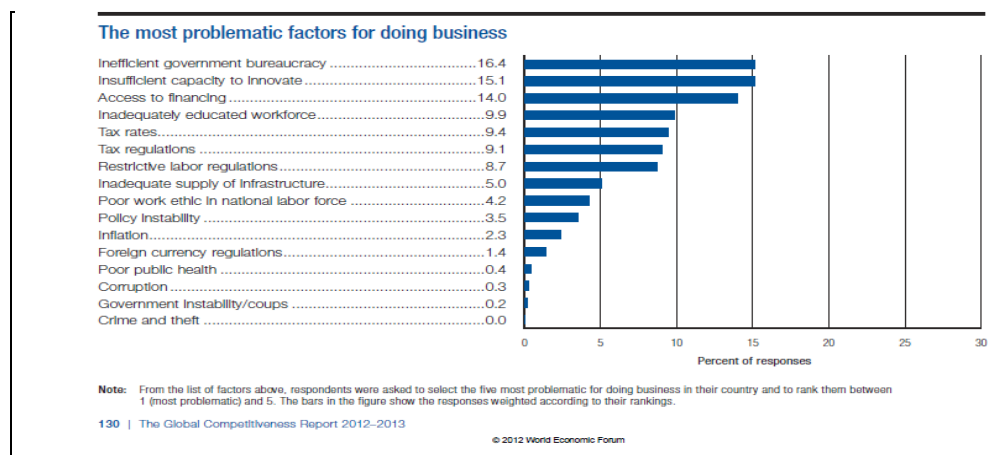

Tax is a perennial headache of the small business (Carrere and Schiff, 2005; Herander and Saavedra, 2005, Lain and Chun, 2004). A study in 2008 revealed that the annual cost for business compliance with tax obligations was \$12.6 billion, with 90.5% of that cost largely shouldered by small firms and partly by medium size firms (CGA, 2012). Many low and middle income sole proprietors face punishingly high marginal effective personal income tax rates that discourage them from working, saving and taking further education and training.

Demographics are a study of human population trends with variables such as age, gender and education (Schiffman and Wisenblit, 2014). Small firms face a shortage of skilled labour for two main reasons. Canada has a big boomer generation who are retiring and there are not enough people to replace them. Secondly, small firms have to battle with large firms to attract and retain talent. While employees in large firms have specialized job functions that attract new graduates, the employees in small firms need a range of multi-tasking skills from administration to finance to marketing to customer service which are generally available among more experienced personnel (Aschick, 2011; Brichard, 2010; McMillan, 2009; Craig et al., 2006).

The most consistent and comprehensive study on the barriers to small business has been undertaken by the World Economic Forum (WEF) since 2004. The results are

reported in the WEF's annual Global Competitiveness Report which ranks countries based on the Global Competitiveness Index, developed by Sala-i-Martin and Artadi (Global Competitiveness Report, 2014). Before that, the macroeconomic ranks were based on Sach's Growth Development Index and the microeconomic ranks were based on Porter's Business Competitiveness Index. The Global Competitiveness Index integrates the macroeconomic and the micro/business aspects of competitiveness into a single index.

The launch of the Global Competitiveness Index introduced an Executive Opinion Survey that comprised 14 most problematic factors to doing business, expanded to 16 factors from 2012 as shown in Figure 3.

Source: Global Competitiveness Report 2012-2013 p. 130.

Figure 3: The 16 Most Problematic Factors for Doing Business in Canada in 2012-13

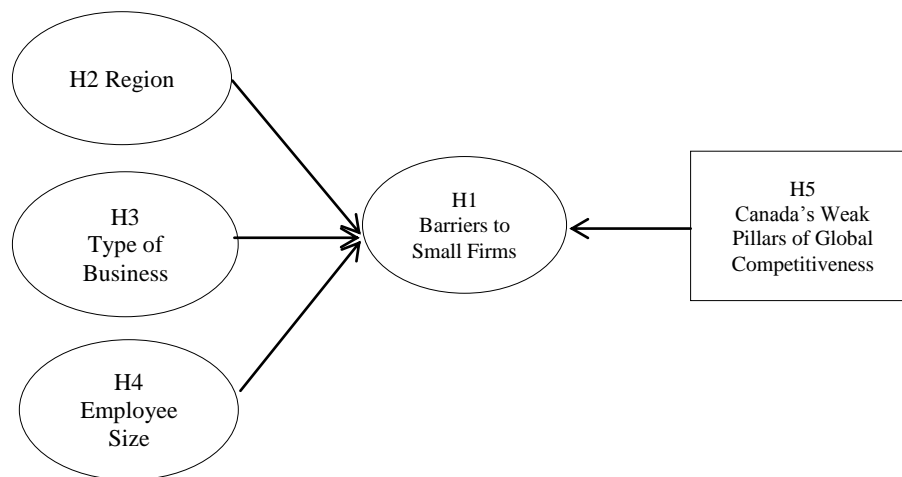

As can be seen from Figure 3, the survey covers a comprehensive range of factors including tax, financing, labour, infrastructure and government policies and stability – factors that comprise the external and internal environments as shown in Appendix 1. The survey covers 15,000 business respondents averaging 98 per nation from over 140 countries. The findings identify the most problematic factors for doing business, providing indicators where governments could collaborate with businesses to improve economic health. The data is studied by various institutions in each country for policy formulation which include government agencies, institutes of strategic studies, consulting firms and not-for-profit research organizations (Conference Board of Canada, 2014).

While the findings provide advice and competitive data that stimulate and direct the activities for collaboration between the government and its business constituents, the Executive Opinion Survey (EOS) does not focus on small firms but is likely to interview captains of industry as well as medium and small firms, and in this research the EOS sample is referred as “bigger firms.” The information on the barriers faced by small firms are all the more critical considering that small firms are the biggest employer and rescuer of the Canadian economy in the last decade with its export revenue. This lack of information leads back to the two questions at the start of literature review: *What are the barriers to small business? Are the barriers to small firms the same with or different from bigger firms?*

The best way to answer the two questions is to replicate the “16 most problematic factors to doing business” survey among small firms. This will be the first test to validate if the factors also apply to small firms and if they do, will the top five factors be the same with the bigger firms?

2.1 Hypotheses

In the earlier section, five research objectives were specified. In this section, a theoretical framework is established to guide research. Figure 4 shows the key variables representing the five research objectives under study. The key objective is to identify the most problematic factors to small firms (H1). Different provinces/regions (H2), types of business (H3) and employee sizes (H4) may experience different problematic factors and these three demographic variables contribute collectively to the barriers to small firms. Finally, the research extends to investigating the pillars of Canada’s global competitiveness that impact small firms negatively (H5).

Source: Developed by author for this research.

Figure 4: Theoretical Framework

2.1.1 Identify the significant barriers to small firms in Canada and investigate any differences with bigger firms.

Replicating the WEF’s survey of the 16 most problematic factors will help determine the significant barriers to small firms and the extent of similarity or difference between small firms and bigger firms. Although the Global Competitiveness Report by the WEF does not state the size of the respondents’ firm, a major emphasis will be to interview corporate figures who are regarded as captains in their respective industries and their views of the evolving barriers are important to governments to improve business and global trade.

Appendix 2 shows the weighted responses according to the rankings of each problematic factor in the surveys from 2009/10 to 2013/14. As ratings by respondents may fluctuate by the year, consistency is sought and thus, averages are used to indicate the consistency of respondents’ views. The results in the average column show the five most problematic factors are Access to Financing, Inefficient Government Bureaucracy, Insufficient Capacity to Innovate, Tax Rates and Tax Regulations.

Small firms are expected to share four problematic factors. Tax Rates and Tax Regulations are expected to be among the top five most problematic factors as small

firms bear the most of the burden of the heavy cost of tax compliance as evidenced by the study by the CGA in 2008.

The next most problematic factor would be Access to Financing. New ventures that received financing have dropped to 25% of the number a decade ago. As small firms are the most affected by rising prices which include a recent postage hike by 35 % (Flavelle, 2014) and escalating fuel costs which drive up freight transportation costs (Buonoguore, 2014), small firms need financing to sustain and grow their business.

The last two most problematic factors would be Restrictive Labour Regulations and Poor Work Ethic. The current warning from Restaurants Canada that many restaurants are forced to close if the foreign temporary workers (FTW) program is discontinued (Tencer, 2014) attests to perceived Restrictive Labour Regulations. While supporters for the program's closure cite low wages as disincentive for Canadians among 6.9% population who are unemployed, small firm owners explain that FTWs bring specialized skills and work ethic. Poor Work Ethic may be in part attributed to the difficulty to stay loyal to small firms due to more attractive benefits from bigger firms. These two factors are expected to be unique to small firms as bigger firms are more concerned with government bureaucracy for large contracts and capacity to innovate to grow in multinational giants and conglomerates.

Related to the labour issues would be Inadequately Educated Workforce and Insufficient Capacity to Innovate. However, they are not expected to be among the top five most problematic factors as most small firms are family-operated retail or service business, largely personal services or support services to bigger firms. They tend to be more concerned with sustaining the business against rising cost and competition, and many lack the finance to hire more staff to help grow the business.

Inefficient government bureaucracy is not expected to be a major problem to small firms as Canada has been rated the "second most business friendly" after Hong Kong, beating the U.S., Germany and Japan in a Bloomberg ranking of the best countries for doing business (Argistis, 2014). Thus, the hypothesis is:

H1 The significant barriers to small firms are Tax Rates, Tax Regulations, Access to Financing, Restrictive Labour Regulations and Poor Work Ethic.

2.1.2 *Investigate the significant differences in barriers to small firms between Western and Eastern Canada.*

The dominant industries in Western and Eastern Canada would suggest significant differences in barriers to small firms. Eastern Canada comprises the Atlantic Provinces and Central Canada. The Atlantic Provinces are made up of Newfoundland and Labrador, Prince Edward Island, Nova Scotia and New Brunswick, and their industries are focused in fishing, farming, forestry and mining. Quebec and Ontario make up Central Canada, the manufacturing and industrial heartland that produces over three-quarters of all Canadian manufactured goods (Citizenship and Immigration Canada, 2011).

Western Canada comprises the Prairie Provinces of Manitoba, Saskatchewan and Alberta, and the Western Coast which is British Columbia. The Prairie Provinces are rich in energy resources and some of the most fertile farmland in the world. Vancouver in British Columbia is Canada's largest and busiest port, handling billions of dollars in goods traded around the world (Citizenship and Immigration Canada, 2011).

Further, studies have suggested that there are legitimate, localized labour shortages, particularly in Alberta and Saskatchewan. For example, Restaurants Canada lamented that the changes the federal government made to the temporary foreign workers (TFW) program in 2013 has resulted in the decline of TFWs in the restaurant industry, falling 28% between 2012 and 2013, and dropping another 38% in the first quarter of 2014. The industry group cited numbers from Economic and Social Development Canada and informed that the decline had led to more unfilled restaurant jobs, particularly in Western Canada (Tencer, 2014). Thus, the hypothesis:

H2 There is a significant difference in barriers to small firms between Eastern Canada and Western Canada.

2.1.3 *Investigate the significant differences in barriers to small firms between types of business in Canada?*

Table 2 shows the number of employer businesses by sector and firm size. By definition, the goods-producing sector in Table 2 consists of manufacturing; construction; and forestry, fishing, mining, quarrying, and oil and gas. The service-producing sector consists of wholesale and retail trade; accommodation and food services; professional, scientific and technical services; finance, insurance, real estate and leasing; health care

and social assistance; business, building and other support services; information, culture and recreation; transportation and warehousing; and other services (Statistics Canada, 2014). As shown in Table 2, about 21% of small business employees work in the goods-producing sector and 79% in the service-producing sector.

Table 2: Number of Employer Businesses by Sector and Firm Size (Number of Employees), December 2012

Number of Employees	% of Employer Businesses	Cumulative % of Employer Businesses	Number of Employer Businesses				
			Total	Goods-Producing Sector		Service-Producing Sector	
				Number	%	Number	%
1-4	55.1	55.1	610,178	138,526	22.70	471,652	77.30
5-9	19.8	74.9	219,771	45,958	20.91	173,813	79.09
10-19	12.5	87.4	138,031	26,905	19.49	111,126	80.51
20-49	8.2	95.6	91,026	18,491	20.31	72,535	79.69
50-99	2.6	98.2	28,797	6,686	23.22	22,111	76.78
				Average	21.33	Average	78.67

Source: Adapted from Statistics Canada, Business Register, December 2012.

Statistics Canada (2014) further reports that over half of the 1.08 million small businesses are concentrated in four industries: wholesale trade and retail (18.8 %), construction (11.7 %), professional, scientific and technical services (11.6 %) and other services (10.6 %). The range of industries suggests that a significant difference can be expected between different types of businesses. Thus, the hypothesis:

H3 There is a significant difference in barriers to small firms between different types of businesses.

2.1.4 Investigate the significant differences in barriers to small firms by employee size in Canada.

Table 2 also shows small firms with less than 10 employees are the biggest employer at 74.9 % followed by 10 to 19 employees at 12.5%, and 20 to 49 employees at 8.2 % and 50 to 99 employees at 2.6%. Firms with less than 10 staff would indicate they are in the introduction stage of business or stagnant growth phase, while those with 50 to 99 employees show evidence of expansion and have the potential to grow into medium-sized firms.

In terms of the total number of employees, industries that had the largest number of employees working for small firms were, in order of magnitude, wholesale and retail trade (1.84 million), accommodation and food services (0.91 million), manufacturing

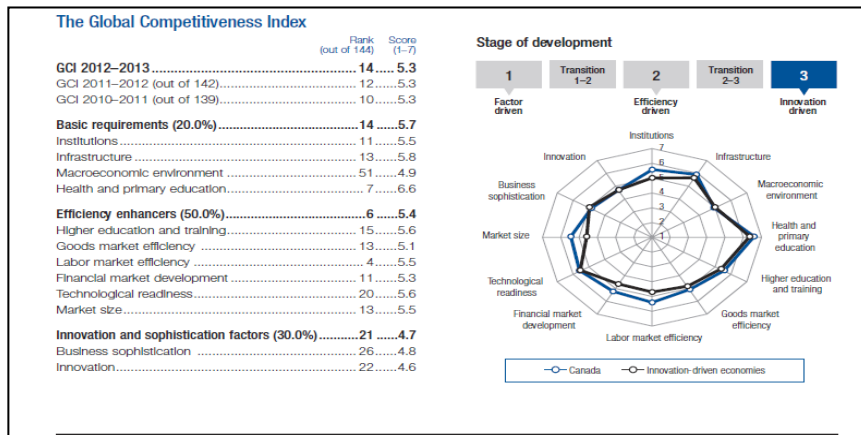

(0.86 million) and construction (0.72 million). These industries alone accounted for 56% of all jobs in small businesses in Canada. Overall, industries in the goods-producing sector accounted for 27.3 % of total employment and 24.0 % of employment in small businesses (Statistics Canada, 2014).

All these suggest that a significant difference can be expected between firms with different number of employees, termed employee size. Based on the statistics in Figure 2, there is a need to collapse the various employee sizes into categories to allow statistical analysis, resulting in the hypothesis below.

H4 There is a significant difference in barriers to small firms between employee sizes of 1 to 10 and 11 to 20, and 1 to 10 and 21 to 99.

2.1.5 Investigate the performance of Canada’s global competitiveness to determine the weak pillars that affect the sustainability of small firms.

Canada’s fluctuating performance in global competitiveness in recent years can be seen in Figure 5. The Global Competitiveness Index (GCI) shows Canada was ranked 10th of 139 countries in 2010-2011 but slipped to 12th of 142 countries in 2011-2012, and declined to 14th of 144 countries in 2012-2013. Canada holds on to 14th place of 148 countries in the Global Competitiveness Report 2013-2014.

Source:

Global Competitiveness Report 2012-2013

Figure 5: Canada’s Global Competitiveness Rankings 2012-2013

The GCI shows the rankings of the 12 pillars of competitiveness in three stages of economic development: *factor-driven* which demands Basic Requirements (20%), *efficiency-driven* where the nation has Efficiency Enhancers (50%), and finally *innovation-driven* where the nation has strong Innovation and Sophistication Factors (30%). Canada is in the innovation-driven stage and Canada's performance equals the average performance of innovation-driven economies in eight pillars and exceeds in four pillars – Institution, Market Size, Financial Market Development and Labour Market Efficiency. However, Canada's current performance in 2013-2014 continues to see six pillars ranked below its 14th rank: Pillar 3 Macroeconomic Environment ranked 50th, Pillar 11 Business Sophistication ranked 25th, Pillar 12 Innovation ranked 21st. Pillar 9 Technological Readiness ranked 21st, Pillar 6 Goods Market Efficiency ranked 17th, and Pillar 5 Higher Education and Training ranked 16th.

Among the 12 pillars, Pillar 3 Macroeconomic Environment and Pillar 5 Higher Education and Training are expected to impact small business as the key barriers to small firms are related to tax, financing and work ethic.

H5 Pillar 3 Macroeconomic Environment and Pillar 5 Higher Education and Training are the two pillars of competitiveness that impact the most problematic factors to doing business for small businesses.

3. Methodology

3.1 Research Instrument

The WEF's survey of the 16 most problematic factors was replicated. Following an exploratory research among 50 small firms, demographic variables covering location/province, number of employees and type of business were included. Appendix 3 shows the final questionnaire. The respondent was requested to rate each factor from 1 as most problematic to 5 as least problematic. The Likert scale was maintained without modifying the description such as 3 for neutral as each factor is a problem varying in degree from country to country.

3.2 Research Sampling

The sampling process followed five key steps (Luck and Rubin, 1987; Malhotra, 2013).

1. Define the population: Firms with 1 to 99 employees. There are 1,087,803 small firms in Canada and 151,866 small firms in Alberta as at August 2013 (Statistics Canada, 2014).
2. Establish sampling frame: All respondents must be based in Canada. As the author and research assistants are based in Edmonton, Alberta is the main sampling frame. However, online surveys are targeted to yield responses beyond Alberta to provide a comparative analysis between Western and Eastern Canada.

Alberta is the most populous Prairie Province, and the largest producer of oil and gas. Alberta is also renowned for agriculture, especially for the vast cattle ranches that make Canada one of the world's major beef producers (Citizenship and Immigration, 2011). In a 2012 survey report that reviewed 103 cities by the Canadian Federation of Independent Business (CFIB), nine of the Top 10 cities best suited for entrepreneurs is situated in Western Canada, with five in Alberta: Grand Prairie, Lloydminster, Red Deer, Edmonton and Lethbridge (Somerset, 2013). In 2014, the CFIB found 72% of Albertans would recommend starting a business in their province behind only Saskatchewan at 88%. Small businesses represent 96% of total businesses and contribute nearly a third of Alberta's GDP (Tonneguzzi, 2014). Thus, Alberta has a heavy concentration of small firms to facilitate sampling.

3. Specify sampling method: There were three key sampling methods – interviews, fax and social media.. With interviews, systematic random (probability) sampling was used to generalize the results as much as possible. Research assistants were instructed to systematically sample every third office or retail outlet within a commercial complex. Research assistants also participated in small business events at the Leduc Chamber of Commerce to interview participants. The interview methods comprised personal interviews and self-administered questionnaires in the presence of a research assistant to help when needed. The questionnaire was made available online via email, Facebook and Reddit to reach small firms beyond Alberta. The questionnaire was also faxed to 50 small firms.

4. Determine sample size. A sample size of at least 200 was recommended to provide a sound basis for estimation (Hair, Black, Babin, Anderson and Tatham, 2006). This research aimed for at least 300 respondents.
5. Execute sampling process: The procedures specified to research assistants were firstly, survey only firms with less than 100 employees and secondly, select every third office or retail outlet within the survey areas.

Six students representing a diverse mix of Caucasian, Asian and African ethnicity were recruited based on their projection of professionalism, enthusiasm and confidence to establish rapport with respondents. Each assistant could speak at least one other language apart from English as retailers such as those in food business were expected to be largely visible minorities. They were trained to motivate respondents to accept the survey and answer all questions. During weekends and mid-semester breaks, these students visited their hometowns and collected data via online and interviews.

3.3 Methods of Statistical Analysis

For research objective 1, analysis by Mean will help determine the rank order of the 16 most problematic factors and One-Sample Test will determine the significance of each factor. Analysis by Mean will also be used in research objective 5 to determine the weak pillars of global competitiveness that affect small business.

For research objectives 2 to 4, the Chi-square test for independence and Independent Samples Test will help determine significant associations between variables and significant differences between samples. The Chi-square test is suited to explore the relationships between two categorical variables for research objectives 2 to 4. Interpreting chi-square results, the minimum expected cell frequency should be 5 or greater, or at least 80% of cells should have frequencies of 5 or more (Pallant, 2010). In other words, no more than 20% of the expected counts are less than 5 and all individual expected counts are 1 or greater (Yates, Moore and McCabe, 1999 p. 734). The most important value would be the Pearson chi-square value and the Sig. value needs to be 0.05 or smaller for significance (Pallant, 2010).

Independent samples test were used to test for significant differences. The test shows results under two main labels: Levene's test for Equality of Variances and t-test for Equality of Means. The procedures for testing (Pallant, 2010) are explained below.

Levene's test for Equality of Variances

- If Significant (Sig.) value is larger than 0.05, *Equal variances assumed* (EVA) would be used.
- If the significance level of Levene's test is $p = 0.05$ or less, the variances for the two groups are not the same. This means the data violates the assumption of equal variance and *Equal variances not assumed* (EVNA) would be used.

t-test for Equality of Means

The Sig. (2-tailed) values under t-test for Equality of Means will show whether there is a significant difference. The Sig. (2-tailed) value will be chosen according to the Sig. value selected in the Levene's test:

- If the value in the Sig. (2-tailed) column is equal or less than 0.05, there is significant difference in the mean scores of the dependent variable for each of the two groups.
- If the value is above 0.05, there is no significant difference between the two groups. (Pallant. 2010)

4. Results

This section will discuss the results by demographics followed by the research objectives.

4.1 Demographics: Respondents' Characteristics

A total of 316 fully completed questionnaires collected were usable and the respondents' characteristics were analyzed by frequency tables according to province, type of business, employee size and data collection method.

4.1.1 City and Province

The respondents represented 57 cities from 10 provinces. Edmonton yielded the highest number of respondents at 170 as expected being the residence of the author and research assistants. Alberta has the highest number of respondents at 251 or 79.5%, followed by Ontario at 33 or 10.4%. The other provinces have less than 3% of respondents. The information by city and province is presented in Table 3 and Table 4.

Table 3: Respondents by City and Province

City, Province	N	City, Province	N	City, Province	N
1. Bonnyville, AB	1	2. Rathwell, MB	1	3. Richmond Hill, ON	1
4. Calgary, AB	2	5. Sanford, MB	1	6. Scarborough, ON	1
7. Drayton Valley, AB	1	8. Selkirk, MB	1	9. St. Catharines, ON	1
10. Edmonton, AB	170	11. Saint-Leolin, NB	1	12. Stoney Creek, ON	1
13. Elk Point, AB	5	14. St. Josephs, NL	1	15. Stratford, ON	1
16. Frog Lake, AB	2	17. Sydney, NS	1	18. Toronto, ON	11
19. Leduc, AB	24	20. Athens, ON	1	21. Windsor, ON	1
22. Nisku, AB	2	23. Blackstock, ON	1	24. Woodbridge, ON	1
25. Spruce Grove, AB	2	26. Carleton Place, ON	1	27. Cardigan, PEI	1
28. St. Paul, AB	41	29. Dunnville, ON	1	30. Gatineau, QC	1
31. Vegreville, AB	1	32. Elmira, ON	1	33. Kingston, QC	1
34. Dawson Creek, BC	1	35. Innisfil, ON	2	36. Kirkland, QC	1
37. Fort St. John, BC	1	38. Lions Head, ON	1	39. Montreal, QC	3
40. Pritchard, BC	1	41. London, ON	1	42. Saint-Hyacinthe, QC	1
43. Richmond, BC	1	44. Markham, ON	1	45. Biggar, SK	1
46. Surrey, BC	1	47. Mississauga, ON	1	48. Chitek Lake, SK	1
49. Vancouver, BC	3	50. Orleans, ON	1	51. Herbert, SK	1
52. Winnipeg, MB	3	53. Ottawa, ON	2	54. Outlook, SK	1
55. Lorette, MB	1	56. Peterborough, ON	1	57. Saskatoon, SK	2

Key: N = Number of respondents; AB = Alberta, BC = British Columbia, MB = Manitoba, NB = New Brunswick, NS = Nova Scotia, NL = Newfoundland, ON = Ontario, PEI = Prince Edward Island, QC = Quebec, SK = Saskatchewan

Table 4: Frequency by Province

	Frequency	Percent	Valid Percent	Cumulative Percent
Valid AB	251	79.4	79.4	79.4
ON	33	10.4	10.4	89.9
BC	8	2.5	2.5	92.4
QC	7	2.2	2.2	94.6
SK	6	1.9	1.9	96.5
MB	7	2.2	2.2	98.7
PE	1	.3	.3	99.1
NS	1	.3	.3	99.4
NB	1	.3	.3	99.7
NL	1	.3	.3	100.0
Total	316	100.0	100.0	

AB and ON are the only two provinces with a sample big enough for statistical analysis. As the rest of the provinces were too small in sample size to allow meaningful statistical analysis, they were collapsed into two major categories:

- Western Canada (BC, AB, SK and MB) represented 273 respondents, and
- Eastern Canada (ON, QC, NB, PE, NS and NL) represented 43 respondents, totalling 316 respondents.

4.1.2 Employee Size

Employee size range from one to 98 employees. Employee size 1 to 10 represented 72.8% of respondents. Three employee sizes had more than 10% of respondents: 2 employees at 12.3%, 4 employees at 11.7% and 3 employees at 10.4% as shown in Table 5.

Table 5: Frequency by Employee Size from 1 to 98

	Frequency	Percent	Valid Percent	Cumulative Percent
Valid 1.00	22	7.0	7.0	7.0
2.00	39	12.3	12.3	19.3
3.00	33	10.4	10.4	29.7
4.00	37	11.7	11.7	41.5
5.00	31	9.8	9.8	51.3
6.00	15	4.7	4.7	56.0
7.00	12	3.8	3.8	59.8
8.00	16	5.1	5.1	64.9
9.00	12	3.8	3.8	68.7
10.00	13	4.1	4.1	72.8
11.00	5	1.6	1.6	74.4
12.00	7	2.2	2.2	76.6
13.00	6	1.9	1.9	78.5
14.00	6	1.9	1.9	80.4
15.00	7	2.2	2.2	82.6

17.00	1	.3	.3	84.2
18.00	3	.9	.9	85.1
20.00	2	.6	.6	85.8
22.00	2	.6	.6	86.4
23.00	3	.9	.9	87.3
24.00	1	.3	.3	87.7
25.00	4	1.3	1.3	88.9
26.00	1	.3	.3	89.2
29.00	1	.3	.3	89.6
30.00	2	.6	.6	90.2
34.00	2	.6	.6	90.8
38.00	2	.6	.6	91.5
43.00	1	.3	.3	91.8
44.00	1	.3	.3	92.1
45.00	3	.9	.9	93.0
47.00	1	.3	.3	93.4
50.00	4	1.3	1.3	94.6
51.00	1	.3	.3	94.9
55.00	1	.3	.3	95.3
60.00	1	.3	.3	95.6
61.00	1	.3	.3	95.9
75.00	2	.6	.6	96.5

76.00	1	.3	.3	96.8
77.00	1	.3	.3	97.2
79.00	1	.3	.3	97.5
85.00	1	.3	.3	97.8
87.00	1	.3	.3	98.1
88.00	1	.3	.3	98.4
90.00	1	.3	.3	98.7
95.00	1	.3	.3	99.1
96.00	1	.3	.3	99.4
98.00	2	.6	.6	100.0
Total	316	100.0	100.0	

As the majority of the respondents have one or two employees, they were collapsed into three main categories to facilitate statistical analysis:

- 1 to 10 employees represented 222 respondents
- 11 to 20 employees represented 51 respondents and
- 21 to 99 represented 43 respondents.

4.1.3 *Type of Business*

Table 6 shows Retail and Service are the two most dominant types of business at 47.5% and 34.2% respectively. Restaurants, food catering, auto repair and construction services are the more frequent small businesses. Some of the service and retail/service small firms play an auxiliary role to the oil, agriculture and manufacturing industries, while others provide personal services such as tailoring and fashion, jewellery and accessories, hair grooming, dental and medical services.

Table 6: Frequency by Type of Business

	Frequency	Percent	Valid Percent	Cumulative Percent
Retail	150	47.5	47.5	47.5
Service	108	34.2	34.2	81.7
Oil	22	7	7	88.7
Valid Agriculture	18	5.7	5.7	94.4
Retail/Service	16	5.1	5.1	99.5
Manufacturing	2	0.6	0.6	100
Total	316	100	100	

As some types of business were too small in sample size for statistical analysis, they were collapsed into three main categories:

- Retail representing 158 respondents

- Service representing 116 respondents, and
- Others (Oil, Agriculture and Manufacturing) representing 42 respondents.

4.1.4 Data Collection Method

Table 7 shows the most frequent data collection method was Interview at 32%. Social media surveys via Reddit and Facebook yielded 21.5% and 15.5%, totalling 37%. Email and Self-Administered surveys were least frequent with less than 5%.

Table 7: Data Collection Method

	Frequency	Percent	Valid Percent	Cumulative Percent
Valid Interview: Personal	101	32.0	32.0	32.0
Online: Reddit	68	21.5	21.5	53.5
Fax	50	15.8	15.8	69.3
Online Facebook	49	15.5	15.5	84.8
Interview: Conference Participants	25	7.9	7.9	92.7
Online: email	14	4.4	4.4	97.2
Interview: Self-Administered	9	2.8	2.8	100.0
Total	316	100.0	100.0	

4.2. Research Objectives

4.2.1 *Identify the significant barriers to small firms in Canada and investigate any differences with bigger firms.*

The results of the ranking of the 16 most problematic factors are presented in Table 8. The hypothesis for research objective 1 expected the top five significant barriers to be Tax Rates, Tax Regulations, Access to Financing, Restrictive Labour Regulations and Poor Work Ethic. The first three factors were in the right order but Poor Work Ethic was viewed as more problematic than Restrictive Labour Regulations. The mean values of Tax Rates, Tax Regulations, Access to Financing and Poor Work Ethic fall between 2 and 3 indicating the degree of the factor being problematic. The mean of Restrictive Labour Relations at 3.04 is in the zone of somewhat problematic although it leans close to problematic.

Table 8: One-Sample Statistics

	N	Mean	Std. Deviation	Std. Error Mean
1. Tax Rates	316	2.57	1.223	.069
2. Tax Regulations	316	2.63	1.187	.067
3. Access to Financing	316	2.78	1.248	.070
4. Poor Work Ethic in National Labour Force	316	2.84	1.256	.071
5. Restrictive Labour Regulations	316	3.04	1.158	.065
6. Insufficient Capacity to Innovate	316	3.19	1.117	.063
7. Inadequately Educated Workforce	316	3.25	1.207	.068
8. Inflation	316	3.27	1.173	.066
9. Crime and Theft	316	3.27	1.298	.073
10. Inefficient Government Bureaucracy	316	3.42	1.100	.062
11. Inadequate Supply of Infrastructure	316	3.48	1.085	.061
12. Policy Instability	316	3.75	1.025	.058
13. Poor Public Health	316	3.92	-1.069	.060
14. Foreign currency regulations	316	4.05	1.008	.057
15. Corruption	316	4.05	1.027	.058
16. Government Instability	316	4.17	.955	.054

Are all 16 factors significant? A One-Sample Test would help provide the answer but first the test value has to be determined. As the Likert scale 1 represents most problematic and 5 least problematic, the mean between:

- 1 and 2 would indicate the degree of being most problematic as it moves closer to 1,
- 2 and 3 would indicate the degree of being problematic as it moves closer to 2,
- 3 and 4 would indicate the degree of being somewhat problematic as it moves closer to 3 and finally,
- 4 and 5 would indicate the degree of being least problematic as it moves closer to 5.

Thus, the mean 4 would be the point that a factor has become less problematic, graduating to least problematic as the mean becomes 5. Taking 4 as the test value between 3 and 4 indicating the degree of a factor being somewhat problematic, a One-Sample Test was run with the following results in Table 9.

Table 9: One-Sample Test

	Test Value = 4					
	t	df	Sig. (2-tailed)	Mean Difference	95% Confidence Interval of the Difference	
					Lower	Upper
Inefficient Government Bureaucracy	-9.307	315	.000	-.576	-.70	-.45
Insufficient Capacity to Innovate	-12.839	315	.000	-.807	-.93	-.68
Access to Financing	-17.401	315	.000	-1.222	-1.36	-1.08
Inadequately Educated Workforce	-11.094	315	.000	-.753	-.89	-.62
Tax Rates	-20.784	315	.000	-1.430	-1.57	-1.29
Tax Regulations	-20.566	315	.000	-1.373	-1.50	-1.24
Restrictive Labour Regulations	-14.718	315	.000	-.959	-1.09	-.83
Inadequate Supply of Infrastructure	-8.502	315	.000	-.519	-.64	-.40
Poor Work Ethic in National Labour Force	-16.440	315	.000	-1.161	-1.30	-1.02
Policy Instability	-4.334	315	.000	-.250	-.36	-.14
Inflation	-11.123	315	.000	-.734	-.86	-.60
Foreign currency regulations	.837	315	.403	.047	-.06	.16
Poor Public Health	-1.263	315	.208	-.076	-.19	.04
Corruption	.931	315	.352	.054	-.06	.17
Government Instability	3.239	315	.001	.174	.07	.28
Crime and Theft	-9.969	315	.000	-.728	-.87	-.58

From the above table, all the factors are found significant as barriers to small business except Foreign currency regulations, Poor Public Health and Corruption at $p < 0.005$.

How do the results compare with the WEF's findings of bigger firms? Appendix 4 shows the detailed results of the comparison. Table 10 shows the comparison between the findings from the 316 respondents and the WEF's findings for 2013/14 and average of 5-year period from 2009/10 to 2013/14.

Table 10: Comparison of the findings between WEF's surveys and this research

Rank	WEF 2009/10 to 2013/14	WEF 2013/14	This Research: 316
1.	Access to financing	Access to financing	Tax rates
2.	Inefficient government bureaucracy	Insufficient Capacity to Innovate	Tax regulations
3.	Insufficient Capacity to	Inefficient government	Access to financing
4.	Tax rates	Tax regulations	Poor Work Ethic in national
5.	Tax regulations	Tax rates	Restrictive labor

Note: WEF = World Economic Forum

Table 10 also shows that small firms share three barriers with bigger firms: Tax Rates, Tax Regulations and Access to Financing. However, these three factors are ranked 1st, 2nd and 3rd by small firms compared to the WEF's 2013/14 and 5-Year Average where Access to Financing was ranked 1st, and Tax Rates and Tax Regulations ranked 4th and 5th in the 5-Year Average, and reversed as 5th and 4th in 2013/14.

Poor Work Ethic and Restrictive Labour Regulations ranked 4th and 5th are unique barriers to small firms versus Inefficient Government Bureaucracy and Insufficient Capacity to Innovate which are second and third in the 5-year average and reversed in 2013/14.

Hence, the top five barriers to small firms are different from bigger firms being Tax Rates, Tax Regulations and Access to Financing as the top three in rank order. Poor Work Ethic and Restrictive Labour Regulations are the remaining two factors, unique to small firms.

4.2.2 Investigate the significant differences in barriers to small firms between Western and Eastern Canada.

Table 11 shows Chi-square tests established a significant association between Regions and five Barriers: Tax Rates, Tax Regulations, Inadequate Supply of Infrastructure, Access to Financing and Restrictive Labour Relations as the Pearson Chi-Square Asymp. Sig. (2-sided) value is below 0.05.

Table 11: Chi-Square Tests for Association between Barriers and Regions (Western and Eastern Canada)

Barriers	Pearson Chi-Square		
	Value	df	Asymp. Sig. (2-sided)
1. Tax Rates	20.102 ^a	4	.000
2. Tax Regulations	15.879 ^a	4	.003
3. Inadequate Supply of Infrastructure	14.078 ^a	4	.007
4. Access to Financing	13.291 ^a	4	.010
5. Restrictive Labour Relations	10.042 ^a	4	.040

a. 1 cells (10.0%) have expected count less than 5. The minimum expected counts are greater than 1.

The next test is to verify significant differences between Western and Eastern Canada. Table 12 shows the results of independent samples test between Western and Eastern Canada, and between Alberta (AB) and Ontario (ON).

Table 12: Independent Samples Test for Significance Difference between Regions/Provinces

Provinces/Regions	Barrier	Levene's Test for Equality of Variance		t-test for Equality of Means	
		F	Sig	Sig. (2-tailed)	
Western and Eastern Canada	Insufficient Capacity to Innovate	EVA	3.902	0.049	0.016
		EVNA			0.007
Western and Eastern Canada	Access to Financing	EVA	0.119	0.73	0.001
		EVNA			0.001
Western and Eastern Canada	Tax Rates	EVA	16.426	0.000	0.000
		EVNA			0.000
Western and Eastern Canada	Tax Regulations	EVA	6.272	0.013	0.000
		EVNA			0.000
Western and Eastern Canada	Restrictive Labour Relations	EVA	2.529	0.113	0.005
		EVNA			0.001
Eastern and Western Canada	Inadequate Supply of Infrastructure	EVA	5.183	0.023	0.001
		EVNA			0.01
Western and Eastern Canada	Foreign currency regulations	EVA	0.45	0.503	0.005
		EVNA			0.008
AB and ON	Insufficient Capacity to Innovate	EVA	4.368	0.38	0.024
		EVNA			.008
AB and ON	Access to Financing	EVA	6	0.937	0.004
		EVNA			0.006
AB and ON	Tax Rates	EVA	15.146	0.000	0.000
		EVNA			0.000
AB and ON	Tax Regulations	EVA	3.103	0.079	0.000
		EVNA			0.000
AB and ON	Restrictive labour Regulations	EVA	1.311	0.253	0.018
		EVNA			0.010
AB and ON	Inadequate Supply of Infrastructure	EVA	8.444	0.004	0.002
		EVNA			0.001
AB and ON	Foreign currency regulations	EVA	0.916	0.339	0.022
		EVNA			0.037

Note: Levene's test for Equality of Variances – Sig. > 0.05 *Equal variances assumed* (EVA) would be used, **Sig. < 0.05 *Equal variances not assumed* (EVNA) would be used.** t-test for Equality of Means - Sig. (2-tailed) value will be chosen according to the Sig. value selected in the Levene's test; Sig. (2-tailed) = or < 0.05, there is significant difference.

Based on Table 12, there is a significant difference between Western and Eastern Canada, and between AB and ON. The two regions and two provinces have significant differences in seven identical barriers: Insufficient Capacity to Innovate, Access to Financing, Tax Rates, Tax Regulations, Restrictive Labour Regulations, Inadequate Supply of Infrastructure and Foreign currency regulations.

4.2.3 *Investigate the significant differences in barriers to small firms between types of business in Canada?*

Table 13 shows Chi-square tests established a significant association between Type of Business and eight Barriers: Inadequately Educated Workforce, Inflation, Crime and Theft, Restrictive Labour Relations, Inadequate Supply of Infrastructure, Insufficient Capacity to Innovate, Poor Work Ethics and Access to Financing, as the Pearson Chi-Square Asymp. Sig. (2-sided) value is below 0.05.

Table 13: Chi-Square Tests for Association between Type of Business and Barriers

Barriers	Pearson Chi-Square		
	Value	df	Asymp. Sig. (2-sided)
1. Inadequately Educated Workforce	29.794 ^a	8	.000
2. Inflation	37.919 ^a	8	.000
3. Crime and Theft	37.852 ^a	8	.000
4. Restrictive Labour Relations	23.533 ^a	8	.003
5. Inadequate Supply of Infrastructure	19.750 ^a	8	.011
6. Insufficient Capacity to Innovate	17.185 ^a	8	.028
7. Poor Work Ethic in national labour force	16.494 ^a	8	.036
8. Access to Financing	21.704 ^a	8	.05

a. 1 cells (6.7%) have expected count less than 5. The minimum expected counts are greater than 1.

The next test is to verify significant differences between the Types of Business. Table 14 shows the results of independent samples test between Types of Business.

Table 14: Independent Samples Test for Significance Difference between Types of Business

Types of Business	Barrier		Levene's Test for Equality of Variance		t-test for Equality of Means
			F	Sig	Sig. (2-tailed)
Retail and Service	Access to Financing	EVA	.028	.868	.000
		EVNA			.000
Retail and Service	Restrictive Labour Relations	EVA	5.436	.020	.002
		EVNA			.002
Retail and Service	Inadequate Supply of Infrastructure	EVA	1.359	.245	.046
		EVNA			.049
Retail and Service	Crime and Theft	EVA	.089	.765	.000
		EVNA			.000
Retail and Others*	Insufficient Capacity to Innovate	EVA	1.256	.264	.007
		EVNA			.014
Retail and Others*	Access to Financing	EVA	0.77	.782	.019
		EVNA			.033
Retail and Others*	Inadequately Educated Workforce	EVA	1.075	.301	.000
		EVNA			.000

		EVNA			.030
Retail and Others*	Tax Regulations	EVA	1.806	.181	.012
		EVNA			.010
Retail and Others*	Inflation	EVA	11.260	.001	.000
		EVNA			.000
Retail and Others*	Government Instability	EVA	4.309	.039	.000
		EVNA			.000
Retail and Others*	Crime and Theft	EVA	.284	.595	.001
		EVNA			.001
Service and Others*	Insufficient Capacity to Innovate	EVA	.001	.977	.009
		EVNA			
Service and Others*	Inadequately Educated Workforce	EVA	4.922	.028	.000
		EVNA			
Service and Others*	Tax Rates	EVA	.806	.371	.020
		EVNA			
Service and Others*	Tax Regulations	EVA	2.062	.153	.018
		EVNA			
Service and Others*	Restrictive Labour Relations	EVA	.451	.503	.001
		EVNA			
Service and Others*	Inadequate Supply of Infrastructure	EVA	.027	.871	.004
		EVNA			
Service and Others*	Inflation	EVA	9.203	.003	.000
		EVNA			
Service and Others*	Government Instability	EVA	6.911	.009	.014
		EVNA			

Note: *Others - Oil, Agriculture and Manufacturing; Levene's test for Equality of Variances – Sig. > 0.05 *Equal variances assumed* (EVA) would be used, **Sig. < 0.05 *Equal variances not assumed* (EVNA) would be used.** t-test for Equality of Means - Sig. (2-tailed) value will be chosen according to the Sig. value selected in the Levene's test; Sig. (2-tailed) = or < 0.05, there is significant difference.

The similarities and differences in the significant differences of the three types of business are summarized in Table 15.

Table 15: Summary of Significant Differences among Types of Business: Retail, Service and Others

Barrier	Retail and Service	Retail and Others	Service and Others
Access to Financing	Yes	Yes	No
Crime and Theft	Yes	Yes	No
Inadequate Supply of Infrastructure	Yes	No	Yes
Restrictive Labour Relations	Yes	No	Yes
Government Instability	No	Yes	Yes
Inadequately Educated Workforce	No	Yes	Yes
Inflation	No	Yes	Yes
Insufficient Capacity to Innovate	No	Yes	Yes
Tax Rates	No	Yes	Yes
Tax Regulations	No	Yes	Yes

Note: Others - Oil, Agriculture and Manufacturing; Yes = Significant Difference and No = No Significant Difference

As can be seen from Table 15, there is a significant difference in four barriers between Retail and Service and a significant difference in eight barriers between Retail and Others, and between Service and Others. No barrier was found with significant difference among them.

4.2.4 Investigate the significant differences in barriers to small firms by employee size in Canada.

Chi –square tests did not establish any significant association between employee size and barriers, but there were significant differences between Employee Sizes. Table 16 shows the results of independent samples test between Employee Sizes.

Table 16: Independent Samples Test for Significance Difference between Employee Sizes

Employee Sizes	Barrier		Levene's Test for Equality of Variance		t-test for Equality of Means
			F	Sig	Sig. (2-tailed)
1 to 10 and 11 to 20	Tax Regulations	EVA	6.457	.012	.034
		EVNA			.024
1 to 10 and	Corruption	EVA	1.654	.200	.009

11 to 20		EVNA			.019
11 to 20 and 21-99	Access to Financing	EVA	1.987	.162	.021
		EVNA			.023

Note: *Others - Oil, Agriculture and Manufacturing; Levene's test for Equality of Variances - Sig. > 0.05 *Equal variances assumed* (EVA) would be used, **Sig. < 0.05 *Equal variances not assumed* (EVNA) would be used.** t-test for Equality of Means - Sig. (2-tailed) value will be chosen according to the Sig. value selected in the Levene's test; Sig. (2-tailed) = or < 0.05, there is significant difference.

Referring to Table 16, there is a significant difference between Employee Sizes 1 to 10 and 11 to 20 in two barriers: Tax Regulations and Corruption. There is also a significant difference between Employee Sizes 11 to 20 and 21 to 99 in one barrier: Access to Financing.

4.2.5 Investigate the performance of Canada's global competitiveness to determine the weak pillars that affect the sustainability of small firms.

Table 17 shows Canada among the Top 15 nations in global competitiveness and their average ranks over three 5-Year periods from 1999 to 2013/14. Appendix 5 shows the detailed performance for each nation each year. Canada was strongest in global competitiveness between 1999 and 2003 averaging 8th rank and achieved 3rd in 2001. However, between 2004 and 2008/09 Canada's average performance dropped by four ranks to an average 13th but improved by one rank at 12th between 2009/10 and 2013/14.

Table 17: Canada's average performance among Top 15 in Global Competitiveness from 1999 to 2013/14

Country	1999-2003 Average	2004-2008/09 Average	2009/10-2013/14 Average
Switzerland	8.4	4.8	1.0
Singapore	5.6	6.6	2.4
Sweden	6.6	4.6	3.8
Finland	2.2	4.0	4.6
United States	5.4	1.4	4.6
Germany	12.8	9.4	5.6
Netherlands	8.2	10.4	7.6
Japan	15.8	8.6	8.4
Denmark	9.6	3.6	9.8
Hong Kong SAR	16.4	16.4	9.8
United Kingdom	11.2	9.4	10.6
Canada	8.2	12.8	11.8
Taiwan, China	8.8	10.6	12.6
Norway	11.4	12.6	14.0
Qatar	NA	27.0	15.4

Source: Global Competitive Reports from 1999 to 2013/14

Table 18 shows Canada's global competitiveness rankings from 2009/10 to 2013/14 among the Top 15. Canada has been slipping in rank each year from 9th in 2009/10 to 14th in 2012/13, and maintained the same position in 2013/14. Even Qatar, from a distant average of 27th between 2004 and 2008/09, has surged past Canada at 13th place. What caused Canada's decline in global competitiveness?

Table 18: Canada's Global Competitiveness rankings from 2009/10 to 2013/14 among Top 15

Country	2009/10	2010/11	2011/12	2012/13	2013/14
Switzerland	1	1	1	1	1
Singapore	3	3	2	2	2
Sweden	4	2	3	4	6
Finland	6	7	4	3	3
United States	2	4	5	7	5
Germany	7	5	6	6	4
Netherlands	10	8	7	5	8
Japan	8	6	9	10	9
Denmark	5	9	8	12	15
Hong Kong SAR	11	11	11	9	7
United Kingdom	13	12	10	8	10
Canada	9	10	12	14	14
Taiwan, China	12	13	13	13	12
Norway	14	14	16	15	11
Qatar	22	17	14	11	13

Table 19 shows Canada's performance in global competitiveness over six years, measured by 12 pillars in three stages of economic development, from 2008/09 to 2013/14. The first stage, *Factor Driven Economies*, is driven by four basic pillars weighted at a total of 20%: (1) Institutions, (2) Infrastructure, (3) Macroeconomic Environment and (4) Health and Primary Education. The second stage, *Efficiency Driven Economies*, is built by five pillars weighted at a total of 50%: (5) Higher Education and Training, (6) Goods Market Efficiency, (7) Labour Market Efficiency, (8) Financial Market Development, (9) Technological Readiness and (10) Market Size. The third stage, *Innovation Driven Economies*, is powered by two pillars weighted at a total of 30%: (11) Business Sophistication and (12) Innovation.

As the rankings fluctuate from year to year, the rankings of the 12 pillars are averaged over a 3-year period from 2008/09 to 2010/11 and from 2011/12 to 2013/1 as shown in Table 19. The last column in Table 19 shows positive or negative Change in Average Rank (Average Rank 1 minus Average Rank 2). Three pillars show positive

change: Institution 2.3, Labour Market Efficiency 2.3 and Market Size 1.3. However, the remaining nine pillars declined in performance.

The pillars that suffer a critical decline of nearly 5 or more ranks need priority attention. Under Basic Requirements, Macroeconomic Stability declined by an average 13.3 ranks and Infrastructure, 4.7 ranks. Under Efficiency Enhancers, Higher Education and Training declined by 5.7 and Technological Readiness, 5.3. Under Innovation and Sophistication Factors, Innovation declined by 6 ranks.

Table 19: Canada's Performance in Global Competitiveness from 2008/09 to 2013/14

Pillar	2008/09	2009/10	2010/11	Average Rank 1	2011/12	2012/13	2012/14	Average Rank 2	Average Rank
Basic Requirements (20%)	8	10	11	9.7	13	14	15	14.0	- 4.3
Institution	15	17	11	14.3	11	11	14	12.0	2.3
Infrastructure	6	7	9	7.3	11	13	12	12.0	- 4.7
Macroeconomic stability	43	31	36	36.7	49	51	50	50.0	- 13.3
Health and primary education	6	7	6	6.3	6	7	7	6.7	- 0.3
Efficiency Enhancers (50%)	5	4	6	5.0	6	6	6	6.0	- 1.0
Higher education and training	9	9	8	8.7	12	15	16	14.3	- 5.7
Goods market efficiency	7	16	11	11.3	12	13	17	14.0	- 2.7
Labour market efficiency	10	7	6	7.7	5	4	7	5.3	2.3
Financial market sophistication	9	11	12	10.7	13	11	12	12.0	- 1.3
Technological readiness	14	11	16	13.7	16	20	21	19.0	- 5.3
Market size	16	14	14	14.7	14	13	13	13.3	1.3
Innovation and sophistication factors (30%)	16	12	14	14.0	15	21	25	20.3	- 6.3
Business sophistication	18	17	16	17.0	2	26	25	17.7	- 0.7
Innovation	13	12	11	12.0	11	22	21	18.0	- 6.0

4.3 Summary of Findings on Research Issues 1 to 5

As a summary, the findings of research issues 1 to 5 are tabulated in Table 20.

Table 20: Summary of Findings of Research Issues 1 to 5

Research Issue	Hypothesis	Findings
1. What are the barriers faced by small firms in Canada and are they different from bigger firms?	The significant barriers to small firms are Tax Rates, Tax Regulations, Access to Financing, Restrictive Labour Relations and Poor Work Ethic.	<p>The hypothesis is partly supported. Tax Rates, Tax Regulations, Access to Financing and Poor Work Ethic fall below the mean value 3 qualifying as problematic factors, while Restrictive Labour Relations has a mean value of 3.04, measured as somewhat problematic although close to problematic.</p> <p>The barriers to small firms are different from bigger firms. The top three of five barriers to small firms in rank order are Tax Rates, Tax Regulations and Access to Financing versus Financing, Inefficient Government Bureaucracy and Insufficient Capacity to Innovate for bigger firms.</p> <p>The remaining two of the top five barriers are unique to small firms: Poor Work Ethic and Restrictive Labour Regulations.</p> <p>Except Foreign Currency Exchange, Poor Public Health and Corruption, the remainder 13 are significant barriers.</p>
2. Is there a difference in the barriers faced by small firms between Eastern and Western Canada?	There is a significant difference in barriers to small firms between Eastern and Western Canada.	The hypothesis is supported. There is a significant difference between Eastern and Western Canada in seven barriers: (1) Insufficient Capacity to Innovate, (2) Access to Financing, (3) Tax Rates, (4) Tax Regulations, (5) Restrictive Labour Relations, (6) Inadequate Supply of Infrastructure and (7) Foreign Currency Regulations. The same significant differences are found between AB and ON.
3. Is there a difference in the barriers faced by small firms among different types of business in Canada?	There is a significant difference in barriers to small firms between different types of business in Canada.	The hypothesis is supported. There is a significant difference in four barriers between Retail and Service, six barriers respectively between Retail and Others and between Service and Others.

4. Is there a difference in the barriers faced by small firms of differing employee size in Canada?	There is a significant difference in barriers to small firms between employee sizes of 1 to 10 and 11 to 20, and between 1 to 10 and 21 to 99.	The hypothesis is supported. There is a significant difference between employee sizes 1 to 10 and 11 to 20 in Tax Regulations and Corruption. There is a significant difference between employee sizes 11 to 20 and 21 to 99 in Access to Financing.
5. What are the areas of Canada's global competitiveness affecting the sustainability of small firms?	Pillar 3 Macroeconomic Environment and Pillar 5 Higher Education and Training are the two pillars of competitiveness that impact the most problematic factors to doing business for small firms.	The hypothesis is partly supported. Pillar 3 Macroeconomic Environment impacts financial issues such Tax Rates and Tax Regulations but the tax indicators are in Pillar 6 Goods Market Efficiency and the Access to Financing indicator in Pillar 8 Financial Market Development. Pillar 5 Higher Education and Training impacts Poor Work Ethic in national labour force. Pillar 7 Labour Market Efficiency, not in the hypothesis, impacts Restrictive Labour Regulations. Pillar 7 has seen improvement and has been consistently ranked among the Top 10 nations.

Source: Developed by the author for this research.

5. Discussion

There are at least three managerial implications from the research findings. The first implication is that the allocation of resources to resolve the barriers should be prioritized according to the degree or magnitude of the problem and by province, type of business and employee size. The second implication is the need for policies to strengthen the weak pillars of competitiveness that impact small business. The third managerial implication is to develop a holistic knowledge management model that continuously monitor, study and analyse the variables that impact small business for a proactive approach to sustaining small business growth.

5.1 Allocation of Resources to Overcome Problematic Factors

5.1.1 Priority based on Measurement of Problematic Factor

In relation to research objective 1, although 13 of 16 most problematic factors are found significant, priority for resources to overcome the barriers should be based on the magnitude of the problem. The barriers should have a mean value below 3.5 indicating is between most problematic to somewhat problematic, and there are 11 factors that qualify.

While none of the 16 barriers were found most problematic, there are four problematic

factors that deserve immediate attention: Tax Rates (2.57), Tax Regulations (2.63), Access to Financing (2.63) and Poor Work Ethic in national labour force (2.84).

The remaining seven factors lie within the clearly somewhat problematic zone: Restrictive Labour Regulations (3.04), Insufficient Capacity to Innovate (3.19), Inadequately Educated Workforce (3.25), Inflation and Crime and Theft (3.27); Inefficient Government Bureaucracy (3.42) and Inadequate Supply of Infrastructure (3.48).

5.1.2 Priority based on Province, Type of Business and Employee Size

In relation to research objectives 2, 3 and 4, the results show a significant difference in the barriers to small business by region/province, type of business and employee size. Appendix 6 shows the differences in mean value between provinces, types of business and employee sizes. As presented in the findings, Ontario small firms view six factors significantly more problematic than Alberta: Tax Rates (1.73 vs. 2.74), Tax Regulations (2 vs. 2.78), Access to Financing (2.27 vs. 2.94), Restrictive Labour Regulations (2.67 vs. 3.17), Insufficient Capacity to Innovate (2.82 vs. 3.29) and Inadequate Supply of Infrastructure (2.97 vs. 3.57).

Retail businesses view four factors significantly more problematic than Service businesses: Access to Financing (2.5 vs. 3.06), Restrictive Labour Regulations (2.91 vs. 3.36), Poor Work Ethic (2.62 vs. 3.08), and Crime and Theft (2.82 vs. 3.65).

While firms with 11 to 20 employees view Tax Regulations significantly less problematic than firms with 1 to 10 employees (2.96 vs. 2.57), they view Access to Financing significantly more problematic than firms with 21 to 99 employees (2.51 vs. 3.09).

5.2 Strengthening Pillars of Competitiveness that Impact Small Firms

As discussed, there are four problematic factors: Tax Rates (2.57), Tax Regulations (2.63), Access to Financing (2.78) and Poor Work Ethic (2.84). Tax and Financing issues are impacted by Pillar 3 Macroeconomic Stability and Poor Work Ethic is impacted by Pillar 5 Higher Education and Training.

5.2.1 Recommendations for Overcoming Tax Barriers

Table 21 shows the five indicators in Pillar 3 Macroeconomic Stability and their rankings over the last six years from 2008/09 to 2013/14. Canada has been excellent in managing Inflation achieving 1st rank in the last three years as well as Country Credit Rating at an average 4th rank. However in the last three years, the average rank in Gross National Savings is 73rd, Government Budget Balance 97th and worst, General Government Debt, 130th – these ranks place Canada in the second half of the 140 plus countries surveyed.

Table 21: Canada's Indicator Rankings in Pillar 3 Macroeconomic Stability from 2008/09 to 2013/14

	2008/09	2009/10	2010/11	Average Rank 1	2011/12	2012/13	2012/14	Average Rank 2	Change in Average Rank
3.01 Government budget balance, % GDP	44	39	34	39.0	10 2	10 4	86	97.3	- 58.3
3.02 Gross national savings, % GDP	61	58	80	66.3	80	73	67	73.3	-7.0
3.03 Inflation, annual % change	26	3	24	17.7	1	1	1	1.0	16.7
3.04 General government debt, % GDP	10 7	10 8	12 0	111. 7	12 9	12 9	13 3	130. 3	- 18.7
3.05 Country credit rating, 0-100 (best)	N A	N A	4	4.0	4	3	5	4.0	0.0

Source: Global Competitiveness Reports from 2008/09 to 2013/14

Running fiscal deficits tend to limit the government's ability to react to business cycles and enhance competitiveness. Governments tend to lower the debt by raising taxes and reducing services which in turn hurt business and productivity. The indicator for Total Tax Rate and Effect of Taxation on Incentives to Invest are found in Pillar 6 Goods Market Efficiency as shown in Table 22. The Canadian government has improved the rank of Total Tax Rate to 30th rank in the last three years from a prior 75th rank, as well as the Effect of Taxation on Incentives to Invest to 34th rank from a prior 67th.

Table 22: Canada's Indicator Rankings Related to Tax Rate from 2008/09 to 2013/14

	2008/09	2009/10	2010/11	Average Rank 1	2011/12	2012/13	2012/14	Average Rank 2	Change in Average Rank
6.05 Total tax rate, % profit	72	75	79	75.3	29	32	25	30.5	44.8
6.04 Effect of taxation on incentives to invest	88	65	48	67	40	28	26	34	33

Source: Global Competitiveness Reports from 2008/09 to 2013/14

Although improvements have been achieved, the two indicators are far from Canada's overall 14th rank. The Certified Accountants Association of Canada (CGA, 2012) argues that the annual cost for business compliance with tax obligations at \$12.6 billion is too high for small and medium firms to shoulder \$11.4 billion or 90.5% of the cost. The CGA made two proposals:

- Simplify the tax forms by removing unnecessary information so that the intent and benefit of tax measures are better understood and easier for businesses to comply.
- Conduct a comprehensive review of Canada's tax system to reduce complexity and reform its structure. For example, the marginal tax on labour needs a review as many low and middle income sole proprietors face punishingly high marginal effective personal income tax rates that discourage them from working, saving and taking further education and training.

In 2013, representing 109,000 small business owners, the Canadian Federation of Independent Business wants the federal government to lower the small business tax rate to 11%. The general corporate tax rate has been reduced from 22% to 15% over the last six years but the small business tax rate has only dropped by one percentage point during the same time (Financial Post, March 13, 2013). The federal government granted the request for small business tax rate at 11% that unfortunately meant an increase by 1% in British Columbia. Ontario has its own system of taxation with small firms paying 13% comprising 5% federal and 8% provincial tax rates. Thus, the CGA's appeal to overhaul the country's entire and differing tax system by province is lauded.

Canada over relies on income and profit taxes which has been cautioned as the most damaging forms of taxation. Switching the tax mix toward consumption based taxes like the GST or HST would encourage work and capital formation, stimulate productivity and economic growth. Nations such as Singapore and New Zealand have successfully

switched to a more consumption-based tax system (Poh, 2003) and this has proven a wise decision. World Bank has consistently ranked Singapore as 1st and New Zealand as 3rd among 185 countries to start a business in the last five years.

Finally, closing the issue related to tax, there are no indicators for Tax Regulations and it would be best for WEF to incorporate an indicator in Pillar 6 Goods Market Efficiency to supplement the 6.05 Total Tax Rate % profit and 6.04 Effect of Taxation.

5.2.2 Recommendations for Overcoming Access to Financing

Table 23 shows the indicators for Access to Financing in Pillar 8 Financial Market Development.

Table 23: Canada's Indicator Rankings Related to Access to Financing from 2008/09 to 2013/14

	2008/09	2009/10	2010/11	Average Rank 1	2011/12	2012/13	2012/14	Average Rank 2	Change in Average Rank
8.04 Ease of access to loans	25	25	24	24.7	22	18	26	20.0	4.7
8.05 Venture capital availability	19	18	19	18.7	19	20	23	19.5	-0.8

Source: Global Competitiveness Reports from 2008/09 to 2013/14

Although the Ease of Access to Loans has improved to an average 20th rank in the last three years from a prior 25th rank, Venture Capital Availability is at its lowest rank at 26th in 2013-2014.

As mentioned earlier, despite being one of the largest customers of commercial banks, loans to small firms are often limited to short periods, ruling out financing any considerable investments (Lloyd, 2009). Money lenders are reluctant to fund small firms because of the difficulty to evaluate the risk of the new, innovative products (Craig et al., 2006). Access to seed capital remains restricted (Canadian Chamber of Commerce, 2013).

There are various government support programs available for small businesses to access funding:

1. International Business Funding
 - a. The Export Guarantee Program increases the chances of small businesses of securing bank financing from with a government guarantee on their export-related activities (About Exporting, n.d.).
 - b. The Global Opportunities for Associations provide funding to support national associations undertaking new or international business development activities (Global Opportunities for Associations, n.d.).
2. Small Business Financing and Assistance
 - a. The Small Business Financing Program helps small businesses to secure up to \$250,000 from a financial institution (Canada Small Business Financing Program. n.d.).
 - b. The Business Development Bank (BDC) provides services for entrepreneurs including financing, venture capital, and consulting services to entrepreneurs (BDC is the only bank exclusively dedicated to entrepreneurs, n.d.).
3. Research Incentive and Assistance
 - a. The SR&ED offers tax incentive for scientific research and experimental development.
 - b. The Industrial Research Assistance Program (IRAP) provides more than 200 industry technical advisers to assist companies in plan layout, productivity, cost control, production process improvement, and assessment of new manufacturing technology (Industrial Research Assistance Program, n.d.).

However, not all small firm owners or entrepreneurs are aware and if they do, they view the process of succeeding in their application is long and difficult. There are two recommendations to help increase access to financing for small firms:

1. Active promotion campaign of government assistance programs. For example, financial institutions could schedule regular seminars for clients, public and undergraduates to disseminate information of assistance programs (Riding, Orser, Spence & Belanger, 2012).
2. An angel investment tax credit to support the early stages of innovation (Canadian Chamber of Commerce, 2013).

5.2.3 Recommendations for Overcoming Poor Work Ethic

Table 24 shows seven indicators that have a bearing on Poor Work Ethic.

Table 24: Canada's Indicator Rankings Related to Higher Education and Training from 2008/09 to 2013/14

	2008/09	2009/10	2010/11	Average Rank 1	2011/12	2012/13	2012/14	Average Rank 2	Change in Average Rank
4.10 Primary education enrolment, net %	6	7	8	7	6	3	3	4.5	2.5
5.01 Secondary education enrolment, gross %	6	21	19	15.3	21	25	32	23	-7.7
5.02 Tertiary education enrolment, gross %	24	25	27	25.3	29	35	38	32	-6.7
5.03 Quality of educational system	8	5	5	6	7	6	10	6.5	-0.5
5.05 Quality of management schools	4	2	3	3	4	5	7	4.5	-1.5
5.07 Availability of research and training services	10	11	11	10.7	13	13	18	13	-2.3
5.08 Extent of staff training	19	12	12	14.2	18	23	34	20.5	-6.2

Source: Global Competitiveness Reports from 2008/09 to 2013/14

Except for Primary Education Enrolment which has improved to 3rd rank in the last two years, the rest of the six indicators have declined. Nevertheless, despite slipping in rank, Quality of Educational System, Quality of Management School and Availability of Research and Training Services have managed to stay higher than Canada's GCI at 14th. However, there are two alarming trends:

1. While Primary Education Enrolment is ranked 3rd in 2013/14, Secondary Education Enrolment is nearly 30 ranks behind at 32nd and Tertiary Education Enrolment a further six ranks behind at 38th. This means a drastic drop out rate at secondary schools which will influence a lower tertiary rate that depends on high school graduates. The high drop out at secondary schools indicate a disinterest or negative attitude towards studies, the formative tool for self-discipline, that will result not only in lack of skill but also poor attitude at work.
2. Extent of Staff Training has deteriorated to 34th rank in 2013/14 and overall dropped by an average six ranks in the last three years. A lower level of training would mean a stagnation of skill may lead to the old adage "familiarity breeds contempt" festering a lackadaisical attitude at work.

While schools (and homes) are a critical place to teach responsible work ethic, there

may be several reasons contributing to the perception of Poor Work Ethic among small firms:

- There is a shortage of skilled workers as much as 550,000 by 2016 and possibly over a million by 2021 according to the Chamber of Commerce (2013). This means bigger firms are willing to pay more attractive perks and salaries to induce job hoppers.
- While there is a shortage of skilled labour, 48% of adults in Canada are below Level 3 literacy skills which mean they are unable to use new technologies and absorb training effectively to recover cost of investment (Murray, McCracken, Willms, Jones, Shillington and Stucker, 2009).
- Value differences among generational categories could result in an older employer labelling a younger colleague as lazy or rebellious. While baby boomers value recognition and interpersonal communication, Gen Y value freedom and digital communication.
- Over coddling of children has resulted in a new generation of workers who are now known as the entitled generation, over protected until they lack basic skills in communication and self-help (Hyper Parents, Coddled Kids, n.d.).
- With all the above reasons, employers are discouraged from investing in talent development to avoid the train-to-drain syndrome.

The strategies to overcome Poor Work Ethic is not just about teaching work ethic. They are also about creating a bigger pool of talent to minimize job hopping, stimulate innovation and motivate employee loyalty. There are two key recommendations:

1. Collaboration between educators and employers to balance supply with demand for skilled trades and occupations, for example, the Alberta government's allocation of \$282 million for three years to the Northern Alberta Institute of Technology (NAIT), Norquest College, University of Calgary, Lethbridge College and Mount Royal University (Alberta rolls out austerity budget: CAUT Bulletin, March 2013) to train and fill the skilled vacancies.
2. Up-skilling underutilized segments, primarily the youth, older, immigrant and Aboriginal workers.
 - a. Job shadowing and work ethic training for the youth should be strengthened from senior high to post-secondary institutions.

- b. Older workers could be retained as they are a valuable source of skills and knowledge to younger colleagues. For example, faced with labour shortage and an aging population, employers in Singapore are re-offering employment to retiring employees (Retirement and Re-employment Act, n.d.).
- c. Immigrants to Canada under the skilled category are found to earn 60 to 70% of the wages of Canadian-born workers, a decline from the 85 to 90% in the late 1970s (Garnett & Sweetman, 2012). If it is a question of skill-fit, then up-skilling or re-skilling should begin pre-entry to Canada. The government could advise applicants to take online programs with Canadian universities while waiting for their landing permits. Canadian educational institutions should consider starting campuses abroad, where there is a proliferation of American, Australian, British and French universities, to compete for the best immigrant talents.
- d. The Aboriginal population is much younger, providing a source for longer-term employment: 28% of Aboriginal are aged 14 and under compared to 16.5% for non-Aboriginal, and only 5.9% of Aboriginal are aged 65 and above, less than half the rate of 14.2% of non-Aboriginal. With the median age of the Inuit at 23, First Nations at 26 and Métis at 31, the average median age is 26.6 years, 13.3 years younger than the median age in Canada at 39.9 years (National Aboriginal Day... by the numbers 2013, n.d.).

5.3 *Developing a Model for Knowledge Management for Small Business Issues*

Figure 6 shows a proposed model for knowledge management for small business issues to capture, monitor, analyse data and develop strategies to sustain small business growth.

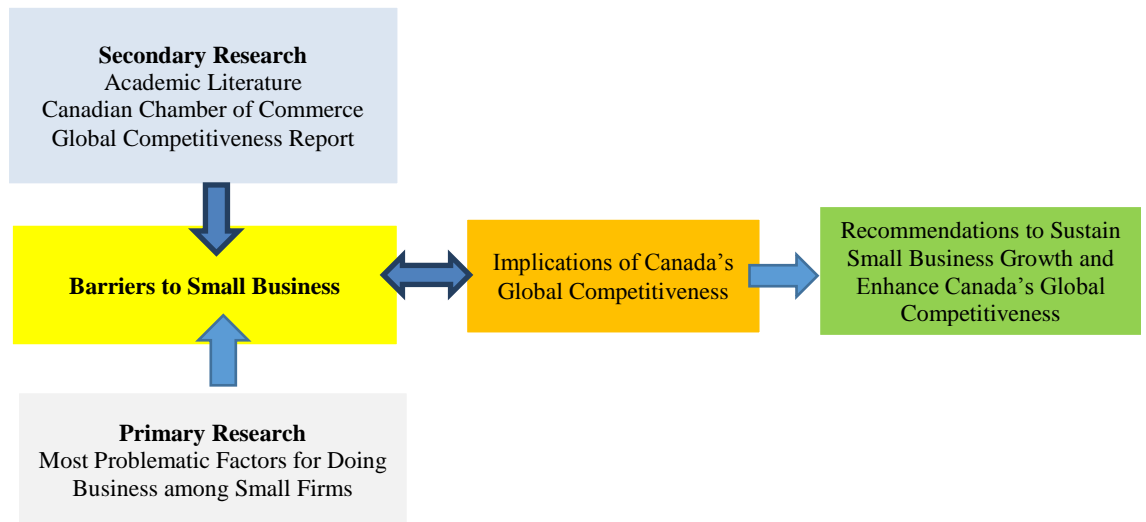

Figure 6: A Knowledge Management Model for Small Business Issues

There are two research components critical to accurately identifying barriers to small business. First, there should be consistent secondary research to understand the factors that influence small business issues and the areas for future research to gain deeper insights for policy development. In this regard, relevant sources must be made available for analysis. Apart from academic literature, reports from the Canadian Chamber of Commerce, Conference Board of Canada and Global Competitiveness Reports from the World Economic Forum, World Bank and other trusted global not-for-profit research organizations. An analysis of trends would help identify the recurring issues to small firms.

Second, there must be continuous primary research in at least three forms: (a) scanning the macro and micro environments to identify strengths, weaknesses, opportunities and threats to small business, (b) conducting annual surveys to understand the challenges faced by small firms in sustaining and growing their business, and (c) inviting participation of small firms at various small business forums and seminars where focus groups can be conducted on a more regular basis to collect valuable data. Information can be collected from respondents regarding the policies at federal and provincial levels that hamper their growth.

Valuable information has been provided by global economic bodies of research. Thus, a systematic and measurable approach to identifying the deeper issues that impact

small business is a diligent study of the indicators of global competitiveness from global not-for-profit organizations such as the World Economic Forum and World Bank. Much of the information, if not all, is available free online.

Finally, strategies and action programs that are implementable should be recommended to help the government and business sectors collaborate to sustain small business growth and thereby, enhance Canada's global competitiveness.

6. Conclusion

This research represents the first attempt to replicate and test the universal model of the World Economic Forum's 16 most problematic factors to doing business. This research also represents another first in examining the impact of a nation's global competitiveness on small business growth. Of greater significance is that this research provides an insight to Canadian small business challenges compared to the overwhelming studies from other western nations, especially the United States.

As a summary, this research has made six major contributions:

1. identified the significant barriers faced by small firms
2. Identified the significant barriers faced by small firms by province/region, type of business and employee size.
3. Recommended prioritization of resources to overcome the barriers according to the magnitude of the problem, from most problematic to somewhat problematic.
4. Reviewed and identified trends from Canada's global competitiveness performance over a six-year period.
5. Identified the weak pillars and respective indicators that need attention.
6. Proposed recommendations to overcome small business barriers related to tax, access to financing and poor work ethic.

This research has its limitations which form the two key recommendations for future research:

1. Enlarge demographic categories for significance testing. The researcher has to determine the province, type of business, employee size or even new variables such as gender and ethnicity for an in-depth study or comparative studies. .
2. Test model across business sectors. As further research is needed to generalize the model to broader settings, future studies may examine, for example, the needs of small firms in the oil and gas industry.

Appendix 1: External and Internal Factors Influencing the 16 Most Problematic Factors

Most Problematic Factor (Issue)	Issue Category	Environment	
		Macro/External	Micro/Internal
Tax rates	Tax	External: Economic	
Tax regulations	Tax	External: Economic	
Access to financing	Limited loans & interest rate	External: Economic	
Insufficient capacity to innovate	Lack funds Lack technology	External: Technology	Internal: Finance, Talent, Technology
Restrictive labor regulations	Labour	External: Economic	
Inadequately educated workforce	Labour	External: Economic	
Poor work ethic in national labour force	Labour	External: Social Cultural	
Inadequate supply of infrastructure	Infrastructure	External: Economic	
Inefficient government bureaucracy	Government	External: Political	
Policy instability	Government	External: Political	
Government instability/coups	Government	External: Political	
Poor public health	Government	External: Political, Technology	
Corruption	Government	External: Political	
Crime and theft	Government	External: Economic, Political	
Inflation	Economy (Government)	External: Economic	
Foreign currency regulations	Economy (Government)	External: Economic	

Appendix 2: The 16 Most Problematic Factors to Doing Business in Canada from 2009/10 to 2013/14

Most Problematic Factor	2013/14	2012/13	2011/12	2010/11	2009/10	Average
1. Access to financing	16.50	14.00	14.10	15.40	22.60	16.52
2. Inefficient government bureaucracy	12.90	16.40	17.70	13.20	12.80	14.60
3. Insufficient capacity to innovate	13.00	15.10	NA	NA	NA	14.05
4. Tax rates	9.90	9.40	12.90	18.00	16.70	13.38
5. Tax regulations	10.20	9.10	10.00	13.10	12.30	10.94
6. Restrictive labor regulations	9.50	8.70	7.20	12.10	13.30	10.16
7. Inadequate supply of infrastructure	7.80	5.00	11.40	7.30	6.00	7.50
8. Inadequately educated workforce	7.50	9.90	8.50	6.00	4.10	7.20
9. Policy instability	3.40	3.50	8.50	5.70	4.70	5.16
10. Poor work ethic in national labour force	4.70	4.20	1.90	4.40	3.60	3.76
11. Inflation	0.50	2.30	3.30	2.10	1.20	1.88
12. Foreign currency regulations	1.60	1.40	2.10	1.30	1.60	1.60
13. Government instability/coups	0.2	0.2	1.8	0.4	0.1	0.54
14. Poor public health	0.40	0.40	0.70	0.30	0.60	0.48
15. Corruption	1.3	0.3	0	0.2	0	0.36
16. Crime and theft	0.6	0	0	0.5	0.5	0.32

Note: The numbers to each factor for each year represents the responses weighted according to their rankings. The factor “insufficient capital to innovate” was introduced from year 2012/13.

Appendix 3: The Final Research Questionnaire replicated from the World Economic Forum's survey of 16 most problematic factors and modified to include demographic variables.

This research seeks to identify the challenges faced by small businesses in Canada. We appreciate your kind cooperation.

Name of Respondent (optional but appreciated):

Name of Company/Type of Business:

Province:

Number of employees:

City/Town:

Contact number (optional but appreciated):

Email address (optional but appreciated):

Please rate each factor with the scale of **1 as most problematic and 5 as least problematic**. Please **circle only one choice** from 1 to 5 for each factor.

Factor	Most problematic				Least problematic
1. Inefficient government bureaucracy	1	2	3	4	5
2. Insufficient capacity to innovate	1	2	3	4	5
3. Access to financing	1	2	3	4	5
4. Inadequately educated workforce	1	2	3	4	5
5. Tax rates	1	2	3	4	5
6. Tax regulations	1	2	3	4	5
7. Restrictive labor regulations	1	2	3	4	5
8. Inadequate supply of infrastructure	1	2	3	4	5
9. Poor work ethic in national labour force	1	2	3	4	5
10. Policy instability	1	2	3	4	5
11. Inflation	1	2	3	4	5
12. Foreign currency regulations	1	2	3	4	5
13. Poor public health	1	2	3	4	5

14. Corruption	1	2	3	4	5
15. Government instability/coups	1	2	3	4	5
16. Crime and theft	1	2	3	4	5

Please list other challenges that were not included above.

Thank you for your kind participation.

Appendix 4: Comparing Ratings of 16 Most Problematic Factors between This Research and WEF's 2013/14 and 5-Year Average from 2009/10 to 2013/14

Rank	WEF Average Responses over 5 Years from 2009/10 to 2013/14		WEF 2013/14		This Research: 316 Respondents	
	Factor	Average	Factor	Rank	Factor	Average
1.	Access to financing	16.52	Access to financing	16.5	Tax rates	2.57

Structured Abstract

Purpose – The main purpose of the research is to increase our understanding of the factors which affect innovativeness of successors in smaller family firms (SFF) and what is the role of the founder in strengthening (deterioration) of successors' innovativeness.

Design/methodology/approach – We research which factors affect – supportive or dampening – innovativeness of the next generation, and as well, if the innovation potential of the founder can be transferred to the next generation. Especially we study effect of knowledge transfer on innovativeness of successors. Therefore, the research questions are: *Why and how transfer of experiential knowledge and routine knowledge of founders affects innovativeness of successors? Why and how academic knowledge on the field of entrepreneurship affect innovativeness of successors? Why and how external working experiences affect innovativeness of successors?* We adopted a qualitative empirical research approach – using multiple-case study research method where replication logic was possible.

Originality/value – The originality and the value of the paper lies in the identification of factors affecting successors' innovativeness; we limit our research on those factors which are tightly linked to the knowledge and knowledge transfer during a succession process.

Practical implications – The empirical findings will have practical implications for key stakeholders in the SFF succession process and provide basis for a broader empirical research.

Keywords – Smaller Family Firms, Founders, Successors, Innovativeness, Knowledge Transfer.

Paper type – Academic Research Paper

1 Introduction

Family firms represent an important share in the structure of all firms. According to some recent research results, 70 % of all firms worldwide are family ones (Mandl, 2008) and most of them are micro, small or medium-size (smaller family firm: SFF). SFF, innovation marketing and excellent research systems are recognized as drivers of innovation growth in EU, thereby the increase of SFF's innovativeness is of crucial importance in every national economy in order to become innovative societies (Innovation Union Scoreboard, 2013). Since SFF's innovativeness is closely connected with the innovativeness of their key stakeholder (e.g., owners who are very often also managers), we limit our research on innovativeness of founders and successors in SFF. Previous research has revealed that innovativeness of founders differs from innovativeness of successors (e.g., Ganzarolli *et al.*, 2006; Litz and Kleysen, 2001).

Since knowledge is viewed as relevant and actionable information based on experience and education (Cabrera-Suárez *et al.*, 2001; Nonaka, 1994), and as such an important source of innovation, creativity and competitive advantage (Nonaka *et al.*, 2000; Delgado-Verde *et al.*, 2011), we focus our research on knowledge transfer during the succession. Many research findings show that the transfer of ownership and management to the next family generation is crucial period in the SFF's life, and many family firms do not survive this transfer. However, several authors (e.g., Dyck *et al.*, 2002) suggest that succession (i.e., the replacement of incumbent with capable leader) can represent a strategic opportunity in rapidly growing firms or firms in emerging and dynamic markets which are facing changing managerial needs. Due to complex and rapid changes in firms' environment we believe that the survival of SFF across generations depends on their ability to renew through innovation. Members of succeeding generation should bring fresh perspectives in the family firm and add new knowledge to the firm's existing knowledge base thus fostering innovation.

Research findings suggest that the firm's specific knowledge (so called tacit knowledge) and the ability to transfer it, are the key strategic asset that may be positively associated with higher levels of performance and sustainable competitive advantage because they are difficult to trade and imitate, scarce, appropriable and specialized (Cabrera-Suárez *et al.*, 2001 Chirico, 2008). Sharma (2004) specially points to strategic importance of transferring tacit knowledge to the next generation in order to maintain and develop a family business after taking over the control by the next family generation.

However, also knowledge created outside a family firm and transferred to a successor is of crucial importance. Especially, the academic education (in entrepreneurship), external working experiences and additional training outside a family business play an important role and are positively related to innovation ability of the next family generation. Namely, founders/managers of SFF often do not have education and training related to innovation, invention, diffusion processes (Romano, 1990), and innovativeness in SFF is positively related with employing managers with relevant external training and formal education.

The goal of our study is to broaden our understanding on knowledge transfer during family firm succession and its effect on innovativeness of the next family generation.

The following research questions have been addressed in our research study:

Q1: *Why and how transfer of experiential knowledge (tacit knowledge shared through common experiences) and routine knowledge (tacit knowledge routinized and embedded in actions and practice) of founders affects innovativeness of successors?*

Q2: *Why and how academic knowledge on the field of entrepreneurship affects innovativeness of successors?*

Q3: *Why and how external working experiences affect innovativeness of successors?*

The case research study has been conducted on the case of Slovenia. SFF of the first generation still prevail in Slovenia and large transfer to the second generation is expected. As the research results of Duh and Tominc (2005) show, less than 60 % of founders/managers of SFF, age 51 or more, actually already plan transition of ownership/management to the next family generation in the next five years. This is the reason why the question of innovativeness of the second generation of owners and/or managers of SFF is of key importance. We believe that our research results are important not only for Slovenian family businesses but also for family businesses in other environment due to the fact that only small proportion, 30 %, of first generation family firms survive to the second (e.g., Morris *et al.*, 1997; Miller *et al.*, 2003).

Limitations of our research are the size and geographical location of the included family firms. Research has been conducted in micro, small and medium-sized family firms (SFF), as we assume that many micro family firms with up to 9 employees as well face the problem of transfer of ownership and of management to the next generation. As the research is limited to Slovenia, the findings and conclusions are acquired on the basis

of experiences of the Slovenian SFF. Additional limitation is in very few theoretical sources with combination of studied research fields – innovation management and family businesses. Many researchers explore individual aspects of succession in family firms, but not as well the factors that have impact on innovativeness of successors in SFF.

The paper is structured as follows: following the introduction chapter the theoretical backgrounds of research (i.e., family business succession, successor's innovativeness, knowledge typology and knowledge transfer), are briefly discussed. Research design based on case study approach and sampling strategies with data collection are presented. They are followed by data analysis and findings with development of propositions. The paper ends with a conclusion chapter indicating main future research directions.

2 Family business succession

One of the major problems family businesses face is the transfer of ownership and/or of management to the next family generation (e.g., Miller *et al.*, 2003; Sharma *et al.*, 2003), although in most SFF (as well non-family firms) both processes go hand-in-hand (e.g., Gersick *et al.*, 1997; Sharma *et al.*, 2003). A family member as a potential successor is especially preferable when so-called idiosyncratic, family business-specific experiential knowledge is considered especially important for gaining competitive advantage (e.g., Bjuggren and Sound, 2001; Royer *et al.*, 2008). Research findings indicate that family business succession should be seen as a multistage process that occurs over time, beginning before heirs even enter the business (Handler, 1994) and is characterized by growing involvement of a successor in the business (Cabrera-Suárez *et al.*, 2001). Due to high proportion of SFF (30 %; e.g., Miller *et al.*, 2003), which fail to move to the second and subsequent generations, considerable amount of research have explored factors impacting success of a succession process (e.g., Dyck *et al.*, 2002; Le Breton-Miller *et al.*, 2004).

Success of a succession process crucially depends on the next generation which has to develop some important characteristics (e.g., Cabrera-Suárez *et al.*, 2001; Chrisman *et al.*, 1998; Mazzola *et al.*, 2008; Sharma and Rao, 2000): business and industry knowledge, several abilities (e.g., decision-making ability), networks and social capital, passion, innovative spirit, legitimacy and credibility from both family and non-family stakeholders. For this reason, several research studies explore nurturing, preparation and development of successors (e.g., Dyck *et al.*, 2002; Le Breton-Miller *et al.*, 2004; Morris

et al., 1997) as an important predictor of successful succession. Morris *et al.* (1997) found that succession is realized more smoothly when successors are better prepared and a family firm's performance after transition is positively affected by successors' education level. Tightly linked to questions on how to prepare the competent leader is research that deals with the transfer of knowledge during the succession process (Sharma, 2004). Especially the transfer of tacit knowledge from predecessor to successor and successor's training to assume the top management functions have been found to be key processes in developing and protecting knowledge (especially tacit one). It should guarantee the survival of a family business across generations since family firms often "... maintain their own ways of doing things – a special technology or commercial know-how that distinguish them from their competitors" (Cabrera-Suárez *et al.*, 2001, p.38). Customers believe in a high level of products and services, when specific family techniques and knowledge are transferred to the next family generation (e.g., Dumas, 1998).

3 Successors' innovativeness and knowledge transfer

3.1 Successors' innovativeness

In family firms, innovativeness is regarded as a highly important dimension of entrepreneurial orientation for long-term performance, together with autonomy and pro-activeness (Nordquist *et al.*, 2008). It is a necessary condition for a family firm continuity; firms must constantly seek ways to recognize and exploit new opportunities as well as refine existing resources in order to successfully grow and compete (Zahra, 2005). McCann *et al.* (2001) find that younger and SFF are more likely to be innovative than older, larger family firms. Furthermore, innovativeness is described as having greater potential for high performance, if it is driven by comprehensive strategic decision-making and long-term orientation (Eddleston *et al.* 2008; McCann *et al.*, 2001). Innovativeness refers to "a firm's tendency to engage and support new ideas, novelty, experimentation, and creative processes that may result in new products, services, or technological processes" (Lumpkin and Dess, 1996, p. 142).

Previous research has revealed that innovativeness of founders differs from innovativeness of successors, some authors argue that successors are less innovative, others say opposite. But, it has not been researched yet how innovativeness of founders affects innovativeness of successors. According to some research findings family firms

are found to become more conservative and less innovative over time (e.g., Donckles and Frölich, 1991; Zahra, 2005), and second generation family firms often fail due to inaction and reluctance to seek out new business opportunities (Ward, 1997).

Ganzarolli et al. (2006) determined that succession does not have positive impact on increase of firm's innovativeness (innovation capability); on the other side Kepner (1991) says that while family firms of the first generation wish to maintain status quo, successive generations wish to introduce new modes of operation, as they are necessary to maintain the same level of growth and of financial success of the previous generation (Jaffe, Lane, 2004). Litz and Kleysen (2001) even argue that the next generations are the driving force of innovation in family firms. Salvato (2004) agrees with the argument, as well.

As previous research has shown a family environment affects innovative potential of individuals (e.g., successors; proper education, family values, size of family, birth order) (Mumford *et al.*, 2002).

Factors leading to innovation at the individual level (for references see Litz and Kleysen, 2001) are: divergent thinking (Guilford, 1963), a propensity for risk-taking (Glassman, 1986), cognitive style (Kirton, 1976), intrinsic motivation, domain relevant skills, creativity skills (Amabile, 1988), political prowess (Maute and Locander, 1994), self-confidence, autonomy and openness (West and Farr, 1989), energetic charge, talent, creativity of individual family members (Kanter, 1988), family culture, freedom, flexibility, intergenerational respect, and family atmosphere (Kanter, 1988).

On the level of organization, factors that affect innovativeness, according to Fatur and Likar (2009, 52-63), overlap with some internal factors, as predicted by Srića (1999, 28), and are: culture and climate, goals, strategy, HR, rewarding, communication, management, management of ideas, creativity, organization, perception. As regards the innovation measurements, some authors (see e.g. Brower and Kleinknecht, 1999) classify indicators distinguishing whether they are based on inputs or on outputs of the innovation process. Indicators based on inputs are, for example: research and development (R&D) budget, existence of formalized R&D, educational background of staff, etc. Indicators based on outputs (see for references Massa and Testa, 2008) are, for example: number of patents (and Lampert, 2001; Chin et al., 2009; Deyle and Grupp, 2005; Jaffe and Trajtenberg, 2002), information disseminated in literature (Sorenson and Fleming, 2004), the absolute amount of sales of innovative products (Negassi, 2004), the number of innovations, the number of new products (Brower and Kleinknecht, 1996), and the

increase in market share (Mascitelli, 2000). New indicators such as perceived innovation effectiveness have been put forward in recent decades (Kivimaki et al., 2000).

3.2. Knowledge and typology of knowledge

Knowledge is defined as “justified true belief” and is the capacity to define situation and act accordingly (Nonaka *et al.*, 2000; Nonaka *et al.*, 2006). Knowledge is embodied in the individual, and is therefore history dependent, context sensitive, specific and aimed at problem definition rather than problem depiction and problem solving (Nonaka *et al.*, 2006). Nonaka et al. (2000, p. 7) especially point to the fact that knowledge is context specific; according to the authors “... information becomes knowledge when it is interpreted by individuals and given a context and anchored in the beliefs and commitments of individuals.” One of the most recognized typology of knowledge is the one which differentiates between explicit and tacit (implicit) knowledge (e.g., Nonaka, 1991; Nonaka, 1994; Nonaka *et al.*, 2006; Nonaka and von Krogh, 2009). Explicit or codified knowledge is the one which can be transmitted in formal, systematic language. So it can be uttered, formulated in sentences, captured in drawings and writing (Nonaka *et al.*, 2000). On the other hand, tacit knowledge has a personal quality and therefore this kind of knowledge can hardly be expressed or formalized. Tacit knowledge is deeply rooted in actions, procedures, routines, commitment, ideals, values and emotions (Nonaka *et al.*, 2000) and involvement in a specific context – a craft or profession, a particular technology or product market, or the activities of work group or team (Nonaka, 1994). According to Nonaka and von Krogh (2009) tacit and explicit knowledge are not two separated types but inherently inseparable and dynamically interact with each other in creative activities by individuals and groups. Therefore knowledge will hardly be entirely of one type or another (Schulze and Hoegl, 2008).

3.3 Knowledge transfer during succession

Firms need to transfer and acquire new knowledge as they seek to innovate and enhance performance (e.g., Nonaka et al., 2000; Nonaka and Von Krogh, 2009). In SFF it is very important how and in which way predecessors/founders transfer their tacit knowledge to successors thus enabling successor to get »hands-on« knowledge about the SFF and the industry.

According to Nonaka (1994, 22) the enhancement of individual tacit knowledge subjected to a continuous interplay with the evolution of relevant aspects of explicit knowledge raise the total quality of an individual's knowledge. Therefore, the quality of successor's knowledge and capability to innovate depends on the possibility to enhance tacit knowledge by diverse high quality experiences and combined it with different explicit knowledge. Successors should acquire knowledge within and outside the SFF and actively participate in a wide range of business and management activities within and outside the SFF (Duh, 2014).

Early exposure to a business is a critical period for forming successor's impressions of the family business (e.g., a sense of the quality life the family business provides; the business's impact on the parents' marriage and family relationships) and lesson which are learned intentionally or unintentionally during that period will not be easily changed later and will importantly impact the family business's continuity in the future (Gersick *et al.*, 1997).

When the next generation enters the business, successors should become familiar with the culture, values, mission and philosophy of the firm (e.g., Mazzola *et al.*, 2008). They should also learn about other aspects of the business (e.g., products and/or services, productions processes, technology, suppliers, customers) and acquire knowledge or "recipes" about the firm's industry and management skills (e.g., Cabrera-Suárez *et al.*, 2001; Duh and Belak, 2008; Mazzola *et al.*, 2008).

Tacit knowledge can be transferred to the next generation in the form of apprenticeship (Chirico, 2008) or by mentoring, which is an effective way of transferring critical skills from a founder to a successor. According to Nonaka (1994) it can be passed as well through a process of "learning-by-doing". Practical training courses within the family business also allow individuals to acquire, share and transfer knowledge across generations (Chirico, 2008). As well, family meetings (e.g., in the form of a family council) are an excellent opportunity for successor's to learn about the rights and responsibilities that come with ownership (Gersick *et al.*, 1997). Involvement of successors in decision-making process and strategic planning process enables them to learn how to make strategy (Mazzola *et al.*, 2008). The main advantage of such involvement is a "progressive transfer of tacit knowledge" (Cabrera-Suárez *et al.*, 2001), both at the firm's level as well as the individual level. Team work is another important

way of passing knowledge to the next generation since it expands the previous boundaries of the knowledge of the individuals (Nonaka and von Krogh, 2009).

The knowledge transfer activities discussed are important for the development of successors managerial carrier (e.g., Ganzaroli *et al.*, 2006) and enlarge domain relevant skills and creativity relevant skills as well as enhance intrinsic task motivation of successors (Litz and Kleysen, 2001), thereby positively influencing successors' creativity. However, acquired knowledge may make successors "... more productive within the firm but not necessarily outside the context of that business" (Sardeshmukh and Corbett, 2011, p. 113). So it could be dangerous if the successor preparation and development to take over the leadership role relies only on internal tacit and explicit knowledge. Nowadays rapid changes in a firm's global and complex environment require from succeeding generations to be up-to-date with recent technological, product, market and industry developments in order to contribute to the dynamic nature of their family businesses. Research findings suggest that more innovative R&D projects draw on greater amounts of external information (Turner and Makhija, 2006 and there cited references) and high-impact innovations are made by people who based research on scientific knowledge (for references see Amar and Juneja, 2008). When conceptualizing and developing new product, the project team can create valuable new knowledge by exploring and synthesizing of diverse existing explicit knowledge within and outside the firm (Schulze and Hoegl, 2006).

Therefore, several authors (e.g., Cabrera-Suárez *et al.*, 2001; Chirico, 2008; Duh, 2014) emphasized the importance of academic courses and practical training outside the family business in schools, universities, firms, institutions, which enables successors' to add new knowledge and offer new perspectives for the sustainability of the SFF. Successors' experiences gained by working outside the family firm are found to be of great importance in developing specific abilities, getting different view of the business and how to do business (e.g., Cabrera-Suárez *et al.*, 2001; Chirico, 2008; Le Breton-Miller *et al.*, 2004; Ward, 1987). Such experiences are of special importance since they offer exposure to new ideas and perspectives (Sardeshmukh and Corbett, 2011) and provide "... access to new bodies of knowledge that are relevant for the future development of firm's innovation capacity" (Ganzaroli *et al.*, 2006, p. 14).

4 Method

4.1 Case study approach

In our research we adopted a qualitative research approach, which we found as a suitable research approach due to the nature of research questions and the field development level on the topic researched. We used a case study research methodology (e.g., Yin, 2003), which has been widely accepted in family business research (e.g., Chirico, 2008). A multiple-case study approach was applied since multiple cases “... permit replication logic where each case is viewed as an independent experiment that either confirms or does not the theoretical background and the new emerging insights” (Chirico, 2008, p. 435). Although there is no general agreement on the ideal number of cases, Eisenhardt (1989) suggests that between four and ten cases is best in order to increase rigor. We selected ten cases from the database which authors of the paper have been creating for many years. Case studies' analysis was used to identify themes emerging from the data in relation to succession, knowledge transfer and innovativeness of successors in SFF.

4.2 Sampling strategies and data collection

We selected ten cases of family firms in the size class of micro, small and medium-sized family firms (from 0 to 249 employees). Namely, not only small and medium-sized firms but as well as many micro firms face the problem of transferring ownership and management to the next generation. Limitation for the sample was that founder of the firm is employed in a firm, still owns a firm or is active in the firm, although retired, and that next generation is involved in a firm. For the purpose of our research we defined a family firm as the one in which a founder (i.e., an owner/manager) considers the business as a family one (e.g., Chua *et al.*, 1999; Sharma *et al.*, 2003). Research was geographically limited to Slovenia.

The authors conducted personal interviews with a founder and a successor since they are very well qualified to provide information and insights as well as there might be significant differences in perceptions between founders and successors (e.g., Zahra and Sharma, 2004). Interviews took place at premises of a company during the working days. We built ten extensive case studies and interviews of two respondents from each firm. When analyzing cases we were guided by a theoretical framework created from

existing literature. Interpretation and propositions were refined in several iterations before finalizing them.

4.3 Findings with development of propositions

In this section we discuss findings and provide propositions for the future research arising from our case studies analysis. Our research is exploratory and thus seeks to stimulate further work focusing on innovativeness of the next generation and innovative performance of SFF (a case of Slovenia).

4.3.1 Innovativeness of SFF and their successors

Different authors define innovativeness/innovation ability as “skills and knowledge, needed for effective absorption and improvement of existing and creation of new technologies, products and processes” (Kim, 1997; Lall, 1992).

Our research revealed that although most founders report constant development of new products, services, and processes, in order to remain competitive in their industry, only four (40 %) have protected know-how, one of them (10 %) has registered six and one (10 %) eight patents on his name, two founders (20 %) report over five registered patents on the name of the company. One founder (10 %) has protected brand. Three successors (30 %) are developing new processes and services with their parent. Successors all (100 %) report constant development activities, seven (70 %) report up to ten own developments of new solutions, especially in IT, improvements of existing services and processes, simplifications, which lead to cost reduction. They are less involved into development of new products. This is result of their non-technical formal education (only one successor, 10 %, has technical background). In the recent five years eight (80 %) of the studied SFF have introduced more than 500 new products, services and processes. According to our observation successors are taking active role in introducing rationalization of processes, development of new solutions, leading to reduction of costs, they are taking lead in innovation activities of SFF – they are self-confident, open, and creative, have the necessary energetic charge, thus confirming Litz and Kleysen (2001) and Salvato (2004).

4.3.2. Knowledge transfer

Knowledge transfers in SFF origins from two main sources and according to our opinion, both are very important for successors' innovativeness:

- from the founders, who expose their children/successors early to the family business environment, who mentor their children, supervise their apprenticeship in SFF, involve them in planning and decision-making processes, and
- from the outside, from external environment of the SFF: when successors study and get formal education, when they look for external working experiences before they formally enter the SFF, when they attend external training programs at universities or other institutions, or when these institutions provide training programs for them and other workers in SFF environment.

4.3.2.1 Founder related knowledge transfer

In our research we explored different methods of tacit knowledge transfer (experiential and routine knowledge) from founders to successors of SFF.

Many authors (e.g., Cabrera-Suárez *et al.*, 2001; Gersick *et al.*, 1997) suggest that early exposure to a family business through summer and lower category jobs are valuable experiences for successors since they acquire in this way tacit knowledge, which is usually linked to a founder and therefore of particular importance during the transfer from the founding to the second generation (e.g., Cabrera-Suárez *et al.*, 2001). The successor can also absorb tacit knowledge about the business at home (Gersick *et al.*, 1997, 71) and maintaining creative families' environments are prerequisite for creativity and innovation in businesses (e.g., Litz and Kleysen, 2001; Zenko and Mulej, 2011).

The findings of our research show that majority (seven, 70 %) of successors found early exposure and involvement into SFF as an important way of acquiring founder's tacit knowledge. Most of them (nine, 90 %) were exposed early, already as small children, to the family business environment. Successors who have been early exposed to the family business, have mostly done simple work on the week-ends (e.g., folding paper in the office, sweeping parents' office or a workshop with a broom); they were around, when their parents were discussing business with their workers or even business partners, they were observing, listening and were involved in discussions at the family dinners or at Saturday breakfasts, tackling the business issues; some were accompanying parent at the business travel, listening to parent's explanations why and how he/she did something;

most of them have worked summer-jobs since they were in the primary school, age of 12 and up. The only successor who has not been exposed and involved in the SFF as a child is a son-in-law of the founder.

Another important way of knowledge transfer is by mentoring and supervising relationships with family business leaders since they believe that the close interactions between them and their successor is a superior form of experience supporting development of tacit knowledge by successors (e.g. Cabrera-Suárez *et al.*, 2001; Chirico, 2008). Mentoring is an effective way of transferring critical technical and managerial skills, knowledge on managerial systems (especially of informal ones) as well as norms of behavior and firm's values (Swap *et al.*, 2001). There is no common agreement on whether the parents are the most suitable mentors (e.g. Gersick *et al.*, 1997). Some authors argue that parents are not the best mentors since they find it very difficult to give honest feedback to their children (e.g., Gersick *et al.*, 1997) and suggest to include non-family mentors (e.g., a trusted non-family senior manager) who can provide the potential successors with knowledge on how to run the business (e.g., Ward, 1987). Research carried out by Boyd *et al.* (1999) showed strong presence of informal mentoring by a family member. Even though this kind of mentoring have numerous strengths (e.g., flexibility; unforced, unstructured, and opening-up communication; establishing caring relationship), the weaknesses should be considered such as the absence of objectives or an agenda, the presence of emotion (e.g., potential for bias, personality conflicts, unrealistic expectations) and lack of feedback or review. Therefore, it is recommended to incorporate positive aspects of formal mentoring such as "... goal setting and review, recognition of milestone events, and a time line on the relationship" (Boyd *et al.*, 1999, 307).

Our analysis revealed that all ten (100 %) successors found mentoring as an important way of assimilating critical knowledge and skills (technical and managerial), mostly informal knowledge about management, norms of behavior, and SFF values. Nine (90 %) of successors were informally mentored by their parent, minority were formally mentored by a non-family member. Mentoring their children in an informal way means there were no plans, no programs have been worked out in advance. Often founders defined a problem and then jointly developed possible solutions with their children; often they told them how something has to be or has to be done, so their children developed their own living concept and gained experience; some have simply tried to motivate their children to do certain work in a best way. As well technical knowledge, "hidden recipes", tricks were

more likely subject of transferring knowledge by learning-by-doing, a kind of internal training, then mentoring. Mentoring has been more transferring knowledge about management and managerial practices. Early insight into family business has enabled most of the successors (90 %) to grow with the firm.

As one of the founders said: “.... *my daughter is not a technical type, and I can't transfer my technical know-how to her; but she, being a ski and board teacher, perfectly understands how the products should work for the benefit of the customer. Thus she enables feed-back I need to improve development of the final products....*”, and more: “... *having pedagogic and entrepreneurial education she understands easily the managerial issues of the family business and I am preparing her for the role of a manager, while technical know-how and support will have to be provided by a non-family member in the future.*”

The research has revealed that mentoring by a parent/founder contributes to emotional interactions between him/her and the successor; often parents understand successors' standpoints very personally, as an objection and successors have to remind their parents to treat them as responsible adults, not as children anymore.

Another way of transferring knowledge across generations is in the form of apprenticeship (Chirico, 2008), which can constitute excellent training especially in traditional industries that do not operate in environments of rapid change. However, such type of training is insufficient, when markets change quickly (Le Breton-Miller *et al.*, 2004).

The findings of our research reveal that most (eight, 80 %) of successors went through the apprenticeship in their SFF and four (40 %) of them stressed that apprenticeship with observing, imitating and practicing represents an excellent method of transferring founder's tacit knowledge and their training.

“My father has often said, that he rather sees me learning from his mistakes, not from my own ones, knowing it would be better that I learn from my own mistakes. As if he wanted to save the pain and time. And although he has not shown specific technical design, at the age of five, I assembled alone my first car-battery as a result of observing him at work. Later on he has always asked me to think with my own head and to apply in practice what I studied at the faculty. He has never specially praised me for my achievements, and he has always found something, so he could comment that I could still do better. So, practice, practice, practice....” one of the successors revealed in the

interview. Successors have the opportunity to learn directly from founders in a “learning-by-doing process” how to run the family firm, and all the ‘tricks of trade’ related to the business (Chirico, 2008). The findings showed that learning-by-doing, according to all ten (100 %) successors' high agreement, enables them indirect access to founder's knowledge about technical solutions, managing the family business and business tricks. Seven (70 %) of successors could learn about their family business directly from their parents.

Successor should also be involved in meetings and communication with business partners since this way the tacit knowledge of customers and suppliers can be acquired (e.g., Becerra-Fernandez and Sabherwal, 2001; Nonaka *et al.*, 1994) and incorporated into new concepts, technologies, products or systems (Nonaka *et al.*, 2006). Nine (90 %) of successors said that they have accompanied their parent at the meetings with business partners, so they could listen and observe how the deals have been negotiated. This enabled them insights in and information about the business, they could not find in the books; early established personal contacts with business partners contributed to development of trust into them. This is an important factor for the future development of the SFF. One (10 %) of the successors has been taken to the meetings with partners already as a child, but could negotiate the first deal only at the age of 26, while the others (eight, 80 %) have been involved into meetings first as observers, later as active participants. Mostly successors had to show serious interest for their career in the family firm before they could participate actively in the meetings and this coincided with their study time and before they formally entered the family firm.

In terms of successor's skills requirements, the decision-making ability is ranked as the most important besides successor's commitment to the business and interpersonal skills (Motwani *et al.*, 2006). Therefore, it is of crucial importance that preceding generation allows succeeding generation to actively participate in decision-making, where both generations should have opportunity to offer suggestions for improving processes and to learn from the other (e.g., Kellermanns and Eddleston, 2004). Mazzola *et al.*'s (2008) findings on the role of strategic planning in the strategic decision-making process revealed that the involvement of the next generation family members in the strategic planning benefits their developmental process. Such involvement enables the creation of shared vision, provides the next generation with important tacit business knowledge and skills as well as contributes to building credibility and legitimacy for the next generation.

Regarding strategic planning and decision-making processes situation is different in explored SFF. Eight (80 %) of successors reported that they have started to participate in the strategic planning and decision-making processes since they were employed in the family firm, which coincides with the finding, that they did not participate actively in meetings with business partners, before they showed serious interest for the SFF. One (10 %) has not been involved as he is still a student and one (10 %), being son in law of the founder, has started to participate in strategic planning and decision-making processes only when he became a director of the SFF. The only exception, where they mostly get involved earlier is the challenge of succession.

Case analysis revealed that majority (seven, 70 %) of successors highly agree, while eight (80 %) of them were also included, that involvement in the planning processes, especially strategic planning, enables them to assimilate critical tacit (business) knowledge and skills, insight into industry development, improves successor's relationships within SFF and with business partners out of the SFF thus contributing to their innovativeness.

“We have daily meetings. Problems are promptly addressed and solved. When one of the children does not find a solution by him/herself, I get involved, in up to 80 % of all problems. Family life is pervaded with constant transfer of knowledge,” said one of the founders.

According to Shahid (2009) always bigger share of discoveries are result of team-multi-disciplinary cooperation, associating knowledge, functionality and insights of professionals from different fields. Team members articulate their own perspectives and reveal hidden tacit knowledge (Nonaka, 1994). Thus, team knowledge is viewed as an important source of innovation since the combination of team member's knowledge creates the new knowledge (Delgado-Verde et al., 2011). Team work is important for preparing a successor for a leadership role (e.g., Ganzaroli et al., 2006) and is essential for a family firm to be creative and innovative entity (e.g., Litz and Kleysen, 2001). Family members' specialized knowledge and its recombination in a team work enables the adaptation of a SFF to shifts in environmental conditions (Chirico and Salvato, 2008).

Majority of successors (eight, 80 %) agree on the importance of the team work for knowledge transfer and creation of new knowledge as a source of innovations. Eight (80 %) successors reported on working in teams as part of their training. Team work of family

members is often related to development of new projects, improvements of processes, products and services.

The founders are well aware how crucial it is to transfer their experience and knowledge to the younger generation in order to assure competitiveness and sustainability of a SFF. Mostly they share their knowledge and experience also with non-family members, but never tacit knowledge.

In the light of the above discussion the following proposition has been developed:

Proposition 1: Early exposure to a family firm (socialization of the successor), mentoring, apprenticeship, learning-by-doing, as well as successor's active involvement in decision-making, strategic planning and team work are effective ways of knowledge transfer from founders to the next generation, thus positively influencing innovativeness of the next generation in SFF.

4.3.2.2 Outside the SFF related knowledge transfer

Outside the SFF related knowledge transfer is very important since it enables successor to bring fresh insights into the firm, get new ideas and in combination with tacit (experiential) knowledge transferred from the founder and leads to new developments and improvements of products, services, processes in SFF.

The knowledge absorptive capacity of successors, which is needed for assimilation of knowledge during a succession process, depends as well on their previous academic and professional education (Szulanski, 1996) which teaches successors concepts and generic skills that can be applied to most business contexts. It also enables them to develop analytical skills and abilities that are crucial for decision making. During education process successors are also exposed to new ideas and trends in management and technology (Sardeshmukh and Corbett, 2011). Nowadays, formal education is getting more and more important since successors are selected also on the basis of their experiences and skills (e.g., Ganzaroli *et al.*, 2006; Cabrera-Suárez *et al.*, 2001; Steier, 2001). Successor's educational level should meet requirements needed to be an entrepreneur in a knowledge-based economy. It is no longer enough just to know how to perform a specific activity and/or function. Being competitive requires being able to create new knowledge.

Successors in our study are all very well educated, on average better than founders: one of successors has a technical university degree, one in economics, others graduated or

(three) still study entrepreneurship. In the eyes of successors, the most important significance is given to formal education's impact on development of technical knowledge and competences, followed by marketing, administrative knowledge and competences and attitude toward team working. The least impact is given to working commitment and motivating skills. Formal education is basis for formation of human capital. In teaching the accent should be given to skills like critical thinking, creativity, communication, user orientation and team work, using domain specific and language knowledge. Entrepreneurship studies cover all these. The research has revealed that formal education in the eyes of successors affects development of creativity, but not to the same extent as e.g., technical knowledge and competences.

All of the founders in our research believe that academic knowledge is important for competitiveness of the firm as it opens horizons, but they also believe that this knowledge should be combined with work experience of successors, their joy for work, feeling for trade. They believe that academic knowledge was not as important for their generation as it is for the generation of successors.

On the basis of above discussion we develop the following proposition:

Proposition 2: Formal education (e.g., entrepreneurship) is positively related to innovativeness of successors in SFF.

Previous working experience, especially from working outside the family firm gives the successors "a more detached perspective over how to run and how to introduce changes and innovation in the business" (e.g., Cabrera-Suárez *et al.*, 2001; Chirico, 2008, p. 447) and usually occurs before a successor enters a family business for full time. Having previous working experience in another firm a successor can integrate the knowledge transferred by the founder with the knowledge acquired during training process (e.g., Cabrera-Suárez *et al.*, 2001) and especially, in circumstances of fast changing markets is training in competing organizations or in firms that are leaders in a related industry of crucial importance (Le Breton-Miller *et al.*, 2004). Experiences gained outside the family firm enable successors to bring in a family business new knowledge on markets, technology and industry, and apply it effectively in the context of a family business (Sardeshmukh and Corbett, 2011). Such experiences play a crucial role in creativity and innovation processes (Litz and Kleysen, 2001) on the individual and firm level.

Findings of our research reveal that most of successors (seven, 70 %) have no previous working experience in other firms; only two (20 %) of the successors have previous working experience from the other firm in a different industry, and one (10 %) has worked before in two other firms, in a different and same industry. Two (20 %) successors also report internships in other firms in a different industry, as well in a different country. Lack of working experience in other, but family firms, is strongly connected with economic situation and lack of job opportunities in Slovenia.

According to opinion of seven (70 %) successors, the ones that have and the ones who have no previous working experience in other firms, working experiences from other firms can foster development of communications skills, of attitude toward negotiation and of marketing knowledge. They say as well, that according to their opinion, previous working experiences are not significant for development of the attitude toward risk or toward problem solving.

Zahra (2005) claimed that long tenure of predecessor negatively affects a family firm's emphasis on innovation and new market entry as well as lead to strategic simplicity. For this reason, many authors (e.g., Cabrera-Suárez *et al.*, 2001; Chirico, 2008; Duh, 2014) exposed the role of academic courses and training in schools, universities, and institutions, that allow successors to acquire new knowledge that is essential when a family business is active in markets which undergone fast changes (Chirico, 2008).

In our research most of the founders find external training programs very important for further development, increasing and upgrading of successors' potential for future management of the SFF. As most of successors (70 %) do not have previous working experience in other firms, it is crucial, that they have opportunity to absorb/adapt other up-to-date knowledge and skills enabling them competitive edge in the future operations of SFF. In some cases they invite external experts into their environment and enable "internally" training for all employees, not only for successors, but micro firms tend to send their employees to training programs outside the firm. Some examples of such training programs are: quality management, accounting and financial practices, insurance programs, ISO standards like ISO9001, preparation of applications for tenders, safety at work, rhetoric, marketing, foreign languages, working with customers etc.

A right mix of out- and inside training experience is fundamental to acquire technical and managerial knowledge of the business and leadership abilities (Cabrera-Suárez *et al.*, 2001). It plays a key role in creativity and innovation process (Litz and Kleysen, 2001).

The following proposition is derived upon above described findings:

Proposition 3: Previous working experiences outside a SFF and access to expert know-how through external training programs are positively related to innovativeness of successors in SFF.

5 Conclusions

Combination of different methods is a usual way of transferring knowledge to the generation of successors in SFF. Founders in our research believe that it is very good to let successors observe them at work, get involved in daily operations, into business meetings and negotiations with partners and to let them find solutions by themselves, to learn by problem solving, and also take responsibility for decisions. Studying and getting academic knowledge in combination with early socialization, as well as work experience in other firms is important for the development of successors, of firm's products, services and processes.

In the recent five years founders and their successors report intensive and constant development of new or of improved products, product models, services and processes. Thus they maintain and improve SFF's operations. This is a result of a strong and dynamic relationship between the parent/founder and successor, of a high level of confidence and successors' willingness to learn. Younger generation is sparkling with new ideas, which mostly result in introduction of improvements or new processes in a firm, many of them leading to rationalization of business processes.

We believe that our research findings contribute to broadening our understanding of family business succession from the knowledge transfer perspective as well as it opens some new research directions. The future research should address the ways of managing the early exposure of children to a business as a part of knowledge transfer process. It should address as well social networks, social capital. According to Steier (2001), innovation ability of firms is complemented by social capital, which is defined as a stock of resources and abilities in a network of relationships between firms and/or people. Social capital facilitates mobility of know-how and its sharing between firms and individuals. This contributes to promotion of innovation. It is extremely important that

SFF are well connected as this enables access to complementary resources of production, know-how. Another direction of future research can be corporate entrepreneurship, as innovativeness is connected with it. According to Kellermanns and Eddleston (2006) corporate entrepreneurship is of key importance for survival of SFF, their profitability and sustainable growth. The future research should address as well the question of founder's management style. A too strong involvement of the founder into operative decisions and family issues can decrease his/her readiness for risk-taking, and risk taking is related to innovativeness of a SFF (Sethi et al., 2001). According to Szulanski (1996) there might be some obstacles that hinder knowledge transfer from founders to the next generation in SFF, which affect innovativeness of the next generation, and that are: random ambiguity and unproven correctness, founder not interested to transfer knowledge, successor not motivated to accept knowledge, factors of circumstances, like limitations in organizations and bad relationship between predecessor and successor. These obstacles and how they affect innovativeness of the next generation in SFF can be another direction of the future research.

Structured Abstract

Purpose – This paper introduces initial insights into how Mediolanum Asset Management Limited (MAML), an innovative and expanding Italian asset manager based in Ireland, relies on a knowledge-based organisational structure fostering innovation in order to generate a sustainable competitive advantage. Knowledge-based SMEs such as MAML face a recurring challenge in the highly competitive asset management industry: they rely heavily on their staff expertise in order to generate innovation while trying to downplay at the same time their dependency on their human assets. The company fosters innovation while resting on KM practices and IC to build a social and organisational capital.

Design/methodology/approach – Primary and secondary data are gathered from observation, documentation and semi-structured interviews and provide the material on which this study is based. Knowledge management and intellectual capital theoretical lenses are elicited for the critical analysis and interpretation of the results.

Originality/value – This paper based on empirical evidence demonstrates how intellectual capital stocks and knowledge management practices are actually approached and implemented in order to create value through innovation-led processes. To our knowledge, MAML constitutes a rare case of a SME in the asset management industry that is positively and consciously concerned with managing and capturing intellectual capital so thoroughly.

Practical implications – This paper provides interesting and valuable insights to other small asset managers on how they can employ intellectual capital and knowledge management practices as an alternative way to generate an innovation-led sustainable competitive advantage while reducing at the same time their dependence on human assets.

Keywords – Knowledge Management, Intellectual Capital, Innovation, Asset Management, Ireland

Paper type – Academic Research Paper

1 Introduction

The asset management industry has dramatically changed since the beginning of the millennium under the combined influence of a profound mutation of the prevailing business models and the consequences of the last financial crisis. The historical supply-led, product-push distribution model has been revealed as increasingly obsolete in the current environment. Understanding clients' needs and demonstrating a real capability in delivering value translates into a shift of power towards those nearest the client (Griffin et al. 2013; Rajan 2013). Asset managers are no longer in a stable and predictable business environment. In the aftermath of the financial crisis, they suddenly became part of an increasingly dynamic industry fraught with uncertainties and with a heavy and prolific regulation that stretches companies' resources further while adding complexity to operating models. Griffin et al. (2013) identified that asset managers are evolving towards a more focused and better-structured approach to their markets. They also stress that companies are better off moving away from fragmented or silo-based ways of working to make coordination, collaboration and effectiveness their new organisational philosophy. Furthermore, asset management firms need deeper skills and capabilities in order to develop relevant client-centric dialogues while at the same time simplifying and flattening their operating models.

One of the favoured avenues for creating a better fit between market requirements and company's resources and capabilities is to foster and nurture innovation. Innovation is viewed as an intellectual agility driven primarily by competition, an ability to use knowledge and skills, and an ability to build on prior knowledge and generate new knowledge (Roos et al. 1997). It is the implementation of both discoveries and inventions, and the process at the origins of new products, systems or processes (William 1999). Creating new ideas that add value for clients under a certain time frame in the same fashion as Apple, Johnson & Johnson or Toyota has gradually gained popularity among asset managers. Firms will generate a sustainable competitive advantage by implementing the four sequential activities of the innovation value chain that consist of idea generation, evaluation, design and delivery. Idea generation emerges from spotting gaps in the

product market; then the feasibility of a business case is studied; design consists in stress-testing the chosen solution and delivery involves convincing the client and making things happen (Rajan 2013). Scholars made a compelling argument in demonstrating the intrinsic dependence of innovation on intellectual capital (IC) stocks and, how knowledge management (KM) processes and practices support organisational innovativeness (Andreeva & Kianto 2011; Kianto et al. 2013; Santos & Wane 2013).

IC is understood as a collection of intangible assets and flows that contribute to the company's value creating process (Bontis et al. 1999). IC is traditionally understood as a combination of human assets, structural assets and relational assets. Stewart (1997) defines it broadly as a "package of useful knowledge" introducing as such the approach in terms of IC stocks. KM is a broad and multi-dimensional concept that covers most aspects of an organisation's activities. Whereas, knowledge encompasses data, information and tacit knowledge, KM can be seen as a management function that consists in creating or locating knowledge, in managing the flow of knowledge within the firm and in ensuring that knowledge is used efficiently and effectively for the long-term benefit of the organisation (Darroch & McNaughton 2002). It is understood in terms of processes or practices such as knowledge creation, acquirement, organisation, storage and distribution, and application between people, technique and technology (Bhatt 2001; Nonaka 1994). In other words, the overall objective of KM is to make a firm act as intelligently as possible in order to secure a sustainable competitive advantage, achieve organisational performance and optimize the use of its knowledge assets (Wiig 1999).

Within a background of both a rapidly changing asset management industry and a rising interest in the innovation potential of using a combination of IC and KM, Mediolanum Asset Management Limited (MAML), a Dublin-based asset manager, part of an Italian group, with circa €28 billion assets under management (AUM), is singled out as an organisational exemplar within a broader research project involving several firms. Led by Furio Pietribiasi, MAML demonstrates a clear focus for innovation, knowledge management practices and intellectual capital in order to create a sustainable competitive advantage and build social and organisational capital. And, this is clearly asserted in its strategic statement.

This paper aims at introducing initial insights into how MAML strives to design a knowledge-based organisational structure instilling an innovation-driven culture that is able to generate a sustainable competitive advantage within a highly competitive industry.

Exploring one case study can be seen as problematic if one looks for generalizations. However, this is not the purpose here. Following the example of Starbuck (1992), gaining exceptional business success does not rest on imitation of other firms and exploitation of shared properties and in our views, MAML fits the profile. In addition, the value creation process is firm and context-specific (Bollen 2005). Focusing only on one particular case is sometimes the best avenue to make a contribution to knowledge (Starbuck 1993). The first section reviews the relevant literature. The research design is then introduced followed by the initial results stemming from the study in a second section. A conclusive section discusses the findings. Finally, the limitations of the study and potential further research are suggested.

2 Relationships between intellectual capital stocks, knowledge management practices and innovation

The rationale for intellectual capital (IC) and knowledge management dates back to the 1980s where it became obvious that business differentiation and sustainable competitive advantage could not rest solely on tangible assets but more and more on developing unique resources, capabilities and endowments. Hence, the resource-based view of the firm introduces knowledge as a driver for the definition and implementation of a business strategy (Grant 1991; 1996). How the literature envisages the possible relationships between IC, KM practices and innovation is explored in the following paragraphs.

2.1 Intellectual capital and innovation

Bontis et al. (1999) defines IC as the collection of intangible resources and their flows. The former are under the control of the company and contribute the company's value creating process. Formatively, IC is divided three pillars: human capital, structural capital and customer capital. Human assets encompass individual tacit knowledge, intelligence, skills, expertise, learning, capability, changing, innovativeness, creativity (Bontis 1998; Lynn 1998), problem solving, leadership, entrepreneurial skills, and managerial skills (Roos et al. 1998). Brooking (1996) includes also competence, attitude, motivation, and leadership qualities of top management as well as intellectual agility, innovation and adaptation capabilities into these assets.

Lynn (1998) defines structural assets, the second pillar, as organisational routines consisting of systems that organise the intellectual efforts in order to generate more routine, a supportive culture, information systems, efficiency, and procedural innovativeness. They are the mechanisms, structures and systems that turn individual assets into group assets (Bollen 2005). They also comprise infrastructural assets such as corporate culture (Roos et al. 1998), internal structures such as management and legal structure (Edvinsson & Malone 1997), proprietary software, networks, corporate culture and policies (Bontis 1998), relationships with external organisations and, structural capital renewal development (Brooking 1996).

The third pillar, relational capital, supports the organisation's market orientation and relations with other organisations (Bontis 1998; Lynn 1998). Edvinsson & Malone (1997) depict the idea of external structure of the company versus the internal structure that is market assets such as brands, customers, repeating business, licences and, franchises (Roos et al. 1998).

Intellectual Property Rights (IPRs) are legal mechanisms aiming at protecting corporate assets and infrastructure assets (Brooking 1996). They are the most tangible element of IC and the one most widely embraced by management and shareholders (Bollen 2005). This creates an issue when determining which category they belong to. Consequently, Bontis (1998) suggests supplementary family of assets that constitutes a fourth pillar of IC. Brooking (1996) considers IRPs as part of the structural assets groups while Roos et al. (1998) assign them as relational assets. This issue is of importance as following Edvinsson & Malone (1997), IPRs would rest whether in realm of the firm and strengthen its position vis-à-vis human assets or on the contrary, shift towards human capital.

Bollen (2005) establishes a clear connection between IPRs and company's performances in the pharmaceutical industry. He outlines that a comprehensive understanding of IC including IPRs impacts positively on company's performance. In his views, IPRs constitute a kind of "interface" between human capital, structural capital and relational capital.

While human capital is best approached as human-centred assets that cannot be owned by the company, structural capital refers to organisation-centred assets supporting employee's productivity which are left behind when the employees go home (Edvinsson and Malone 1997). In turn, we can suggest that relational assets may be viewed as a

shared attribute of the human and structural capital. Resting on firm-specific structural capital, employees are usually ensuring the relationships with clients and carry company's culture with them. Furthermore, the existing dichotomy between human, structural and relational assets should not be so strict in our view. It can be argued that corporate culture for instance is a determinant for stirring innovative capabilities, creativity or a positive attitude to work. In the same manner, it influences the customer relationships. Table 1 offers a general view of different elements of IC. Consistent with a view following which a classification of IC elements pertains more to general guidelines rather than a strict compartmentalisation that could be counterproductive within the rationale of intangible assets, the elements of IC in Italics in Table 1 refer to the elements that are viewed as overlapping.

Table 1. Elements of Intellectual Capital

<i>Human capital</i>	<i>Structural capital</i>	<i>Relational capital</i>
<ul style="list-style-type: none"> • Individual tacit knowledge • Intelligence • Skills • Expertise • Learning capability • Competence • Leadership capability of top management • Intellectual agility • Adaptation capability 	<ul style="list-style-type: none"> • Organisational routines • Risk assessment methods • Information database • Communication systems • Management • Legal structure • Manual systems • Attitude • R&D • Proprietary software • Networks • New plants and new products 	<ul style="list-style-type: none"> • Knowledge of marketing channels • Relations with other organisations • Brands • Repeat business • Organisation's image and reputation

	<i>IPRs</i>	
	<ul style="list-style-type: none"> • Brands, licences, franchises, know-how, trade secrets, copyrights, patents, trade, service marks 	

2.2 KM practices and innovation

KM is best understood as the principles, models, approaches, techniques and tools aimed at developing and using organisation knowledge in order to deliver organisation performance (Carlucci & Schiuma, 2006). Knowledge-based processes are typically composed of four elements: knowledge creation, intra-firm knowledge sharing, external

knowledge acquisition and knowledge repository (Davenport & Prusak 1998; Andreeva & Kianto 2011). KM is posited as the fundamental prerequisite for innovation (Nonaka & Takeuchi 1995) with Santos & Wane (2013) demonstrating a positive relationship between the four steps of the knowledge cycle and innovation performance. However, knowledge creation is paramount and mediates the three other steps (Andreeva & Kianto 2011). Knowledge creation depicts the firm's ability to generate novel and useful ideas and solutions in terms of products, technological processes or managerial practices (Nonaka 1991; Un & Cuervo-Cazurra 2004 in Andreeva & Kianto 2011). Darroch & McNaughton (2002) provides empirical evidence of the existing relationship between types of innovation and knowledge management practices. Six managerial implications that positively affect innovation are identified: *"being sensitive to information about changes in the marketplace, having a science and technology human capital profile, working in partnership with international customer, using technology, and being flexible and opportunistic"* (Darroch & McNaughton 2002 p. 219). KM is viewed as the perfect medium for the networked, interactive and knowledge-driven nature of the innovation process. It is itself an outstanding example of what is referred to as interactive innovation, a practice that is knowledge-based and team-based that is dependent on the collaboration of a wide variety of groups (Scarbrough 2003).

Leadership is an important element in choosing an implement KM practices in a knowledge-based innovative organisation. By instilling a supportive culture, leaders may influence innovation of both teams and individuals. Leaders stimulate innovation by influencing creative self-efficacy and by introducing a framework conducive to team reflection processes (Denti & Hemlin 2012); creating the environment and decision-making capability within which knowledge is generated and implemented (Noruzi *et al.*, 2013). They stimulate a shared vision of knowledge and emphasise its importance (Nonaka 1994). Organisational culture influences the behaviours central to knowledge creation, sharing and usage. Culture shapes the connection between employees and organisational knowledge, hence creating the environment for social interactions and shaping the processes by which knowledge is managed (De Long and Fahey 2000). Top management is then a catalyst, an architect and protector of knowledge, considering the personnel in its entirety rather than through the intermediary of management (Hedlung 1994). Furthermore, the choice of flatter organisations favours collaboration, adaptability and lateral communication. Flexibility and opportunism are two other organisational

attributes to consider as they foster particularly incremental innovation (Darroch & McNaughton, 2002). Transformational leadership or inspirational leadership are phrases that better reflect leadership as a KM practice as it inspires employees through constant motivation, intellectual stimulation, charismatic speech and being an exemplar.

On a continual basis and through heuristics organisational learning and performance as they encompass any process, KM mechanisms participate in enhancing the practice of creating, acquiring, capturing, sharing and using knowledge wherever it resides (Scarbrough et al. 1999). It facilitates strategic renewal (Crossan et al. 1999). In turn, information technologies create an infrastructure and environment that support knowledge processes and ensure that individuals play an active part in knowledge management processes (Dalkir 2005). KM reinforces its underlying dynamics, scope and overall synergy (Alavi & Leidner 2001). It supports working in teams and seeking out knowledge (Lee & Choi 2003). However, empirical evidence shows that the quality of information actually overrides the importance of IT investments (Andreou & Boone 2002).

Finally, Scarbrough (2003) makes a compelling case for the role of human resources management (HRM) activities in organising the flow of people (selection methods, compensation strategies and career systems) for the development of innovations. More specifically, HRM is of a particular concern for innovation-driven firms. Knowledge resides in individuals; hence knowledge needs must be properly managed. In order to strengthen their IC, firms should design HR architectures that fosters knowledge acquisition, knowledge sharing and knowledge application (Intan-Soraya & Chew 2010).

Table 2 – Sample of knowledge management practices leading to innovation

KM processes	KM practices	Innovation dynamics
<ul style="list-style-type: none"> • Knowledge creation dynamic • Intra-firm knowledge-sharing orientation • External knowledge acquisition capabilities • Useful and usable knowledge repositories 	<ul style="list-style-type: none"> • Transformational leadership • Supportive corporate culture • Network-based structure and infrastructure • KM-driven HR architectures • <i>Ad hoc</i> organisation structures • ICT and science friendly structure and infrastructure • Etc. 	<ul style="list-style-type: none"> • Incremental innovation • Radical innovation • Intellectual property portfolio
		

The literature overall establishes clear relationships between IC, KM and innovation. Kianto et al. (2013) explore the potentials that accrue from a holistic understanding of IC and KM and identify seven groups of KM practices: strategic KM practices, organisational structural arrangements, KM-friendly organisational culture, ICT practices, learning mechanisms, KM-related HRM practices, knowledge protection practices. Intan-Soraya & Chew (2010) suggest a framework capturing the ways in which an organisation's knowledge management capacities have a positive relationship on its IC, which in turn has a positive influence on its innovative capabilities. Fig. 1 suggests a representation of a holistic view of KM, IC and innovation, which is the one that is retained for this study.

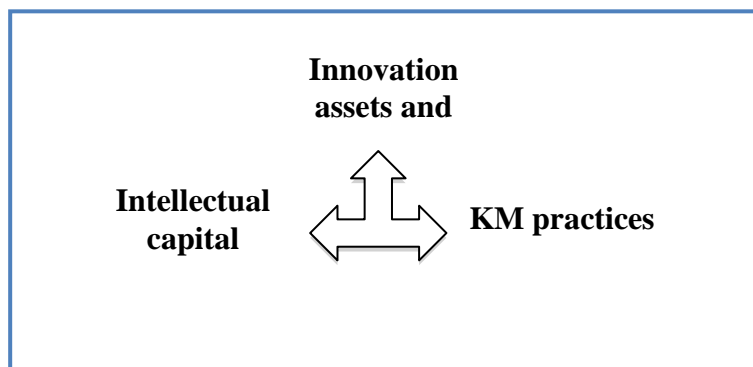

Fig. 1. The relationship between KM, IC and innovation

3 Mediolanum Asset Management Limited: KM practices, IC and innovation

An exploratory strategy of inquiry is implemented drawing on multiple sources of evidence inclusive of observation, documentation and semi-structured interviews. Documentation includes company documents and electronic data. Fourteen executives of the company identified as decision-makers were interviewed at the Dublin-based premises of the MAML. This process allowed a certain degree of observation, in particular on the layout of the working stations and the culture of the company. The KM and IC theoretical lenses are elicited for analysis and interpretation while considering at the same time how the firm is interacting with its business environment. At the end of the inquiry process, clear concerns are identified and constitute at the same time the drivers

and the framework of the innovation dynamic. The data collected was analysed using Dedoose.

MAML is one of the asset management companies of Mediolanum Banking Group, an Italian financial market leader based in Milan and founded in 1982 by Ennio Doris. It provides portfolio management, cash management and investment advisory services. MAML is characterised by a client-centric approach and targets principally a retail market. The Dublin-based asset manager works very closely with Mediolanum International Funds Ltd (MIFL), which has a proprietary product development process (MedInSynC®), leveraging on open innovation, and develops and markets mutual funds through its distributors to a very broad network of clients primarily located in Italy, Germany and Spain. Consistent with the current business and economic environment requirement, MAML addresses several challenges with a view of maintaining and developing its sustainable competitive advantage through innovation. It strives to (1) identify clearly how it creates value and convince its clients that Alpha (i.e. active return of an investment) does not rest on luck or minor accidents; (2) align its business operations and ethos with the industry requirements and the emerging business model while (3) develop business agility; (4) build organisational skills and capabilities. (5) Systemic tensions such as reducing firm dependency on its human assets or determining plans that are too ambitious are other challenges the firm must address. While the previous points are more concerned with process innovation, the last point (6) is about product innovation. The following section introduces the initial results of the data analysis. Using IC and KM practices lenses, document analysis as well as coding, axial coding and selective coding techniques were applied. For the purpose of clarity, the IC and KM-related results are shown consecutively. However, the separation is only theoretical as in practice, IC, KM and innovation in MAML constitute a sole entity.

3.1 The IC view: a process-driven innovation in the first place

When considering the three foundational pillars of IC, MAML favours with no doubt structural assets. For this case study, IPRs fit then naturally within these structural assets. Prior developing further the three elements of IC, Fig. 2 describes the approach MAML has on its entire capital. It reflects clearly the emphasis on structural capital that is echoed by our findings.

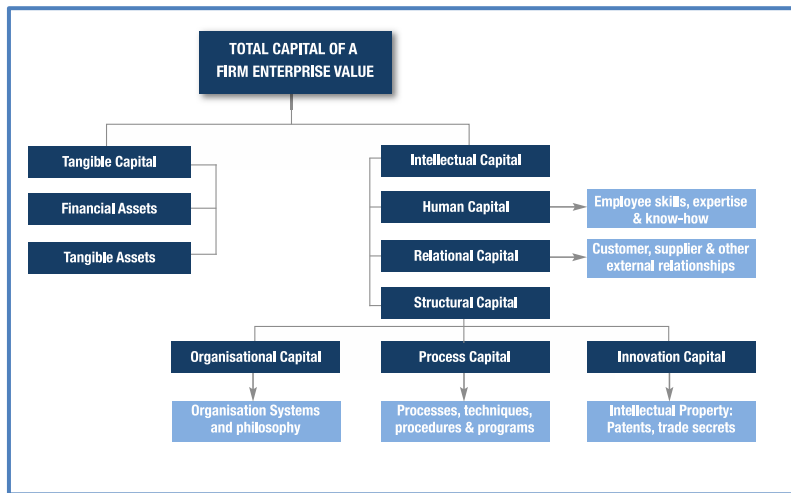

Fig. 2. Mediolanum’s view of corporate tangible and intangible capital

(1) Structural assets

Structural assets are identified as the backbone of MAML’s success and instil an innovation-driven culture and performance. Basically, they encompass a solid portfolio of IPRs that protects unique processes in terms of investment, product development, R&D and risk assessment. MAML refers to the previous as “innovation capital”. It also overlaps with “Process capital” mentioned in Fig. 2 and outlines the reliance on clear processes, techniques and procedures that are developed in the following section. These items are the core value-adding centres that have been identified by the firm, conceptualised and protected. In particular, Med3® encapsulate MAML’s investment process and captures the know-how and IC accumulated over the years. It is constantly refined and amended by reviewing each active investment choice pay-out to improve decision making (“Hit Ratio”) aiming at better future outcomes. Also this process leverages on global intelligence and delineates different identified steps to translate into investment decisions the opportunities and risks arising from financial markets (see appendix). These processes constitute strong points of reference for company’s and Group’s stakeholders, foster a strong corporate culture, organisational routines and participate in communicating the company’s strategic vision. Those processes are designed with a view to generate innovation.

A network-based philosophy is central to internal and external organisational structure and infrastructure. Focusing primarily on value-adding activities, the philosophy strives to

outsource other functions to selected external partners with whom they build long-term relationships, i.e. other companies, universities, research centres or governmental bodies. MAML refers to this as ‘Global Intelligence’. In MAML’s view, this pertains to relational capital and outlines the endeavours to ‘collaborate with partners’ rather than ‘work with suppliers’. Internally, a so-called flat organisational structure is observed together with an open-plan layout office where the desks are not attributed following the ranks (only two individuals have closed offices as they handle confidential matters). This facilitates lateral communication, learning, knowledge sharing and collaboration between all staff. This pertains to the ‘organisation capital’ section of the company’s structural assets.

Supporting IPR and the network-based ethos, information technologies are another strong structural asset on which company’s organisational performance rests. Within budget constraints and a prioritization agenda, it strives to implement the most updated systems that are deemed relevant. Substantial investments are made into information systems, equipment and software with a view to alleviating staff workload, gaining flexibility and speed and enhancing risk assessment. This infrastructure is also key in easing knowledge flows. Proprietary systems are developed in-house such as their Data Warehouse (Big Data platform), a Virtual Library with its collaboration tool MedCred® or, its Knowledge-Network Platform (KNP). The KNP is an idea management tool involving local and Group stakeholders and guaranteeing maximum transparency and collaboration among the different stakeholders that often inadvertently work in silos when it comes to managing their relationships even if they are all dealing with the same provider.

(2) Relational assets

Relational assets are strongly embedded in the client-centric culture of the company. Consistent with their value-centred outsourcing model, final investors’ relationships are primarily in the hands of MIFL distributors and their network of ‘family bankers’ in Italy, Spain and Germany. Those ones are professional ‘Financial Advisors’. Following the model and spirit instilled by the original founder, Family Bankers possess a very deep knowledge of the local market and their clients’ needs; but they also demonstrate a certain level of expertise in the product itself that bring them closer to asset managers *per se*. A very close relationship exists between the asset management unit based in Dublin and the distributors. Consistent with its technology-driven and client-centric philosophy, MAML has bespoke services (Connect and Learn® and MedRadar®) to provide to MIFL

distributors' final investors regular training on investment strategies, product investment updates, etc., in the Dublin offices or through video-conferencing. They also provide insights to the Irish-based teams about their experience. All sessions are video-recorded and made available to the staff and distributors via the Virtual Library.

(3) Human capital

In terms of human capital, the leadership capabilities of the top management are a very strong asset. This represents a good example of transformational leadership with the individuals in charge constantly stimulating and sharing the company's vision, instilling a supportive innovation-driven culture, organising a framework favouring team reflection and nurturing a creative self-efficacy. The people interviewed that were not part of the top management had a positive reaction to leadership and a positive attitude towards providing inputs into the in-house processes under copyright.

MAML demonstrates also a strong emphasis on managing its employees and address the pertaining issues in terms of 'Human Capital Management' (HCM) and Talent Management instead of Human Resources Management (HRM). The company applies HCM practices and policies in order to increase its innovation capability. The senior management plays a central role in nurturing tacit knowledge which is understood as *"personal, context specific and hard to formalise; (...) it gets embedded into our corporate memory through collaboration and learning by doing"* (quote from 2013 Financial Statement).

The IC foci and design of MAML are geared towards open innovation that consists in tapping into and exploiting technological knowledge available outside the firm's area of expertise or R&D structure. It represents a solid competitive advantage accruing to companies that do not rely exclusively on in-house approaches to innovation (Whelan 2013). MAML refers to this in terms of 'crowdsourcing' that is a type of incremental innovation; it consists of the use of external resources in order to start or strengthen existing assets in a cost-effective manner.

3.2 The KM practices view: identified supporting knowledge management practices

We found overall that KM practices participate actively in strengthening MAML's IC. They act as bridge between IC and innovation and set the bases for a dynamic of knowledge creation. The coding and decoding process run during the qualitative analysis outlined in the following eight themes.

- (1) *Collaborative and knowledge sharing organisational platforms* based on networks and team-based work and this is constantly incentivised for example through MedCred®, a virtual rewarding in-house tool. This rests on an extensive internal network connects the different employees in the company and sets the foundations for learning and sharing knowledge. It fosters a positive attitude of individuals for sharing knowledge which reflects their intertwined relationship of dependence. External networks are also of importance and it is the vector that allows access to global intelligence. The latter referred also as crowdsourcing, is composed of external research companies, consultants, brokerage firms, etc, that provide complementary expertise.
- (2) *Organisational learning aimed at building the company's knowledge repository* at the centre of which the company's in-house processes play a major role. They generate an internal dynamic of incrementally building a knowledge base. Continuous learning and understanding is constantly emphasised and the staff show a positive attitude towards learning and sharing. The Virtual Library and the project around the development of the Knowledge Network Platform is set to contain also the tacit knowledge generated.
- (3) *Innovation is process-driven and stems from organisation learning*. It focuses on contemporary value-creating activities.
- (4) *Transformational leadership* is a strong quality of the top team which is in charge of creating the right environment for creativity, motivation and innovation. They actively encourage employees to stay close to the company and closely follow market developments as well as adopting any new information and technology innovation.
- (5) A strong *worker engagement and commitment* characterises the company. The employees mentioned on many occasion how much they learned and they were learning everyday and how they appreciated the challenges they had to face. The company was considered to be very supportive of them with its talent management programme.
- (6) MAML can be viewed as possessing the *organisational structure and infrastructure* that favours innovation. There are very few hierarchical level with people working in an open-plan structure and within teams.

- (7) MAML is considered as a *technology-intensive* firm by its drive to be a “high-tech” company, but also by the substantial investments made in updated IT and the training provided to the staff. It also strives for a paperless working environment.
- (8) The last important theme identified relates to the *portfolio of IPRs* the firm possesses and intends to develop.

Table 3 provides practical examples of knowledge management practices that relate to the eight themes.

Table 3. Identified knowledge management practices generating innovation

	Leading themes	Identified corresponding KM practices
1	Establishing a collaborative platform fostering knowledge-sharing	<ul style="list-style-type: none"> • Establishing external networks for open innovation • Outsourcing – focus on core activities • In-sourcing global intelligence / relationships with suppliers • Partnerships with Irish leading universities • Intra-group client-supplier relationships – client-centric culture at all levels • Teamwork
2	Organisation learning – fostering an incremental knowledge base	<ul style="list-style-type: none"> • Company culture for learning and sharing • Staff teaching to other staff on specific issues • Regular meetings for sharing topics chosen by the staff • Importance of attitude • Knowledge Network Platform project
3	Process-driven innovation and organisational learning	<ul style="list-style-type: none"> • Product development process • Investment process • R&D process • Other processes currently under development
4	Transformational leadership	<ul style="list-style-type: none"> • Physical office space shared by all staff levels • On-going communication • Collaboration incentivised by MedCredit • Constant sharing of insights • Innovation-driven attitude • Engagement based on freedom and responsibility/accountability
5	Worker engagement	<ul style="list-style-type: none"> • Corporate culture and working environment • Outsourcing repetitive and non-value adding tasks when possible • Requirement for regular contributions in the processes • Commitment partly driven by the in-house processes
6	Organisational structure and infrastructure	<ul style="list-style-type: none"> • Flat organisation • Open-plan offices • Prevailing teamwork culture • Use of collaborative technologies
7	Technology-intensity	<ul style="list-style-type: none"> • Substantial investment in up-to date equipment and

		technologies <ul style="list-style-type: none"> • Regularly upgrading with relevant information technologies • Striving for paperless environment • Keeping staff up-to-date in terms of training
8	Building an Intellectual Property portfolio	<ul style="list-style-type: none"> • MedInSync, Med3, MedLab, etc • Drive for protecting and patenting any new innovation

4 Discussion

The eight themes identified for MAML in the previous section demonstrate the existing interdependence between IC, KM and innovation (Fig. 2). The leading themes pertain to the different components of IC while pointing overwhelmingly to the structural assets and are backed by a whole set of knowledge management practices. A strong relationship exists then between innovation and KM (Darroch & McNaughton 2002). The IPRs that exists in this case in process innovation provide evidence of the outcome generated by a combination of IC and KM practices. This illustrates the idea of interactive innovation (Scarbrough 2003).

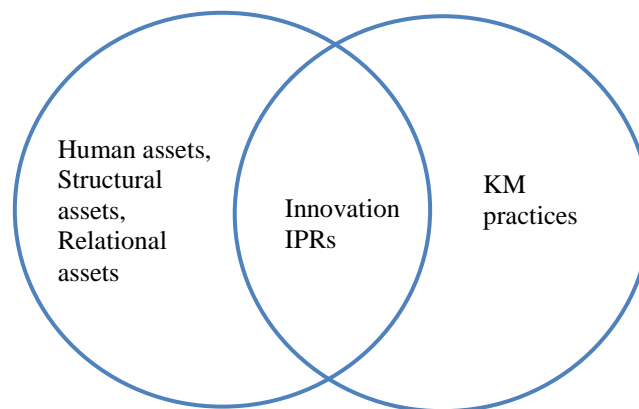

Fig. 3. The relationship between IC, innovation and KM practices

This study shows that the company demonstrates a conscientious and strong concern for knowledge management practices and IC. It positively addresses the issues and strives to identify and implement the right organisational structure and infrastructure that is a “flat” one in order to foster knowledge creation and sharing (Hedlung 1994; Noruzi et al. 2013). Such features are synonymous with hierarchical levels which are reduced to the

minimum and simplified internal communications. This is consistent with Andreeva & Kianto (2011) who put knowledge creation at the centre of the processes that drives knowledge sharing, acquisition and storage and, ultimately innovation.

MAML demonstrates its reliance on a strong transformational leadership that plays a key role in instilling the cultural and supportive environments that are innovation-friendly (Denti & Hemlin, 2012). This can be observed at the level of the Dublin-based business unit where “*Even when our Managing Director is in London, he is still here*” (employee’s quote). At the group level, the presence of the original founder who lives in Italy is also very perceptible as numerous examples of his actions were regularly mentioned. The business style and culture he adopted decades ago is still strongly imprinted in today’s company culture. Furthermore, an *ad hoc* understanding of HRM called HCM and Talent Management provides a compelling account of MAML’s investment in managing its human assets. The right HR architecture fosters knowledge acquisition (Intan-Soraya & Chew 2010) and participates in achieving the strategic objectives (Scarborough 2003).

Next, there is a strong emphasis on IT that is crucial in supporting the company’s knowledge processes and innovative intent (Dalkir 2005; Alavi & Leidner 2001; Lee & Choi 2003). The quality of information that constitutes one of the primary inputs shows also as a concern. Consistent with Andreou & Boone (2002), it overrides the knowledge creation process and, MAML’s investment decisions, for example, rest primarily on independent research companies.

In terms of addressing the challenges emerging from the asset management industry, MAML develops a clear market orientation that is relayed by technology and a strong historical client-centric culture allowing a good understanding of clients’ needs (Griffin et al. 2013; Rajan 2013) providing investment solutions and not products that leverage only on specific market opportunity (Alpha versus Beta). It perfectly illustrates the rationale for incremental innovation whose purpose is to meet immediate market needs. It accrues both to market-oriented firms that are sensitive to information about market changes and the ones that respond to knowledge about technology. MAML is also driven by radical innovation that manifests in the launch of new products or significant organisational changes. The latter type of innovation is said to preserve the future and, is an outcome for firms with a technological orientation (Darroch & McNaughton 2002).

MAML is well positioned to deal with its identified challenges mentioned at the beginning of the second section. (1) It has a clear view of its value-creating assets that are protected legally. (2) Its business operations are very much aligned with the industry requirements and it shows so far an adequate business model. (3) Its focus on IC and KM practices provides the company with agility and adaptability. (4) It is well equipped to build organisational skills and capabilities. (5) The strong process-driven rationale and the focus on relational capital on which the firm is firmly grounded provide some relief from its reliance on human assets. (6) Finally, product innovation is an outcome of process innovation that constitutes the backbone of MAML's business model and strategic intent. Meeting those six challenges enables the Dublin-based asset manager to address asset management industry competition that is briefly described in the introduction in terms of changing business model, market approach, hectic pace in regulatory changes, etc.

5 Conclusion

Consistent with the leading extant literature, the importance of intangible assets in achieving a sustainable competitive advantage is corroborated once again in this study. Moreover, this paper provides an interesting and in-depth illustration of IC and KM approaches within an original small asset management company - firms that are usually excluded from the realm of knowledge-intensive organisations in literature. MAML constitutes a unique organisational exemplar as it negotiated the worst of the financial crisis not only in terms of surviving it, but also in terms of thriving through product development accompanied with new investment solutions and the evolution of the existing ones. This has enabled MIFL and its distributors to grow in terms of AUM. Its innovation-driven culture implying a heavy reliance on its IC stocks and KM practices is at the core of MAML's organisational performance. The firm managed to build a strong knowledge-based business process that fosters innovation. Another interesting practical implication worthy of note is that this paper provides insights into how the human capital has been transformed into organizational capital, aiming at reducing the firm's dependence on the individual capital.

The results of this empirical study are limited from some aspects and first, by its reliance on a single case. The qualitative analysis and interpretative approach chosen here to make a contribution to research is highly subjective and reflects the authors' points of view. Then, the choice of the particular context offered by the Irish asset management

industry is not random as it is assumed to exacerbate companies' strategic actions in order to compete successfully. Further research should consider investigating more cases in an attempt to generalise results. A fruitful avenue would also emerge from a comparison with small asset managers' competitive moves in a more stable and bullish environment.

Using the knowledge to implement innovations versus changes of business models at SME

Jan Brzóska *

Institute of Management and Administration
Silesian University of Technology
Roosevelta St. 26-28, Zabrze 41-800, Poland

Structured Abstract

Purpose – The competitive edge is to great extent connected to the development and use of knowledge based economy (KBE), and in particular to innovation being the result of the knowledge. The aim of the paper was to present relationships between the selected knowledge components (relevant to innovation implementation) as well as between innovations and changes of business models. These relationships are shown both in terms of theoretical - cognitive and empirical aspect in the enterprises applying innovations. The research problem concerned the identification of business model elements changes caused by the implemented innovations.

Design/methodology/approach – Creating and implementing innovations in the enterprise is possible by the use of knowledge. The research hypothesis concerned the impact of innovation on the change of business models. The basic survey was carried out in the form of an enhanced diagnostic survey which attracted 150 intentionally selected Polish enterprises, belonging to SME sector. The structural analysis of the business model is based on the concept of "The new age of innovation." Prahalad C. K, M. S, Krishnan, by modifying it to the research needs.

Originality/value – This research focused on two important issues of the knowledge-based and innovation -based management. The first of these is the importance of particular elements of company knowledge (both knowledge about potential business and environment) for creating and deploying innovation. Another important issue of the research was to assess the changes in business models under the influence of implemented changes. The research results underline a significant importance of innovations (as an important element and stimulus of KBE) not only for a strategically management of enterprises, but also for the dynamics of their business models.

Practical implications – The outcomes of the application of the research show that companies have implemented various kinds of innovations. Presentation of the nature and relationship between knowledge components, innovation and modern business models represent an important knowledge and tips for both the entrepreneurs wanting to implement such innovations and for organizations that decide about financial support of innovation at SME. The results of the tests should contribute to understanding of the

importance of innovation related to gaining competitive edge and encourage companies to use modern business models that are able to create and implement innovations.

Keywords – Innovation, Knowledge Based Economy (KBE), business models, small and medium enterprises (SMEs)

Paper type – Practical Paper

1 Introduction

The growing competition and globalization have a substantial influence on changing strategic and operative action of the company. As a result, it is important to search new ways of reaching and keeping competition advance. The competitive advance is to a great extent connected with the development and use of Knowledge Based Economy (KBE). Modern and competitive enterprises are not only the part of KBE, but they also make use of its basic elements such as innovation system, Research and Development environment, business environment and ICT system. Nowadays the crucial factor and condition of competitiveness and efficiency of running a business is its ability to implement innovations. Such a capacity affects the changes of business models' conceptions and structures. However, these models enable the diffusion of various kinds of innovations. The research concerns the relations between knowledge components and innovations implemented based on them and the changes of business models. The research problem concerned the identification of business model elements changes caused by the implemented innovations. The following hypothesis was formulated, that the creation and absorption of innovations is accompanied by changes of business models in companies implementing such innovations. The following research questions were asked:

1. What are the most crucial components of knowledge used during implementation of innovations?
2. What are the most important changes in the business models caused by the implemented innovations?

The object of research was to show some changes of business models innovatively - run companies, called small and medium enterprises(SMEs).They implemented at least five various innovations in three recent years. The article presents the results of the research on changes in business models as far as the implementations of innovations are

concerned. The innovations mentioned above were conducted in carefully selected 150 Polish companies.

2 The increasing role of knowledge and innovation in business models

Gaining competitive advantage is to a large extent made possible by capacity and effectiveness of companies to use knowledge and implement innovations. These are both closed (internal) as well as open (external) innovations applied because of the transfer or diffusion of knowledge from the environment. The ability to create and absorb innovation is the biggest challenge for the company because of their complexity and risk, which often condition its existence and development. Innovations represent also one of the four, next to knowledge, trust and the business connected with the organizational culture, paradigms of "sustainable enterprises"[Grudzewski, Heduk, Sankowska, Wańtuchowicz,2010], Regardless what innovations will be applied by company they are always the result and element of the management of knowledge.[Stankiewicz, 2006; Dohn, and Gumiński and Matusek and Zoleński, 2013] Within the environment of enterprise operating on a competitive market, knowledge management is the most important method for its growth in the knowledge-based economy (KBE). It includes both the base elements, such as data and information, but also knowledge and wisdom creating innovations deciding about skills and competences to absorb innovations and their effective use. Although knowledge is a concept that is difficult to define (as evidenced by variety of its understanding in the content-related literature), as well as the lack of one, generally accepted definition, it is treated as a resource that has a particularly high importance for the company. This is due to the fact that the resources of tangible nature are relatively more available than ever and easier to imitate than knowledge resources. Creation and absorption of innovation is influenced by possession and use of appropriate knowledge base by an organization. It is considered as a unique and non-depleting resource. This last great feature means that the knowledge, not only is not consumed, but rather increases as it is used. Knowledge, after data and information, is another (third) level of hierarchy leading to the most precious result of knowledge management for organizations which is innovation

For the purposes of the research, results of which are presented herein, it is assumed based on the Oslo Manual, that „An innovation is the implementation of a new or significantly improved product (good or service), or process, a new marketing method, or a new organisation” [Oslo Manual , 2005].Innovations play a significant role in the

operation and development of companies, representing a factor conditioning their competitiveness. However, as A. Szmal[Szmal, 2013] noticed, creating competitive edge depends on the selection of the type of innovation and ability to transfer and diffuse it.

Innovations may take different forms in four dimensions of innovation space ("4P"): product, process (technological), standing (position) and paradigm innovations [Tidd ,and Bessant , 2011]. Differentiation of incremental innovations, improving, linearly affecting competitiveness and radical one of step-wise nature, creating new products and services, processes, business models and sources of competitive edge is important from the business model changes point of view. Innovations implemented by evolution are necessary in a company, but the value is created and competitive edge is won by radical innovations [Hamel ,2002]. Market transformation necessitates new look on current innovativeness paradigms, affecting the business model changes. The rooted propensity of a company to respond to existing needs of the best clients may hinder to see and use development opportunities on the markets of less demand or on peripheral markets of potential clients [Anthony and Johnson and Sinfield and Altman ,2008]

Noticing the real opportunities of break-through innovations may also be impeded by improper market segmentation. The concept of "tasks to do" assuming that clients do not buy products or service but rather "employ" them has better chances comparing to traditional segmentation. [Christensen, and Anthony, and ., Berstell, and , Nitterhouse,2007] An element that might affect company's innovations is taking decisions based on the most important competences. Lack of knowledge concerning the most important competences may lead to missing development opportunities appearing within the environment [Christensen, and Overdorf,2000]

New look at innovativeness processes require critical assessment of the applied operation schemes and changes towards the creation of an organization apt to create break-through innovations. Break-through innovations is the key to fill a gap to increase and constantly surprise the market. Restructuring towards innovative company covers creation of environment for innovations: change of business model and organizational structure in aid of innovation propitious for creation, implementation of new financing methods, partnership cooperation strategies or development of technological factors. It is also important to build innovative organizational culture and the change of current principles of human resources management. Important element favourable for open innovations is creative cooperation, common solution of problems by people of different

qualifications and experiences, which is a valuable component of assets of each team and the source of company competitiveness. Contacts and cooperation between economic companies is of increasing importance, including developing and using wider network of relationships that allow achieving creative synergy. Open innovations require creating of innovation networks based on variety of participants, including suppliers, partners, competitors, market regulators and other players [Chesbrough, 2003].

In the economic practice, creating and implementing innovations in the enterprise is linked to the relevant strategy and business model [Brzóška,2013]. Hence the business models problems, during the last decade, faced the increasing interest of both theoreticians and practitioners. In the literature both scientific and practical one can found the opinion, that there should be a common scientific base for a better and more efficient research of business models.[Zott, and , Amit, and Massa, 2010]At the moment, researchers of business models still have different approach to their definition and creation. Despite differences in concepts and approaches of different researchers to business model, you will find a number of common elements.

- Business models are a new way to analysis of the product, company, sector or enterprise networks. Their center is enterprise, but research limits go much further.
- Business models provide a holistic approach explaining the company functioning and its business concept;
- Processes (operations) play an important role in virtually all concepts of business models.
- Business models attempt to explain the creation of value, and its measurement. .[Zott, and , Amit, and Massa, 2010]

Due to the subject matter of the presented business model concept, it is worth to mention the ones that are oriented at application of innovations. It is to emphasize that in many enterprises, creating and implementing innovations affect the business model dynamics [Brzóška, 2012;Kramarz, and Kramarz ,2012].

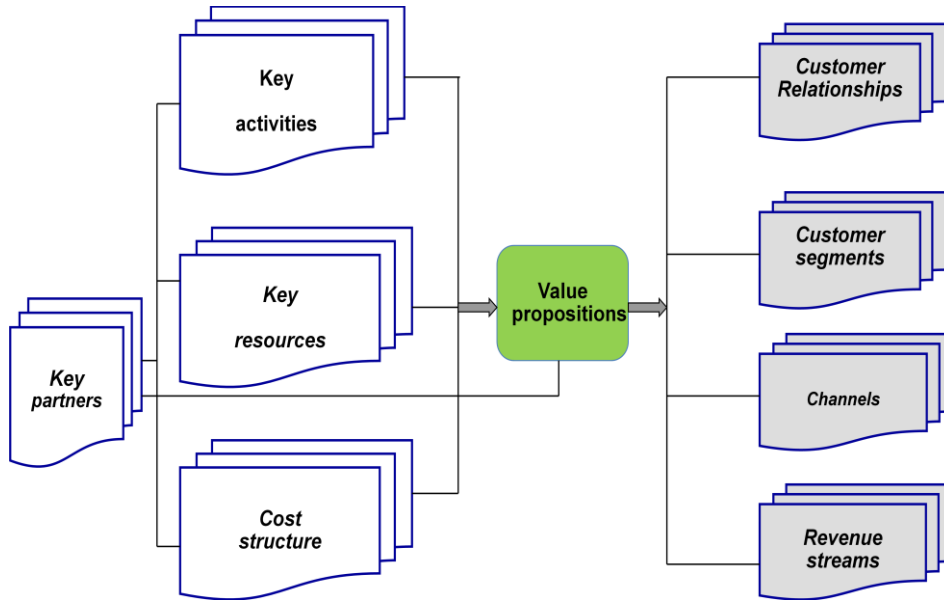

Referring to the impact of innovation to increase of the competitiveness and development organization, G. Hammel [Hammel ,2002]formulated business concept innovation, the result and application base of which is proper business model. His opinions are expressed in the business concept innovation, the result of which and basis

for application is proper business model. In order to use business model for carrying out radical (revolutionary) changes (innovations), one must understand business model as the whole consisting of many elements cooperating with each other. G. Hamel creates architecture of such model consisting of four main components: basic strategy, strategic resources, communication and customers relation, value of the network. The two last elements of the model require innovative utilization and generation of information to create knowledge for innovation. Business models oriented at innovations, to significantly higher extent, than e.g. new technologies, change the existing system of competition, frequently destroying the existing state of the art. Companies and sectors perceived as modern (IT telecommunication, pharmaceutical industry), are the space for such radical changes

K. Oblój [Oblój, 2002] in his paper, when defining business model “as combination of company strategic concept and technology of its practical execution understood as a construction of value chain that allows for efficient operation and restoration of resources and skills” - sees threats emerging from competitive surrounding. The most severe are related to imitations. Elimination of such threats requires the need for continuous improvement of business models that can be specified as some form of “running forward”. The most important instrument of their improvement is partial and breakthrough innovations. The first of them are such changes within the scope of the existing model, which express themselves with constructing competitive edge. Introduction of breakthrough innovations is the second way of “running forward”. It consists in innovative shaping of the value chain in order to create innovation that initiates a wave of creative destruction on the market leading to creating completely new business model, which fact is represented by market successes of many companies [Oblój, 2002]

Business model concept based on nine components was developed by A. Osterwalder A., Y. Pigneur. [Osterwalder and Pigneur, 2010]. It is interesting that authors of the model (Figure 1), presented it in terms of Blue Ocean Strategy developed by W. Chan Kim and R. Mauborgne [Chan Kim and Mauborgne, 2005], that is based on construction of a new market space. Attaining this space is possible by two types of operations. The first operations are to lead to a reduction of the costs which can be attributed to the elements on the left side of the business diagram, which are not shaded. The second group are operations leading to step-wise increment of value for both the customer and for the

company. Business model elements presented on the right side of the diagram are held responsible for that (shaded part).

Source : [Ostrewalder, Pingeur ,2010]

Figure1.The business model canvas template

Blue Ocean Strategy developed by W. Chan Kim and R. Mauborgne [Chan Kim and Mauborgne ,2005],, that is based on construction of a new market space. Attaining this space is possible by two types of operations. The first operations are to lead to a reduction of the costs which can be attributed to the elements on the left side of the business diagram, which are not shaded. The second group are operations leading to step-wise increment of value for both the customer and for the company. Business model elements presented on the right side of the diagram are held responsible for that (shaded part).

The performed own research (partial results of which are included herein) is based on business model presented by the authors of the principles of so called new age innovations, i.e. .C.K., Prahalad and M.S, Krishnan[Prahalad and Krishnan,2008] . They treat business model as one of the most important elements of the business transformation structure.

Two principles are the pillars of the transformation:

1. Value is based on exceptional personalized experience and expectations of customers. Companies must focus on individualization of value for customer. Regardless of the customers number, attention should be centrally focused on the position of a single person. The pillar is identified as $N = 1$ (experience of a single customer in time).

2. All companies have the access to the global ecosystem that also covers resources. Attention of the companies is focused on the access to the resources, not only on possessing them. This pillar is identified as $R = G$ (global resources from many suppliers, frequently from many places around the world).

Elements of this model are:

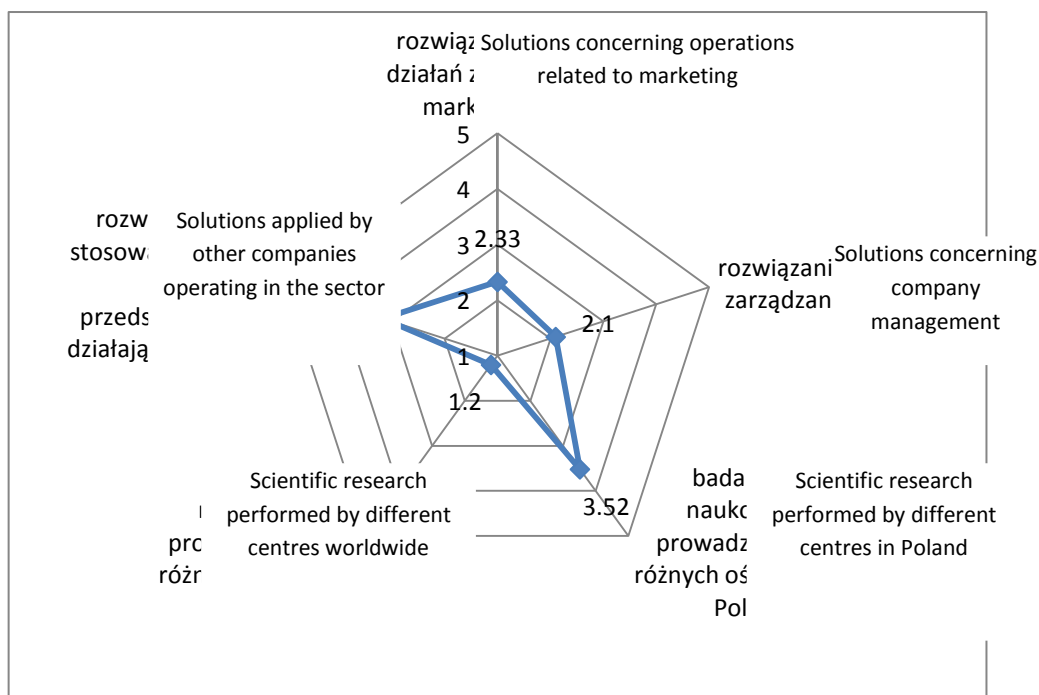

- Social architecture covering: management systems, human resources, competences, skills and HR development systems.
- Business processes: marketing, production, customer service, services, sales.
- Technical architecture: ICT systems, technical systems, equipment, logistics

3 Research related to changes of business model in the companies.

The research covered 150 economy entities. The survey consisted of 26 specific questions concerning knowledge components and various aspects of innovation processes and their impact on business models. Selection of the samples was purposeful. The entities were categorized according to the below criteria. Examined companies:

- - belong to SME sector,
- represent different sectors of the industry, services and trade,
- implemented at least 5 innovations (of any kind) within the last 3 years,
- they are not companies under liquidation

Question 1 assessed the level of knowledge components in the enterprise closely related to the innovation field before its implementation(Figure 2). In the five-grade knowledge scale (from 1-low knowledge to 5- very high knowledge) the highest average grade was related to knowledge about research conducted in various centres in Poland (3.52). Knowledge about solutions used by other operators in the industry has received an average of 3.17. The level of knowledge about solutions to marketing activities has been estimated at 2.33. Knowledge about the possible solutions for business management gained low result (2.1). The lowest result was gained by the knowledge of the research carried out by centres worldwide (1.2).

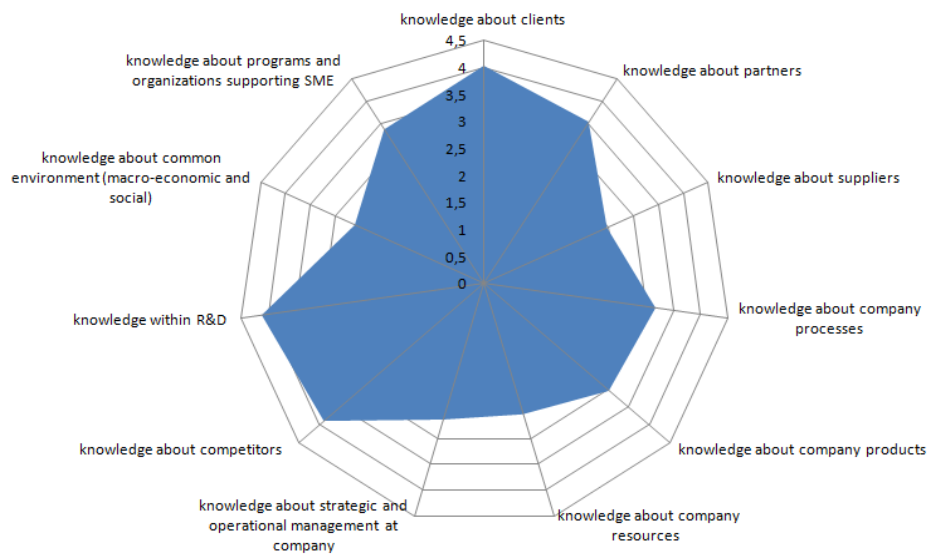

Source: own study

Figure 2. Level of knowledge in the company before implementation of innovation

The interviewed, when assessing the knowledge level in enterprises, found the knowledge of scientific research conducted in various centers in Poland and the solutions used by other operators in the industry, to be at the highest, although average, level. Deficiency of knowledge about solutions for marketing activities, solutions for business management was diagnosed together with the lack of knowledge on the tests conducted by centers worldwide. Knowledge about the results of the studies performed by research centers in Poland, having the highest result, is rather surprising. It has proved to be higher than knowledge about the business environment operations, thus the knowledge which determines possible competitive operations. Such a result suggests better communicativeness while exchanging common information by Polish research and scientific centres, and at the same time acknowledges that business relationships in Poland have not so many elements of potential synergetic cooperation that allow building a knowledge-based market advantage reinforced with cooperation.

The next question concerned general knowledge in the aspect of its importance for creating and absorption of innovation (Figure 3). In the five-grade knowledge scale (from

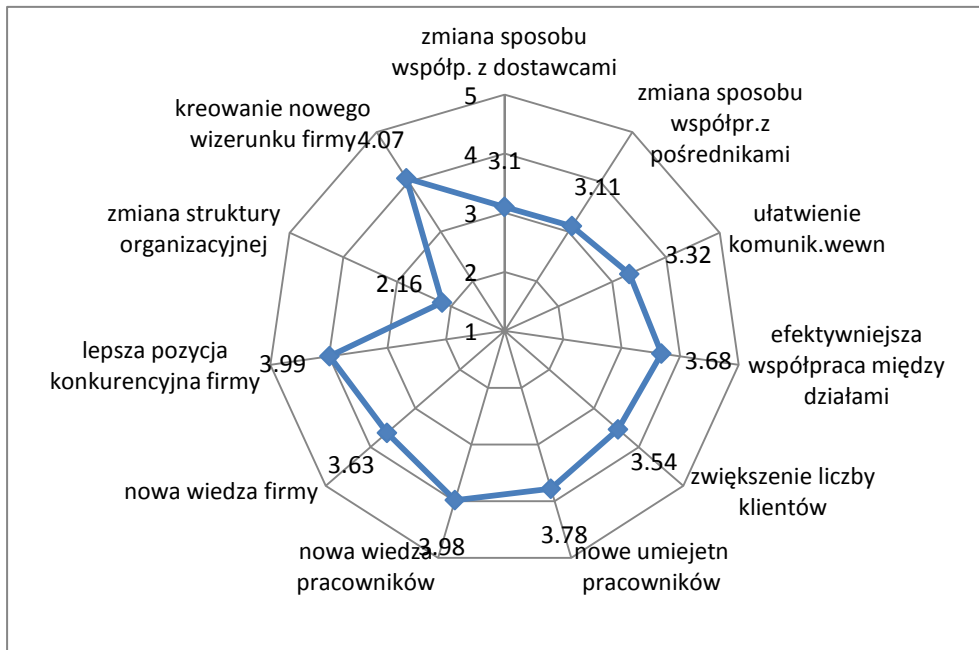

1 - low meaning of knowledge - to 5- very high meaning of knowledge) knowledge of the research and development was found to be the most important (4.11) and also the knowledge about business clients (4.02). The knowledge about competitors (3.88) and partners (3.55) is also placed high. In the situation of significant EU funds to support innovation in SME, quite high recognition of the importance of knowledge about programs and support SME (3.38) is not surprising. The meaning of knowledge about the processes and products is found to be higher than average (respectively: 3.18 and 3.03). The following types of knowledge were found to be close to average: importance of knowledge within strategic and operational management (2.62), knowledge of macro-economic and social environment (2.60), of resources (2.52) and suppliers (2.48). The feedback indicates that enterprises find the meaning of knowledge components important while creating and absorbing innovation.

Source: own study

Figure 3. Meaning of knowledge components important while creating and absorbing innovation

In the next question the interviewed made the assessment of the impact the implemented innovations had on the company operations(Figure 4) . In the five-grade scale - the impact of improvements to the way of creating

Source: own study

Figure .4.Magnitude of implemented innovations to company operation

the image of the company gained the highest result (average 4.07). Attaining better competitive position has been given the average result of 3.99. Acquiring new knowledge (i.e. hidden knowledge) gained very high rating rating of 3.98 and the category "new skills" was slightly lower (3.78).

Question 5(Figure 5) concerned directions and magnitude of implemented innovations on organizational

Source: own study

Figure 5. Direction and magnitude of business model change after innovation implementation

business model. In the five-grade scale, the highest result was obtained by the category "change of business process courses" (4.01). Impact of innovation onto resources necessary to create value (tangible and intangible resources) was rated to 3.84. The interviewed noticed also to impact of innovation onto the field of creating company's relationships (3.73). It may be stated that innovations affected, but not strongly, the reinforcement of value delivered to clients (3.65). When analyzing the structure of implemented innovations (Figure. 6), one may see that the companies were

Source :own study

Figure 6. Generic structure of implemented innovations

not limited to improvement of only one area of its operations – the sum of all indications was 361 innovations. Organizational innovations (96 indications) were the most frequent. The second, as regards popularity, was the category of services innovation / related to customer service (68 indications). Product innovation was slightly less popular (62 indications). In 55 cases, the companies changed their approach to the method of financing the investments. Process technological innovation was performed 46 times. The least number of indications was related to marketing communication with the market innovation.

Assessment of business model changes under influence of the implemented innovations was a very important part of the research. The research results are presented in figures: 6, 7, 8.

- 1 Key resources important for the company
- 2 Building product portfolio
- 3 Awareness of approach to cluster – network partnership
- 4 Competitive edge concept
- 5 Competitive standing
- 6 Structure of hierarchical and functional relationships system

(80 indications), change of approach to social potential of an organization (69 indications) and

change within the area of business processes (60 indications). The following categories were change within the area of business processes (60 indications). The following categories were

Source :own study

Figure 9. Areas of business model change as a results of implementation of innovations, part 3.

included in the group of frequent changes of the business model: structural changes in the system of hierarchical and functional relations (36 indications), change of philosophy of creating product portfolio and financial stream generated by individual products (42 indications), changes within the area of management processes (34 indications) and in the area of auxiliary processes (33 indications). The following options belong to the group that was seldom indicated: HR changes and development (17 indications), changes of the sales systems and advertisement operations (16 indications), changes of the IT and telecommunication systems (15 indications), changes leading to better utilization of intellectual capital to define the basis of market distinguishing (13 indications), changes of approach awareness to cluster – network partnership (13 indications), changes

consisting in more significant involvement of e-business and Internet sales support (12 indications), changes in the customer relations (9 indications) and changes of organizational identity and entrepreneurship culture (8 indications).

4 Conclusions

The implemented innovations have influenced the way to create the image by the examined organizations, helped to achieve a better competitive position and gain new skills for workers. Through the innovations, cooperation between departments became more efficient, and the organization and its employees gained new knowledge. Gaining more clients, facilitating internal communication (although not at the highest or high level) was also reported. The implemented innovations did not affect the method of companies' cooperation with agents and suppliers. Even though the organizational innovations were found to be the most common, they do not affect the changes of organizational structures at companies, in the interviewed opinion. The most common benefits related to implementation of innovations were the options to compete within the scope of: company image, special features / product usability as well as variability of the assortment (56 indications). Innovation implementation allowed the companies to compete with quality of service in 44 cases and with price in 28 cases. Innovations also made it possible to broaden the scope of activities: in 32 cases it was found that a company entered new, additional fields of business and in 21 cases it entered new fields of business withdrawing from the previous ones. The most common changes of the business model concerned re-capture of competitive edge concept, change of key resources important for the company, change of competitive standing of a company, new approach to social potential of organization and reorganization within business processes. Referring to the working hypothesis work" that the creation and absorption of innovation is accompanied by changes of business models at companies implementing these innovations", the research results enabled its positive verification.

The research results related to the first question indicate an extensive meaning of knowledge about the research and development field and knowledge about customers, partners and competitors. Selection of the meaning of knowledge about the environment as an important for innovation implementation depicts orientation of companies to open innovations. In the case of the second question, answers clearly show the impact of innovation on business model changes linked to value creation for the customer (new

concept competitive edge based on customer value, increase market position, business processes).

The research (part of which is presented in the paper) was a diagnostic survey concerning relationships between utilization of knowledge during implementation of innovation and the nature changes of business models. Because of their nature, they represent an opinion about the investigated phenomenon. At the moment, more thorough studies are performed, based on multiple case studies, which should be a valuable addition to knowledge concerning this field.

Structured Abstract

Purpose – The purpose of this paper is to present a theoretically grounded model for incorporating reflective practice into the competence assessment process for measuring human capital in organizations. The literature on knowledge capital and intellectual assets contains many tools to identify, assess, and plan critical strategic knowledge resources. This paper responds to the need for determining how an assessment can activate and drive the knowledge processes, i.e., generating and sharing knowledge. We propose that reflective practice can be considered as a primary enabler for developing, structuring, and organizing knowledge resources and optimizing their use.

Design/methodology/approach – The paper presents an explorative single-case study based on a conceptual analysis of reflective practice in organizations and the potential of reflection to further develop the existing competence assessment practices. A process model for Reflective Competence Assessment (RCA) is built and tested in a case organization. The concluding analysis enables an investigation of the gap between theoretical intentions and practical realization. The RCA process consisted of the following five parts: incorporating four necessary dimensions of reflective practice, activating reflective capacity, engaging in reflective dialogue, experimenting, and building on reflective control. The competence areas assessed included multi-professional collaboration, sharing of knowing, partner collaboration, and the meta-competence of reflective practice.

Originality/value – The main contribution of this study is the RCA model for incorporating reflective practice into the process of competence assessment. The literature on reflective practice offers very little guidance for researchers or practitioners developing reflective practices as part of everyday work. Based on the four necessary elements of reflective practice, an ordinary competence assessment can be created to evaluate and actively develop the selected strategically critical competencies. The case

example further explores the possibility of utilizing measurement tools in a reflective manner to activate and explore the learning process attached to measuring.

Practical implications – The RCA process model is a measurement tool that evaluates critical knowledge assets while simultaneously functioning as a reflective practice itself. As a practical case description, this paper offers management practitioners and human resource development professionals a model for implementing competence assessment in a reflective manner to measure and also construct new know-how. The study also offers argumentation for considering reflective practice as a primary tool for breaking away from routine thinking and extending competencies. In addition, it provides a concrete tool for arranging measurement and evaluation in a manner that activates and revives learning and renewal.

Keywords – Reflective competence assessment, business-critical competences, reflective practice, management control

Paper type – Academic research paper

1 Introduction

Knowledge management has been defined as the set of processes, approaches, practices, and systems used to generate, develop, renew, and integrate knowledge-based resources into capabilities that the organization can leverage to seize opportunities quickly and proficiently in order to create market value and increase and sustain competitive advantage (see the full list of references in Moustaghfir and Schiuma 2013). Earlier research presents many tools to identify, assess, and plan critical strategic knowledge resources (Brooking 1996, Edvinsson and Sullivan 1996, Edvinsson and Malone 1997, Lev 2001, Schiuma 2009, Schiuma et al. 2008, Sveiby 1997 in Schiuma 2012). More recently it has been pointed out that we need to understand the “means and ways how” an assessment can actually activate and drive the knowledge processes, i.e., generating and sharing knowledge (Schiuma 2012).

In this paper we present a practical intervention case in which a reflective competence assessment (RCA) was constructed by deducting competence drivers from the business’s critical competencies. A guiding principle was that the employees’ professional competence needs to be evaluated against the value it adds to organizational competence, and not merely its input to a particular profession, task, or process. Since organizational competencies are dynamic, cumulative, and constrained by past experience, the assessment method should also respond to the challenges of asset asymmetry, social complexity, and causal ambiguity (Moustaghfir and Schiuma 2013, Zollo and Winter

2002). Competencies, though rooted in individual characteristics and skills, are essentially learned patterns of collective activity through which an organization generates and modifies its routines (Nelson and Winter 1982). This is why the assessment process has to include not only self-reflective components, but also dialogue between all stakeholders, i.e., employees, top management, owners, and the customers.

Knowledge management literature benefits from utilizing the theories of psychology and sociology to advance the understanding of competence and learning in organizations. The very core element of learning – reflection – has been both widely neglected and/or restrictedly conceptualized in management research; however, it is very much present in educational literature. Reflection is often associated with individual, intellectual exercise, and we wish to present a more holistic overview of its potential as a source of professional and organizational competence.

The notion of reflection has been strongly present in recent research on management and organizational learning, and has been mentioned in many other distinct fields of management theory as a core process of individual and collective learning (e.g., Boud et al. 1985, Hoyrup 2004, Mezirow 2008, Reynolds and Vince 2004), sense-making (Weick & Sutcliffe 2001), reconfiguring the mental frames (Schwandt 2005), and as a driver of profound strategic change (e.g., Crossan et al. 1999). Reflection is suggested to offer organizational actors increased awareness in critical and complex situations which require new responses and broad action repertoires (Zundel 2012, Keevers and Treleaven 2011). Though the significance of reflection is broadly accepted, it has been discussed mostly as a separate exercise outside the normal activities of an organization. On paper the construct of reflective practice is considered as a potential means to complement *assessing* competence with *creating* competence. In the organizational context, we look at reflective practice as an individual and collective way of working that manifests reflective skills and experimentation and is enabled by the institutionalized structures. Reflective practice allows the members of the organization to slow down and engage in critical evaluation of their own thinking. It also allows them to investigate the shared, collective assumptions and expectations as well as the institutionalized rules and routines. It captures the idea of a style of working, thus reflecting both on-action and in-action (Jordan et al. 2009).

This study presents a process for reflective competence assessment (RCA) developed for a single case organization providing occupational health care services for various

business organizations. The process is based on a review of literature of professional competence evaluation contents and techniques. More specifically, it emphasizes the elements of reflective practice throughout the process to enable learning, sense-making, and taking action as an outcome of the process. A notable difference between the assessment tradition present in earlier research and the case organization's practice is that the drivers of professional competence elements were deducted from acute and business-critical competencies. Technical knowledge and skills related to tasks and professions were left out.

2 Literature

2.1 Identifying competence

Due to the changes taking place in society, professional cultures, knowledge production, and the nature and content of professional expertise are challenged. Professionals are expected to be talented in social relations and communication; to be able to reflect on and integrate different aspects of expert knowledge; and to act based on the ethical base of their profession. The expertise has to be constructed and reconstructed continuously in a process of life-long learning (Tynjälä, Nuutinen, Eteläpelto, Kirjonen & Remes 1997). Nowadays the skills of developing oneself as a professional and of developing work practices and organizational functions are emphasized.

Though there are numerous definitions of professional competence (e.g., Bloom 1956; Eraut et al. 1994, Nordhaug 1993), there is no single agreed-upon definition that would encompass all important domains of each professional's practice. Epstein and Hundred (2002; 2014, 226) have defined professional competence based on prior definitions as "habitual and judicious use of communication, knowledge, technical skills, (clinical) reasoning, emotions, values and reflection in daily practice for the benefit of the individual and community being served." Based on Cheetham and Chivers's (1998) model, which harmonizes the reflective practitioner and competence-based approaches, professional competence is seen as consisting of knowledge/cognitive competence, functional competence, personal/behavioral competence, values/ethical competence, and meta-competences (e.g., communication, problem-solving, learning, reflection). Competence is context dependent. The context of work and the physical, cultural, and social conditions of work are considered to affect competence. In other words, a person

may be highly competent in one particular context or environment, but less so when these change. Competence is also developmental. It is based on ongoing updating, through which individuals and groups/teams secure their ability to carry out and develop continuously changing work practices (Cheetham & Chivers 1998; Epstein & Hundert 2002).

Here, competence is examined as a personal, social, and organizational asset. Referring to the definitions below, personal competences include, e.g., self-confidence, interpersonal skills, and control of emotions. These are gained through learning from experiences. In addition to self-perception, competences are constructed and developed based on feedback from others. The social dimension of competence can be examined as an interprofessional competence. Interprofessional competence reveals how different professionals meet and work together in groups/teams. In practice, this means carrying out collaborative practice, e.g., joint discovery of a problem, sharing knowledge with other professionals, searching a common language for communication and general working methods, and reflecting (Wilhelmsson, Pelling, Uhlin, Dahlgren, Faresjö & Forslund 2012).

There is always a context in which professionals think and act. However, what the individuals or groups learn is not automatically embedded as organizational knowing (i.e., institutionalized). Based on the situational and practice-based approaches, the organizational context and the work context create the frame of reference for practice and competence construction as well as development.

There is a particular emphasis in this paper on a meta-competence – reflective practice – which is seen to be the grounding of the other competences. Following Schön's (1983; 1987) idea of a reflective practitioner, reflection is the primary professional competence and key to acquiring other competencies and maintaining a process of continuous development and learning. Reflection is thought to act as a “gate-keeper” (Cheetham & Chivers 1998, 274) to developing the competence. Although people reflect on their experiences by nature, systematic reflection differs from what professionals are accustomed to doing (Korthagen & Vasalos 2005). Therefore, professionals need to learn how to reflect. At the heart of professional competence is individuals' reflective capacity consisting of self-awareness, description of experiences, analysis of situations, synthesis to develop new perspectives on a situation, and evaluation of the learning experience (Atkins & Murphy 1993).

2.2 Reflective practice as a meta-competence

Both researchers in academia and practitioners have shown a growing interest toward development interventions that pay attention not only to employees' knowledge and skills but also their personal qualifications and meta-cognitive capability to practice professional self-reflection, constructive dialogue, and creative sense-making (e.g., Schön 1987, Cope 2003, Elkjaer 2001 Vince 2002, Reynolds 1998). As a practice-based approach, reflection can be seen as a "tool" for questioning routine thinking, triggering learning, and sense-making through practical managerial methods. According to broadly established learning theory frameworks (e.g., Boud et al. 1985, 2010, Hoyrup 2004, Kolb 1984), reflection represents the necessary link between experience and goal-oriented learning. In other words, no experience leads automatically to learning unless we reflect it against our existing understanding and assumptions. Thus reflection is needed for changing routine thinking and behavior – for innovations and renewal.

The study defines reflective practice as the actual ways that reflection is manifested through individual and collective action within the organizational realm. Reflective practice allows the members of the organization to slow down and engage in critical evaluation of their own thinking. It also allows them to investigate the shared, collective assumptions and expectations as well as the institutionalized rules and routines. It captures the idea of a style of working, thus reflecting both on-action and in-action (Jordan et al. 2009).

Evaluating the reflective practice of an organization involves analyzing three distinct yet intertwined levels: reflective practice on the individual, group (collective), and organizational levels. These levels are broadly accepted as critical levels of analysis regarding organizational learning processes (Crossan et al. 1999).

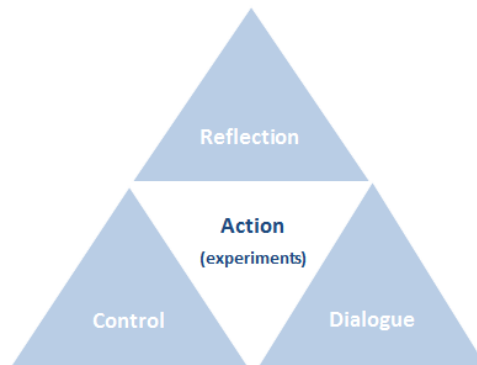

Figure 1: Reflective practice in organizations – four dimensions

Reflection - Reflective capability

Reflection has been defined as questioning one's intuitive understandings, taking on-the-spot experiments, and engaging in thoughtful dialogue about the situation with others (Schön 1983). The grounding premises for reflection to occur relates to individuals' capability of reflectiveness. Jordan (2010) describes the reflective practitioner by 1) the ability and 2) willingness to question routinized ways of thinking and acting, either after having acted or in the midst of acting. This requires meta-cognitive capabilities, self-awareness, and the ability to regulate cognitive and affective processes (e.g., Mezirow 1981, Hodgkinson & Healey 2011). Yanow and Willmott (1999) describe the attitude suitable for reflective practice as *passionate humility*, which allows one to be surprised and to view a situation from diverse perspectives. Reflective capacity consists of self-awareness, description of experiences, analysis of situations, synthesis to develop new perspectives on a situation, and evaluation of the learning experience (Atkins & Murphy 1993). In practice, professionals should be able to reconstruct their professional competence based on the demands springing from practice.

Dialogue - Reflective dialogue

In situations where an individual notices that the old patterns of thinking do not apply, he or she needs to test his or her emerging thinking and develop it further. Collective reflection is a way to make visible and investigate the inter-subjective mental models and

shared frames of reference. The crucial prerequisite for this type of collective reflection is individuals' ability to dialogue. Based on Raelin (2001; 2002), the skills needed for this collective form of reflection include being, speaking, disclosing, testing, and probing. Being means opening up to the experience and to the interpersonal environments around oneself (see also Isaacs 1999). Speaking refers to articulating the collective voice at a given time, for example, by suggesting group norms and/or bringing out uncertainties or unfounded assumptions. When disclosing, the participants share their doubts or voice their passion. By disclosing, participants unveil their feelings or tell stories to reveal their deep experiences. In testing, members try to promote the process of collective inquiry. Through probing, members of the group attempt to point out inconsistencies in members' reasoning patterns and uncover the assumptions behind the actions. Dialogue is a process of discovering and interrogating to achieve understanding or agreement (Isaacs 1999).

Reflective dialogue is a process involving internal and external dialogues. In internal dialogue one examines one's own articulations and listens to one's own voice aiming to understand one's values, assumptions, and blind spots (Tsang 2007). In the external form of dialogue, individuals together try to find something new, surprising, or touching in open interaction. In the organizational context, one can use various reflective tools to facilitate reflective dialogue, including storytelling, reflective and reflexive conversations, reflective metaphors, reflective journals, critical incident analysis, repertory grids, and concept mapping (Gray 2007).

Action - Reflective experimenting

Sense-making and learning underlie the coexistence of thinking and acting. In addition to the cognitive and analytical level of reflection, reflective practices take the form of embodied reflection that widens the experience into the embodied level and re-embodies the experiential knowledge and learning (Jordi 2010). The aim of the experiment is to apply and explore the ideas and principles in practice, and thus acquire new experiences to be reflected upon. This means exploring new ideas and work practices with a "reflective mentality."

However, we believe that if reflective practice is not automatic for the members of the organization or in the predominant culture, then reflective thinking and acting might not happen simultaneously. There might be a need for a reflective group session or internal dialogue, after which the ideas can be experimented with and implemented in daily work

practices. Then these new experiences are taken back again into group sessions or an individual's internal dialogue under critical evaluation. This follows the ideas of the classical cycle of experimental learning, where an individual's learning takes place through a process of concrete experience, reflective observation, abstract conceptualization, and active experimentation (Kolb 1984).

In the process of experimenting, experiences and knowledge become a professional activity, i.e., knowing.

Control - Reflective management control

Collective reflection, processes of interaction, sharing interpretations, and experimentation are all strongly affected by social, cultural, and political factors (Reynolds 1998) and supported by organizational routines and practices (Elkjaer 2001, 2004, Korthagen 2005). In order to assess and develop an organization's reflective practices, there is need for a structured analysis regarding those managerial systems that represent the organization's structural aspects, rules, and routines. In this study, the management control system (MCS) framework presented by Malmi and Brown (2008) is utilized for understanding the means of control and how they influence and drive competence. The reflective practice should be visible in MCS, so that the forms and use of control encourage individuals and groups for reflection, create time and space for reflection, and follow the results of reflection. On the other side, it also means that the MCS should be utilized in a reflective manner. For example, only through reflection can measurement information be utilized in provoking new interpretations and critical questions. This active and dialogic use of control tools is necessary for the self-renewal of a control system, as the observations and insight changes the control in use (Hilden et al. 2012).

Reflective practice in organizations also deals with how we do things around here (in our organization) and how we are organized to reach our goals (Boud et al. 2006, Jordan 2010, Vince 2002). A reflective culture is defined as one which allows voicing and criticism without a fear of retaliation. There should be "a structure that reflects" (Nicolini et al. 2011), i.e., practices that mobilize dialogue. Organizations might endorse encouraging the use of supporting reflective actions (e.g., reflective note taking, debriefing episodes after meetings) on the individual and team levels. They may also build learning communities for small groups to share and test ideas and knowledge,

exchange good practices, and/or give feedback to each other. Feeding the culture of learning enables reflective work behavior to become a way of living in the organization (Raelin 2002). The ideal is to integrate the reflective practices into the present strategy and work practices.

Raelin (2002) proposes the following strategies that organizations might endorse to encourage use of reflective practice: *supporting reflective actions* (e.g., reflective note taking, debriefing episodes after meetings) on the individual and team levels; *building learning communities* for small groups to share and test ideas and knowledge, exchange good practices and/or give feedback for each other; and *feeding the culture of learning*, which enables reflective work behavior to become a way of living in the organization. However, we believe that the ideal is to integrate the reflective practices into the present system of management control, including strategic plans, work practices, measurement systems, rewards, and embodiments of the culture. So far, ideas for incorporating reflectivity into corporate practice unfortunately remain largely unrealized (Vince 2002).

2.3 From measuring to reflective assessment

Measuring professional competence is a necessary element of developing and managing an organization's human intellectual capital. However, the human focus in IC metrics is often focused at the amount of training and support programs, level of degree, or employment duration (Liebowitz & Suen, 2000). These metrics, as clear and precise as they are, do not capture the full prism of employees' professional competence or the value-added to the organization. The critical change needed in evaluating professional competence as a source of competitive advantage relates to understanding and managing the relationship between what people know and their value delivery (Marr and Spender, 2004).

Typically, a comprehensive assessment is targeted at evaluating the core components of professional competence, such as cognitive and functional knowledge related to the task; behavioral or personal competence; values or ethical competence; and meta-competences, such as creativity, analytical capabilities, learning, and reflection (Cheetham and Chivers 1998, Delamare le Deist & Winterton 2005, Epstein and Hundert 2002). Epstein and Hundert (2002) have reviewed assessments of professional competence in the field of medical practice. They conclude that most of the assessments concentrate on cognitive and technical knowledge and skills, and underemphasize some

critical areas of professional competence. The areas that lack attention in the assessment tradition include integration of knowledge and skills, context of care, information management, teamwork, health systems, and patient-physician relationships. In their analysis, the authors emphasize that assessments must take into account what is assessed, how it is assessed, and the assessment's usefulness in fostering future learning (Epstein & Hubert 2002, p. 228).

Epstein and Hubert (2002) have pointed out that assessment should provide useful feedback for employees regarding their strengths and weaknesses and guide future learning. It encourages self-reflection as an institutionalized practice and as a professional habit. Assessment also expresses institutional values by determining what is assessed and how assessment is conducted. Lerro and Schiuma (2013) have proposed a typology for IC assessment practices according to their strategic significance. The typology is based on an idea that, in this case, an assessment can be considered as both competence management and competence communication. The authors distinguish between the following four main strategies of assessment: measurement strategy, domain assessment strategy, asset accounting strategy, and asset communication strategy. The assessment process explored in this paper could be utilized for at least measurement and communication strategies, but also proposes a fifth strategy, i.e., a "knowledge asset reflection strategy," the purpose of which is to use assessment to renew the interpretations of asset value, thereby making the knowledge asset enablers visible and questioning routine knowledge that is inadequate or passive.

The goal of reflective competence assessment (RCA) responds to the challenge voiced by Schiuma (2012) that knowledge management activities, such as competence assessment, should *activate* knowledge processes and *drive* the development of strategic organizational competences (p. 518). Through reflective practice throughout the process, the assessment actively challenges the existing perceptions of competence, thus creating a more honest opportunity to look into the mirror, both privately and together with others.

3 Research design

The paper presents a process model for reflective competence assessment for evaluating, critically investigating, and creating shared understanding in the organization regarding the state of selected organizational competencies. The process model has been developed as a part of the interventionist (Suomala & Lyly-Yrjänäinen 2012) research

program, REFINNO¹, investigating the potential on reflective practice in improving the performance and innovative capability of organizations. It has been noted the interventionist mode of research may be particularly fruitful in intellectual capital discourse as it allows the researcher to be “grounded in action,” thus helping to reduce the gap between theory and practice (Dumay 2009, p. 499, Chiucchi 2013).

The research aim presented in this paper deals with investigating how reflective practice could improve the assessment and management of professional competence and the organization’s capabilities. One of the case organizations within the research program had a practical challenge to renew their competence assessment tool, and they were ready to engage in an interventionist and constructive (Kasanen, Lukka and Siitonen 1993) effort, where a process model would be developed in a dialogue between the management team and the researchers.

In the first phase, the researchers formulated an idea of a process that utilizes the guiding ideas of reflective practice developed by the researchers earlier in the research program (Hilden & Tikkamäki 2013, Tikkamäki & Hilden 2014). In addition, the process needed to make visible how measuring and reporting of competence issues is able to increase attention and mobilize actions toward competence management (Chiucchi 2013).

The theoretical groundwork was discussed together with the top management of the organization. The practical challenge identified by the management was that the traditional competence measurement tool was focused too heavily on technical competence, thus providing little inspiration for future competence development plans. Much of the competence development initiatives were formal and classroom training, and there was increased attention to more reflective methods, such as mentoring, peer learning groups, and coaching. In addition, it had become obvious for the management that the strategic focus should be aimed at competencies related to working together as professionals and partnering with the customer. Both competence types were thought to benefit from more reflective working practice. In the end, four central competence areas were selected for a renewed competence assessment.

Based on this interaction, the researcher constructed a new questionnaire, which was to be the individuals’ self-reflective tool to become familiar with the vocabulary and to

¹ *The authors wish to acknowledge the REFINNO research team, Petri Suomala, Sanna Pekkola, Johanna Rämö, Minna Saunila, Juhani Ukko and Sanna Vauranoja, for the insightful and constructive academic discussions and joint efforts in case interventions. They have enabled the multi-disciplinary development of the interpretation of reflective practice. Moreover, funding by the Finnish Agency for Technology has enabled the research projects underlying this publication.*

find personal meaning in the capabilities. This was to represent the critical point of pausing to reflect and analytically detach from the routine thoughts and action (Kolb 1984). The RCA process is described in more detail in the next chapter, but according to the interventionist research tradition, the researchers were closely involved during the process, offering practical support for designing the organizational communication during the intervention and pedagogical approaches in the team sessions for ensuring the collective reflection.

The researchers facilitated the process, which was meant to be led by the management team and result in concrete actions regarding the assessment results. Toward the end of the process, the role of the researchers shifted more toward observing, understanding, and evaluating the effectiveness of the process in promoting the capabilities, the levers, and obstacles along the way. At this point, the researchers actively searched for dialogue with the management team in order to strengthen the process in the detected weak points. The dialogue has meant management team coaching, discussions, and focus group interviews, which have been used both in gathering information for the theory advancement and to intervene in the practical challenges in the organization. The observations regarding the potential of RCA are discussed in the final conclusions of this paper.

4 Reflective Competence Assessment

4.1 Selecting the key competences and the drivers

The key competences were selected regarding the current organizational challenges, competition, changing legislation, and other perceived drivers of success. The health care sector is very much driven by the professions' assumed roles and duties. It is a fairly new phenomenon that doctors and nurses work closely together (Figure 2, point A), and authority over each patient's care is distributed among various professions, such as physiotherapists, psychologists, nurses and doctors. In occupational health care, another issue is to share (Figure 2, point B) not only the patient-specific knowledge between professions, but also the customer's company-specific information between service teams. The health problems are often specific to the working environments, and thus the history of problems, treatments, and solutions are valuable in the service production. Though the

need for trans-professional knowledge-sharing is widely accepted, the practice does not reflect the ideal.

Another challenging area was the customer interface (Figure 2, point C). In an occupational health care organization the nurses or doctors are actually the sales force for the service. It was noted that a lot of timidity and sensitivity is present in the negotiations related to selling the service. The managers knew that some individuals excel in the customer interface, while others feel intimidated. While the health care professionals are not expected to be hardcore salespeople, they should feel confident in discussing the impact of the service on customers' business and should actively search for a partnering role. This was another highly crucial competence area which the researchers realized required more attention in order to figure out what kind of support people need.

During the course of the discussions between the researchers and the management, it became obvious in many ways that the company needs a cultural change in order to become more innovative and proactive. The competence that enabled the organization to succeed in the past does not seem to be enough for it to thrive in the future. Many old ways of thinking need to be questioned, and new foundations need to be identified for greater competitiveness. For this purpose, the reflective practice (Figure 2, point D) was selected as a critical meta-competence. It was seen as a "gate-keeper" (Cheetham & Chivers 1998) to developing the other competences.

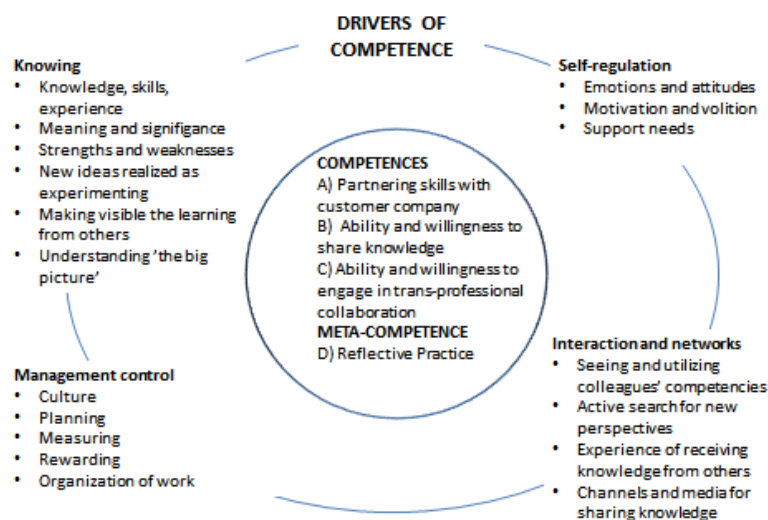

Figure 2: Business critical competencies and their drivers

The drivers of the competences (Figure 2) were constructed hand-in-hand with these organizations' strategically critical competences. For example, the active sharing of knowledge was seen as a matter of constructing and sharing knowing, self-regulation, networks, and organizational structures. These drivers, presented below, were seen as certain types of focus dimensions of promoting reflective professional competence and practice. In the RCA model the competence drivers consist of individual (self-regulation and knowing), social (knowing, interaction, and networks) and organizational (management competence) dimensions (Crossan et al. 1999, Hilden & Tikkamäki 2013).

Knowing consists of knowledge and competences constructed in practice, during the processes of participation in the organization's daily life. It means co-creation of competences where learning and doing are intertwined. Thus, knowing is socially constructed. Knowing includes thinking, doing, and feeling (Wenger; Nicolini et al. 2003). It gives the significance and meaning for actions and makes both individuals' learning experiences and learning from others visible. It helps employees to understand the "big picture" of professionalism and the work organization. In the RCA questionnaire, using the customer partnering as an exemplary competence, the professionals were asked to estimate their knowing by answering questions (see Table 1).

Table 1. Examples of the questions related to knowing in the RCA questionnaire

- I have enough knowing related to partnering skills with customer
Scale 1–5 (totally agree – totally disagree)
- My strengths in being a partner to our customers are as follows:
- What kind of support do I need to become more successful in partnering with our customers?

Self-regulation means the willingness, patience, and emotional awareness to use (Epstein & Hundert 2002) the knowing. Self-regulation is the individual's competence to guide themselves toward important goal states (Vohs & Baumeister 2004). In practice it means acting quickly to take opportunities, ignoring dis-interactions, acting flexible in response to various situations, overcoming obstacles, and managing conflicts between goals (Fitzsimons & Bargh 2004). Good self-regulation also aids group membership, e.g., by controlling emotions and directing behavior toward social belongingness (Vohs &

Ciarocco 2004). Several examples of questions related to self-regulation are presented in Table 2.

Table 2. Examples of questions related to self-regulation in the RCA questionnaire

- I'm enthusiastic about my work Scale 1–5 (totally agree – totally disagree)
- I'm motivated the most in my work by (1–3 factors)...
- I can set, get enthusiastic about, and achieve goals at work Scale 1–5 (totally agree – totally disagree)

Interaction and networks refer to interpersonal competence. In practice this means, e.g., effective communication with customers and colleagues (Epstein & Hundert 2002), seeing and utilizing others' competences, and searching actively for new ideas and perspectives. It is the co-creating and sharing of knowing inside and outside the organization. Several example questions related to interaction and networks are presented in Table 3.

Table 3. Examples of questions related to interaction and networks in the RCA questionnaire

- I understand and utilize our customer's viewpoint in my daily work Scale 1–5 (a lot – very little), especially when...
- I utilize our organization's networks in my work Scale 1–5 (a lot – very little). How do you do this in practice?
I like to share my expertise with my colleagues
Scale 1–5 (a lot – very little). How do you do this in practice?

Management control defines the strategy, structures, routines, and procedures for individuals and groups to construct and develop their competence and practice reflection in their everyday work. In this study, the typology presented by Malmi and Brown (2008) is utilized for understanding the variety of managerial tools and systems (related to culture, planning, measuring, rewarding, and work organization) that may or may not induce the utilization of competences and reflective practices (see examples in Table 4).

Table 4. Examples of questions related to management control in the RCA questionnaire

- Efforts to partner with our customers are visible in my personal work goals
Scale 1–5, (to a great extent – not at all). How? (This question is not clear. How what? I would recommend writing a more complete question here.)
- I'm rewarded when customer partnership is successful
Scale 1–5, (to a great extent – not at all)
- My organization's structures and work practices support developing partnerships with customers

In the RCA model all four of these drivers, i.e., knowing, self-regulation, interaction and networks, and management control, were seen to affect the realized competence to develop and practice partnering with customers, along with other strategically relevant competences needed at work.

4.2 The process of RCA

The process (Figure 3) follows a classic planning, implementation, follow-up schema, complemented with special attention toward the theoretical prerequisites of reflectivity.

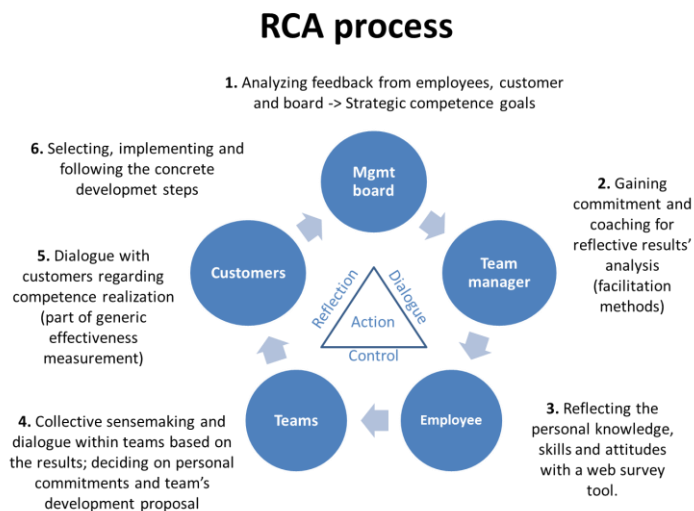

Figure 3: The process of reflective competence assessment (RCA)

In the first phase, the strategic competencies were identified in a reflective discussion between the core management team and the researchers (1). The point was not to settle with picking the capability goals from the official strategy slides, but to stop and question whether the managers truly feel that strategy is up to date and provides concrete support for deciding on competence development issues. The management team was interested to learn which drivers are behind trans-professional collaboration and active sharing of professional knowledge.

The competencies and needed cultural change was discussed among all the organization's team leaders in order to verify and modify the goals if needed (2). This was to ensure the commitment of all managers, and also to practically coach the team leaders in communicating the questionnaire and dealing with the team sessions after the survey. The researchers offered a set of reflective facilitation techniques, from which the team leaders could choose the applicable methods for their own team sessions. The goal was to ensure that all members of the organization are heard. Furthermore, the focus is on open and dialogical interaction – not on the statistical results. The development ideas were supposed to be created with the inspiration of the assessment information and based on collective reflection.

Based on the four final key competencies, the researchers deducted the drivers (Chapter 4.1) behind each area. Based on these drivers of competence, propositions were formulated and a web questionnaire formed. The goal of the questionnaire was to construct propositions that encourage employees to reflect on the meanings they relate to each competence and to investigate their emotions and perhaps hidden assumptions (3). The purpose of the self-reflective part was primarily to offer the time and space for critical self-inquiry, and only secondarily to gather measurement data.

In the fourth phase, the team leaders arranged sessions where the team's results of the web questionnaire were presented and collectively reflected upon (4). The teams experimented with the facilitation methods presented earlier by the researchers. These methods were aimed at activating the participants, changing perspectives, voicing different opinions, and searching for personal meaning and development goals.

During the process, it had become clear that the organization needs to learn both how the customer sees the collaboration and how the competencies look from the outside. A regular customer satisfaction survey does not necessarily provide detailed information on the service impact or on the critical competencies of the customer perspective. Therefore,

at this point, it was decided that in the future, the RCA model should include the idea of shifting the perspective from the inside of the organization to customers and perhaps other parties as well (5). The customer interviews, which will be integrated in the next round, need to tackle the following three goals: first, to assess the real customer value and impact of the selected capabilities; second, to intentionally change the perspective from resources to expectations, perhaps searching for new interpretations through the customers' eyes; and third, the customer could provide new information regarding what the critical competence areas could be during the next process round.

Finally, the fruits of each team discussion, together with the entire web questionnaire results, were discussed in the management team (6). (No customer dialogues were available during this preliminary test round.) The researchers presented the major observations by utilizing images, paradoxes, and dilemmas that were intended to trigger curiosity, open debate, and even emotional reactions.

Throughout the process, the prerequisites of reflective practice were held present; i.e., actively questioning the routine thinking and management structures, engaging in open dialogue with colleagues, different levels of the organization, customers, researchers, and practitioners. Avoiding overconfidence in the cognitive exercise, the process encourages practicing reflection in managerial and team work by approaching and asking the customer.

When reflecting back on the process, the following highlights are worth mentioning. The process was facilitated by researchers who, in addition to their expertise in management theory and practice, have an education and practical experience with adult education, learning at work methods, work counselling, and reflective facilitation methods. This was a significant help in the co-creation of the model with the organization.

The facilitation for team leaders was necessary in order to ensure reflective dialogue during the team sessions. The "learning cafes" related to the questionnaire results were considered extremely good and personally meaningful as they were filled with a positive spirit and produced concrete development ideas. This was probably related to using the assessment information in an interactive and dialogic manner.

Since the researchers were not present at the team session, the ideas produced were left on the flip chart and were never consolidated and presented to the management board. This reveals how the process is vulnerable to any discontinuities in the facilitation. Team

members felt frustrated as the ideas were not put forward, and thus no actions really followed the facilitation. Deciding on responsibilities is highly necessary if the process is meant to continue without the researchers' active facilitation.

Throughout the process it seemed that an outsider or a dedicated facilitator can provide significant support for the reflective assessment process, working as an objective party to handle the feedback and feed forward processes. It is perhaps valuable that the process never becomes too routine-like and maintains its quality of producing surprises with the help of critically reflective questions.

As a final remark, it needs to be noted that many of the observations may be valid only in the selected case organization in the context of its current culture, market situation, and management structures. The idea of investigating the potential of reflective practice in the competence development area has analytical generalizability which is based on the conceptual analysis – not based on the illustrative case example. Dubois and Gadde (2002) point out that the essence of single-case studies lies not in their power to generate generally held theories but in their capacity to understand phenomena (Dubois & Gadde 2002, Halinen & Törnroos 2005, Lukka & Kasanen 1993).

5 Discussion and conclusions

The purpose of this study was to incorporate the theoretically further developed concept of reflective practice into the competence assessment process for measuring human capital in organizations. As the model was constructed along interventions in a real-life organization, there was also a possibility to evaluate how well the process enabled reflection and provided added value to competence management.

The RCA process was aimed at stimulating awareness, discussion, and development actions through the help of a facilitated self-reflective questionnaire, the results of which were shared and discussed among teams; furthermore, development ideas were collected and provided to the management team. After the researchers had provided the assessment tools, the analysis of the results, and technique coaching, the organization was expected to take the leading role in driving the process. The feedback from team sessions was very positive, and the reflective brainstorming techniques were widely accepted. Yet, the development ideas collected in the sessions were not put actively put forward to implementation, and the process seemed to be paralyzed in the “actions and experimenting” phase. This observation is similar to Chiucci's (2013) case narrative,

where the change process tended to stop in the abstract conceptualization phase and did not lead to real changes in principles and practice without the researcher's strong support in increasing the aptitude for concreteness.

As researchers, we felt that throughout the process there was a paradox between the enthusiasm and expectations regarding reflective techniques and work practice and how much effort people were willing to put into an open-minded evaluation of their own work. This critique is directed at the management practices and organizational structures as well as the group of managers who could influence the organizational prerequisites. The biggest constraint for not utilizing reflection in developing competencies – or at work in general – was a perceived lack of time. We argue that based on what is known about human learning and changing mental models, reflection is crucial for any real change – in both individuals and in organizations (Hodgkinson & Healey 2011). We are thus presented with the following paradox: why is there no time to stop in order to speed up?

Regarding the competence goals, i.e., sharing of knowledge, trans-professional collaboration, partnering with customers, and reflective practice, the RCA process revealed another dilemma. Members of the organization at all levels wanted to have more assertive and systematic supervision. It was said that the common rules and guidelines are too vague and that good ideas rarely materialize. A common perception was that tight measurement of “billable hours” discourages formal and informal meetings where collaboration could be created. On the other hand, quite often it was admitted that perhaps the majority of the employees in health care strongly prioritize the work with customers, and that “internal or development work” should not take too much time in daily work. In developing the work practices toward strategic goals, people at the same time want independence, but do not necessarily accept full accountability for the results. This dilemma was discussed in the management board in order to reconstruct the collective understanding of expected results and the purpose of the organization as a service provider. The RCA slowed down the management team to enable them to understand the extent to which the orientations may differ within the organization as well as why it is practically indispensable to use all the time needed to agree on the values and mission of the organization in order to create the attitude and culture to support the competence development.

Toward the end of the process, the attention was directed at “the way we speak and express our concerns.” Practicing reflective skills pointed out how much significance lies

in voicing opinions and suggestions – or in the absence of such voices. In organizational contexts, we often believe that we can build the image of professional competence by making strong and absolute statements. Yet, in today’s volatile environment, we need the kind of competence that balances the experience-based, routine thinking and active questioning of existing interpretations and mental models (Weick et al. 2005). And thus we arrive at another paradox: how can one express doubt, ambivalence, and uncertainty without losing one’s convincing, professional reputation?

This leads back to the discussion of what constitutes professional competence. In the case organization, an intensive debate emerged regarding a “driver’s license for a health care professional,” and the value of meta-competences besides the traditional technical and clinical skills. Now if we consider knowledge formation and sharing as happening within the work practice (Lave and Wenger 1991), the role of the community (of practice) becomes critical. Professionals as learners learn the subjective viewpoint of the community and learn to speak its language (Brown and Duguid 1991). What is considered as competence is actually produced within the community, i.e., its sociopolitical, structural setting and power relations (Contu & Willmott 2003). Reflection offers a possibility to investigate and ultimately change the meaning structures, language, and forms of competence which are recognized and valued in the community.

Managing the organizational renewal, and consequently changing competence needs, is inherently a process of managing paradoxes and conflicting demands (Van de Ven & Poole 1988, p. 83). The complex and ambiguous challenge for renewal includes seemingly exclusive elements – demands, emotions, perspectives, and ideas (Cameron & Quinn 1988). This complexity can represent a source of organizational paralysis, as the actors struggle to make sense of the underlying tensions (Smith & Berg 1987). To summarize the value of reflective assessment, based on this preliminary case exploration, we suggest that its value is its ability to make visible the conflicting demands related to competence assets. Contrary to its reputation, reflection produces very concrete results, as it aims at changing the ways we talk, listen, understand, and act. Karl Weick had already posed the following question in 1979: “How can I know what I think till I see what I say?” Often the needed knowledge, or more broadly, the competence assets are already in the organization, and the solution can be seen by taking a closer look at the mirror.

Structured Abstract

Purpose – This article aims to investigate the relationship between performance management systems (PMS) and knowledge in a service organization. A PMS could be defined as *a control framework which attempts to ensure that certain ends are achieved and particular means are used to attain these ends* (Broadbent and Laughlin, 2009: 293). The basic idea is to consider the PMS in the organization as an important process in order to go deeper on the level and quality of know-how of the member of the organization. Typically performance systems are used as a tool to plan and to coordinate activities and workers. Notwithstanding there is a key dimension related to the possibility of

interpreting PMSs not just as an information box, but as an opportunity to reflect on what is going on and why inside the organization (in terms of performance and activities).

Design/methodology/approach – Franco-Santos et al. (2010) point out that, although it is possible to design, maintain and use a PMS without organizational learning occurring, such an outcome is extremely unlikely: in fact, one of the primary effects during the system design is improved knowledge of the organization. In according to Ferreira and Otley framework (2009), we want to address these research questions: what type of use is made of information and of the various control mechanisms in place? Our studies relies on a single case study. We selected a service organization which could provide a consistent, differentiated and information rich setting for studying the phenomenon under scrutiny.

Originality/value – This paper would like to propose new lens in order to interpret PMSs, overcoming the positivist/functionalist paradigm characterized by a focus on the causes-effect relationships, statistical testing, and linear thinking (Latham et al., 2005).

Practical implications –This paper would like to offer a critical perspective (Micheli and Neely, 2010) regarding the use of traditional managerial tools in a service organizations, pointing out how the principles of efficiency and effectiveness risk to remain vague in their applications and overlooking the issue of knowledge.

Keywords –performance management systems, knowledge

Paper type – Academic research paper

1. Introduction

The role of knowledge in service organizations is generally described as the only way to compete in a market characterized by radical and continuous change. Common expressions such as knowledge economy or new information age are shared among scholars and practitioners and they are typically taken for granted. In many industries and particularly in the service one, knowledge plays a critical role in facilitating innovation and creativity. As stated by Kandampully (2002:21): “In this competitive environment, knowledge is progressively being perceived as the core driver of competitiveness”.

In coherence with the ideas even the accounting literature started during the 90’s to discuss about the role of knowledge in the control management systems, arguing that even this tools should be evaluated on the their capacity to contribute to manage knowledge (Bhimani and Roberts, 2004): control and knowledge became two different sides of the same coin.

This paper would like to offer a critical perspective regarding the use of traditional managerial tools in a service organizations trying to verify how and to what extent it is

possible to interpret a Performance Management System (PMS) as a typical control mechanism or in more innovative way as a knowledge enabler (Brudan, 2010). The paper is organized as follows: in the first paragraph is presented a literature review on the relationship between PMS and knowledge. We then describe the methodology used for the empirical analysis and analyze the research context. We then set out and discuss the data and information from the empirical research before summarizing the main findings and our conclusions.

2 Performance Management System and knowledge

The relationships between management accounting research and knowledge are not new in the literature. An important contribution coming from the accounting literature was published on Management Accounting Research in 2003 in a special issue related to the topic of “*Management accounting and knowledge management: in search of intelligibility*”.

The idea was to emphasize the role of accounting and control as knowledge enabler. In particular Bhimani and Roberts (2004; p.1) state: “If it is believed that within organisations, “future wealth and power will be derived mainly from intangible intellectual resources: knowledge capital” (Burton-Jones, 1999, p. 3), management accounting will increasingly be judged in terms of its impact on knowledge management activities.”

At that time we were experiencing the knowledge management fashion, scholars and practitioners were discussing about the role of knowledge within society and organizations: there was the common idea knowledge would be the most important resource, the only way to compete. Knowledge was becoming one of the main issue in the scientific community as shown also by the number of journals founded in that period (the first number of Journal of Knowledge Management appeared in 1997, the first number of Journal of Knowledge Management research and practice in 2003).

Notwithstanding the effort of scholars in the field, the relationship between control and knowledge was still underestimated in the mid 2000’s. As Turner and Makhija (2006:197) argue: “The literature provides us with only a rudimentary understanding of such organizational processes associated with the treatment of knowledge”. For this reason they proposed a contingent model in order to analyze the influence of control systems on the different kind of knowledge attributes. The main idea was that control

systems have inherent information processing properties that influence how knowledge is shared and disseminated within the organization (Turner and Makhija, 2006).

Ditillo (2004) used a contingent approach to investigate the interconnections between knowledge and control/performance systems in knowledge intensive firms. According to his model, Management Control Systems play a double role in knowledge-intensive firms: they help coordinate activities and foster a specific mode of knowledge integration.

During these years there was an effort to make control a more strategic issue, based on the concept of Performance Management System (PMS).

A PMS is “the set of metrics used to quantify both the efficiency and effectiveness of actions” (Neely et al. 1995, p. 81). As stated by Otley (1999, p. 364), PMSs provide the information that should be useful to managers “in performing their jobs and to assist organizations in developing and maintaining viable patterns of behaviour”. According to Ferreira and Otley (2009, p. 264) management control system has become “a more restrictive term than was the original intention and we prefer to use the more general descriptor of PMS to capture an holistic approach to the management and control of organizational performance. We see this term as including all aspects of organizational control, including those included under the heading of management control systems”. In other words, PMS is a new label for an old concept: it represents a way to describe a new theoretical framework, whose aim is the design and the implementation of the “package of controls”.

The main goal is to gather and provide information to help managers in their decision-making activities in order to efficiently and effectively achieve the desired organizational goals, acting on the employees motivation and the performance assessment (Canonico and Söderlund, 2010).

In the traditional accounting research (as mentioned in Melnyk et al., 2013:1) performance measurement and management is set up to facilitate *effective control and correction by reporting the current level of performance, and comparing it with the desired level of performance (i.e., the standard)*...To some researchers (e.g., Magretta and Stone, 2002), *PMM is more important than the mission statement: metrics enable the organisation to convey the strategy to everyone else in terms they can understand, thus making the strategy concrete and meaningful. The use of performance measurement and management systems is frequently recommended for facilitating strategy implementation*

and enhancing organisational performance (e.g., Davis and Albright, 2004) – a view that coincides with much of the Balanced Scorecard rhetoric.

Meanwhile many scholars are pointing out the broader functions of a PMS that should be implemented in order to accomplish different tasks and goals, among the others (Melnyk et al., 2013: 4): influencing behaviour – good and bad performance; stimulating action – identifying when to intervene; facilitating learning – both single and double loop; Implementation of strategy – ensuring change happens.

In particular the issue of learning refers to feedback and feed-forward information flows that characterize organizations (Ferreira and Otle, 2009): in this sense, PMSs could be interpreted as a process where interaction and communication among members support learning and the creation of knowledge within the organization, both in a tacit and an explicit dimension (Viavio, 2006).

Franco-Santos et al. (2010) point out that, although it is possible to design, maintain and use a PMS without organizational learning occurring, such an outcome is extremely unlikely: in fact, one of the primary effects during the system design is improved knowledge of the organization.

Brudan (2010) distinguishes between performance management as “command and control/ mechanistic system” and performance management as “systems thinking”. The first one focused priorities on volume, standards and control through product standardization, work process specialization and the use of goals, interpreting organizations as top-down hierarchies, where managers make decisions using budgets, standards and targets. Differently, systems thinking promotes a holistic approach to managing organizations, placing more focus on the learning and human relationships. In particular, a systems thinking approach to performance management focuses on the definition of the system, its purpose and the measuring of how its purpose is achieved. Instead of an isolated approach, the focus is on integrating all components of the system and mapping the relationship between them in addressing and satisfying demand. In other words, Brudan (2010) points out the tension between the measurement and rewards ethos to learning and improvement. In Table 1 we refer to the main characteristics related to PMS for control compared the features of PMS for learning.

In according to Brudan framework (2010) our study wants to understand how and to what extent PMS is used as a knowledge enabler, as a tool to facilitate communication inside the organization, or just as a traditional control mechanism.

Table 1 - Measurement for control compared to measurement for learning

Source: Brudan (2010)

Characteristic	Measurement for control	Measurement for learning
Measurement drivers	Management	Employees
Measures development	Top-down commands	Process-oriented bottom-up approach
Measurement role	Measuring and managing work in functional activities	Measuring and managing the flow of work through the system
Measurement focus	Productivity output, targets, standards: related to budget	Capability, variation: related to purpose
Results communication	Restricted	Open
Target driven by	Budget/political aspirations	Understanding achievement versus purpose
Follow-up to results	Rewards, punishment and action to improve results	Dialogue and improvement
Learning cycle	Single loop	Double loop learning
Link to rewards	Link to individual rewards and recognition system	Group rewards, based on improvement

3. Methodology

The empirical analysis is based on a qualitative investigation. The empirical analysis consists of a specific case study, carried out in the period January- April 2014, showing the relationship between PMS, control design and knowledge in an Italian airport management company (Gesac).

The collection of data was carried out using a heterogeneous plurality of instruments. Such pluralism is coherent both with the theoretical framework and with the differentiated nature of the information required by the multiple case studies method. The case study was developed, in the first phase, through 3 unstructured interviews (with the Human Resource Management, the Quality, Safety and Environment Manager and the Passenger Traffic Manager), to investigate the purpose and rationale of design that characterizes the PMS. Subsequently, the investigation continued with participant observation in the 3 different organizational units, involving two of the authors in all stages of the PMS.

4. Empirical Analysis

Gesac S.p.A. – *Società di Gestione Servizi Aeroporti Campani* – is the management company of the Capodichino Airport in Naples, based on a forty-year concession expiring in 2043. Capodichino is the third-ranking regional airport in Italy, with 5,8 millions of passengers in 2012.

The company was established in 1980 by the city of Naples, the Province of Naples and Alitalia as a majority state-owned company. In August of 1997, each of the state agencies sold 35% of the share package to BAA plc. Fully aware of the strategic importance of private management for the future development of not only the airport but the city as well, the public partners (City and Province) decided to privatize Naples airport making it Italy's first privatized airport. In June, 2006, the ADI Consortium – Airport Development and investment Limited – under the leadership of the Spanish Ferrovial Group, acquired ownership of the BAA Group thus become the management company's majority shareholder. Finally, on December 21, 2010, pursuant to an agreement signed on October 1st, the sale of majority shares in Gesac was finalized and the ownership of the company was definitively transferred into the hands of the Italian F2i – Fondi Italiani per le Infrastrutture- Group. The main traffic and infrastructure data are summarized in Table 1:

Table 2 – Gesac traffic and infrastructure data

5.444.422 million passengers in 2013
7.515 tonnes of cargo and mail
55.940 movements (take-offs and landings)
11 domestic destinations
40 international destinations
50 charter destinations
23 airlines
25/26 aircraft stands
56 check-in counters (T1)
15 check-in counters (T2)
15 gates
28 shops
9 café and restaurants
2 Exchange Bureau
2257 car parks and 74 motorbike parks
8 Car Rentals

The primary duties of the airport management company include:

- maintenance, management and development of the infrastructure and airport systems;
- coordination and control of the quality parameters related to all flight operation services;
- management, coordination and control of passenger boarding and arrival services;
- airport security and control of passengers and hold baggage;
- coordination and control of handling activities related to flight operations;
- development and control of the commercial services provided for airport users.

The company employs approximately 300 employees, to which are added (on average) 40 seasonal workers a year. In 2013, at the height of the financial crisis, the company launched a major process of change and organisational development, which began with the appointment of a new Chief Executive Officer.

Since privatisation, the company has always invested in the design and implementation of a PMS, the aims, features and functionality of which have subsequently changed over time in line with the different strategic approaches preferred by the management.

Currently, GESAC's *mission statement* gives the PMS a central connecting role between the operational management and strategic development of the employees. *“Working at Gesac means joining an organisation in which everyone is given a chance to participate and to express their own talents and professional skills, contributing towards high individual and team performance. Our strength, the mainstay of success and our competitive edge, is our people. In a service-providing company like ours, human resources are the fulcrum of each and every activity ... Our resources join a structured system in which training and continuous performance-monitoring activities enable them to enhance their technical and managerial skills, resulting in added value for the service offered ... For example, a structured Performance Management system enables the effectiveness of our training activities to be monitored continuously and new needs to be identified”.*

GESAC's PMS, strongly supported by top management, is managed by the Human Resources Department with the cooperation of the Quality, Safety and Environment Directorate, and by the Finance department.

The GESAC PMS involves about 30 managers and supervisors, and 8 sectors that make up the operational directorates.

The process is divided into the traditional four stages of strategic planning, operational planning, monitoring and measurement / evaluation of performance. Specifically:

A) The QA management assists senior management in strategic positioning with regard to benchmarking and the customer satisfaction with which the company is constantly engaged;

B) The HR team, in collaboration with QA and Finance teams, supports the leadership in the structuring of operational objectives;

C) The HR team, in collaboration with QA management, monitors the partial mid-term results;

D) The HR team, in collaboration with the QA team, supports executives and senior management in the collection of data to enable assessment of individual and departmental performance.

Performance management results are due strictly to an incentive system of variable remuneration. The instrument used for monitoring PM is a "*management dashboard*" divided into 5 strategic objectives connected to an MBO designed to evaluate managers and supervisors, and a productivity report for employees of different departments.

The MBO system is the key to the PMS. For executive / board bonuses, 50% will be based on organisational performance goals (EBTDA, traffic levels, quality) and the other 50% based on quantitative achievement of individual goals (from one to three), set by top managers in the various functional areas in accordance with the HRM unit (e.g. labour costs, results of *customer satisfaction* surveys, maintenance levels, employee absenteeism rates, team-working skills, etc.). Achievement of individual goals is divided into four levels of achievement: the bonus is, therefore, made on the basis of how close the result is to the stated objective (e.g. 25% - 50% - 75% - 100%). The total bonus can reach up to 20% of the gross salary of executives and up to 7% of gross salary for middle management. The evaluations do not include items related to organisational behaviour (if we exclude team-working).

The degree of achievement of organisational and individual objectives is closely linked to the measurements of highly centralised control systems and, at least in part, administered by bodies outside the company that oversee important functions of quality assurance and security levels at airports. Specifically, the objectives reflect the typical measurements of the following systems:

- the regulated system of 54 indicators endorsed by ENAC (the Italian Civil Aviation Authority), which is part of the company's list of services;
- the Quality of Service Monitor (QSM), for monitoring of passenger satisfaction in quality of airport services, both those provided by GESAC and those provided by other parties present at the airport, identified by 80 indicators based on face to face interviews with passengers. A system of “face-to-face” surveys of passengers is based upon a 5 level scale of satisfaction. The surveys regard all airport services provided by either the airport management company or other operator present at the airport and are conducted by an independent specialized company;
- the Quality Control System (QCS), aimed at monitoring the quality delivered by the various parties responsible for the management of airport services, through analysis of statistically significant samples of customers. QCS includes the measurement of waiting times considered to be critical to airport customersatisfaction based upon a statistically significant sample;
- the benchmark analysis system for a group of 250 airports in the world by perceived quality;
- trend analysis of performance with more than 4,000 interviews conducted each year by an external company.

The data published in the Table 2 have been obtained from QSM and QCS, complaints and other Quality Management System instruments. They represent the main indicator related to the airport quality (i.e. service regularity, cleanliness, counters and gate services, etc.) and the Gesac targets for 2014.

Table 3 - The targets for 2014, grouped together according to quality factors

	Indicator	Unit of Measure	Target
SERVICE REGULARITY	delayed departing flights due to airport operator	% (nr. delays/nr. flights)	0,3
	delayed departing flights	% (nr. delays/nr. flights)	21
	misrouted baggage	nr. misrouted baggage/1000 departing passengers	0,8
	baggage claim time	maximum waiting time in 90% of cases	first bag 24' last bag 33'
CLEANLINESS	perception of hygiene levels and working order of toilet facilities	% satisfied passengers	98
	overall perception of cleanliness levels in airport	% satisfied passengers	99
COUNTERS AND GATE SERVICES	waiting time in check-in queues	maximum waiting time in 90% of cases	15
	perception of waiting time in check-in queues	% satisfied passengers	95
	waiting time in security check queue	maximum waiting time in 90% of cases	7
	perception of waiting time in check-in queues	% satisfied passengers	98
	perception of waiting time in queues at passport control	% satisfied passengers	99
CONNECTIONS BETWEEN AIRPORT AND CITY CENTRE	perception of clarity, comprehensibility and efficacy of external signs	% satisfied passengers	95
	perception of the availability, frequency and prices of buses and taxis	% satisfied passengers	90

As mentioned, the HR department supports and negotiates with management to define of operational objectives that meet performance expectations drawn from the monitoring systems indicated. Finally, during the performance evaluation, the executives receive support from the HR department for guidance and homogenisation of their evaluation behaviour. The assessments determine the size of bonuses for executives and productivity bonuses for employees of different departments.

5. Discussion and conclusions

The discussion of the results of the case study focuses on two main points:

1. The functionality of the PMS;
2. GESAC's approach to the design of the PMS.

The GESAC PMS is interpretable as one of the most important and effective control levers employed by the company. During the interviews with the Director of HR, it was found that the PM is, in fact, identified as one of the essential operation systems for the company: "*Evaluation is an asset: if you stop performance measurement, the airport shuts down!*" The HR Director – process owner of PMS – also argues that it should be viewed primarily as an operations support system and only indirectly supports the strategic management of people. "*In our company, in terms of functionality, the system represents 70% of control functions and 30% innovation and staff development*". The HR director adds: "*The PMS is used for the remuneration policies of the staff but also has significant impacts, especially in terms of policy*". The same interpretation is shared by the leadership: that, under PMS, they are not only subjects for evaluation themselves, but are also themselves evaluating the management and control function's performance.

During the focus groups, the Director of Passenger Services says: "*The PMS is primarily a tool of control; certainly the PM system also improves the commitment of workers and generates satisfaction through rewards, but the real development lever consists in the definition of tools for the identification of clear targets and ongoing monitoring*"; the Director of Infrastructure confirms: "*The PMS mainly supports the ability of managers to integrate critical processes in a cross-cutting and strategic dimension*"

Finally, the Head of Quality highlights: "*The PMS is the essential link between the two planning moments: strategic planning supported by the important process of analysis and benchmarking, which our company is also undergoing to respond to regulatory requirements and contractual obligations on an international scale; and operational planning that defines our final management position with respect to the challenges posed by the markets in general.*"

The documentary analysis and interviews have revealed the level of maturity of the GESAC PMS. The results of management of this system are described by the Head of HR in terms of the timing of operational characteristics, the skills shown by operators in using the PMS tools, and the degree of homogeneity in behavioural evaluation. The Director of

HR says: *"The PM system has a long history in our company. This year alone, we are implementing an organisational development project that will permanently remove some small inconsistencies that we have highlighted in recent years. But essentially the system continues to provide good results: managers know how to interpret the goal setting phase, are encouraged in their role as leaders, are punctual in the delivery of schedules, and there are no contentious situations at the end of the evaluation cycle."*

The quality and robustness of the results are also described in terms of availability and involvement of employees in the different phases of the PM process, and the satisfaction that emerges from the connection to incentivising policies. According to the HE manager: *"The unions want the evaluation. Employees are motivated by rewards and would be in trouble without the strong leadership from management providing clear business objectives."*

The totality of the PMS' positive results is due, according to interviews with top management, to a clear managerial approach adopted in the design of the system itself. The PMS is known to deliver objectivity, especially in the measurement of the contributions of the various organisational units, and support for coordination through standardisation of objectives. During the redesign process of the PMS (which coincided with the last change of ownership of the company), management has decided, therefore, to entirely exclude measurements and evaluations of behaviours and skills associated with job performance from the system. According to the Director of HR: *"The behaviour measurements can be manipulated and are not objective... so these should not be linked to the bonus. Evaluating behaviour opens up potential for excessive margins for negotiation... and may open the way to opportunism for the evaluator. For this reason we have decided to remove these behavioural items from the set of tools used for performance evaluation."*

Official statements attribute the PMS with strong strategic value for HR development: *"Our resources are included in a structured system that, through training and continuous monitoring of performance, allows them to increase their technical and managerial skills, thus adding value to the service offered."*

Performance management is mostly driven by financial indicators and customer satisfaction quotas, used for checking if people were completing their tasks as assigned by top managers. The selection process of PMS objectives is, in fact, of the top-down type: those in charge of functions set the resulting targets using cascade logic. The high degree

of attention that the management holds for those targets "legitimised" by international certification and measuring systems outside the company results in a strong connection of the PMS to the focus of control tools through automated mechanisms. Through the objectives and standards of hetero-specific performance measurements, the PMS supports processes that centralise planning and boost the effectiveness of managerial control.

PM design emphasizes financial measures and a command and control approach, based on monitoring the achievement of targets: the measurement is driven by the management; measures development is linked to top-down commands; measuring and managing work is embedded in functional activities; measurement focus is on productivity targets, and standards related to budget; results communication is restricted (top management); follow-up are individual rewards, punishment and action to improve results (and non-inter-hierarchical dialogue); and the learning cycle is single loop way.

Observing the performance management practices, it emerges the dominance of the measurement and rewards ethos (as opposed to learning and improvement). In this sense, the gap between the formal intention of the company and the real implementation of the PMS is clear for all to see.

The higher degree of centralization and the use of PMS as a way to manage power are directly related to the real goal the management wanted to achieve: to have a higher level of control inside the organization.

Challenges of knowledge management in transdisciplinary urban planning

Katharina M. Borgmann

IN-EAST School of Advanced Studies
University of Duisburg-Essen
Universitätsstraße 2, 45141 Essen

Structured Abstract

Purpose - This research paper is addressing the difficulties of interdisciplinary and transdisciplinary knowledge transfer in respect of urban textures and furthermore the impact of knowledge, about surroundings and environment, on sustainable and holistic growth. In order to channel resources and set the focus at the right place at the right time, one important key factor is understanding and therefore decoding the transforming urban structures. Generating a base for an interdisciplinary dialogue about the potentials, risks and possibilities of the existing urban structure and its development between business organizations, public authorities and organizations is one purpose of this paper.

Design/methodology/approach - It is the approach to contribute to the well-established discussion about urban textures and its complex structure connecting to correlating research topics, not only for the benefit of the community of architects and urban planners in research and practice but also for the larger target group of experts from other research fields and practices.

Originality/value - Are the known tools of Knowledge Architecture, knowledge transfer and knowledge management adequate to generate and transfer the necessary knowledge of complex urban structures? Do we need to rethink, question or expand those described methods in order to meet the transdisciplinary requirements by not only transforming but also translating knowledge for diverse, heterogeneous recipients in order to be applicable in research as well as in practice? Having the effect of the increasing globalization in mind the importance of accessible, understandable knowledge gains significance in order to follow the approach of supporting a sustainable and holistic growth on multiple levels.

Practical implications - Bridging the still existing gap between architecture and urban planning on one hand and non-architectural disciplines and professions on the other hand is a second aim of research. Hence it is a necessity to transform the knowledge about urban structures into a more universal accessible language. The identification and establishment of existing interdisciplinary knowledge transfer tools, in order to make possible recommendations. Spheres of influences for various fields of expertise might be discovered and identified. This is possible only by translating the respected expert knowledge and offering this processed, transformed knowledge to an audience of various disciplines.

Keywords – Urbanism, Transdisciplinarity, Sustainable Urban Growth, Knowledge Transfer, Innovation

Paper type – Academic Research Paper (Doctoral Consortium)

1 Introduction

The challenges, the possibilities and the chances to create sustainable growth, more specifically sustainable growth and sustainable transformation within the urban context are the main foci of this paper.

The complexity of sustainable urban development calls for transdisciplinary working partnerships. These collaborations have the aim to effectively create the best possible environment for sustainable urban transformation and growth. The research area of urban planning, among others, is strongly transforming from theoretical and disciplinary 'Mode 1' research approaches towards interdisciplinary more practical oriented 'Mode 2'¹ research approaches. Because of the existing multiple layers and diverse structures in the field of urban planning there is a demand for transdisciplinary approaches in order to respond to the challenges of today's professionals creating the cities of tomorrow.

It is not only important to understand the multiple factors of influence acting upon the process of urbanization, but also to keep in mind the actors and the process of creating and developing a sustainable urban environment. Urban growth is sustainable in its approach when it is considering and benefitting from all involved and respected disciplines in a holistic line of action in order to create individual urban solutions. Developing and translating the specific requirements (kind of project, recipients, demands of the surroundings 'genius loci', historical background, socio-cultural factors etc.) of each urban project into urban physical environment is the common intension of the involved stakeholders.

2 Development of Urban Planning

Urban design and urban planning as well as the research of urban design focuses on the physical, including topography, climate and many more up to the built components of the city. Urban planners and designers are trained to translate the needs and demands of the urban residents into physical environment considering multiple factors of influence in order to meet the requirements of today's as well as tomorrow's inhabitants and institutions. Fainstain describes this discipline, including some aspects which contribute to the complexity of urban planning: *„urban planning draws upon ,engineering, architectural, and social and political concerns, it is variously a technical profession, an*

¹ Page 10, Chapter '3.1. Mode 1 and Mode 2 research methodology' gives detailed information about Mode 1 and Mode 2

endeavour involving political will and public participation, and an academic discipline“ (Fainstein, 2014).

Because of the rapidly transforming factors of influence acting on urban agglomerations on one hand and on architects and urban planners on the other hand, the process of designing, shaping and creating urban structures is undergoing a transformation in order to fulfil on-going and future design and research approaches.

Processes of Urban Planning

The well-established disciplinary approach of urban planning transforms more and more towards joint ventures, formed by experts from involved disciplines depending on the respective project type, in the process of carrying urban projects into execution with a sustainable concept.

Certain factors of influence shape our urban environment physically as well as ‘atmospheric’ and contribute to the complexity of urban structures as much as the process of designing the city. These - in the following called ‘urban factors of influence’ - not only influence and transform all aspects and components of the city, but also influence the experts designing and creating cities.

On a superordinate level of influence, affecting the urban structure and its transformation, several factors exist: cultural influences, demographical-, ecological-, economical-, political- and technological influences, just to name some of them in alphabetical order, without claiming to be exhaustive.

The project initiator, the client, who is in direct dialogue with architects and urban planners, represents one further level of influence. Mostly public institutions like governmental agencies or semi- public contracting authorities, commission the architect or urban planner with the respective project types of urban scale. Most of the times the kind of client determines certain needs and expectations regarding the specific project. This could mean for example budgetary limitations, the external impact and image represented by the visual appearance of the project to name some. Furthermore the characteristics seen and experienced of the project results are very much related and determined by the project type. Redesigning the existing structure of a city centre in central Europe, developed during the 1960es, towards a shared space concept for example, differs to a considerable extend from an urban project type like developing a new central business district (CBD) or science park in the outskirts of an Chinese or

South American city. Despite the multiple differences of the just mentioned urban projects, there is still a uniting factor to them, the architects and urban planners challenged with these different types of projects² could be the same, working in a western architectural or urban planning office and dealing with these diverse projects.

Hence the transformation of the global urban environment is not only in the hands of and controlled by architects and urban planners but rather shaped by the respective factors of influence.

Architects and urban planners of course represent one of the proactive, shaping and creational stakeholders involved in urban growth, by translating the assignment of tasks into physical built innovation with impact on the visual appearance of the city (Fig. 1: ‘Urban Factors of Influence I’).

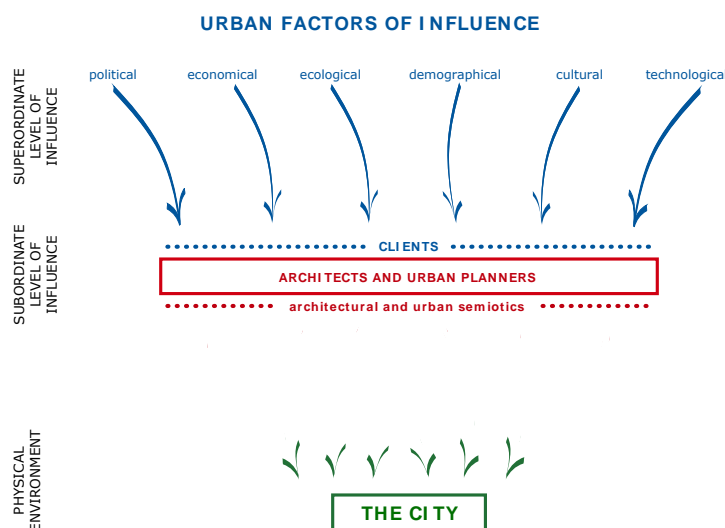

Fig. 1: ‘Urban Factors of Influence I’

Architects and urban planners are educated, affected and influenced by their surroundings as much as anybody else therefore the way they translate the individual

² Architectural and urban planning approaches of so called ‘signature architects’ are not taken into account within the scope of this paper since the purpose of these projects is not necessarily always coherent with sustainable approaches.

design tasks into physical urban space depends very much on the factors of influence mentioned above. The end product, our built environment, designed by architects and urban planners, needs to meet the current and future requirements of cities.

Challenges in Urban Planning

Disciplinary, Mode 1 approaches, of architects and urban planners both in practice and research, turn more and more out to be an insufficient approach for some of the future sustainable urban developments. The requirements and needs of cities got more and more complex and diverse within the last decades, environmentally challenging, and technologically trying to keep up with the highest possible level. Today's cities transform towards 'smart' and 'green' cities, and therefore the disciplinary design approaches of architects and urban planners alone are not always sufficient anymore in order to meet the future requirements of the complexity gaining different urban projects.

The rapidly happening technological progress, since the last century, leads to a raising demand of certain facilities provided by the respected urban environment. This process of meeting the claim of the urban population and trying to keep up with the existing technology by implementing whichever possible technological innovations further increased the already high complexity of the urban environment. This is even more relevant if we broaden our perspective to the global urban issues, the results of the described urban achievements get more obvious for example almost collapsing metropolitan areas in East Asia.

In the following several important factors adding to the raising complexity are going to be described in more detail. All of the below mentioned factors and urban challenges, without claiming to be limited to the enumeration, need to be considered, and focused on in order to find a sustainable approach and to lead current and future urban growth to a more sustainable direction.

One of the main urban challenges of today's and future's urban agglomerations is the *traffic overload*, a side effect of the growing demand and use for one's own means of transportation, especially in the East Asian raising countries like China and India. A result obtained from the above mentioned traffic overload is the increasing load of *pollution of the environment*, caused mainly by industries and traffic, concentrating in dense urban agglomerations. The so called mega cities stand highly at risk to cause and experience ecological collapses, like health effecting air or water pollution - as can be seen in Beijing

- by not being able to manage the problems or by acknowledging them too late (Lu, 2009, pp. 1–2). The sometimes underestimated challenges for the city and its inhabitants regarding the urban climate, water and energy supply is an additional layer necessary to consider. The global urban growth, affect both European industries and citizens on multiple layers, because of short and long term consequences like shortage of natural resources, environmental pollution, waste management and many more.

The constantly growing number of urban inhabitants, due to *migration* of the rural population into the rapidly growing cities, generate great demands on the urban *infrastructure*, such as social and educational infrastructure, local business and supply and the technical infrastructure, like transportation. To equip today's urban inhabitants with the widest possible range of options is an important factor to satisfy the claim for today's quality of urban life in western cities. The flexibility and immediate availability, everywhere and at all times, of multiple transportation options (metro, tram, bus, car sharing, city bikes, etc.) and the necessary basic requirements coming along with it (well-developed road networks, well extended rail and bus networks, etc.) became substantial components of the urban quality of life.

Since the past two decades the mental urban space (Contin, Paolini, & Salerno, 2013), the so called 'Cybercity' (Graham, 2004), reaches new levels of technologically demanding infrastructure. The demands of constant unlimited connectivity and access to digital and social media is one of them. Furthermore the increasing need for immediate availability of multiple choices for sports- and leisure time facilities (i. e. alternative break out spaces from the urban environment, local recreation areas, demanding and wide range of cultural offerings, etc.) is also adding to the increasing complexity of urban components in cities.

Hence new urban solutions and technological innovations need to be implemented into current and future urban design developments in order to satisfy and meet the demands and challenges of the constantly transforming cities. The temporal dimension of urban development considering both on one hand the necessary time for urban projects in order to be allowed to develop in a sustainable way and the contingency and limitations of adaptability of urban inhabitants especially in fast urban developing countries like China - Shenzhen - where the urban environment is changing its substantiality within one generation.

The latter mentioned challenges of today's and future cities is not only a task possible to be accomplished by the design of urban planners and architects alone but rather achievable by linking experts of the above mentioned areas, in order to meet the requirements of the diverse urban layers.

The already existing approach of project based diverse working collaborations, formed with experts from important disciplines involved in creating the urban environment, has the aim to lead to sustainable urban solutions. According to the needs and requirements of the project, expert groups are being composed and vary in their composition. Involved stakeholders of these joint ventures could be project developers, landscape architects, civil- and traffic engineers, waste and resource managers, political scientists, sociologists, mathematicians, architects and urban planners as well as representatives of the public, or the industries, etc., but the composition of these collaborations vary according to the project type and its individual requirements (Fig. 2: 'Urban Factors of Influence II').

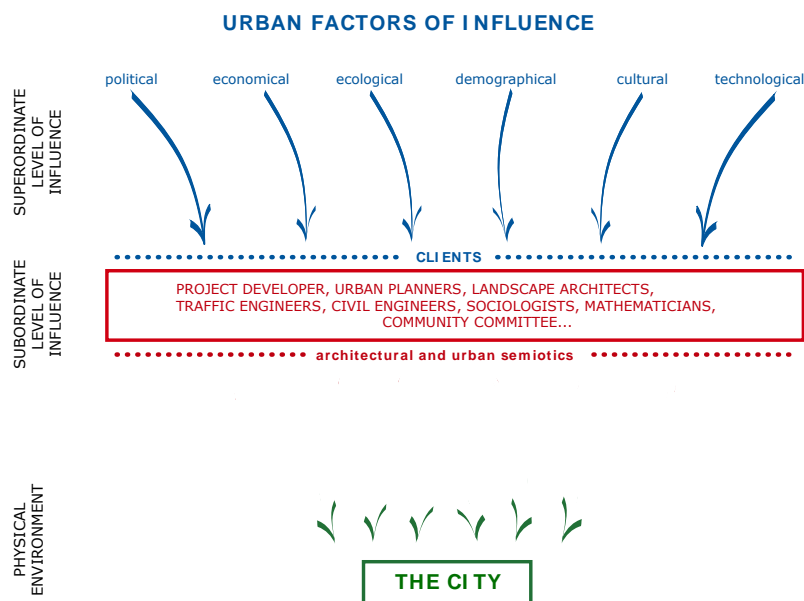

Fig. 2: 'Urban Factors of Influence II'

The ideal approach of these diverse project teams is sharing one's individual expertise and know-how with the other stakeholders in order to create urban projects, which meet

the complex extensive requirements of a sustainable urban environment. Knowledge transfer and knowledge transformation within the mentioned collaborations is thought to create the base in order to let the stakeholders benefit from each other's expert knowledge. In order to achieve this it is important to generate the ideal possible work environment to support the transfer of knowledge between the above-mentioned experts.

The latter mentioned transformation of urban planning both in the research area as well as in practice is developing towards diverse transdisciplinary, Mode 2, project teams. Further detailed explanation about urban transdisciplinarity project based teamwork and its ideal work environment is given in the following.

3 Tools and Methods in urban planning research and practice

The following chapter gives an introduction and an overview of methods and tools used in urban planning research and practice. The applicability of tools and methods for urban planning such as Mode 1 and Mode 2, transdisciplinarity, knowledge architecture tools, scenario development and Transdisciplinary Integrated Planning and Synthesis (TIPS) are going to be analysed from a critical perspective.

3.1. Mode 1 and Mode 2 research methodology

The collaboration of disciplines in order to enrich the research environment and to be equipped to give justice to the complexity of reality as needed in urban planning is discussed and named as 'Mode 2' knowledge production. The established Mode 1 research is described as theoretical and experimental science, mainly a disciplinary approach used by autonomous scientists and research institutions, whereas Mode 2 is characterized as application-oriented and broader distributed. The most important criteria for Mode 2 approaches is transdisciplinarity, as a description for a cooperation of multiple disciplines with shared accountability and responsibility to handle highly complex practical problems.

The "Mode 2" approach is hereby not seen as an alternative for Mode 1, but an extension of Mode 1 and will always need the disciplinary research as a base. (Nowotny, Scott, & Gibbons, 2003, p. 179)

To visualize the different dimensions of Mode 1 and Mode 2 approaches, Dunin-Woyseth and Nilsson created figure 3, which is not only adaptable for his field of study, architectural research, but can broaden the perspective for research approaches in general.

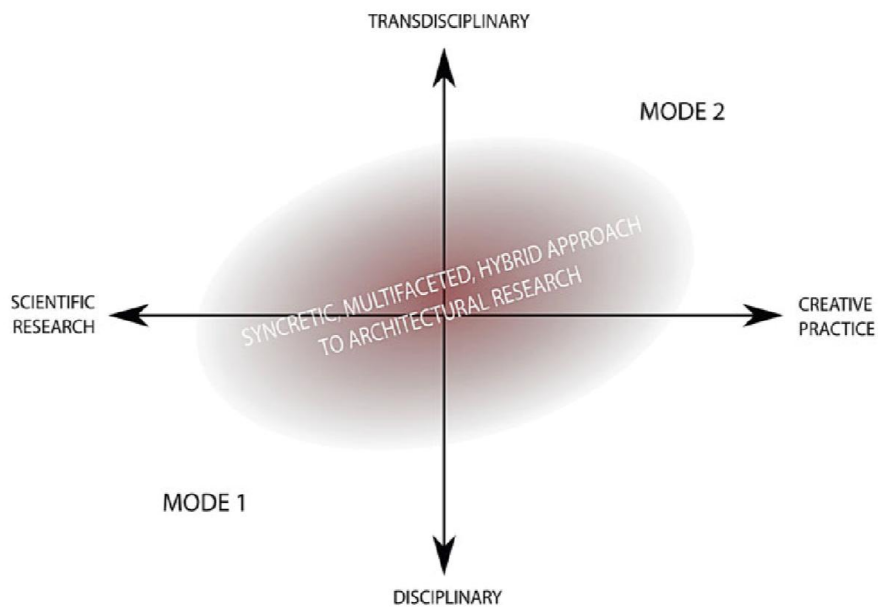

Fig. 3: *‘Expanding architectural research with syncretic, multifaceted, hybrid approaches within the field of dialogues between Mode 1 and Mode 2 of knowledge production’ (Dunin-Woyseth & Nilsson, 2011, p. 93)*

Transdisciplinarity as a new approach within urban planning needs to be well defined and differentiated from related terms such as Multidisciplinary and Interdisciplinary. Both approaches do not have the goal of a combined cooperation of several disciplines in order to understand and solve complex practical problems. In the ‘Manifesto of transdisciplinarity’ Basarab Nicolescu describes transdisciplinarity as follows: *“Transdisciplinarity is [...] distinct from multidisciplinary and interdisciplinarity because of its goal, the understanding of the present world, which cannot be accomplished in the framework of disciplinary research.”* (Nicolescu, 2002, p. 2)

In general, transdisciplinarity is focused on solving complex problems from practice with the collaboration of research and theoretical methods and tools and, especially used for complex problem with a high importance and reach. Bridging the missing knowledge with transdisciplinary approaches is a result of a mismatch between knowledge production in academia, on the one hand, and knowledge requests for solving societal and

practical problems, on the other (Pohl et al., 2007, p. 124; Hirsch Hadorn et al., 2008). Transdisciplinary Mode 2 approaches in urban planning aims at identifying, structuring, analysing and handling issues in problem fields with the aspiration to grasp the relevant complexity of a problem, to take into account the diversity of life-world and scientific perceptions of problems, to link abstract and case-specific knowledge, and to develop knowledge and practices (Pohl & Hirsch Hadorn, 2007, p. 124).

The above described theoretical transdisciplinary collaborations seem not only to meet the complex requirements of urban planning approaches but also seem to be consistent with some of the approaches implemented in today's practice of developing sustainable urban projects. At a closer look various challenges and difficulties appear, especially regarding the necessary and important expert- layman communication, so called expert knowledge transfer.

3.2.1 Knowledge Architecture

Knowledge Architecture is a tool offering structural conditions for an optimized knowledge management environment. It aims to support effective communication and collaboration within diverse teams in order to strengthen the transformation of implicit and explicit knowledge. Spatial, temporal and financial flexibility can increase the usability of creativity and innovation in diverse working groups. Knowledge Architecture as a prerequisite can create a supportive environment and a base to execute transdisciplinary research approaches not only in urban planning. (Noennig & Hentschel, 2011)

This can after all only be a starting point to meet all the challenges and needs of a transdisciplinary research and working situation. For the actual transdisciplinary research approach there are other tools, like scenario planning or TIPS, needed and necessary to be brought into practice.

3.2.2 Scenario Planning

Scenario Planning in the form of multiple disciplinary concept developments is a common and well-known tool in architecture and urban planning. Scenario planning used in multidisciplinary environments is a well-established tool and supporting collaborations. Therefore it should be more intensively used for transdisciplinary approaches in order to

be better equipped to meet the requirements of sustainable urban planning (Zegras & Rayle, 2012, p. 304).

Scenario planning is a quite established method in the practice of certain urban planning projects, but the combination of this method in a Mode 2 approach, along with a higher complexity, because of simultaneous involvements of several disciplines is not fully reviewed in research and not transformed into practical adaptability.

3.2.3 *Transdisciplinary Integrated Planning and Synthesis (TIPS)*

The most complex and fitting support tool as well as research method for dealing with several disciplines to solve complex reality problems is Transdisciplinary Integrated Planning and Synthesis (TIPS) described in the Handbook of Transdisciplinary Research.

„TIPS is an approach to embed a formal, scientifically based, integrated planning approach into a real world setting, allowing for mutual learning among scientists and practitioners.“ (Walter, Wiek, & Scholz, 2008, p. 223)

Within the scope of this definition, the following properties of TIPS are further described:

1. Transdisciplinary approaches are case based and goal oriented.
2. The active involvement of all respective stakeholders as co-leaders with problem ownership through expertise, resources and responsibility is necessary.
3. A high level of interaction between all participants under a common shared problem view is mandatory.
4. The differentiation of involved scientists into disciplinary experts, who are responsible for contributing their disciplinary knowledge and methodology, and transdisciplinary scientists, whose expertise lies in methods of knowledge integration is needed to define clear responsibilities. (Walter, Wiek, & Scholz, 2008, p. 223)

TIPS as a research and practical approach in urban planning is a recommended tool to meet several of the complex requirements faced by the involved stakeholders of interdisciplinary collaborations. However it cannot be identified as a general tool and method to solve all the above-described challenges.

Since TIPS is explained only for a single example in Switzerland, the flexibility of the method and its adaptability still need to be proven.

4 Conclusion and Outlook and Impulses

Which tools and methods of urban planning are applicable and therefore helping to solve the described issues of urban sustainable growth? Is an ideal tool or method existing?

In order to achieve a sustainable urban development, from the perspective of the urban designers as well as from the perspective of urban design research, transdisciplinary collaborations need to be strengthened and the connectivity of theoretical approaches to be expanded towards practical adaptability. Transdisciplinarity is an indispensable approach but needs further development in order to solve the existing difficulties in the expert- layman communication (for laymen of certain expert fields inaccessible resources and knowledge due to technical terminology) in order to benefit from the research results of the other involved fields of expertise.

For further research approaches one of the main questions necessary to be raised at this point is: *How can we provide urban planning Mode 2 research environments with the needed and suitable knowledge management infrastructure?*

Followed by the important resulting hypotheses and questions: *Most of the urban planners and related professions do not know about existing tools of knowledge transfer and knowledge management. How can the outreach of knowledge management and knowledge transfer tools be widened and the impact of these tools increased?*

Existing transdisciplinary approaches like TIPS give important impulses to lead urban planning approaches to more sustainable results on several levels, but it does not do justice to projects which deal with the additional levels of tremendous fast urbanization and cultural differences. Such urban projects happening in China designed by western architects and urban planners face cultural differences which can't be solved alone by approaches like TIPS.

The aim has to be to match the appropriate palette of tools and methods with the fitting complex urban projects, handled by the individual transdisciplinary working collaborations. In order to achieve this, the knowledge about the possible methods and tools helping to create sustainable urban growth needs to be brought to the respected transdisciplinary project based collaborations.

From Idea to Innovation – The Role of Creativity in Knowledge Management

Anja Jannack

Department of Architecture
TU Dresden (Dresden University of Technology)
Germany

Structured Abstract

Purpose – The paper reports on a doctoral thesis at the professorship of Knowledge Architecture, an emerging scientific field at TU Dresden (Dresden University of Technology). This paper is going to focus on the meaning of creativity and its use in knowledge management.

Problem description / Background – Today’s society and work transforms into “knowledge society” and “knowledge work”. Inventive developers and managers are required in each field in order to answer ever more complex tasks and to create innovation. Yet, there is not much knowledge application of scientific results on the relationship of the innovation process and the term *creativity* into manager’s daily life.

Experiment / Approach There is a vast body of literature dealing with the term creativity. Though a clear definition of creativity and its application in terms of knowledge- and innovation-management is still absent. This paper is focusing on the main aspects of creativity defined in the literature and is introducing an architectural perspective into the discussion. The found literature is contrasted with first-hand experiences from technology and science clusters, industry-university cooperation, and other work experiences. Investigations, experiences and experiments by researchers of Knowledge Architecture form the basis for hypotheses about creative processes.

Findings / Practical implications - The process of generating ideas and innovation is complex and escapes simple description. Creativity is one of the most important variables in the innovation process, not only in its early stages. Creativity seems to be a significant success factor. Hence, future knowledge work has to be supported in two directions. Firstly: towards a theoretical discourse on the role of creativity due to knowledge- and idea-generation. Secondly: towards practical applications and translation of ideas, e.g. from architecture and design sciences towards management.

Keywords – Creativity, Knowledge, Ideas, Management, Idea-generation, Criteria

Paper type – Doctoral Thesis

1 Introduction

The paper is going to report on one component of an ongoing doctoral thesis at the professorship of Knowledge Architecture, TU Dresden (Dresden University of Technology). The aim of the thesis is to investigate in the Innovation processes and the transferability of architectural methods to this process in terms of Innovation- and Knowledge Management especially within cross-disciplinary teams.

2 The Value of Creativity

Today's society and work transforms into "knowledge society" and "knowledge work". In the developed world, innovation is the engine of economic and social welfare (Drucker, 2001). Organizations must develop the capacity to initiate or quickly adopt innovations, according to research literature as well as to popular media, since those who do not increase their rate of ex-change will lose their ability to survive (e.g. Csikszentmihaly, 1999; Janszen, 2000). Regarding the level of organization, creativity is an essential factor for innovation and consequent organizational success. In this sense Prabhu, Sutton and Sauser stated that: *"In today's competitive world, the only thing that is constant is change. A Product that may be a huge success today could be extinct tomorrow. In the backdrop of such fierce competition, new ideas and new products have become a necessity, rather than a luxury. To be competitive in the global market, organizations must develop creativity and high quality products and services."* (2008).

In order to gain innovation a wide range of innovative ideas are needed. Yet, there is not much knowledge about the early steps of the innovation process – the idea-generation-phase. From observation so far *creativity* is obvious closely related to this. However, with increasing dynamics in industries, sciences and society and the demand of cross-disciplinary teamwork in order to solve the related tasks and with adding phenomena like shifting targets, I hold that creativity is needed in all phases of the innovation process. Inventive developers and creative managers are required in each field of sciences as well as in economy in order to answer ever more complex tasks with innovative and problem-oriented ideas, products and services. In terms of managing creativity investigation so far figured out that future knowledge work has to be supported

twice: 1) towards a theoretical discourse on the role of creativity, and 2) towards its practical applications.

3 Theoretical Background and Aim of the paper

There is a vast body of literature dealing with creativity almost impossible to be completely overviewed or summarized. In the scope of this paper I am going to focus on some main aspects and definition criteria of the found literature.

3.1 How Literature defines Creativity

An intuitive conception of creativity holds that the production of new Ideas is involved (Guilford, 1950). However, creativity is not simply a matter of idea-production. It is rather defined as the production of high quality, original, and elegant solutions to problems (Besemer & O'Quin, 1999; Christaans, 2002; Mumford & Gustafson, 1988).

The problem of managing creativity and innovation is three folded: 1) the known complexity of this phenomena (Sternberg, 1999); 2) its multi-levelness, influenced by variable operating on individual, group, organizational, or environmental levels (Mumford & Hunter, 2005), and 3) the not well aligned-ness of these variables. Several organizational scientists noted that the study of team-level creativity is still an under-researched area (Kurtzberg & Amabile, 2001; West, 2002).

Csikszentmihaly, the founder of the Flow theory (1997), stated that: *“Creativity is not an attribute of individuals, but of a social system making adjustments about individuals... The social and cultural conditions, interacting with individual potentialities, brought about the objects and behaviours we call creativity.”* (1994). And Sawyer explained that: *“Creativity is a novel product that attains some level of recognition.”* (Sawyer, 2006).

And Teresa Amabile, Chemist, Psychologist and Edsel-Bryant-Professor of Business Administration and director of research at Harvard Business School, defined: *“Creativity is a process resulting in a product; it is the production of a novel and appropriate response, product or solution to an open-ended task. The response must be new, but it must also be appropriate to the task to be completed or the problem to be solved. In addition the task must be open-ended, rather having a single, obvious solution.”* (Amabile, Müller, 2008)

Surprisingly, practitioners' approaches to organizational creativity appear to better reflect the scientific literature than the scientific literature reflects applied interests and

application. The increasing attention on creativity by organizational scientists indicates, though that practical interests of work creativity is slowly influencing science (James, 2012).

3.2 How I define Creativity

“To make the most out of almost nothing.” might be the shortest answer to this question. In my definition creativity is the ability of human beings to solve problems under (time) pressure and in uncomfortable circumstance with few resources like material, tools, money, and to gain the best possible (problem-solving) solution out of these. Therefore (creative) people do not think about standardization too much. A wide range of creativity is found in the process of problem-solving e.g. in the world of sciences, engineers or production. Where one has to deliver new solutions to acute and dynamic problems with limited resources may this be tools, materials or time being available.

4 The Creativity of Architectural Processes

From observation so far, creative people often act unconventional. E.g. they use tools against their designated purpose or combine materials and processes in an unusual way. Understanding creativity is not only about the unique product moreover it is about the creative process itself. Though the result may appear as the “right” solution to answer the task in the end the way to get there is not clearly (scientifically) describable yet. Within the creative path, hard work and moments of frustrations are often included. To overcome this “uncanny valley” seems to be the creative moment on the way towards problem solving. Hence, peoples experiences, skills and their internal knowledge as well as the phenomena of peoples trust in the ability of finding a proper solution seem to be important influences on a successful creation process.

Anyway, creativity has to be taught, trained and practiced. This is not an easy task beneath daily routines and considering the diverse structures existing in our modern world. Creative workers as artists, designers, or architects appear to be useful “professional”-partners for this complex task of training and support.

Modes of (architecting) Creativity

Since 2011, researchers of Knowledge Architecture were asked to conceive and conduct creativity and innovation workshops for different stakeholders, such as scientists, teachers, administrators or innovation- and knowledge-managers. As most of the members of Knowledge Architecture are trained architects Knowledge architecture utilizes architectural processes and tools in order to develop conceptions of non-architectural items, as organizational design, product development, innovation- or knowledge management. Whereas groups and teams of divergent scientific fields and professions are focused.

By these workshop activities, a variety of creative techniques were developed, which are mostly based on modeling techniques and visualization tools, on design thinking and spatial representation. In the analysis of the workshop participant's behavior and workshop results indicated that methods of Knowledge Architecture may increase the probability of Innovation. In order to deliver a more scientific approach we developed a conceptual framework on the used modes of creativity:

- IDEATION – Idea Creation, Artificing
- PROGRAMMING – Contest and Demand analysing, describing and defining
- SELECTION- Criteria defining, Assessment and Evaluation

For each mode we collected and developed a set of tools and methods within main three categories 1) Visualization, 2) Modelling, and 3) Interaction. (For further details: "Programming Creativity: methods for Empowering Innovation in Interdisciplinary Teams" - IFKAD Proceeding 2013).

Architectural Process – an Example of a design project

To illustrate the aspects of architectural processes I shortly want to introduce my diploma project. The task was to design a multifunctional High-rise Building in Shenzhen, China. The following figures depict some of the media and modes of used in the architectural processes.

First Description of elements of the Architectural Process

During the history of this discipline architects get to make use of different modes of creativity to overcome problems of managing complex tasks and conditions. Yet, there are only few scientific investigations on understanding and exploring of this process (Alexander, 1964). Though there is limited scientific research there are is a common approach and useful methodology within the internal knowledge of the architectural discipline developed over a long time period of practice.

When it comes to creativity, I state that architecting creativity is based on knowledge, experience and trained skills. Because they have to act as generalists they have to have a common understanding and the ability to communicate with very different fields of terminology. They have a broad – but not in depth – knowledge on different contextual field as Building Technologies, Physics, Civil Engineering, Organization Structures, Laws, Societal Responsibilities, or Psychology in order to produce customer-oriented

results. Most of the architectural tasks are rather complex and often no real references are existing at the beginning of a project. Architects are working often in groups and dealing with different details of the task simultaneously. They have to loop in between different scales and to change media several times during the design process - as sketching, computing, modelling, discussing and presenting. Architectural tasks are of a never-ending nature until the project is finished or the building is built finally.

In most sample cases architects produce unique results. In this manner they are comparable to artists somehow. However, artists are using modes of “real creativity” of a more escalating character in order to find their answers. Compared to that, the architectural processes are containing a programmed creativity in order to fulfil its tasks. Though, it often includes real-creativity moments in the different steps, it is somewhere in-between real creativity and product-oriented engineering. Creativity of architecture is knowledge driven, problem- and customer-oriented.

5 The Architecture of Creativity

Yet, the main investigators I found in fields of psychology and economics. They deliver valuable insights on the architecture of creativity. But the transferability of each disciplines’ result is still an unanswered question. There is a large amount of existing knowledge on creativity, partially very deep and specific, but there are limited findings in a general moreover theoretical and area-combining explanation on the nature of creativity. From Observation so far, people’s behaviour – for instance the behaviour of the workshop participants – are indicators of creativity. If they are moving around and produce certain level of noise, or if they are silently scrabbling seems to be connected to the different modes of creativity.

So the question is still how to get creativity to work within daily live routines? There are multi starting points to be found in the recent research which has to be still transferred and made adaptable.

6 Summary

Hence the nature of Creativity is still a mystery. The process of generating creative ideas is complex and escapes simple description. Though a complete definition of creativity and its application in terms of knowledge- and innovation-management is still absent future knowledge work has to be supported twice: 1) towards a theoretical

discourse on the role of creativity, and 2) towards its practical applications. So far I assume that architectural creativity and methods are valuable for other fields in science as well and in economic especially in terms of managing knowledge work within cross-disciplinary group work

Managing reputation as part of intellectual capital management

Marjukka Nyberg

Department of Management and International Business
Lappeenranta University of Technology
Skinnarilankatu 34, 53850 Lappeenranta, Finland

Structured Abstract

Purpose - Reputational capital is part of a company's intellectual capital. Communications has been defined as main vehicle for managing reputational capital. The term communications can mean part of managerial work, referring to the communicational capacity an organization has as a whole, whereas communications conducted by a professional function forms a set of clearly distinguishable practices which can be studied.

The purpose of the research is to

- 1) look into the communications processes and practices through which the best performing publicly listed companies strive to manage their reputational capital and
- 2) test whether this correlates with better reputation, performance and better financial result

The link between performance and financial result has been proven many times, and so has the link between reputation and financial result. The impact of communication practices on reputation or performance has been harder to prove and is therefore the focus of this work.

Design/Methodology/Approach - The project will start with a quantitative analysis of appr. 100 public Finnish companies, comparing their long-time (10 years or less) data on financial performance with semantic analysis on the content of the publicity they have gained during the same period. In measuring organizational performance one or several of these measures will be used: market value vs. book-keeping value, revenue growth, share price, ROA. Some 10-15 firms that show the best positive correlation are identified and approached with a survey exploring in their corporate communications processes and practices. The survey is complemented with individual interviews and collection of communication documents from the companies. Performance measures for the companies are set by external and internal standards.

Originality/Value - Present IC research is strongly rooted in either management consultancy or accounting. The issue of reputation or brand management in a dynamic sense seldom appears in IC literature. Communications and marketing research again has focused on the correlation of brand image on consumer behavior or corporate value. There is strong evidence on these correlations, but what is missing is a genuine integration of IC management and communications research. However, now that we have moved into the knowledge-intensive business era of ours and gone through the explosive development of the internet, the concept of external reputation has gained a relevance

never seen before, and reputational capital has to be taken seriously due to its huge impact on corporate performance and monetary outcomes, such as share price and market value.

Practical implications - The aim is to produce a work that combines academic intellectual capital research and communications research, and at the same time offers new tools for business executives and for the communications industry to manage reputation and be able to measure its monetary impact. The study should produce knowledge that allows practitioners to make better decisions and improve the effectiveness of their work. The aim is to hold a *dynamic* perspective, approaching the issue from a *reputational capital management* perspective. The author will try to seek best practices and solutions to business executives' everyday problems – namely how to *manage* your reputation as far as it is possible.

Keywords – reputation, reputational capital, communications, intellectual capital.

Paper type – Academic Research Paper

1 Introduction

The importance of intellectual capital has never been as striking as today. Most of the discussion around future prospects of today's business deals with the companies' ability to manage their immaterial assets. In the present knowledge-intensive business environment this ability is the main source of success for whatever type of company, may it be in the manufacturing business or in service industry. Several studies show that intellectual capital plays a far more dominating role in building companies' market value than the tangible assets do.

The tradition of IC research has its roots in the 90s when a group of scholars started to look more closely at the intangible assets of corporations. The background of these academics was strongly rooted in either management consultancy or accounting, which obviously affected the view they had on the subject. The issue of reputation or brand management in a dynamic sense seldom appears in IC literature.

Now that we have moved into the knowledge-intensive business era of ours and gone through the explosive development of the internet, the concept of external reputation has gained a relevance never seen before. Relationships to the external world – customers, consumers, suppliers, decision makers, NGOs – cannot be handled in the traditional way that was meant when creating the concept of relationship or customer capital. The issue of trust or brand appeal has reached another level, where a lot of what is said about a company simply happens without the company being able to manage it in any way. At the

same time global internet communications have instant and far-reaching impact on companies' reputations and their performance. General understanding is that brand value and reputational value are essential parts of a company's market value, thus building financial success. Therefore reputation management cannot be ignored, but should be explored in more detail to deepen our insight in the subject.

In spite of that the importance of reputation has been largely recognized, not only in the communication research circles, its role within IC research has been close to non-existent. Going through a body of relevant IC literature from the last two decades you will find only few mentions about reputational value. On the other hand present mainstream of communications or marketing research focuses on the correlation of good or poor brand image on consumer behavior or corporate value. There is strong evidence on these correlations, but what is missing is a genuine integration of IC management and communications research.

The author also has another, personal reason for being interested in the chosen subject. Having been engaged in public relations and communications consultancy throughout one's professional career (apart from the last 15 years of running a business intelligence service firm) meant facing clients' frequent requests for evidence concerning the concrete benefits of reputation management. Communication research concentrates either in the effects of a good or bad reputation defined as an overall opinion of the relevant target groups, or in operational/tactical measurement of communications activities, such as media coverage or individual campaigns. Reputations are measured as end results of something, in terms of audience or consumer response or brand appeal. Very little has been done on the impact of activities leading to a particular kind of a reputation, and even less on the potential correlation of these activities and financial performance. The aim of the author is to hold a *dynamic* perspective and approach the issue from a *reputational capital management* perspective. The research aims at seeking best practices and solutions to business executives' everyday problems – namely how to *manage* your reputation as far as it is possible, and being able to *demonstrate evidence on its financial benefits*.

2 Literature review

2.1 About intellectual capital research and literature

In the last 15-20 years the rise of the 'new economy', principally driven by information and knowledge, has caused an increased amount of intellectual capital (IC) research and business literature. Intellectual capital is implicated in recent economic, managerial, technological and sociological developments in a manner previously unknown. There is much to support the theory that IC is instrumental in determining corporate value (Petty and Guthrie, 2000).

Brennan and Connell (2000) have composed an extensive list and classification of intellectual capital frameworks and indicators. They describe three different accounting standards' way of dealing with the definition and recognition of intangible assets. Main part of the paper consists of a list of empirical research and various frameworks developed in classical IC literature. They discuss both classification and management of intellectual capital within the listed frameworks. Measurement tools and indicators are discussed. Thus the work provides a solid and systematic overview of work that has been done so far. The authors particularly stress the importance of a dynamic approach, including acquiring, producing and increasing intangible resources, and measuring and managing intellectual capital. From the accounting point of view, both producing and managing/measurement are investments, and the benefits can be calculated in a grid where the investments and their costs are compared with financial or non-financial outcomes.

According to Edvinsson and Malone (1997), IC is about knowledge, applied experience, organizational technology, customer relationships and professional skills, which make a firm competitive in the marketplace. The importance of IC from the value perspective comes from the gap between an organization's market value and book value. They separate IC into three categories, which include Human, Structural and Customer Capital. Human Capital covers the knowledge, education, skills and characteristics of the members of the organization. Structural Capital falls into two categories: outcomes of knowledge conversion, and the intellectual properties of the firm. Customer or Relational Capital refers to the ability of an organization to interact in a positive manner with the external stakeholders and thereby actualize the wealth-creation potential of Human and Structural Capital. The authors also discuss the so-called SKANDIA model that separates

one more type of intellectual capital, namely Renewal and Development. They suggest specific measures for each kind of capital and recognize the problem of having qualitative, monetary and percentage-based measures, which are hard to co-ordinate in one single index. Edvinsson's and Malone's solution to the problem is the coefficient of IC Efficiency iC , where i is calculated on the basis of an average value of a percentage-based measure and C is money.

Sveiby (1997) as one of the leading long-time theorists on IC divide intangible assets in three parts, external structure, internal structure and individual competence – which could be seen as equivalents to customer & relational capital, process capital and human capital. He focuses on companies operating in the knowledge era, points out the difference between being a knowledge based or information based business, defines knowledge as a capacity to act and in a business context equivalent to competence, and discusses ways professional knowledge and competence is transferred in an organization. Managing external structures is a vital part of managing intangible assets, and in this context he also recognizes customers being particularly important in generating intangible revenues and contributing with their image – thus image or reputation is part of intangibles.

Roos, Roos, Dragonetti and Edvinsson (1998) present an IC Index model, aimed at helping business decision makers to manage their company based on facts and measurements. Their recommendation is to start from a business idea and based on it define the company's Key Success Factors (KSF). Using these as a starting point and selecting the preferred model for forms of intellectual capital one develops indices, set of measures for each KSF. As a result of capital-specific indices it is possible to calculate a certain general IC Index that can be used in predicting and enabling better decision making. The authors' approach is dynamic and practice-oriented, and they call it the Process Model. Their definition for Intellectual Capital also underlines this: *Intellectual capital as a language for thinking, talking and doing something about the drivers of companies' future earnings.*

Brooking (1996) has produced a very straightforward, practical guide to understanding, measuring and developing intangible assets. She uses the breakdown of IC which covers market, human-centered, intellectual property and infrastructure assets. She guides the reader through an IC audit process that helps executives to analyze the

intangible capital in their organization, however like many others, without mentioning image or reputation.

In their overview Petty and Guthrie seek to review some of the most significant literature on IC and categorize it in a way that provides an understanding of how and why the IC movement has developed as it has. They then use the review as a platform to identify and establish paths for future research. They particularly focus on IC measurement and reporting, although they acknowledge the importance of IC management as well. They agree on the definition of IC as ‘the economic value of two categories of intangible assets of a company: 1) organizational (structural) capital and 2) human capital (offered by OECD in 1999). This definition locates IC as a subset of, rather than the same as, the overall intangible asset base of a business. Interestingly, Petty and Guthrie mention reputation as being an item that does not form part of a company’s intellectual capital, but as a by-product of the use of a firm’s intellectual capital.

The authors run through the history of IC literature and discuss issues such as distinctions between intangible assets and intellectual capital, delineation between knowledge management and intellectual capital, and problems with the inability of the present accounting practice to measure ‘new’ intangibles. The review then classifies all major contributions to the IC development and compares the various classification schemes, as well as different reporting and measurement systems for both financial and non-financial measures.

Andriessen (2004b) states that the IC community has entered a phase of consolidation. He himself has focused on the methodology of IC research and in particular on the “why” and “how”. He points out that it is often unclear what the organizational problem is the methods intend to solve, and additionally there seems to be confusion about the distinction between valuation and measurement. According to Andriessen the motives or problems IC valuation or measurement is intent to solve can be grouped under three main headings: Improving internal management, Improving external reporting and Transactional and statutory motives. Each of these contain a number of more specific problem definitions; all in all the author counts 18 different problems addressed in recent research. He discusses each of them in detail and calls for less focus on solutions and more evidence for problems that can be solved with these solutions.

Another important issue he raises is the inconsistency of methods. A distinction can and should be made between financial valuation methods, value measurement methods,

value assessment methods and measurement methods. As part of the consolidation process more research is needed into the strengths and weaknesses of these approaches, related to the type of problems that need to be solved.

In his book (2004a) he systematically analyses 25 commonly used methods from the point of view of identifying which category of valuation or measurement method they belong to and whether they really deal with intangible resources or something else, whether they are capable of dealing with a wide array of intangible resources and whether they offer tools for looking forward and helping users to choose between different strategy options. Andriessen also designs a new model, Weightless Wealth Tool Kit, and tests it on a sample of companies. According to him IC methods should help in solving future orientation and strategy development and creating resource-based strategies. He also starts with a financial valuation of a company's core competencies and designs a value dashboard, which gives the management insight into the company's strengths. This way he believes that information is converted to action through a common language and management agenda that helps in building success and future earnings. His own toolkit seems to work best with knowledge-intensive, middle-sized companies.

A recent systematic review on empirical IC literature comes from Inkinen, who lists different categories of IC stocks and identifies how they are linked to organizations' value creation. He mentions that the phenomenon of IC has been developed in two phases, the first being the era of conceptualizations, whereas the current stream is more diversified and focuses on a large number of issues. According to Inkinen IC research has become a global issue and it covers various types of industries. Majority of the authors agree on three main types of IC stocks, namely Human, Structural/Organizational and Customer/Relational Capital. Some of these seem to be overlapping and depending of each other. Increasing attention has been paid to a fourth dimension of IC, Social Capital, which from the point of view of this research is particularly interesting, as it represents the quality of relationships among people and groups, i.e. stakeholders, and could be seen as equivalent to the concept of reputation. At the same time image and reputation can be part of Relational Capital. In fact in a large number of the papers reviewed by Inkinen describe reputational features in the context of Customer/Relational/Social Capital, but only a few directly mention the concept of image and reputation. 42 out of the 44 works he lists conclude that the effect of IC stocks on corporate performance is positive and significant.

Kianto, Andreeva and Pavlov (2013) have focused on the dynamic dimension of intangibles. They claim that only a handful of studies have empirically examined how the strategic management of intangibles impacts value creation. Most of the existing studies have assessed the value or level of existing intangible assets and then correlated this with performance outcomes. There are far less studies examining to what extent these intangible assets are consciously managed in firms and how their management impacts the success of organizations. The authors define IC management as strategic planning and implementation related to the knowledge-based assets in the firm, and propose a process for the IC management, which includes defining key knowledge assets, identifying processes, planning activities and implementing and monitoring actions. They also conduct a survey testing the connections between IC management, competitiveness and financial performance. They come to the conclusion that the correlation between IC management and competitiveness does exist, but no direct correlation between IC management and financial performance. The impact of IC management is mediated by competitiveness. Time factor is identified as crucial: the results would demonstrate a stronger and direct impact of management on financial performance, had performance data been acquired at a later point in time. It would also have been preferable to obtain financial information from external instead of only internal sources.

In Kianto's earlier paper (2007) a dynamic aspect of Intellectual Capital is discussed from three different perspectives: as value creation processes, activities and change capabilities. Instead of existing statistical data on individuals, structures and outcomes the dynamic research focuses on social processes and organizational characteristics. The research has clearly shown that the main value creation factor is how resources are exploited and explored, rather than what they are as such. The author calls for more research focus on particular activities through which intangible resources are leveraged, developed and evaluated in organizations.

2.2 About reputation management research and literature

Cornelissen (2011) offers a compact set of definitions for concepts that deal with what in the IC literature is covered by 'relationship capital':

Corporate image is the way a company is perceived, based on a certain message and at a certain point in time, the immediate set of meanings inferred by an individual in

confrontation or response to one or more signals from or about a particular organization at a single point of time.

Corporate reputation is defined as an individual's collective representation of past images of an organization (induced through either communication or past experiences) established over time.

Corporate personality or *culture* equal the core values of an organization, as shared by its members.

Corporate identity is defined as the profile and values communicated by an organization, the character a company seeks to establish for itself in the mind of its stakeholders, reinforced by consistent use of logos, colors, typefaces etc.

One of the primary ways in which organizations manage relationships with stakeholders is by building and maintaining their corporate reputations. Reputations are established when organizations consistently communicate an authentic, unique and distinctive corporate identity towards stakeholders. (Cornelissen 2011).

He claims that corporate reputation has a strategic value for the organization that possesses it. It ensures acceptance and legitimacy from stakeholder groups, generates returns, and may offer a competitive advantage as it forms an asset that is difficult to imitate. A general principle for corporate communication practitioners is that they need to link the corporate identity – the picture of the organization that is presented to external stakeholders – to the core values that members of the organization themselves associate with the organization (culture) and define the organization's mission and vision (organizational identity). A good corporate reputation, or rather the corporate identity upon which it is based, is an intangible asset of the organization because of its potential for value creation, but also because its intangible character makes replication by competing firms more difficult.

Aula and Mantere (2008) have recently offered an interesting and different view on the creation of corporate reputations. Instead of considering reputation as capital they analyze it as an interpretation that develops in an arena of meanings and opinions. Interestingly this theory claims that reputation management is partly outside the control of the subject itself; reputation lies to a great extent elsewhere than in its actual subject, i.e. among the company's audience, stakeholders, interest groups and others, in the interpretations of those assessing the subject.

The authors recognize reputation as having real value to organizations, and reputation-building being a competitive activity. Reputation is seen as a negotiation of meaning, taking place between an organization and a number of stakeholders. Strategic management tools are often based on this synthesis of external demands and internal conditions, but in strategic management the market or economic environment is considered to be the most significant for a company. Instead Aula and Mantere think that the strategic management of reputation requires a quite different view of what constitutes an organization's environment. It should be seen above all as an environment of meaning, where the organization and its publics encounter each other and create representations and interpretations.

In their arena model the authors differentiate between the company's own notions about itself ("what we are"), the way the organization perceives how others see it ("how they see 'what we are'") and how the public perceives the organization ("what it is") – "between being" (factual reality) and "seeming" (expressions about reality). Accordingly, reputation is formed through targeted communication and actions that the company takes, as well as through people's perceptions and understanding of the 'true' nature of the company.

Fombrun and Van Riel discuss six different approaches to reputation and encourage further research in each of them, with the aim of building integrated models of reputation research. They list the economic view, consisting of the game theorist framework and signaling theorists' framework, then the strategic view, the marketing view, the organizational view, the sociological view and the accounting view. Each of these schools tries to approach the reputation concept for different reasons. The authors call for better integration and propose the following definition of corporate reputation: *A collective representation of a firm's past actions and results that describes the firm's ability to deliver valued outcomes to multiple stakeholders. It gauges a firm's relative standing both internally with employees and externally with its stakeholders, in both its competitive and institutional environments.*

Majority of reputation research deals with stakeholder perceptions, and they are mainly conducted by practitioners, who themselves largely acknowledge the limitations of the methods. Fombrun, Gardberg and Sever (1999) examine some of the most used indices and document their shortcomings. They then present a new instrument – the reputation quotient RQ – to measure corporate reputations and improve the validity and

reliability of such measurements. According to authors the methods most commonly in use are based on psychometric ratings, and they suffer from two key biases: they lack content validity by focusing on the perceptions of a limited respondent pool of corporate leaders and financial analysts, and survey items do not capture the perceptions of multiple stakeholder groups that are necessary for a valid measure of corporate reputation. The method undergoes a series of large tests by varying stakeholder groups and sample sizes. The proposed method RQ is a construct that combines the measurements of two factors: Emotional Appeal and Rational Appeal. It strives to capture the perceptions of multiple stakeholder groups and establish the multi-dimensionality of the construct. This work is one example of the methods used in reputation research, and it illustrates the type of challenges current reputational measurement deals with.

Recently a strong focus has been put on trying to evaluate the impact of a good reputation on corporate financial performance. This links together the concept of reputation as capital – equivalent to the concept of intellectual capital – and financial performance. However, research does not deal with the dynamic concept of reputation management, the underlying processes and actions companies undertake to manage their reputation. These research projects compare strengths of brands with the market values of the companies and state that there is a strong correlation between brand image and market value or other financial indicators.

Fombrun and Van Riel (2003) have continued their work in this direction and list a number of research projects stating the correlation of a strong brand and financial performance. They claim that a good reputation impacts the operational result of a company and therefore future earnings, because it reinforces stakeholders' belief in the competitiveness of the company. Corporate reputation – being part of the intangibles of a company – improves the market value of the company, whereas this works the other way around as well. There are many other ways the reputation impacts the financial result: employees tend to work harder and produce more when they are emotionally engaged in a brand, a strong reputation succeeds in employing best talents, and it is easier for the company to negotiate low production costs with suppliers, due to the attractiveness and brand value they bring to partners.

Fombrun and Van Riel also illustrate their theory on the role of communication capital: according to them reputation together with intellectual capital form what they call immaterial capital. As good reputation management requires effective gathering of

information from the business environment, reputation management overlaps with other types of intangibles – what you do for the reputation, also improves your overall business performance due to better decisions concerning other functions than communication.

The authors have based their Reputation Quotient (RQ) on a large number of surveys done on well-known consumer brands, but they point out that the stakeholder groups that have been researched usually cover only a limited group of people, who see the company from their specific point of view. Generally consumers tend to value emotional image factors (social responsibility, favorable working atmosphere, good products etc.), whereas the financial community values factors connected with the business performance of the company. Correlations have been found between the Reputation Quotient of a company and the behavior of stakeholders that affect the corporate financial performance, as well as between the RQ and the company's financial result, its sales and revenue growth, and market value. A particular connection exists between the change of RQ and change of market value. The correlation is however not simple. The best RQ companies differ largely in terms of financial performance, and the market situation plays a substantial role. In an upward developing market companies with high RQ generate better share earnings than industry average, and companies with low RQ clearly smaller earnings. In a downward trend high RQ companies create a bigger risk, as their share earnings follow industry average more than companies with low RQ.

One interesting issue is whether companies with good reputations are better to sustain superior profit outcomes over time. Roberts and Dowling (2002) matched data from Fortune's Most Admired Companies with financial data from the corresponding years, combining different reputational measures and financial measures (ROA, market value and turnover) and compared the results with industry averages. As a fundamental mechanism they mention that a firm's financial performance always affects its reputation. Accordingly the connection is complex, and therefore they decomposed overall reputation into a component that is predicted by previous financial performance, and that which is 'left over', and found that each element supports the persistence of above-average profits over time. All firms experience a variety of different financial periods, whereas firms with relatively good reputations are significantly more likely to exit a below-average performance position at any point of time. Good reputations also help poor performing firms in their efforts to return to profitability. The findings complement existing studies of the relationship between reputation and financial performance by articulating the dynamic

implications of good reputations. They are also consistent with the growing body of strategy research that links high-quality intangible assets with sustained superior performance. A firm's financial reputation has a strong impact on profit persistence, suggesting an important self-reinforcing dynamic. Some of the things that firms do to improve profitability also enhance their reputation, and this enhancement, in turn, makes it easier for firms to sustain superior performance outcomes over time. The results also suggest that reputation works in different ways, depending on the initial performance position of the firm.

Communication is often defined as a major vehicle for managing reputation. It can be seen as a set of activities based on corporate strategies and run by a professional, specialized corporate function. It can also be seen as something that cuts through and involves the whole organization, as comprising both internal communications and communications with stakeholders and other groups outside the organization. In other words, communications is a means for engaging personnel and other stakeholders, building trust and motivation.

Malmelin (2007) sees communication as an integral part of management and as a function that impacts the organization's performance and success in increasing its intangible assets. In his model he identifies communication as a function that fulfills a role in building and increasing the company's intangible assets.

Malmelin advocates an understanding of communications as an intangible organizational asset – as communication capital. His model for communication capital covers four types of capital, which can be seen as supporting functions for the corresponding types of intellectual capital. *Juridical* capital is about patents and copyrights, the company's immaterial property, information masses, databases and documented information that the company owns. Also documentation on earlier projects and activities, as well as surveys and assessments and corporate identity manuals etc. belongs to this category. *Organizational* capital means communications practices and systems, styles of corporate management, effectiveness of internal communications, trust of employees on the organization and other elements of internal cohesion and engagement. *Human* capital from a communications point of view is about personal communication competence residing in people, brand management and interactive corporate communications, and it underlines the importance of all employees being responsible for furthering the achievement of the company's objectives. *Relational*

capital has to do with the company's interaction with its customers and other stakeholders, about building brand equity and understanding the consumer or the client.

Malmelin's model of communication capital can be used in charting, analyzing and measuring an organization's communications resources and processes.

A substantial number of works have been written by scholars focused on the excellence and quality of the methods companies use when conducting communications. These books and research projects aim at assessing communications methods in order to build best practices and set normative standards.

The best known of these is produced and edited by Grunig's working group (Grunig et al. 1992) and builds a sort of a foundation for what has been considered to be excellent public relations. The editors do not engage themselves in evaluating the financial implications of 'good PR' for a company. Their philosophy goes even further, as they do not see reputation management as anything that should benefit the company alone but mutually both the company and the society around it. They are mainly interested in stating requirements for good communications and presenting ways to measure whether communications actions of individual companies meets the predetermined goals. They present a comprehensive model for the implementation levels and impact levels for communications and public relations, with the ultimate aim of changing interest group attitudes and behavior. This is a very typical set-up for communications measurement techniques, as it concentrates in measuring only tactical and operational performance within the communications function. The correlations between activities and corporate strategic outcomes are not measured.

Interesting is though that the group considers PR being excellent when it is an integral part of an organization's strategic management process – meaning that everything that is done is being done because of corporate strategic goals, which in turn aim at financial success.

When defining criteria for excellent communications the book searches in the literature dealing with excellence of overall management of organizations. They also claim that excellence in communication is a characteristic of excellent organizations, but that excellent communication can help to make organizations excellent. This conforms easily with the view that reputation management is part of an integrated system of building intellectual capital and financial benefits. The book identifies 12 characteristics that appear repeatedly in the literature and derive implications for public relations from

each of the attributes. These attributes may be useful in considering ways to measure reputation management processes in my own study. They include such as human resources, organic structure, intrapreneurship, symmetrical communication systems, leadership, strong participative cultures, strategic planning, social responsibility, support for women and minorities, quality as priority, effective operational systems and a collaborative societal structure.

Cornelissen (2011) describes in detail the processes and contents of conducting corporate communications, starting from the development of an overall communication strategy across communication disciplines and stakeholders and in line with the overall corporate strategy of an organization. He then discusses the processes of planning and managing strategic communication programs and campaigns as parts of an overall communication strategy. Furthermore, he lists common corporate communication measurement methods. Research helps in establishing the effects of communication campaigns and activities, as well as in documenting the organization's reputation and identity in the eyes of its stakeholders. The book also goes deeper into the various disciplines of communications with practical advice in what works and what does not.

These normative suggestions for corporate communication practices by Grunig et al. and Cornelissen can be used as a basis for designing the research set-up for reputation management processes in the companies that will be studied.

Another view on the quality of communications is offered by Coombs and Holladay (2007), who use the term *public relations* – as substitute for maintaining reputation – throughout their book. They want to develop a more complex and complete understanding of the practice of corporate public relations, claiming that the term is widely misunderstood and misapplied. They define public relations as *the management of mutually influential relationships within a web of stakeholder and organizational relationships*. When this is done with success, it creates a dialogue, a two-way exchange of messages and influence between organizations and stakeholders, which is an effective and ethical way of cultivating and managing these relationships. At the end both the company, its stakeholders and the society, are beneficiaries, as it offers a mechanism for people to be involved and get their messages through, at the same time as the company is pursuing their interests.

In the planned study a two-way mutual communication approach will be applied as one of the criteria for excellent reputation management in the set-up, when analyzing the

communication quality and processes of the object companies. A decade ago it would not have been possible for a firm to engage in a dialogue with its environment to the extent it is possible now. In fact, organizations are forced to listen to their customers, consumers, influencers and decision makers in the society on a constant basis, with the ever-existing global web and social media. This creates both opportunities and threats and puts high pressure on communication practitioners. What Grunig called symmetrical communication systems and two-way communication, has become everyday reality for all organizations. Companies increasingly need to put in place procedures and practices in order to manage their reputation and the risks involved as they set out to engage with the wider community in the social web. Reputation management process now consists of a constant flow of three stages: participating, measuring and monitoring. However, little is known about the practices on strategic level.

3 Preliminary research plan

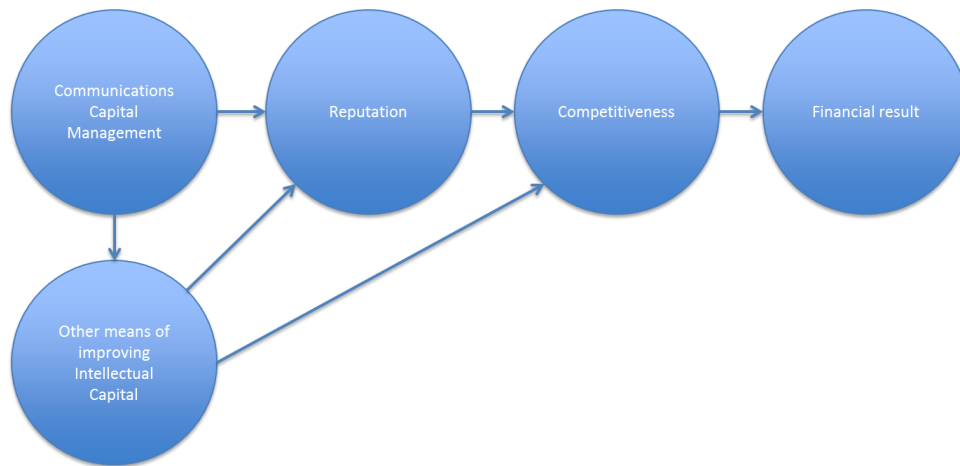

3.1 Scope and focus

The research issue will be approached from a *reputational capital management* perspective. On one hand reputation is something that a company possesses, a part of its intangible assets, and it can be measured in terms of stakeholder or public opinions. There are a large number of research projects exploring the connection of an existing reputation and the financial performance of a company. This alone does not build a new perspective on the reputation issue and is therefore not in the focus of this work. As opposed to a static view on reputational/IC capital, there is a more dynamic aspect to be considered, namely the way an organization manages its intangible assets, i.e. defines, identifies, plans, implements and monitors them – in this case its reputational assets.

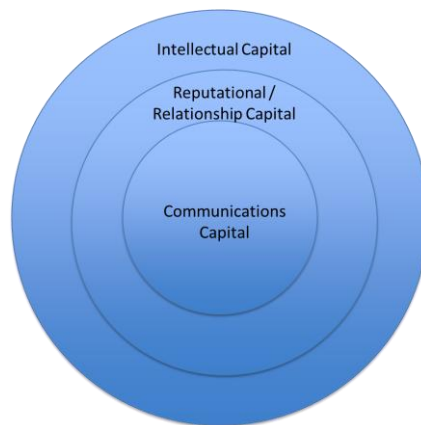

There is a further distinction to be made. Communications as part of managerial work refers to the entire communicational capacity an organization possesses, and the methods and processes it uses for driving its external and internal reputation, thus influencing its intangible assets in general. However, communications conducted by a professional corporate function forms a set of clearly distinguishable practices which can be studied. Studying the entire scope of activities affecting a company's reputation, including day-to-day business decisions, which influence people's real life experiences of the company and thus contribute to building intellectual capital, will fall outside the research focus.

The purpose of the study will be

- 1) looking into the communications processes and practices through which the best performing case companies strive to manage their reputational capital and
- 2) testing whether this correlates with better reputation, performance and better financial result

Another way of describing the relationship between communication capital, reputational capital and intellectual capital is the following:

The aim is to examine to what extent this asset of reputational capital is managed, and whether reputation/communications management has an impact on the performance and the financial results of a company

Preliminary research hypotheses:

H1: The more intensively an organization applies reputation management practices, the better reputation it will gain.

H2: The more intensively an organization applies reputation management practices, the better it is likely to perform.

H2: The more intensively an organization applies reputation management practices, the better financial performance it will reach.

H3: The better reputation, the better performance, and the better financial performance.

3.2 Design/methodology

The project will start with a quantitative analysis of approximately 100 public Finnish companies, comparing their long-time (10 years or less) data on financial performance with semantic analysis on the content of the publicity they have gained during the same period. In measuring the financial performance of the companies one or several of these measures will be used: market value vs. book-keeping value, revenue growth, share price, ROA. Measuring the amount and quality of media publicity following criteria are used:

- the volume of media publicity
- the type of media (editorial or social)
- the favorability and content of the publicity, defined as messages that contribute to a positive reputation

10-15 firms that show the best positive correlation between chosen financial measures and chosen media publicity criteria are identified and approached with a qualitative survey, which explores in their communications practices. The survey is complemented with individual interviews and collection of communication documents from the companies.

In designing the elements of the survey and the structured interviews, the framework of four categories of communication capital created by Malmelin will be used. Research questions are modelled to monitor the level of sophistication and accuracy in each of the categories. Although the concept of communication capital is not used in the study, this structure captures well the various practices and assets a company needs to manage in order to influence its reputation. The research aims at assessing whether the communications strategy, and tactical and operational activities employed contribute to building intellectual capital, as defined in the corporate strategy.

Research questions cover:

Juridical reputation assets: communicational immaterial property rights, information masses, databases and documented information that the company has the right to use. Examples: Graphic guidelines, typographic manuals, plans and strategies for different communications functions, as well as documentation on earlier projects, activities, surveys and research.

Organizational reputation assets refer to the organization's communications practices and procedures that are not dependent on individual people: systems and styles of management communications, the organization and management of the communications function, the role and importance that is given to the communications function, its representation in the corporate management and on board level. Standardized practices and the organization of various types of communications activities, such as media relations, brand management, social media engagement, market intelligence etc. belong to this category.

Human reputational assets: the skills and competencies of the people conducting professional communications in the company, which refer to a broad range of personal attributes, including the individuals' knowledge, skills, experiences, characteristics, abilities, and qualifications. It also covers the competencies of outsourced resources and the quality control maintained when managing them.

Relational reputation assets refer to the level and quality of diverse relations between the company and its stakeholders, which can be divided into business partners and external stakeholder groups. As manifestation and documentation of these assets various types of opinion and media (and social media) research will be used. The extent to which stakeholder opinions and corporate publicity contain messages that are favorable to the company and enhance aspects of the type of intellectual capital the company wants to be known for, is measured.

Performance measures for the companies are set by external and internal standards. Because the object companies are publicly listed, external financial information is easily available. Other potential performance measures, such as different comparisons to industry average – successful product launches, time-to-market, effectiveness of product development, leadership position within the industry – can be based on internal or peer assessments, as well as industry statistics.

3.3 Research structure and presentation of results

A preliminary plan for the presentation of the results consists of 3-4 articles, namely

Article 1: *The Correlation Between Media Publicity and Financial Success of Listed Finnish Companies* – based on the quantitative research

Articles 2-4: deeper exploration in the communicational practices and assets that make it possible to distinguish the best performing companies both in terms of reputation and financial success. These articles could potentially include

- Presentation of the role and importance of communication strategies as part of corporate strategies in the best performing companies
- Analysis on the impact of effective social media communications in the best performing companies
- Analysis of a successful integration of communications and business intelligence, which makes it possible for the best performing companies to run successful two-way communications

4 Final remarks

The aim of the research project is to open a new path within the present intellectual capital research, leading to further inspiration among both academics and communication practitioners. As stated by a number of authors, there is a clear lack of research here, calling for deeper insight and further research in this particular field. Hopefully this work will generate new insights and valuable information guiding to better everyday business decisions as well.

Economic effectiveness and intangible investment in Lithuania

Ilona Bartuseviciene

Faculty of Economics and Finance Management
Mykolas Romeris University
Ateities st. 20, LT-08303 Vilnius, Lithuania

Structured Abstract

Previous research regarding intangible assets and their possible influence over the effectiveness encourages governments to change their perspectives towards the assessment of economic effectiveness. Tangible assets such as equipment, plant, office buildings are no longer considered as competitive recourses contributing towards long lasting competitive sustainability (Benevene and Cortini, 2010; FADUR, 2013). Thereafter intangible assets are becoming the drivers of a long lasting competitive advantage in economy (Suriñach and Moreno, 2012; Mackevičius and Jarmalaite, 2011; Fadur etc., 2013; Goodridge etc., 2013). Countries, such as United Kingdom, Japan and the United States, have already exceeded the investments in the intangible assets as a share of Gross Domestic Product (GDP) compared to the investments in tangibles (Corado *et al*, 2013; Goodridge, 2013). In July 31, 2013 the United States Bureau of Economic Analysis adopted a policy where Research and Development (R&D) were categorized as an investment on the government's books rather than an expense (BEA, 2013). Corado *et al* (2012) argues that capitalizing intangible assets changes the perspective of the indicators that account for economic effectiveness. Chua and Goh (2009) pointed out, that gaining and sustaining the competitive advantage for an economy, one has to identify main components of the intangibles, invest accordingly and capture the return from these investments. Many studies have concluded that investments in intangible assets increase future output and consumption for the entire economy (COINVEST, 2013; INNODRIVE, 2013, INTAN Invest, 2011). According to Corado *et al* (2012) the key point again is whether an increase in intangibles yields returns at some point in the future in the form of higher production efficiency and improved product quality. Webster and Jensen (2006) argues, that certain intangible assets do not meet the characteristics associated with the investment. They are not identifiable, non-rival, sometimes they are not even assessable, therefore quantitative assessment on the returns of the investments of the intangible assets might be challenging. Intangible asset policy in Lithuania follows traditional accounting principles, where most of the intangibles are excluded from the government books. Statistics department provides certain macro level data such as investments into R&D. Konstatinos *et al* (2013) defended, that the size of the investment in R&D is not enough to get a grasp of the intangible asset essence and impact in the economy. According to the study carried out in France, the investment into R&D starting 1995 up to 2010 has increased by 1,9 percent, although the investments into other intangible assets such as human capital, knowledge, networks etc. has followed the increase from 7,4 percent up to 10,6 (OECD, 2013). Such data implies that intangible assets other than R&D are more substantial to our economies, therefore, it is important to identify those assets, assess the

investment accordingly and measure the impact of these investments on the economic effectiveness.

Purpose –The objective of this paper is to investigate intangible investments in Lithuania and assess their impact on the economic effectiveness.

Design/methodology/approach – Analysis and review of scientific literature, and data statistical analysis.

Originality/value – The present study represents a step forward in the understanding of the impacts of intangible assets on economy effectiveness in Lithuania, which still follows traditional accounting practice. The study was performed at the macro level using adaptive model proposed by Corado (2012), where intangible assets are categorized as computerized information, economic competencies and innovative property. The model was adjusted to the available data. The results show the investment level of the intangibles as well as the association with the economic effectiveness of the state.

Practical implications –Knowledge based economy requires innovative methods to assess its effectiveness. Lithuania’s policies regarding intangible assets follows traditional theories, therefore it is very important to identify the level of intangible investments, not recorded in the accounting books and define it’s impact on the economical effectiveness and this will add value to the current status and contribute to a better assessment. Such study provides a benchmark possibility, which would be useful for Lithuania’s potential.

Keywords – Intangible assets, economic effectiveness, intangible asset assessment, intangible investment.

Paper type – Empirical study

1 Introduction

Within the last two decades economists and policy makers has been putting much effort to explore whether intangible assets influence the effectiveness of the economy. Fudur et all (2011) states that economies of developed countries has dematerialized. Economic systems tend to become the systems of technological ideas and innovation (op. cit. Bianchini, 2004, p. 58) Tangible assets such as equipment, plant, office buildings are no longer playing an important role in today’s advanced economy. Increased knowledge and competencies allow modern economies to improve their effectiveness, create more value and consequently become more competitive (Konstantinos et al, 2013). Based on world bank report growth requires improvements in ‘hard’ (tangible) and ‘soft’ (intangible) infrastructure at each stage (op.cit. *Justin Yifu Lin, 2011*). According to the reports from Organization for Economic Co-operation and Development (OECD), countries, such as United Kingdom, Japan and the United states, have already exceeded the investments in the intangible assets as a share of GDP compared to the investments in tangibles (OECD, METAI). If intangibles are playing such an important role in today’s

economy, it is natural to raise questions, whether these investments are worthwhile, and how much should the economies invest to increase their effectiveness.

2 Economic effectiveness and the intangibles

Economic assessment has always been a priority for every government. Limited resources; increased consumption requires innovative economic models to maintain the sustainable growth of each country. Mouzas (2006) emphasized two indicators to assess the performance: the *efficiency* and the *effectiveness*. For economists, policy makers and investors these two terms might be synonymous, yet, each of these terms have their own distinct meaning.

Effectiveness ('doing the right things') oriented governments are concerned with output, sales, quality, creation of value added, innovation, and cost reduction. It measures the degree to which a goal is achieved or the way outputs interact with the economic and social environment. Usually effectiveness determines the policy objectives or the degree to which an economy realizes its own goals (Zheng, 2010). According to Heilman and Kennedy – Philips (2011) economic effectiveness helps to assess the progress towards mission fulfillment and goal achievement.

Efficiency ('doing things the right way') measures relationship between inputs and outputs or how successfully the inputs have been transformed into outputs (Low, 2000). Effectiveness and efficiency are exclusive, yet, at the same time, they influence each other; therefore, it is important for policy makers and economists to assure the success in both areas.

The main problem with the knowledge economy, and intangible investment, in general, is not that the expenditure is hidden, but rather that it is loosely connected to output. Investment in assets such as software, databases, innovative property, and market research, and reputation, human and organizational capital is the main way through which the available stocks of knowledge and information are augmented. Intangibles are regarded as the cornerstone of the 'new' or 'knowledge' economy that emerged with the advent of the information technology revolution, although for economists such as Paul Romer, the role of intangibles in economic growth was established much earlier. According to his argument, what makes people of this era wealthier than their ancestors 100000 years ago is not the quantity of available raw materials, which has not changed

over time, but the ability to rearrange raw materials in ways that make them more valuable (op.cit. Konstantinos et al, 2013; Kaufmann et all, 2009).

The reality is that until now policy makers treat intangible assets as intermediate expenditure, which does not appear in either investment or Gross Domestic Product data. Marrano et al. (2009) states that once intangibles are treated as investment and not as intermediate consumption market sector Gross Value Added (GVA) in the UK rises significantly (13% in 2004). Similar path was demonstrated in Europe According to the OECD (1998, p. 37) in 1992, the share of intangibles in GDP was 11% in Sweden, 10.8% in the Netherlands, 9.4% in Denmark and Belgium, 9.2% in France, 8.5% in Austria and 8.2% in Germany.

Another problem arise when intangibles are being treated only as the production input (e.g. educational human capital, employment in R&D and IT, applied patents by inventor, etc.). This model highlights the importance of intangibles in the production process, although it fails to recognize their impact on the output side. As a result, the question remains unanswered – what is the impact of intangibles, what kind of the results they produce, what is the rate of return the investors should be expecting. In other words, it is not the size of investment that is hidden, but the connection between the input and the output (Konstantinos et al, 2013).

Within the conventional System of National Accounts, expenditure on intangible assets, such as research and development or human and organizational capital, is not considered either as part of Gross Value Added (GVA) or as investment. Although Marrano et al. (2009) argues that these assets should be included into national accounts, the study he had performed in the UK demonstrated, that after these assets have been accounted market sector GVA has increased macro figures by as much as 13% in 2004 (Konstantinos et al, 2013). This study was performed using Corrado et all (2005) methodology, which investigates the potential of intangible assets and economic growth. Here intangible assets are classified into three major blocks:

- **Computerized information:** software and databases.
- **Innovative property:** R&D; design; product development in financial services; mineral exploration and spending on the production of artistic originals.
- **Economic competencies:** market research; advertising; training; organizational capital (own account and purchased).

The analysis of Ferreira and Hamilton (2010) suggests that countries wealth and growth potential relies on two areas: 1) Human capital; 2) Institutional capital.

Investments in human capital today will assure benefits in the future. Institutional capital measures the extent to which policies and rules are applicable. In their Worldwide Governance Indicators (WGI) research project, Kaufmann, Kraay and Mastruzzi, provide data on five additional dimensions of governance: voice and accountability, political stability and absence of violence, government effectiveness, regulatory quality and control of corruption. These indicators are highly correlated -the lowest pair-wise correlation coefficient in our sample is 0.76 between political stability and regulatory quality (op. cit. Ferreira and Hamilton, 2010).

There has been quite a discussion whether intangible assets could be approached as the investment. Broadly accepted concept of intangible assets states, that intangible assets claims to future benefits that do not have a financial or physical embodiment (Bianchi & Labory, 2004; MORE AUTHORS). According to Diefenbach (2006) intangible concept has no materiality, it is not a paper with the idea written on it, but the idea itself, in addition intangible assets are renewable which is not the case with certain tangibles such as ecosystems. Another important aspect of the intangibles is ability to change while being used. In the consumption process tangible assets are being reduced, which is the same for intangibles, although in the consumption, process, intangible asset could be increased, regarding on the nature of the asset, for instance – shared knowledge. Based on these criteria Diefenbach (2006) emphasizes the main difference between tangibles and intangibles – is that intangible asset can growth while being used, which is not the case with tangibility.

According to Konstantinos et al (2013) intangibles should be approached as investment given that they represent a sacrifice of the present level of consumption in order to produce more output in the future. In addition, if these investments produce returns at some point in the future, they should not be only treated as an investment but also included in the gross value added (GVA) calculations, given as much quantitative importance as inputs of tangible nature (op.cit. Konstantinos et al, 2013). According to Goerzig and Gorning (2012) observed return rates on capital have an upward bias if economies are producing with unobserved intangible capital in addition making unobservable intangible capital observable. According to this statement, unobserved intangible capital contributes towards higher returns of observed capital, which also

redounds to the investment in intangibles acknowledgement. Webster and Jensen (2006) claims that intangible assets can not be treated as an investment due to these reasons:

1. They are not identifiable, as many intangibles are produced within the firm that uses them. In this respect, it is not easy to separate them from the business that owns them, or sells them as independent assets. In addition, several intangibles are non-rival.

2. The owner cannot always control access and use of them. Furthermore, in some cases intangibles might not be beneficial. It is not certain that the benefits embodied in assets such as R&D and marketing for instance will materialize eventually. The marginal product of some intangibles may well be zero (op. cit. Webster and Jensen, 2006).

Corrado *et al.* (2009) argues that these concerns could be applied towards tangible capital as well, in addition these statements has no point at macroeconomic level, since the owner of the asset is not important. What matters here, is whether the investment in intangibles increase the output and consumption of the entire economy. According to Hulten (2001) it is irrelevant whether the marginal product of some intangibles is zero. The key point again is whether an increase in intangibles yields returns at some point in the future in the form of higher production efficiency and improved product quality (op. cit. Hulten et al., 2001).

International investment law states (OECD, 2008), that investment concept should meet these criteria:

- The project should have a certain duration.
- There should be a certain regularity of profit and return.
- There is typically an element of risk for both sides.
- The commitment involved would have to be substantial.
- The operation should be significant for the host state's development.

Marrano et al (2009) has proposed to revise the upcoming Systems of National Accounts in Great Britain and include capitalization of R&D. According to their research, the ratio of nominal investment to nominal GDP has stayed more or less, where it was since the 1950s, which raises doubts what happens to the inputs in intangibles. According to Marrano et al (2009) GDP trends would look differently if intangibles have been included in the calculation process, but the process follow traditional accounting path due

to two reasons: 1) investments in intangibles is not popular among policy makers; 2) intangible assets are still encountering measurement problems.

The development of new products, services and business sectors along with the technological progress requires updated financial recording. Financial-accounting reports provide inaccurate information, irrelevant for making forecasts and for determining risks. In addition only a small portion of intangible assets are being recognized and used.

United States Bureau of Economic Analysis after proposed recommendations from certain studies (Corrado et al 2005, Corrado et al 2006) in July 31, 2013 has adopted a policy, where R&D was categorized as an investment on the government's books rather than an expense (BEA, 2013). After the adoption of this policy the GDP of the United States should increase by 3 percent, in addition revised GDP calculation methodology will be applied to re-calculate economic indicators starting 1929 m. (BEA, 2013). OECD (2013) reported that investments in R&D has showed little or no change in France for the period 1995- 2010. Within five years investment in R&D amounted for 1,9 percent of GDP, on the other hand, the investments in knowledge capital, organizational capital and other intangibles, which are not included into R&D has accumulated 7,4 up to 10,6 percent of GDP. These results supports Marrano et al (2009) idea, that R&D is only one of many intangible asset, which impact the effectiveness of our economies.

Up to date policies, capable of supporting nowadays resource allocation trends are essential in rapidly changing economies, better quality investments would expand opportunities to reap scale economies and by facilitate integration into global supply chains, boost productivity and rates of return on investment (OECD, 2013).

3 Intangible investment in Lithuania

Policies, supporting investment opportunities in Lithuania, comply with Europe Union regulations, in addition Lithuania, along with 34 OECD and ii non OECD countries has subscribed to the Declaration and committed to adhere governments to provide an open and transparent environment for international investment and to encourage the positive contribution multinational enterprises can make to economic and social progress (OECD, 2011).

Republic of Lithuania Law of investment states that:

- **“Investments”** means funds and tangible, intangible and financial assets assessed in the manner prescribed by laws and other legal acts, invested in

order to obtain from the object of investment profit (income), social result (in education, culture, science, health and social security as well as other similar spheres) or to ensure the implementation of state functions.

- **Investment**” means the act of investing performed by an investor in the manner prescribed by this Law whereby the investor acquires the right of ownership or the right of creditor’s claim against the object of investment, or the right to manage and use the object.

Investors may invest in the Republic of Lithuania according to the procedure established by law by using any of the following methods:

- By setting up an economic entity, acquiring the capital of an economic entity registered in the Republic of Lithuania or a share therein.
- By acquiring securities of all types.
- By creating, acquiring long-term assets or increasing the value thereof.
- By lending funds or other assets to economic entities, in which the investor owns a share in the capital enabling it to control the economic entity or to exert a considerable influence over the economic entity.
- By implementing concession contracts and contracts of financial lease (leasing).

Table 1: Types of investments according to Republic of Lithuania Law on investments

Types of investments according to Republic of Lithuania Law on investments		
Investor’s influence over an economic entity	direct	the investments aimed at establishing an economic entity and acquiring the capital of a registered economic entity or a share therein, also reinvestments, loans to economic entities the capital whereof is owned by the investor or in which the investor has a share in the capital, the subordinated loans where the objective of investment is to establish or to maintain long-term direct links between the investor and the economic entity into which investment is made, and the share in the capital acquired through investment grants the investor the right to either control the economic entity or to exert a considerable influence over it
	indirect	the investments where the share in the capital acquired through investment does not allow the investor to exert a considerable influence over the economic entity
Investor’s registered office	domestic	the investments in the Republic of Lithuania made by the State of Lithuania, natural and legal persons of the Republic of Lithuania
	foreign	the investments in the Republic of Lithuania made by foreign states, international organisations, foreign natural

		and legal persons
Status of the investor	state	the investments for meeting the needs of the State made using the national budget resources, state (municipal) fund resources, the loans obtained on behalf of the State of Lithuania (municipalities), funds of state-owned (municipal) enterprises and other state-owned (municipal) assets as well as the loan guarantees extended by the State (municipalities);
	private	the investments made by the subjects of private property law of the Republic of Lithuania and foreign states
	the investments made by foreign states and international organisations	
Object of investment	capital	investments in the creation, acquisition or increase of value of tangible and intangible fixed assets
	financial	all investments other than those specified in subparagraph 1 of this paragraph

Source: Republic of Lithuania law of investments

Intangible asset perspective within regional potential has been developed in many regions, such as: OECD countries (2013), United Kingdom (Konstantinos et al, 2013), Japan (Fukao, 2009), Brazil (Dutz, 2012) etc. Baltic States: Lithuania, Latvia and Estonia shares little attention regarding intangible asset recognition, assessment and investment insights, although Intan Invest project (Corrado et al, 2011) has developed a macroeconomic estimates of intangible investment for all 27 European countries, including Baltic States. Statistics for investing in intangible assets in Lithuania, Estonia and Latvia has been recorded for period 1995-2005, data for 2006-2010 is missing, which does not allow to benchmark the statistics.

Data to explore intangible asset patterns in Lithuania in this study has been taken from the Statistics department of the Republic of Lithuania, Eurostat, Innovation Union Scoreboard. Since Lithuania is not an OECD country it has not been included into Supporting Investment in Knowledge Capital, Growth and Innovation study, which focused on the investment patterns in all OECD countries.

According to the Statistics department of Lithuania, investment in Research and Development (R&D) as a share of Gross Domestic Product (GDP) in Lithuania has increased starting 0,79 perc. in 2006 up to 0,9 perc. in 2012. The size of the investment in R&D as a percent of GDP in the Baltic States is much smaller compared to the EU(27) (See Figure 1). Lithuania and EU (27) performance follows consistent trend line in the investing practice compared to Estonia or the United States. Estonia also demonstrates

high growth rates compared to all regions (See Figure 3). For the year, 2004 – 2006 Estonia has increased its investment in R&D by 14 percent; starting 2009 investment trends are indicating the growth again (See Figure 2).

According to Eurostat data, GDP expenditure patterns on R&D by sector for the period 2005-2010 has been changing. Business enterprise sector has increased the investments in R&D in EU (27), all Baltic countries and the United States. Government investment in R&D within the same period in Lithuania has dropped slightly, yet investments in R&D in higher education sector in Lithuania has not showed any changes. Most of the funds to cover R&D expenditure in Latvia and Lithuania come from government institutions, although EU (27) and United States get most of R&D funding from business enterprise (Eurostat data). Looking at the trends of R&D expenditure source of funds Lithuania follows the same pater as EU (27) which is, ascending financial recourses from private sector and descending from the government.

Source: Eurostat

Figure 2. Gross domestic expenditure on R&D 200-2010

Source: Eurostat

Figure 3. Annualized growth performance

Most of the personnel working in the Research and Development field are allocated in higher education sector, there has been 45 perc. growth for the period 2006-2012, government sector on the other hand, has reduced personnel extent working in R&D (See Figure 4). The highest growth belongs to business enterprise sector, which has increase it personnel working in R&D by 83 percent. Shifting trend could be influenced Europe Union strategies followed by national policies and incentives. For instance, Horizon 2020 is the financial instrument implementing the Innovation Union, a Europe 2020 flagship initiative aimed at securing Europe's global competitiveness. Horizon 2020 is the biggest EU Research and Innovation programme ever with nearly €80 billion of funding available over 7 years (2014 to 2020) – in addition to the private investment that this money will attract. It promises more breakthroughs, discoveries and world-firsts by taking great ideas from the lab to the market. That is why major focus belongs to science and private sector collaboration and synergy creation, which leads to innovative outcomes. The main idea behind this strategy is to break down barriers to create a genuine single market for knowledge, research and innovation (Horizon 2020).

Source: Statistics department of the Republic of Lithuania

Figure 4: R&D personnel distribution by sectors in Lithuania 2006-2012

Even though investment patterns in R&D as a percentage share of GDP has been demonstrating ascending trends, which contributes to “Europe 2020” one of the targets - 3 perc. investment rate in Research and Development, it should not be the main focus indicator exploring intangible asset investment trends.

According to the Republic of Lithuania investment program for 2013-2015 almost half of the budget goes to transportation and communication, along with the 5 perc.

growth from 2013 till 2015. Further aims of this study is to explore what part in this distribution could belong to intangible assets (See Figure 5).

Investments in public order and state management areas are the lowest, yet according to Policy Framework for Investment (OECD, 2006) regulatory quality and public sector integrity are two dimensions of public governance that critically matter for the confidence and decisions of all investors and for reaping the development benefits of investment. Reduced R&D personnel in public sector, low government investment policy in these two sectors could negatively affect the extent of the investment.

Lithuania has improved its innovative performance between 2006 and 2013, yet almost all the indicators are below Europe Union average, except for Human resources, which one of the highest once in Europe (See Figure 6). High performance in this area is can be considered quite an achievement.

Source: The Ministry of Finance of the Republic of Lithuania

Figure 5: Republic of Lithuania investment program 2013-2015

Human resource development is a prerequisite needed to identify and to seize investment opportunities, yet many countries under-invest in human resource

development due in part to a range of market failures (OECD, 2006). Lithuania investments in tertiary education, exceeds EU average by 36 percent as well as youth with upper secondary level education. Human resource component – new doctorate graduates underperforms compared to EU average by 53 percent. Estonia and Latvia performs just about even with EU average in Human resource indicator. High growth is observed for Community trademarks, Most cited scientific publications and International scientific co-publications.

Despite of low business investment in R&D indicator there is consistent high annual growth in this area, same goes for intellectual capital. Growth trends are demonstrated in PCT patent applications, PCT patent applications in societal challenges, community trademarks has increased by 28.8 perc.

Source: Innovation Union scoreboard 2014.

Figure 6: Innovation index performance for 2013

Linking economic effectiveness and investment in intangibles aspect it is important to emphasize, that Lithuania puts most of the effort in investing in Human capital, which is the on the input side, although criteria for the output such as patent revenues from abroad, employment in knowledge intensive activities results are one of the lowest in Europe

Union. Lithuania invests in education, but does not get the use out of it. Same path follows scientific publication indicator, which is quite competitive compared to EU average, but what is the outcome of such investment.

Only a few intangible assets, such as good will etc. are included in financial reports, investing strategy focuses on tangible nature areas. Investing strategy in Lithuania follows similar trends since its independence. Rapid changes in global economy adds pressure for policy makers and economist to adopt innovative models to capture the most benefit possible.

3 Conclusions

1. Investments in knowledge capital, organizational capital and other intangibles, which are not under Research and Development (R&D) indicator has been demonstrating ascending trends, compared to the R&D.
2. One of “Europe 2020” strategy targets is 3 percent of each country’s GDP devoted to R&D. According to the Statistics department of Lithuania, investment in R&D as a share of GDP in Lithuania has increased starting 0,79 perc. in 2006 up to 0,9 perc. in 2012.
3. Human resource development is a prerequisite needed to identify and to seize investment opportunities, yet many countries under-invest in human resource development due in part to a range of market failures. According to Innovation dashboard data, Human recourse indicator is one of the highest in Europe. Lithuania investments in tertiary education, exceeds EU average by 36 percent as well as youth with upper secondary level education. Human resource component – new doctorate graduates underperforms compared to EU average by 53 percent.
4. Lithuanian private sector investments into R&D is still below EU average, but there has been a consistent annual growth trend. In addition, private sector has increased its personnel working in R&D by 83 percent from 2006-2012. Higher education has increased its personnel working in R&D, yet for the same period public sector demonstrated negative trends. Shifting trend could be influenced Europe Union strategies followed by national policies and incentives to promote science and private sector collaboration.

5. Investments in public order and state management areas are the lowest, yet according to Policy Framework for Investment (OECD, 2006) regulatory quality and public sector integrity are two dimensions of public governance that critically matter for the confidence and decisions of all investors and for reaping the development benefits of investment. Reduced R&D personnel in public sector, low government investment policy in these two sectors could negatively affect the extent of the investment overall.
6. Linking economic effectiveness and investment in intangibles aspect it is important to emphasize, that Lithuania puts most of the effort in investing in Human capital, which is the on the input side, although criteria for the output such as patent revenues from abroad, employment in knowledge intensive activities results are one of the lowest in Europe Union. Lithuania invests in education, but does not get the use out of it. Same path follows scientific publication indicator, which is quite competitive compared to EU average, but what is the outcome of such investment.

Structured Abstract:

The **purpose** of this study is to describe, analyze and understand how a company keep ambidexterity and knowledge dynamics onboard during change and growth through defining, evolving and defending the vision of working smarter, greener and safer.

The research questions are:

Q1: How does ambidexterity manifest itself at the micro level?

Q2: What kinds of hurdles exist when the noticeable conditions for ambidexterity are elevated from an individual to an organizational knowledge level?

The answer to Q1 is that dividing the responsibilities for exploration and exploitation activities to separate managers are of importance, and that the individual power of these managers will impact the trajectory of the company. The answer to Q2 is that the main concern moving from an individual to an organizational knowledge level is how to organize and energize exploitation activities.

Methodology. This is a case study using the Norwegian Olympic Shipping as a case. We gave the management group of 22 an executive one third of a Master of Management program in 2013 and we got through this program access to all needed primary and secondary sources about the company itself and about their branch of business. All the participants worked with a project assignment analyzing different subjects for the practical realization of the company's strategy for the period 2014-2020. The project assignments included proposals for improvements and implementations and we will follow up this in august 2014. The case represents an action based methodological paradigm.

Practical implications. This is an exploration of how a company has kept the ambidexterity and knowledge dynamics in a long period growing from a small shipping company to a medium sized shipping company on its way to become a large global shipping company. The entrepreneurial spirit is kept in the shipping company through

empowerment, engagement, participation around the agreed upon vision to become greener, smarter and safer. The top-down control work in a dialectical relationship with bottom-up and the company can then take well care of their long term practice of working at the edge of their business.

Keywords - Knowledge Capabilities, Knowledge Dynamics, Exploitation, Exploration, Ambidexterity

Paper type - Academic Research Paper.

1 Introduction

This study is about understanding the knowledge assets for managing the paradoxical requirements between exploitation and exploration as companies grow. Firms have different attitudes and strategies towards innovation. In particular, firms have dissimilar motivations and capabilities to sense, search for, and seize new opportunities. They also have differentiated capacities to absorb new technologies developed externally. In this paper we explore how Olympic Shipping collaborate externally to complement their own resources and capabilities in their efforts to innovate. The theory of dynamic capabilities is combine knowledge, resources, entrepreneurship and complementarities based theories to explain how and why firms link with the market and the local knowledge cluster to leverage their own assets and resources. Dynamic capabilities enable firms to create new products, processes and business models. In addition to entrepreneurial capacities, dynamic capabilities involve combining and reconfiguring the firm's intangible and tangible assets to meet or shape market demand. These orchestration capabilities are hard to observe and replicate for competitors and may thus constitute sustainable competitive advantage for the focal firm. Designing and implementing collaborative mechanisms with a local knowledge cluster to search for and exploit and explore complementarities in innovation processes, may develop into hard-to-copy dynamic capabilities.

Knowledge is a critical asset and an important source of entrepreneurship and innovation (Du Chatenier et al., 2009; Grant, 1996; Nonaka, Toyama & Konno, 2000). Accordingly, knowledge is an important resource, however its effective use will to a great extent depend on its quality (Yu, 2007). Important criteria for knowledge quality are that the knowledge should be intrinsically right, relevant to the context and have practical value (Yoo, Vonderembse, & Ragu-Nathan, 2011). Thus the advantages to take into consideration the quality of work related knowledge shared are many, as a high level of knowledge quality will help employees and a team perform better, develop novel

products and services, increase sales and reduce costs, including reducing information overload.

We are exploring how firms collaborate externally to complement their own resources and capabilities in their efforts to create competitive advantages and innovative business systems. A central concern of a firm's overall strategy and the management of its own renewal is to maintain a dynamic fit between what the firm has to offer and what the environment expects (Miles and Snow, 1978). As such, a firm must possess the essential capabilities so as to constantly reconfigure, renew, and redeploy its resources and capabilities to better capture and exploit the changing opportunities (Teece, Pisano and Shuen, 1997). Dynamic capabilities enable firms to create new products, processes and business models. In addition to entrepreneurial capacities, dynamic capabilities involve combining and reconfiguring the firm's intangible and tangible assets to meet or shape market demand. These orchestration capabilities are hard to observe and replicate for competitors and may thus constitute sustainable competitive advantage for the focal firm. In a lack of a common accepted and well-received definition of dynamic capabilities several scholars have come together and define dynamic capabilities as the capacity of an organization to purposely create, extend, or modify its resource base (Helfat et al 2007). As also pointed out by Easterby-Smith et al. (2009) dynamic capabilities are determined in a variety of forms, involving a diversity of functions including product and process development combining the strategic choices with the delivery of the value chain. Dynamic capabilities are also associated with research on continuous change in organizations (Zollo and Winther 2002, Zahra et al., 2006) and might be looked upon as the theoretical foundation for agile project management (Augustine, 2005, Highsmith, 2004). Agile project management keeps the industrial scope; time and cost framework open much longer than traditional project management. This allows for adjustments of projects through all the phases. This has been identified as the competitive advantage of Norwegian oil service companies (Rosendahl, Olaisen and Revang, 2014).

More and more companies specialize in one area and technology to be efficient. Most innovations take place at the boundaries between specialized domains (Carlile, 2004), as knowledge production relies on the combination of knowledge from a variety of fields and disciplines (Newell et al., 2009; Shalley & Gilson, 2004). To be innovative organisations collaborate with each other. For the collaboration to be successful and generate innovative solutions, knowledge sharing in regional clusters becomes essential.

The case for this study is a fast growing offshore supply vessel company in Norway with the knowledge mission to be smarter, greener and safer than their competitors. Their strategy is to simultaneously explore and exploit their knowledge and technology environment. The challenge of balancing exploration and exploitation has been exhibited in distinctions made between refinement of an existing technology and the invention of a new one (Levinthal & March, 1981; March, 1991). In many ways the formulation “organizational ambidexterity” introduced by Duncan (1976) have been established as the concept that covers the “ability of a firm to simultaneously explore and exploit” (O’Reilly & Tushman, 2008, 2011). The purpose of this study is to describe, analyze and understand how a company keep ambidexterity and knowledge dynamics onboard during change and growth.

The research questions are:

Q1: How does ambidexterity manifest itself at the micro level?

Q2: What kinds of hurdles exist when the noticeable conditions for ambidexterity are elevated from an individual to an organizational knowledge level?

The answer to Q1 is that dividing the responsibilities for exploration and exploitation activities to separate managers are of importance, and that the individual power of these managers will impact the trajectory of the company. The answer to Q2 is that the main concern moving from an individual to an organizational knowledge level is how to organize and energize exploitation activities.

2 Methodology for the case study

In this paragraph we account for the empirical setting of the research project, how we collected data and interacted with key people in the case firm.

2.1 Research setting

This ethnographical case study was conducted in a supply shipping company located in the coastal center of Fosnavåg (population 4000) at the west coast of Norway. It is the most innovative maritime town in Norway, evidenced by housing of eight offshore shipping and four fishing companies and that owns more than 100 offshore vessels and 20 fishing vessels. Our case has approximately 55 people engaged at their headquarters and 900 globally. The company was founded in 1996 with 2 vessels. Today it has grown to 23 supply vessels with operations in the North Sea, the Gulf of Mexico

and Brazil. In the period 2005-2013 the company grew from seven to twenty-two vessels. The intention is to increase from 23 vessels to 50 vessels from 2014 to 2020. The island on the West Coast of Norway with three small towns and a population of 22000 represent a unique dynamic knowledge cluster for offshore oil activities where 27 companies are sharing and competing for the knowledge resources. This local cluster is a part of the maritime cluster at Møre. In 2011 this large cluster included 15 design companies, 14 shipbuilders, 160 equipment suppliers and 17 shipping companies. The export rate of the products and services extend 50% and Rolls Royce has chosen this site as their world center for marine shipping services. The cost level is the highest in the world, but the cluster prospers of increased activities even in a down turn for oil service companies (spring/summer 2014).

2.2 Data and information

The original agenda for our contact with the company was to design and run an executive Master of Management program for the top twenty managers in the company. Included were the two owners. Initially we interviewed the five top executives in two rounds to get an in depth picture of the company. Then we designed a module based, one-year program in six modules, consisting of lectures and group work. Through the program the participants had to analyze their own organization through different theoretical lenses. In parallel, groups of three had to write a project assignment on given topics where they analyzed their own firm and the realization of the firm's strategy 2014-2020. The project assignment should recommend improvements and a plan for implementation of the improvements. During the year we spent a total of twenty-four days each interacting with the top management group. The evidence we got from this case is extremely rich through documentation, interviews, interaction, and observations and through eight Master of Management assignments. We saw demonstrations of their management information systems and had a guided tour at a shipyard to observe the building of a vessel. In addition we collected much material about the industry and the company from secondary sources as newspaper, industry journals and magazines. We will in the fall of 2014 have a follow up of the implementations of the assignments where we also shall validate this paper through presentation and discussions with the top management group. Mansfield (1991, 1995 and 1998) has documented this way of interaction between the academic world and the practical world as the most successful way both to get

improvements/implementations in the practical world and to get valid and reliable research results in the academic world.

2.3 Originality and value

This methodology puts in evidence the possibility to propose an approach to analyze ambidexterity at a micro-level. In our analysis we have framed our observations in theoretical terms. A significant contribution to the literature on ambidextrous organizations is the identification of the close relation between individual competence and their corresponding responsibility for exploitation and exploration activities, and how their power in these positions will impact the paradoxical requirements of how exploration and exploitation are managed. This identifies a property of ambidextrous organizations that has been almost totally neglected in previous research. In investigating state of the art in organizational ambidexterity research Nosella et al. (2012) address future research this way: first it is important to remember that that ambidexterity is viewed as a capability to improve firm performance and that implies analyzing ambidexterity at a more micro level, through the organizational practices underlying the development of this capability (Kim & Rehee, 2009). "Adopting, for example, a 'practice-centered' approach in order to explore ambidexterity, 'to enter into how things get done in organizations' (Antonacopoulou & Pesqueux, 2010:11), would be a useful tool for investigating ambidexterity and providing a micro-foundation for this multifaceted phenomenon" Nosella et al. (2012:459). Our analysis is a micro oriented case study aimed at exploring the 'hows' of this phenomenon within a knowledge perspective.

3 Introducing the case of Olympic Shipping

At an abstract level the case company is based on mediating technology (Thompson, 1967:16-17), developing and linking supply-shipping capacity with clients or customers distributed in time and space. It differs from traditional examples of mediating technology as banks, telecom and insurance in being project based, of all excess both at the supply and demand side. They specify and order new builds from shipyards and they contract these vessels to customers in the offshore oil and gas business as drilling and oil companies. Usually it takes two years from they start detailing a new vessel until it is delivered from the shipyard, and the average contract period with customers are between three and four years. Each build is a unique constellation of technical equipment as

cranes, helideck, engine design, greener technology, new electronics devices and so on. Each customer contract represents a unique bundle of activities to be performed. Accordingly the projects embody stepwise developments, both in technological innovations and in customer requirements. These properties make it easier to spot and pinpoint changes, progress and development and their interrelated managerial decisions, actors and considerations; compared to cases where companies' mass-produce products continuously applying long-linked technology. The project-based context are the common value-creating logic in construction industries and becoming more and more usual both in traditional industries as well as in expanding industries like consulting, R & D, and in high tech firms where shorter product lifecycles enforce renewal processes. So our case firm does not only represent a beneficial context for studying development and processes, it typifies a setting that seems to be more and more common in business. Thompson (1967) labeled project-based organizations as temporary organizations and Olympic Shipping practice agile project management.

4 The theoretical foundation for organizational ambidexterity

In this section we first elaborate on the concept of dynamic capabilities DCs. We will then take into consideration four additional areas of theory: knowledge, resource, complementarities and corporate entrepreneurial-based theory. All of these five theoretical foundations even if they often are overlapping have contributed to our integrated expansion into the concept of organizational ambidexterity (OA).

4.1 Dynamic Capabilities

All organizations have a limited number of resources that must be allocated between conflicting goals. Firms that balance this tension resulting in superior rent over a long period of time is said to have DCs. DCs are defined as a firm's ability to integrate, build and reconfigure internal and external competences to address (respond and create) rapidly changing business environments (Teece et al., 1997:516) or "the capacity of an organization to purposefully create, extend, and modify its resource base" (Helfat et al., 2007:4). The concept of dynamic capabilities is linked to the resource based theory of strategy (Barney, 1991; Wernerfelt, 1984). Initially this theory assumed that resources and capabilities that grant enterprises competitive advantages are relatively fixed. Recently, however, scholars have put entrepreneurial skills to the forefront of dynamic

capabilities to develop the theory as a response to the strategic challenges posed by a fast moving and globalizing business ecosystem (Teece, 2007; Wang & Ahmed, 2007). Wang and Ahmed posit that three main components are at play: adaptive capability, absorptive capability, and innovative capability. Adaptive capability concerns the firm's ability to identify and capitalize on emerging market opportunities, balancing exploration and exploitation strategies (March, 1991). The dynamic capabilities are reflected through the capacity to integrate complementarities into a strategic fit between the firm's resources, organizational design and foresight. Activities include scanning the market, monitoring customers and competitors, and allocate resources to R&D and marketing efforts. Absorptive capability involves "the ability of a firm to recognize the value of new, external information, assimilate it and apply it to commercial ends.... and the ability to evaluate and utilize outside knowledge is largely a function of the level of prior knowledge"(Cohen & Levinthal, 1990). A study of the oil service industry indicates that firms possessing absorptive capacities learn from various partners, share information within multidisciplinary teams, develop and use complementary technologies and possess a high level of knowledge and skills in areas relevant to the applications of the new technology (Woiceshyn & Daellenbach, 2005). Innovative capability refers to a firm's ability to develop new products and services, processes, business models and markets.

4.2 The resource based theory and DC

The concept of dynamic capabilities is linked to the resource based theory of strategy (Barney, 1991; Wernerfelt, 1984). The resource-based theory is also the start of the theory of dynamic capabilities and the theory of agile project management is a part of the theory of dynamic capabilities (Augustine, 2005). Initially this theory assumed that resources and capabilities that grant enterprises competitive advantages are relatively fixed. Recently, however, scholars have put entrepreneurial skills to the forefront of dynamic capabilities to develop the theory as a response to the strategic challenges posed by a fast moving and globalizing business ecosystem (Teece, 2007; Wang & Ahmed, 2007). Wang and Ahmed posit that three main components are at play: adaptive capability, absorptive capability, and innovative capability. Adaptive capability concerns the firm's ability to identify and capitalize on emerging market opportunities, balancing exploration and exploitation strategies (March, 1991). Adaptive capability is defined as a firm's ability to identify and capitalize on emerging market opportunities (Chakrovarthy,

1982). Therefore, adaptive capabilities are essential in the context of commercialization. Adaptive capability focuses on effective search and balancing of exploration and exploitation strategies (Staber and Sydow, 2002). This type of balancing act is brought to a strategic level and linked to the coordination of resources. The development of an increased adaptive capability is linked to a development of new organizational forms like for instance agile project management.

The dynamic capabilities are reflected through the capacity to integrate complementarities into a strategic fit between the firm's resources, organizational design and foresight. Activities include scanning the market, monitoring customers and competitors, and allocate resources to R&D and marketing efforts. Cohen and Levinthal (1990) defined absorptive capability, as "the ability of a firm to recognize the value of new, external information, assimilate it, and apply it to commercial ends the ability to evaluate and utilize outside knowledge is largely a function the level of prior knowledge". Firms ability to acquire external, new knowledge, assimilate it with existing internal knowledge and ability to create new knowledge is an important factor of dynamic capabilities. The absorptive processes are crucial for all learning processing.

A study of the oil industry indicates that firms possessing absorptive capacities learn from various partners, share information within multidisciplinary teams, develop and use complementary technologies and possess a high level of knowledge and skills in areas relevant to the applications of the new technology (Woiceshyn & Daellenbach, 2005). This study concludes that his absorptive capacity is especially important in emergent new markets and territories. Understanding the political, social and cultural values in these societies is an important part of the absorptive and thus competitive capacity. In our opinion the absorptive capacity of the firm in other political and cultural business systems are not well theoretical and empirical based and there is a missing understanding link between understanding how a system might adjust to use their stable components differently in different systems. We are arguing that the flexibility and agility must be found in the business system itself

Innovative business capability refers to a firm's ability to develop new products and services, processes, business models and markets. This encompasses several dimensions such as developing new product and services, developing new methods and production, identifying new markets, seeking unusual and novel solutions (Schumpeter, 1934).

An important part of this innovative capability is the capability to standardize these innovations into standard routines and procedures in such a way that the innovations might be reused in different projects in different political systems. The reuse of procedures and routines is the efficiency needed for delivery of cost, time and quality in any project. The effectiveness for this must however be found in the business system itself.

In his studies of innovation in disruptive circumstances, Christensen argues that existing decision rules and underlying reward and incentive systems favor the status quo or incremental improvements, reinforced through feedback from existing customers and suppliers (Christensen, 1997). Extant competitive advantages are destined to be temporary unless the enterprise learns new approaches and let go of old capabilities related to the search, selection and implementation issues in innovation processes. The ability to review the efficiency of the prevailing routines and the willingness to extend or change them, is a dynamic capability (Teece, Pisano, & Shuen, 1997). In other words, dynamic capabilities may be enacted to overcome inertia and barriers to using new (external) partners in their innovation processes. Introducing the concept of complementarities in this context may serve analytical as well as practical purposes.

The question why some firms persistently outperform their competitors has been elaborated within the resource based theory of strategy, which argues that enterprises consist of idiosyncratic and difficult to trade assets and competencies (Barney, 1991; Foss, 1997; Wernerfelt, 1984). These resources are often classified into four broad categories: physical capital, financial capital, human capital and organizational capital. For the purposes of this study, the two latter categories are most relevant. The human capital assets include the knowledge, skills and attitudes of managers and employees, their training, experience and judgment. The organizational resources typically include attributes of teams or individuals associated with the firm, a firm's culture, its formal and informal reporting systems, decision processes, coordination mechanisms, and its reputation in the market place and its relationships with all stakeholders in the firm. These resources will have differential impact on firms and their capacity to offer potential competitive advantages. For a hotel, the location may be the superior advantage. For oil and gas companies, convenient access to their raw materials increasingly is a differentiating factor. Obviously, not all locations and not all raw materials constitute a

basis for sustained competitive advantage. In a country with strong political control of all resources it will be especially difficult to obtain sustainable competitive advantage.

At a point in time ownership of valuable and rare resources may provide competitive advantage. However, valuable, rare or scarce human or organizational resources may only be sources of sustained competitive advantage when other firms cannot obtain them by duplication or substitution. This requirement may be fulfilled from at least three sources:

- The ability of a firm to obtain or develop the resource is dependent on unique historical conditions, often coined path dependency (Brian, 1994; Pierson, 2000)
- The link between the resource possessed and utilized by the firm and that firm's sustained competitive advantage is causally ambiguous
- The resource or capability generating the firm's advantage is socially complex

These features may all be present in a firm's link to local and non-local suppliers and sub suppliers, but will of course depend on the length and depth of the collaboration.

The resource-based thinking has recently been extended by viewing the firm as a stock as well as a dynamic flow of resources (McKelvie and Davidsson, 2009). The constantly changing circumstances to a firm call for the constant restructuring and transformation of resources (Eisenhardt and Martin, 2009). Dynamic capabilities are now seen as the firm's extant resource base and transform it in such a way that a new bundle or configuration of resources is created so that the firm can sustain or enhance competitive advantage (Ambrosini and Bowman, 2009).

4.3 Knowledge based theories and DC

Knowledge is a widely debated concept without any agreed-upon definition, and different views exist in the knowledge management field. In some approaches knowledge and information have a tendency to be treated as equals (Wang & Noe 2010), however, we can with certainty distinguish knowledge and information from data. Whereas data represent letters and raw numbers, thus provides no meaning without a context, information is regarded as processed data (Wang & Noe, 2010). This article adopts the view that information can be transformed to knowledge by being combined with experience, context, interpretation, and reflection. Subsequently, knowledge represents action and development, and can be characterized as both dynamic and personal (Nonaka, 1994). We further focus attention on the subjective and social constructed nature of knowledge (Alveson & Kärreman, 2001), and from this socio-cultural perspective, it is

argued that knowledge is constructed and negotiated through social interaction (Newell, Robertson, Scarbrough, & Swan, 2009).

Competence might be defined as the integration of knowledge, skills and attitudes into professionalism. The integration might be what we are defining as professional experiences for reuse and relearning. The attitude is crucial for de learning and the attitude is linked to the corporate culture and a corporate positivism as found in Olympic Shipping for de learning might be a dynamic capability for adapting to internal and external changes.

In the same way as knowledge is a debated topic, so is the topic of knowledge sharing. Most definitions include an element of movement of knowledge from person, unit or organization to another that enables creation, acquisition, integration and use of knowledge (Staples & Webster, 2008). A definition that is in line with the socio-cultural view that has been adopted, explains knowledge sharing as mutual exchange of both tacit and explicit knowledge and a joint creation of knowledge (Van den Hooff & De Ridder 2004).

It is possible to delineate between two types of knowledge, namely explicit- and tacit knowledge (Newell et al., 2009). Although the two are often interconnected, they presuppose different methods of sharing knowledge. A common notion is that explicit knowledge easily can be shared with all team members using technology. Hence distributed teams will be more inclined to share knowledge that is explicit in nature, because technology more easily supports this kind of declarative knowledge. On the other hand, tacit knowledge is acquired from experience, and for this reason, healthy social relationships are consequently important for the sharing of tacit knowledge in virtual teams (Maznevski & Atanassiou, 2003). Moreover, the ability to facilitate for the sharing of explicit-, but maybe more importantly, the sharing of tacit knowledge between individuals and in teams is crucial to exploit experiences into new learning to enable the creation of new possibilities.

4.3 The Theory of Corporate Entrepreneurship and DC

In an open and globalizing business environment, sustainable advantage requires more than ownership of valuable, rare and difficult-to-copy resources (Teece, 2007). Resources that created competitive advantages in a particular market context may be obsolete with no value in a new environment. This new environment might have a different political,

social and cultural setting where the rules are changed compared to what have given the company former competitive advantages. Thus if the business system is not flexible enough to find new reconfiguration of their resources they will have difficulties competing in different business cultures. On a general level, we argue that if a firm's ability to implement innovations is valuable, rare and costly to imitate, then a firm's capability to innovate and standardize the innovations into procedure and routines is a potential source of sustained competitive advantage. In the same vein, we argue that an entrepreneurial capacity may represent a hard-to-imitate dynamic capability. By entrepreneurship we mean the capacity to sense and shape opportunities and threats, to seize these opportunities and to reconfigure resources into new flexible business models and successfully introduce new products or services into different marketplaces. Sensing new opportunities and threats implies differential access to knowledge either by seeing something that others don't see, or by understanding something that others don't understand. Secondly, it implies the capacity to transform that knowledge into opportunities. Making sense of local as well as distant political, social and cultural information is another dynamic capability.

4.4 The theory of complementarities and DC

Firms can improve their innovative capabilities by interacting with a variety of partners such as existing suppliers and customers (see e.g. Lorenzoni & Lipparini, 1999; Lundvall, 1992; Von Hippel, 1988), political and bureaucratic institutions (see e.g. Kaufmann & Tödtling, 2001; MacPherson, 2002; Mansfield, 1995; Santoro, 2000), and even potential or existing industry competitors (see e.g. Dodgson, 1993; Hamel, 1991). Why should they collaborate with political institutions, which are inherently difficult to link up with? We argue that potential conflicts are outweighed by the potential benefits of complementarities especially in different cultural settings.

Complementarities involve how the interactions among changes in different activities are affecting performance. Two activities are complements when doing (more of) one of them increases the returns to doing (more of) the other. If one of a pair of complements is instituted or increased, it will be more attractive than before to introduce or increase the other (Roberts, 2004). For example in Venezuela will a strong link to the political system make it much easier to handle time, cost and quality in the different project stages and processes. This is a strategic choice. In this context, Complementarities give rise to

business and innovation systems effects, with the whole being more than the sum of its parts.

Roberts tells the dismal story of General Motor's innovation policy in the 1980's: In that decade GM spent more than the combined market value of Toyota and Nissan on flexible automation and other lean measures to increase its potential agility and flexibility. However, it failed to speed up its product development processes, adjust its product mix, production scheduling and reform its human resource practices according to the market needs outside US which also in the long run made the much less competitive in their domestic market (Roberts, 2004). The GM way was to design and dominate together with acquiring companies making them exclusive outside the emergent way of partnership and relationships through networks and clusters. Connecting and sharing was never a part of GM's policy.

The acquisition of knowledge and resources from external sources has been identified as a key component of both competitive advantage and new product development in firms (Van de Ven, Polley, Garud, & Venkataraman, 1999; Von Hippel, 1988). Van de Ven (2009) argues that the acquisition of external knowledge is not the key for competitive advantage, but the key is of course how the company is using this knowledge in the local market place and thus having a central business system that might adjust to both different market need and different political and cultural situations. This is what we will define as knowledge in action and more importantly a business system in action.

4.5 The theory of dynamic capabilities revisited

Dynamic capabilities are viewed as drivers behind creation, evolution, and recombination of other resources into a new source of competitive advantage (Henderson and Cockburn, 1994, Teece et al, 1997). Barney (1991) described resources as all assets, capabilities, organizational processes, firm attributes, information and knowledge controlled by the firm which enable the firm to conceive of and implement strategies that improve its efficiency and effectiveness. However, resources alone are not enough to explain firm's competitive advantage, they need to be employed in a combination in order to be useful (Penrose, 1959, Grant, 1991). In reply to this critique, the dynamic capability approach has evolved, and defined as the ability to coordinate and deploy resources in order to achieve the firm's goals (Amit and Schoemaker, 1993). This capabilities approach thus overcomes the critique of whether possession or usage of resources is the

primary concern (Wiklund and Shepherd, 2003). Further, as they are not simply inputs into a productive process, capabilities cannot be purchased from the market (Makadok, 2001).

Therefore, the dynamic capability perspective offers an attempt to explain and explore how firms can leverage their strategies and change their valuable resources that enable them to confront and overcome multiple challenges over long time. Eisenhardt and Martin (2009) defined dynamic capabilities as “the firms processes a ‘that use resources – specifically the processes to integrate, reconfigure, gain and release resources- to match or create a market change.

As one of the most central and difficult questions within the domain of business strategy this theme has been characterized as “The Holy Grail of Strategic Management“ (Helfat & Peteraf, 2009:91). Being concerned with change and development the concept of DC contrasts with ordinary or operational capabilities (Winter, 2003:992). The concept reflects an organization's ability to achieve new and innovative forms of competitive advantage given path dependencies and market positions (Leonard-Barton, 1992; Teece et al., 1997:516). The ambition of the framework is to explain the sources of enterprise-level competitive advantage over time (Teece, 2007:1320). As a strategic framework the DC view is said to be of particular relevance in "fast-moving business environments open to global competition and characterized by dispersion in the geographical and organizational sources of innovation and manufacturing. Here sustainable competitive advantage requires more than ownership and difficult to-replicate (knowledge) assets" (Teece, 2007:1319). For analytical purposes dynamic capabilities can be disaggregated into three capacities:

- 1) To sense and shape opportunities and threats
- 2) To seize opportunities
- 3) To maintain competitiveness through enhancing, combining, protecting and, when necessary, reconfigure the business enterprise's intangible and tangible assets (ibid).

Arent and Bromiley (2009) systematically criticized the DC framework for being the "new touchstone firm-based performance-focused theory". They assess the ability of the dynamic capability view (DCV) to explain successful change with logical consistency, conceptual clarity and empirical rigor" (2009:75). The DCV does not live up to these criteria. Their assessment identifies four major problems that limits the potential contribution of the CDV:

- 1) Unclear value -added relative to existing concepts
- 2) Lack of a coherent theoretical foundation
- 3) Weak empirical support
- 4) Unclear practical implications (ibid).

We would add to point 3 that DC is difficult to investigate empirically and such studies are facing an immanent danger of tautological explanations. Does well performing firms in dynamic environments achieve because of their dynamic capabilities? If so, how do we observe these capabilities and seize them in variables or constructs? Or do all firms that create extraordinary rent over time in dynamic business environments pr. definition embody dynamic capabilities? Another research challenge is related to the dependent variable "extraordinary rent over time" which manifest itself at the firm level, while the causes or independent variables may be exogenous like changing markets or at an individual level and related to positions, mindsets, influence and decision making concerning resource allocation over time.

Two of the most famous studies in the search for the Holy Grail of business performance are "In search of Excellence" (Peters & Waterman, 1982)¹ and "From Good to Great" (Collins, 2001)². In both analyses the companies selected for investigations had to pass a number of criteria, among these superior financial performance over a long period of time (30 years). Which would fit the definition of dynamic capabilities at work. However, in both studies firms got into trouble short after the results were published. Enduring extraordinary financial results in the past was not a rock-solid pointer for future success. The explanations for greatness or excellence in both studies are to a large extent given at firm level as culture and discipline. These give little insight in micro foundations or internal competencies in the formation of such firm qualities. Collins (2001) states that "greatness is not a function of circumstance, greatness is largely a matter of conscious choice and discipline", but we do not get any variables we can evaluate or operationalize. Even when they claim "level 5 leadership" (Collins) or "hands on value driven management" (Peters and Waterman) it is hard to grasp a significant link to firm performance. In addition it may also be a long time span between actions taken and change in performance measurements shows up which make it hard to estimate functional

¹ According to Wikipedia the book sold 3 million copies the first 4 years and being the most widely held library book in the United States from 1989 to 2006.

² The book has so far sold more than 4 million copies (<http://www.economist.com/node/21540219>). Both books are translated to a number of different languages.

relationships. These conditions illustrate some of the difficulties concerning theory development within the DCV.

Dynamic capabilities theory started out as a part of the resource based theory and has developed as a theory in its own right explaining how to act upon increased internal and external complexity where the key is both to exploit and explore the reality. This is what Olaisen (1983) labeled as the clarified subjectivity paradigm where explanation is not the key, but exploiting and exploring or in his words “what we don’t know that we know”.

5. Organizational ambidexterity (OA)

The start of ambidexterity was the Bauhaus art period in Germany in the 1920’s. Kandinsky found the mathematical formula for combining colors and mathematical figures. Klee labeled this in 1928 as the ambidexterity of art (Gale 2013) where his pictures “Shooting The Moon” and “The Fire” are examples of exactness in rational form and at the same time subjective irrational strong colors (Paul Klee Making Visible, Tate Modern 2013). It describes the combination of rationality and irrationality describing the entrepreneurial owners of Olympic Shipping as rational and irrational at the same time setting up the company in a bet for greener, smarter and safer. The stock market tolerate only financial rationality and you have to be an entrepreneur and/or artist to tolerate a high rate of irrationality. It represent a tacit knowledge with very objective results either it is art or business.

Another stream of knowledge development concerning superior firm performance over time are labeled organizational ambidexterity (OA). The concept originates from describing a human being able to use both hands with equal ease. In organization theory defined as the ability to manage trade-offs emerging from a simultaneous focus on alignment and adaptation (Rothaermel & Alexandre 2009: 759), or as the ability of an organization to simultaneously pursue both explorative (discontinuous) and exploitative (incremental) change i.e. "explore new opportunities even as they work diligently to exploit existing capabilities" (O'Reilly & Tushman, 2004:74). Because OA facilitates new resource configurations that can offer competitive advantage (Eisenhardt & Martin, 2000) it is dynamic capabilities in practice (O'Reilly & Tushman, 2008: 192-196). In other words successful management of OA over a long time will classify as DC.

As in the DCV the level of analysis is crucial in OA studies. Even if ambidexterity is viewed as a multilevel construct (Birkinshaw & Gupta, 2013: 293-294) most of the

empirical OA-performance studies have been conducted at the firm level (Junni et al., 2013:301). The implication is that the question of how organizations manage the allocation of resources between exploration of future possibilities and present needs is under prioritized at the expense of general mapping of the field through gallant quantitative calculations of measurable general variables.

Ambidexterity has typically been viewed in structural, contextual and sequential terms (Eriksson, 2013:334; Kang & Snell, 2009:66). In structural ambidexterity sometimes called spatial partitioning, organizational units engaged in exploration and exploitation is separated from each other (Tushman & O'Reilly, 1996; Benner & Tushman, 2003). Contextual ambidexterity applies to situations where there is a capacity and competence to simultaneously pursue exploitation and exploration within the same organizational unit (Gibson & Birkinshaw, 2004; Gupta & Birkinshaw, 2013; Gupta, Smith & Shalley, 2006; Teece, 2007). This term allows for the possibility that there is a multitude of ways to handle the tensions involved in doing two different things at the same time (Birkinshaw & Gupta, 2013: 288), and these possibilities arise from features in the context of the focal organization. To understand the ability of organizations to handle the tensions that conflicting goals put on resource allocation we need to give careful consideration to the role of managerial capabilities (Birkinshaw & Gupta; 2013:293). The third category, sequential or punctuated equilibrium terms situations where there is temporal cycling between short rushes of exploration and long stable periods of exploitation (Adler, Goldoftas & Levine; 1999; Gupta, Smith & Shalley, 2006: 698). Sequential equilibrium can take place when exploration and exploitation are mutually exclusive ends of a continuum. For example in the case of system-level architecture (Henderson & Clark: 1990), like building a new vessel equipped with a unique set of technologies (exploration) and then learning to operate it more and more efficient (exploitation).

Most research is concentrated on one of these three categories. Recent contributions have found that all three in combination can be fruitful in giving meaning to empirical data (Andriopoulos & Lewis, 2010; Ericsson, 2013; Raich et al. 2009). Combining them may provide answers to: what kind of knowledge and skills are needed to explore and exploit and what kind of organizational solutions balance the interplay between these needs in a dynamic perspective?

6. Analyzing the case: ambidexterity, tensions and knowledge

6.1 Performance

The company was founded in 1996 operating 2 supply vessels. It is organized as a private limited company and the two founders still own all the shares. The CEO (also chairman of the board) own more than 67% and have full control over the company. The main expansion took place between 2005 and 2013 when the company grew from seven to twenty-two ships. It is now the second largest supply company in Fosnavåg in terms of number of ships. In the same period the estimated value of the vessels increased by 453 percent, making the company the most valuable supply company in Fosnavåg. In 2005 the company was ranked no. three in market value of vessels, approximately half of the most valuable firm, today they are valued 15% more than no. 2. In 2013 they had a turnover of approximately 200 million dollars and a profit margin of 48% before depreciations and tax. Equity is around 40%. Historically the operating margins have been huge - sometimes 60% of turnover, but have varied considerably due to market variations. Evaluated in relative economical parameters our case is a highly successful business. It is not the profit margins that are outstanding compared to competitors, but the increase in the value of the vessels. The underlying explanation is their search for cutting-edge capabilities and eco-friendly technological solutions in their new builds. The market value of these ships decreases more slowly than the value of less complex vessels.

The two project assignment groups including the two owners in the following six questions identified the crucial questions for further development of Olympic Shipping:

1. What are the logistics and value creation of our value chain? Where and how are we making our money or satisfying our primary goals? How do we become a global prime mover in in the supply boat offshore industry?
2. What knowledge, skills and attitudes are needed to deliver a smarter, greener and more secure value chain?
3. What co-creation with local partners and global customers do we need to deliver our value chain?
4. What local cluster do we need to understand, satisfy and take responsibility for our stakeholders in different contexts in our value chain?

5. Will the strategy be dynamic and innovative enough to meet the challenges and changes in the global market? Are the global market willing to pay for smarter, greener and more secure supply boats?

6. How must/can we balance leadership and strategizing entrepreneurship to get the right value dialogue in different corporate contexts? What strategy, leadership and organizational forms are needed to enable what Olympic Shipping describes as healthy greediness? Is it possible to keep the strategizing entrepreneurial owner mind-set when going more global?

6.2 The Business and the Mission of the Case Company

A supply shipping company usually owns a fleet of specialized ships that constitute the production capacity of the company. It is very common that each ship is a separate corporation fully owned by the shipping company. The vessels are contracted by customers in the oil industry, either on long-term contracts (3-5 years) or operate on a spot market.

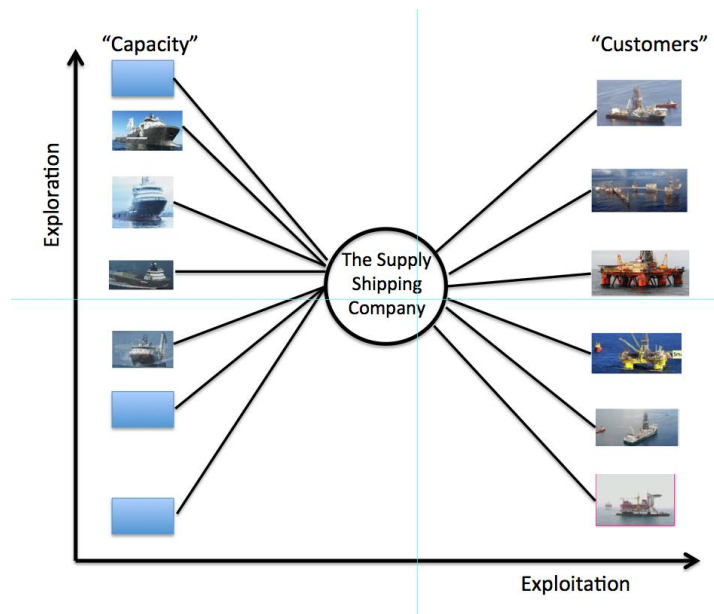

Figure 1. The value creation logic of the supply shipping company

At the organizational level the company is a mediating technology (Thompson, 1967:16-17) with pooled interdependence between the parts, each part renders a discrete contribution to the whole and each part is supported by the whole. Actions taken by one ship can proceed without regard to actions taken by other vessels so long as the overall organization remains viable. Exploration takes place along the vertical axis in the model as development in technology, design and equipment from one build to the next. Exploitation takes place in along the horizontal axis as contracting vessels to customers and efficient delivery of services in accordance with contract. According to Thompson (1967) the proper strategy for firms based on the abstraction called mediating technology is to expand the population served. Hence, growth in capacity by adding more ships, serving more customer driven projects through diversification, expanding into new markets etc., all becomes appropriate strategic actions. The company has established a "best operating practices" mission, operationalized as working "safer, smarter and greener". They strongly believe that performing their activities the right way will give the company the best results.

The practice of operating greener is especially important for the exploration - exploitation tension. Working greener has become a guiding intention when they invest in technologies. So they compose vessels with technology and solutions that are neither obligatory nor mandated by the authorities or the oil companies at the time of construction. The strategic idea is that the market and formal requirements will continually progress in a more eco-friendly direction affecting the market value of "early eco-friendly" vessels positively. This indirectly states that being ambidextrous will exclude the company from being a low-cost actor, but the investments are anticipated to be compensate for this in the long run.

6.3 Mediating projects on two sides

The primary operating activities performed by the company fall in to two main categories 1) "design" and order vessels from shipyards 2) operating the vessels and deliver services according to negotiated contract. In addition there are important supporting activities in different knowledge areas like: financing the builds, the negotiation of contracts, crew staffing, and accounting.

1) The company is located in one of the few complete maritime clusters in the world with several companies in each segment of the industry value chain - shipping, ship

design, equipment suppliers and shipbuilding. This cluster is a world leader in the concept of "advanced marine operations" i.e. operations for the oil industry. In this industry the general trend are greener, deeper and colder. In the sense that environmental restrictions are increasing, and that new discoveries are deeper and further north.

Innovations in isolated technologies as cranes, propellers and engines are to a large extent constructed outside the company. However, there are dyadic relations between the suppliers and our company so both parts can have influence in development processes. An example may be:

We have a zero-tolerance emission target, and this played into our choice of a hybrid (diesel-mechanical/diesel-electric) propulsion solution on our next-generation AHTS/offshore construction vessels. While the technology was in place, it still wasn't in commercial use on these types of vessels as of yet. We then invited three ship design companies and shipyards to try and help us turn this challenge into a reality. We felt that Ulstein Yard and Ulstein Design & Solutions had the best proposition, and their combination of quality, standing, reputation, solidity and knowledge sealed the deal, says senior vice president ...³

For each build there is a process of technology brokering (Haragon & Sutton, 1997) where the end result is technical specifications for a vessel that is ordered from a local shipbuilder. The top management takes part in the discussions about technical solutions and the CEO has the final word. There after project control activities follow where the technical department checks progression and mounted technical equipment during the building period. After the vessel finished and handed over to the shipping company, the technical department shifts focus from building to operations and is responsible for required technical examinations as well as maintenance planning and execution.

2) Vessels are contracted to customers for a fixed period of time usually with an option of prolongation. The contract period can be viewed as an operating project with a priori definitions of time, cost and quality. A central located team of 5-6 persons is following the operations and manages the logistics of fuel, food, equipment, crew etc. The two most advanced segments of the industry are vessels for anchor handling and vessels for subsea operations. The ship's crew performs the operations and can be an important factor when customers decide contracts for a supplier. Repeatedly we were told about customers after having decided the technical level of the ship asked for the captain's name. One of the reasons is that good captains maneuver their vessel efficiently saving

³ <http://www.maritime-executive.com/pressrelease/proven-olympic-shipping-eco-friendly-operations/>

the customer fuel costs and time. An example from the use of hybrid (diesel-mechanical/diesel-electric) vessels:

On one of the first jobs we carried out, our customer wondered if we was actually subsidizing fuel as they didn't think that it was possible to work with such low fuel consumption, says... In order to prove our capabilities I asked permission to move an entire anchor system that was used on a rig. This action normally requires two to three vessels to complete. The system consisted of eight anchors in total with about 10,000 meters of chain and wire, and we carried it out. As far as I know, this has never been done before.

After a number of jobs, we have proven to the market that we in average can run the ship on 70% of the fuel of what a conventional diesel anchor handler can, and that we can save up to 70% in some modes compared to a conventional ship. A true hybrid provides a world of possibilities. Many of our competitors simply cannot carry out anchor handling in diesel-electric mode, even though their systems are hybrid. They only have the capacity to boost the diesel-mechanical system with the diesel-electric mode, so they don't achieve the same fuel consumption and emission savings as we do.

These examples tell us that the technological capabilities of the vessel together with human knowledge about technology besides operative experience and skills are significant factors for a superior execution of operations (exploitation).

We have described and exemplified a process that starts with exploration activities internally, and expands to interaction with external firms to find and finalize technological solutions. How shall we equip the vessel to become greener, and enhance our possibilities of smart and safe operations? It is a process where idea generation and checking out what is possible follow an "unstructured" path.

6. 4 Cross Functional Learning

One of the main issues in March seminal work on exploration and exploitation where organizational learning in the development of individual and collective knowledge (March, 1991:74). Concerning knowledge, learning and competitive advantage he writes "... multiple, independent projects may have advantage over a single coordinated effort. Organizations that develop effective instruments of coordination and communication probably can be expected to do better (on average) than those that are more loosely coupled" (March, 1991: 84). In a supply shipping company the vessels are loosely coupled. They do they job without operational relations to other vessels. Execution of operations generates experience both for efficiency in operations and for the strengths and limitations of the technology. This knowledge is important both for the

development of new vessels and for learning best practices across ships. In other words it can be useful both for exploitation and exploration processes.

The industrial value chain goes from left to right in figure 2. At a general level there are three important phases that have great impact on the firm revenue. First the specification of the vessel and the associated construction cost; second the process where operational contracts are negotiated; and third the performance in executing operative activities.

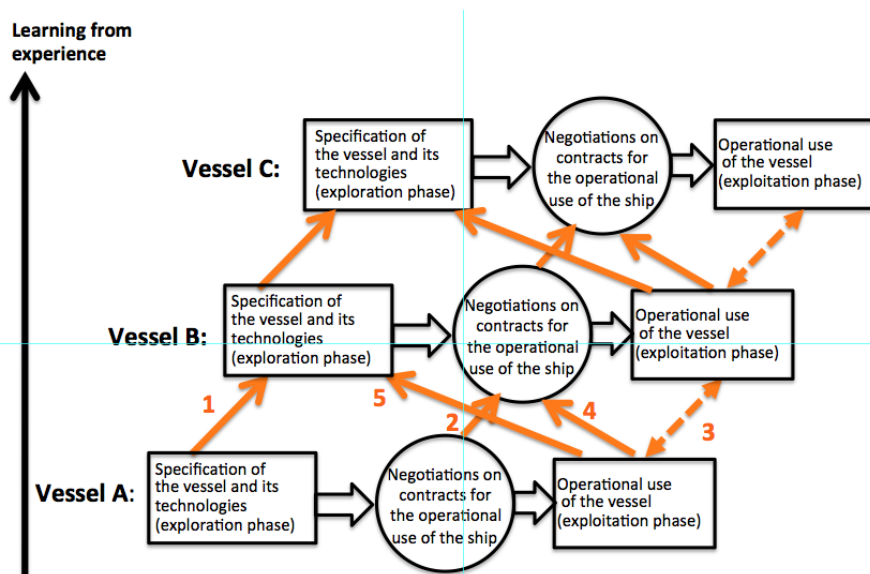

FIGURE 2: Main phases and the internal links of information and learning

Here we identified five main learning relations:

1) Personal experience from working with technical specifications and project control from build to build. This takes place within the technical department and generates a collective knowledge.

2) Experience in negotiations. Although the industry have standard contracts these are negotiated, both existing paragraphs/text and wants and formulations concerning additions to the contract.

3) Experienced learning from operating the ship shared with other crews. The company attempts to standardize the design of the bridge on their vessels, which makes it

easier to change crews, collect data, and share experiences. They also arrange a "seminar" in Fosnavåg once a year where officers share experiences and have dialogues with people at the HQ.

4) Experience from operational use that are of importance for contracting in the future. Contracts are negotiated and it is of great importance to reduce economic risk. However, negotiations are also a question of power. So price, risk and power affect the formulation of the final contract.

5) Experience from operational use that is of importance for the design of new builds. There is a sophisticated data system in use that logs a lot of operational data. For example: load on the engines, fuel consumption, CO₂ and NO_x⁴ emissions⁵, damages, and many more data categories. These data flows across operational units and constitute a ground for learning from experience, and sharing lessons learned. In addition the data flows feeds the people responsible for exploration and innovation considerations with hard data about productivity in operations (exploitation).

From a theoretical point of view stream 4 and 5 originate from structural ambidexterity the division of exploitation and exploration in separate organizational units, but they represent a basis for coordination and learning across these units to constitute sequential or punctuated equilibrium. So here we have a case where sequential ambidexterity works in parallel with structural ambidexterity.

All the knowledge flows above are internal. As previously pointed out the company is located in a maritime business cluster. This business environment constitute a rich source for information on technical innovations, industry news etc. Here there are many informal channels of information that can affect the internal decision process concerning new vessels. Here information flows are more organic, personal and random than the internal processes. In the cluster there has been established a lot of informal meeting places as yearly conferences, network meetings etc. These arrangements facilitate information flows between companies at different stages in the industrial value chain.

6.5 Communication challenges and their solution

Two of the Master Theses investigated the need to improve the communication issues at Olympic Shipping. They found that the fundament for communication was solid

⁴ NO_x is a generic term for mono-nitrogen oxides NO and NO₂.

⁵ Such data must be reported to governmental authorities

and robust in the corporation even if an own department for corporate communication and information systems was needed. Their conclusion was that the mainly informal information system had worked very well owing to the following eight factors, but the key improvement was the formalize the communication and information system and keep the informal trust and togetherness feeling. These two Master theses found that a trusting communication relationship in Olympic Shipping consisted of eight factors:

- (1) Support - Employees felt that through communications with their nearest leader they had their own value and importance established and sustained;
- (2) Influence - Employees felt that they could freely communicate upwards and had an influence on decisions;
- (3) Trust and trustworthiness – Employees felt that communication sources, messages and processes were trustworthy;
- (4) Openness and honesty – Employees felt that their relationships were open and honest with others both listening and conversing; and
- (5) Goals and expectations – Employees were told clearly and explicitly what is expected of all employees in the organization.
- (6) Self-confidence - Employees felt that they were expected to be self-managed and display self-discipline in all work tasks.
- (7) Responsibility for own learning – Employees felt that the organization expected them to take responsibility for own learning. This gave employees motivation to knowledge and information sharing
- (8) Mastery - Employees develop a felt of self-efficacy in that they believed they were the masters of the change and anything is possible.

All of these eight factors were supported by the findings in the Olympic Shipping case. These eight factors are our suggestion as a model for the primary task for any functional informal and formal communication. If you satisfy these eight goals with a good score you are secured knowledge and information sharing.

At the same time, it is important to bear in mind that a good communication climate not only means peace and harmony, but there should also be enough safety to handle complex and emotion laden discussions, conflicts, creative disturbances, and amusements (Erlie 2003). These are a reality in any organization but as Jensen (2002) states, “Battles and conflicts can be difficult, but we are not getting anywhere without it (sic)”. We experienced in the Statoil case how open disagreement is necessary to come up with the

good solutions for the complex issues faced in this change to a smarter, greener and safer organization but no open battles or conflicts. Because Norwegian cultural values cause employees to avoid battles and conflicts (Sørhaug 2010), we did not find any such conflicts at Olympic Shipping. Indeed, we found the opposite as all those interviewed talked very well about each other and told us how easily they were able to share information and knowledge. Olympic Shipping is obviously gaining the benefits of the Norwegian cultural value of avoiding battles and conflicts. This could be due to a cultural difference where the Norwegian collective win-win cultural value of making each other good enhances the company values of Olympic Shipping.

7 Balancing the future and the present - leadership issues

So far we have reported on structural aspects and processes balancing tensions concerning the allocation of resources. Now we turn to leadership issues. In 2005 Smith & Tushman stated that effective management of strategic contradictions as exploitation and exploration has not been at the center of organizational analysis. Contributions during recent years have increased and are centered on top management teams (Smith & Tushman, 2005; Lubatkin et al., 2006; Carmeli & Halevi, 2009), senior teams (Jansen et al., 2008); and leadership action (Gibson & Birkinshaw, 2004; O'Reilly & Tushman, 2011; Tushman, Smith & Binns, 2011).

The two entrepreneurs that founded our case company had very different backgrounds concerning skills, experience and knowledge. At the age of 15 the CEO got employed on a fishing vessel and was captain on his own ship at the age of 22. He has many years of experience in arctic waters. He has always wanted to beat the competition. As a young captain he expressed to the media that in order to be the best he "needed the best boat, the best people, and the best technology. It was too late to do anything with the boat, so I invested in technology and people – and it worked". The other entrepreneur had worked in different shipping companies through his whole life and has unique insight into markets and companies, as well as decades of experience in negotiating contracts internationally. From the beginning the "fisherman" funded most of the shares and became CEO and Chairman of the board. The other took responsibility for negotiation and operations. The CEO had a personal interest in ship technology and eager to bring advanced technology from fishing boats into the supply business. So the entrepreneurs

had CVs that was adequate for a structural split in exploration and exploitation activities.

But he also engages himself in decision concerning contracting and exploitation.

Two examples of internal tensions in negotiations:

1) The minority owner: "I have spent my summer holiday travelling between London, the Canary Islands (where the vessel was) and Dubai, trying to establish an engagement for the XX vessel". I: "I thought you finalized this in May"? The minority owner: "No, we had a customer willing to pay 55.000\$ a day, but he demanded 58.000 \$. A competitor got the contract so we had to find another client for the vessel".

2) The technical director: "We went in and told him that the additional (greener) investments in the vessel would cost approximately 4,5 million dollars, and that it would affect the cash flow, at least in a short perspective. Then he replied: just do it!"

These quotes indicate that the ambidextrous relation between responsibility, and the concern about trade-offs between future and present are not separated into fixed roles. It shows that the CEO is concerned about the present in addition to the future, and is ready to use his power to affect the contracting process. In conclusion, the CEO holds the power to finalize the ratio of resource allocated to exploitation and exploration activities.

The distribution of power, the skillset of two persons and their long time relationship (trust) are main explanations for managing the tensions between the future and present business issues. Here the skills of the co-owner cannot be underestimated as an explanation for the present success in utilizing existing resources. Because the CEO owns most of the company and is well aligned with the other owner, there are no powerful counterforces against his green investments, and it's mainly his own money he "gambles" with.

The most important factor for explaining the successful dynamic management of exploitation - exploration tensions namely: power based on (personal) ownership, has to our knowledge not been highlighted by any study so far. It appears to be a little naive that nobody within the OA tradition has addressed the influence from ownership on balancing tensions between exploitation and exploitation activities. From research on principal-agent theory we know for example that spread ownership can lead to short-termism and that a long-term perspective is better taken care of in cases with concentrated personal ownership. In our case there is no separation between principal and agent and hence no separation between ownership and control (Jensen & Meckling, 1976). In such cases the

personality of the agent will determine the trade-off between allocating resources for short or long time profit.

8 Challenges concerning growth

During many years the company operated all their ships in the North Sea, one of the most demanding environments when it comes to weather and operations. Their vessels were design for the most extreme conditions facing the industry and could easily do jobs in other geographical areas. However, the expansions of operations to new geographical areas raise a number of organizational questions. Where shall the follow up team of be located? How can one ensure that the contract is adhered? How shall we team up with local suppliers? These and similar questions related to efficiency in operations have to be solved.

In addition negotiating activities takes place in foreign and unknown cultures. Being familiar with "Nordic conditions" with a high level of trust between contracting partners, new contracting processes and regimes appear as a paradigm shift.

When all operations took place in the North Sea "right outside" the HQ it was much easier to stay in touch with the officers and get feedback on constructions and technology, and obtain proposals for improvements. In the future such feedback has to be more formalized. On several occasions the CEO reiterated his concern about how the feedback from operations will now be able to reach HQ. Hereby expressing great concern about one of the most important links between exploitation and exploration. If this link is wiped out, the DC's of the firm will be threatened.

9 Conclusions

This paper started with an intention to bring answers to how ambidexterity manifests itself at the micro level? In doing so we have penetrated theory and the practical centered empirical case and combined and confronted theoretical considerations and empirical facts to create meaning and understanding. To sum these up we can highlight a couple of issues that drives exploration and exploitation and conditions that interlink them.

Factors influencing efficiency in exploration:

- Cutting edge technology in the vessel and flexible technology

- Practical knowledge and experience about the technical construction (the vessel)

Standardization across ships (ex. the command bridge)

Learning from others (sharing best practice)

- The quality of the crews
- The quality of the negotiated contracts.

Factors influencing the quality of exploitation decisions:

- Clear formulation about future wants (greener, smarter, safer)
- External info (what is going on in the cluster?)
- Internal info (how does existing technologies perform?)

Factors that balance exploration and exploitation:

- Concentrated decision power based on personal ownership (CEO involvement)
- In-depth knowledge about the market (in different regions)
- Experience and knowledge about vessels and their technology.

With more and more operations taking place in unknown climate the tensions between exploration and exploitation will be filled with more uncertainty. Keeping the present ambidexterity onboard calls for new flows of information and new areas of interactions.

The counterforce to the new uncertainty will be the firm's ability to generate and disseminate knowledge within the company.

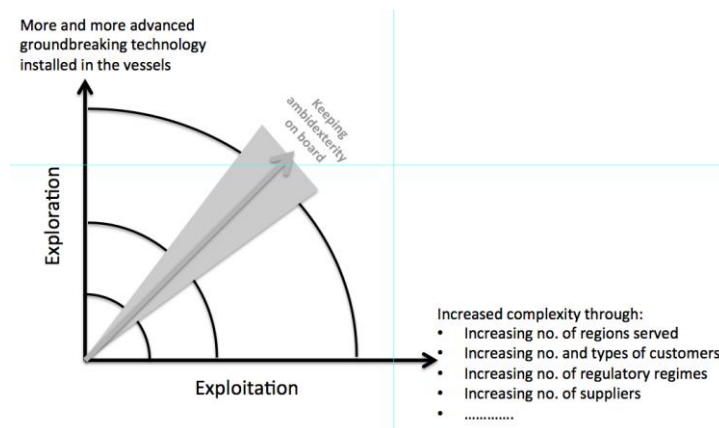

FIGURE 3: Balanced sequential growth through exploration and exploitation

Expanding operations to new geographical markets implies adding complexity to managing exploitation. For example, new local requirements have to be met, contracts with local suppliers, as well as maintenance has to be established and supervised. When operations grow in foreign markets, branch offices are likely to be established. Together these factors will add organizational complexity in the exploitation dimension. The vital question is how to organize responsibilities, communication and control without increasing costs? And how to avoid damage to the existing tension between exploration and exploitation? We need to keep ambidexterity on board and we will use our case to show how this is done in our case for the future strategy 2014-2020 and discuss the practical implications of this strategy. The outcome of this application will be a general model to be used for understanding practical challenges, dilemmas and critical success factors for exploitation and exploration in an ambidexterity organizational setting.

10. Practical implications

10.1 Working at the edge

We have working with Olympic shipping found four clear requirements for working at the edge in business development for Olympic Shipping.

1. The observability – it is few who sees the edge and who are at the same time able to connect the externalities with the internalities. This was according to our observations done by the two owners.

The owners are therefore crucial both in observing the business edge and in taking action upon their observations.

2. The knowledge about the edge must be shared and everybody has both to know their role and have to understand the expectations. When the edge was observed and the direction given this worked well since the middle managers had a long working familiarity with the two owners. They also had a long-term respect according to the delivered results and their own knowledge growth in the process and of course from their monetary reward in the process.

3. Working at the edge. This is getting the organization to work at the edge. We observed this as the most difficult part getting more difficult in a larger organizational setting. We have identified this as a critical success factor for further success in Olympic

Shipping. The whole organization has to be working at the edge to become smarter, greener and safer. This requires better formal systems without losing the creativity.

4. The integrity of the edge involves defining the edge, to evolve the edge and to defend the edge. To define the edge was done by the two owners while evolving the edge were done by the middle managers and defending the edge was done by the whole organization. The key is to define continuously new edges and getting the organization to evolve them and to defend them.

5. The contractual part is extremely important – working at the edge demand that Olympic Shipping has to be secure about their contractual basics – the company must always be sure that the contractual work is solid and robust – being at the edge gives larger risk and the most important part for reducing this risk is contractual management. This was identified as a weak point since the owners and their nearest middle managers had little interest for seeing the contract as a main tool for sustainable success. The contractual process must be changed from success by luck to success by professionalism and contractual systems.

10.2 Leadership challenges

1. Olympic Shipping business model leverage your human assets. All the human assets must participate and this is a democratization of the leadership role since a total participation is expected and during hard phases it is expected to put in up to 50 hours a week and according to the project assignments this is demanding in double income families.

2. The architectural control at the edge must vary from total empowerment to those handling and defining issues to total control from the two owners. This stretch in empowerment and responsibility is difficult to handle.

3. The organizational coherence demand sharing cultural values and attitudes through the work process- this is a hard working hard playing culture where everybody has to rely on each other.

The big issue is if working on the edge can be taken from a large but still local shipping company to a large and global shipping company in 2020. With a needed formalization of the structures and processes including stronger management control will it still be possible to be working at the edge in a dynamic changing organization pushing working greener and smarter than the competitors?

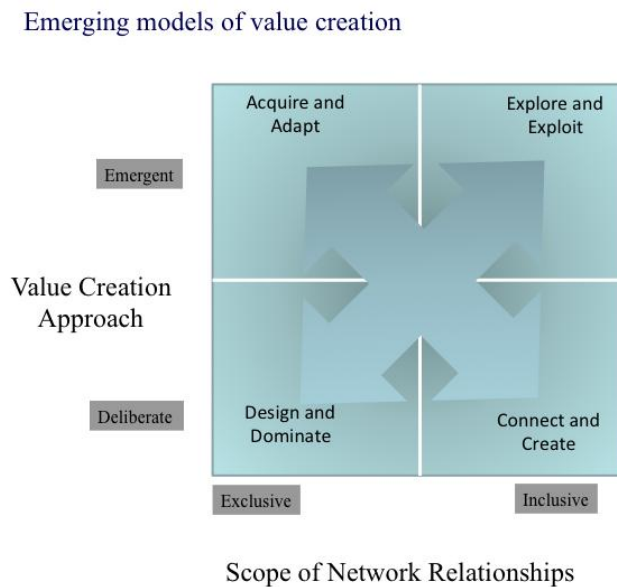

11 The concluding general theoretical model

The case of Olympic Shipping represents an emergent value creation approach of exploring and exploiting the business opportunities. The other way of doing this would be to acquire companies

And/or adapt to the market situation. The position of the market leader would be to design and dominate the market. The scope of local network relationships is inclusive in the Olympic Shipping way of doing business. The key for the company is not to connect and create in partnerships, but to explore and exploit the networks in competition with other local companies. The network relationship might also be exclusive in the value creation approaches of design and dominate and acquire and adapt.

As a third dimension we conclude that to design and dominate is closest to exploring and exploiting while acquire and adapt is closest to connect and create. The first represent more the entrepreneurial mindset of ambidexterity and knowledge dynamic while the latter represent more the planned and traditional business mindset.

We have therefor developed the following theoretical model from our case study:

Structured Abstract

Purpose – The purpose of this paper is to review extant research on outsourcing and knowledge competences to establish our understanding and to identify gaps justifying further research activities.

Design/methodology/approach – The study consists of a systematic review of refereed empirical articles on outsourcing and knowledge competences. In order to get access to the articles we used two scientific databases: ProQuest and Web of Science. As keywords we decided to use multiple keyword combinations. We only included peer reviewed articles published in English. Twelve papers were identified and analysed in the paper.

Originality/value –This methodology proofs evidence that there is a small number of papers addressing outsourcing and its consequences for KM sustainability.

Practical implications – The outcomes of this study can assist researchers, managers and consultants to better understand the link between outsourcing and the sustainability of KM. This can be useful for managers in particular as more specific measures can be derived.

Keywords – Outsourcing, Knowledge management, Knowledge competence, Systematic review

Paper type – Academic Research Paper

1 Introduction

Strategy-driven outsourcing has become more common in recent years, which may result in improved business performance and effectiveness. Perhaps the most prominent strategic reasons for outsourcing involve allowing organizations to better focus on their core competences with which other firms have difficulty in copying. Another widely cited rationale is to gain access to unique resources, skills and talents, and capabilities possessed by other firms. Greater flexibility in managing demand swings and reducing company risk by sharing it with suppliers are also mentioned as motives for outsourcing (e.g. Kremic et al., 2006; Di Gregorio et al., 2009; Quinn, 1999). Despite the benefits, there are also some indication that outsourcing can undermine the knowledge base of companies. Schlosser et al. (2006), for instance, argue that outsourcing weakens organizational learning as its temporary nature undermines the traditions and routines associated with a strong organizational culture. Similarly, firms that outsource their core activities may lose touch with their technological know-how that provides opportunities for product and process innovation (Martínez-Sánchez et al., 2007). Consequently, if the negative aspects of outsourcing overtake the positive ones, the knowledge (management) of the firms concerned is at risk, i.e. its sustainability is threatened, which can also have serious implications for the firms' overall survivability.

Having this in mind, the purpose of this paper is to review extant research on outsourcing and knowledge competences to establish our understanding and to identify gaps justifying further research activities. Thereby, outsourcing is defined here as allocating or reallocating a firm's internal activities and services to outside providers. Whereas knowledge competences refer to a specific set of abilities that enable firms to compete and develop to meet current and future business requirements.

2 Literature background

Much of the existing literature on knowledge management (KM) is concerned with how organisations can capture knowledge from experts within the organisation, and formalise and package knowledge assets for dissemination and reuse by other employees (Markus, 2001). Various mechanisms and structures, often technology-supported, have been proposed to facilitate this endeavour including Intranets (McKinlay, 2002), discussion forums (Hansen, 2001), lessons learned databases (Brown and Duguid, 2000), expert yellow pages (Storey and Barnett, 2000), mentor groups (Zack, 1999) and

communities of practice (Wenger et al., 2002). The emphasis has also been on transferring tacit knowledge into explicit (Nonaka, 1991). KM is thus viewed largely as an internal strategy where the focus is on leveraging knowledge from within the confines of the organisation. This paper proposes an alternative and less widely discussed view of KM, referred to here as “knowledge outsourcing” (KO). In KO, external experts are explicitly contracted to generate knowledge-intensive assets, which are subsequently internalised by the organisation. Hence, KO exploits external sources for knowledge creation rather than relies on internal capability. While the general concept of outsourcing is not new, as evidenced by the wealth of published literature in the area of information systems (e.g. McKeen et al., 2002; Lam and Chua, 2009), the study of KO, however, is in its infancy (Tarn and Chien-Chih, 2012).

Along with the rising share of services and knowledge in the economy, some organizational restructuring has been taking place, such as networking and supply chain change manifested in outsourcing and offshoring. Outsourcing has grown rapidly among public and private organizations in recent years (see Bryson, 2007; Di Gregorio, Musteen & Thomas, 2009; Kadabade & Kadabade, 2002). In all cases, outsourcing always requires third party involvement (Jagersma & van Gorp, 2007).

Outsourcing is a strategic move which involves both sourcing absent activities that new firms may not have completed in-house in the past, or the substitution of internal activities by transferring these, in part or whole, to a third party supplier that performs the task, function, or process (Gilley & Rasheed, 2000; Holcomb & Hitt, 2007). Advances in information and communication technologies have enabled new firms to pursue the outsourcing of value-creating activities such as software development, engineering, and research and development (Hui, Davis-Blake, & Broschak, 2008). To date, researchers have focused on outsourcing by large, established firms (Bhalla, Sodhi, & Son, 2008; McIvor, 2009); however, there is evidence that new biotechnology firms also utilize intermediate markets for a variety of value chain activities (Mills, 2002). Why might new firms outsource activities, including value-creating activities such as research and development, which are known to contribute to the value-creating potential of firms (Kumar, Van Fenema, & Von Glinow, 2009)? Researchers subscribing to the integrated view of transaction cost theory (TCT) and resource-based view (RBV) argue that by establishing relationships specifically with high-status firms, new firms can not only reduce the search and monitoring costs associated with finding a reliable partner but also

acquire recognition and use it to draw vital combinations of resources such as status and physical resources (Lin, Yang, & Arya, 2009). This is crucial for new firms as they face adverse initial resource and capability barriers such as scarcity of talent and operational know-how, presented by liabilities of newness and smallness (Aldrich & Auster, 1986; Baum & Oliver, 1992; Stinchcombe, 1965; Bhalla and Terjesen, 2013).

3 Methodology of literature review

In our review process, we adopted the principles of a systematic review as recommended by Jesson et al. (2011) namely:

- 1) Mapping the field through a scoping review
- 2) Comprehensive search
- 3) Quality assessment
- 4) Data extraction
- 5) Synthesis
- 6) Write-up

First, we developed a research plan comprising the research questions we were interested in answering. This also involved the keywords, and a set of inclusion and exclusion criteria. We were interested in the current status of research on outsourcing of knowledge processes in order to identify promising areas for future research. The questions formulated, as outlined above, were: 1) Which topics are well researched in relation to outsourcing and which are not? 2) Which were the main findings of the studies?

We decided to use multiple keywords to identify relevant studies, such as outsourcing, knowledge competence, knowledge-based service. Our inclusion criteria were: empirical research papers, peer reviewed, English language, ProQuest and Web of Science databases. We excluded grey literature such as reports and non-academic research, other languages than English, and other databases than ProQuest and Web of Science.

Additionally, we produced an excel data sheet consisting of key aspects related to our research aim. In our case these were: name of author(s), year of publication, research aim/objectives, theoretical perspective/framework, method, main findings, and name of the journal.

Second, once we had specified all the relevant issues, one of us accessed ProQuest and Web of Science and searched using combinations of the keywords set. We looked for

combinations of these keywords in the title, keywords and abstract. The literature review included papers published until 19 March, 2014. Depending on the combination of keywords used, different numbers of hits were generated.

Third, each of us manually scanned the abstracts of the respective papers and, if relevant, more parts of the articles to make sure that they actually fell within our scope of interest. This reduced the number of articles without duplications to the final number of 12 articles which fulfilled our criteria and were then analyzed.

Fourth, all authors read the 12 papers individually and entered relevant data regarding our research purpose in the excel sheet.

Fifth, in the next stage we discussed the findings, synthesised the individual data into one and identified themes. This helped us to establish the current body of knowledge with regard to outsourcing (and offshoring) of knowledge processes.

Sixth, the final stage of our review process was devoted to the write-up of our findings.

4 Presentation of findings

Among the twelve papers that formed the basis for our analysis, the oldest publication is from 2006 and the most recent ones are from 2013 (two papers). Four of the papers were published in 2009. Four papers were published in 2010, and one in 2011. No papers were published in 2007, 2008, and 2012.

In the sections below we present our analysis concerning the following aspects: general observations which outline the research methods applied. After that, the study's main findings according to the themes identified are presented.

4.1 General observations

With regard to the methodology, the most common method applied is the case study approach (nine papers). Additionally, surveys, focus groups, and secondary data (one of each) were used as research methods. We identified one paper which was longitudinal in nature (Brege *et al.*, 2010).

The 12 papers were published in 10 different journals. Six of the 12 journals can be assigned to the field of operations, technology and management, two journals to international business, and the remaining journals address fields such as innovation, marketing, entrepreneurship and small business management, and organization studies.

This suggests the topic interests a broad audience.

4.2 Body of knowledge regarding the outsourcing of knowledge competences

We summarized the main findings of the investigated studies under six topics:

- Consequences of knowledge competence (KC) outsourcing
- Reasons for KC outsourcing
- Reasons against KC outsourcing
- Risk
- Framework
- Others

Table 1 displays the different topics and the articles assigned to them.

Authors	Consequences of KC outsourcing	Reasons for KC outsourcing	Reasons against KC outsourcing	Risk	Framework	Others
Agndal & Nordin	x					
Bustinza et al.	x					
Bhalla & Terjesen	x					
Brege et al.	x					
Chang et al.					x	
Cheng et al.					x	
Hanzah et al.						x
Lacity & Willcocks						x
Lam & Chua				x		
Lau & Zhang		x	x			
Mahmoodzadeh et al.				x		
Rundquist & Halila		x	x	x		

Table 1. Topics identified

Consequences of KC outsourcing

Four papers can be assigned to this topic. Agndal and Nordin (2009) highlight in their paper negative (non-financial) consequence KC outsourcing can have for firms (e.g. loss of knowledge and skills). Based on their findings the authors propose ways to overcome these. Bustinza et al. (2010) demonstrate the contribution of outsourcing activities for learning capacities of firms and the firms stock of knowledge resources. Bhalla and Terjesen (2013) show as to how KC outsourcing can help firms to expand their supplier

network and operational knowledge base. Additionally, their findings point at learning as the consequences of activities contribute to reduced relationship specific investments and cost efficiency. Finally, Brege et al. (2010) study highlight lower costs, development of core competences, control and flexibility as consequences. Moreover, their finding suggest that KC outsourcing assists in business development.

Reasons for KC outsourcing

Two papers specifically highlighted the reasons for KC outsourcing. Lau and Zhang (2006) showed that the reasons can be found in three areas: economic, strategic and environmental. Based on their study Rundquist and Halila (2010) concluded that the main reason for KC outsourcing is the need for knowledge that is missing in the firm.

Reasons against KC outsourcing

The same papers as presented before can be assigned to this topic. Lau and Zhang (2006) considered the following reasons as essential: Lack of capable service providers, loss of control, poor transportation and IT infrastructure, local protection regulations, and lack of overall post-outsourcing measurement. Whereas Rundquist and Halila (2010) found strategic decisions from the board and risk of competence drainage as main reasons. The author stressed the relevance of personal interaction for integrative issues regarding KC outsourcing.

Risks related to KC outsourcing

Three papers were positioned under this topic. Lam and Chua (2009) highlighted quality, time and effort as main risks in KC outsourcing. Mahmoodzadeh et al. (2009) who studied outsourcing in the context of business process management and knowledge management found the following risks: “(1) dependency on the suppliers and changing collaborative to opportunistic behavior of the supplier; (2) losing touch with new technological opportunities for product and process innovations; (3) communication and coordination problems; (4) cognitive distance between suppliers and firm therefore makes it more difficult to align decisions and exchange knowledge; (5) outsourcing functions that should not be outsourced; and (6) decreasing control over the outsourced functions” (p. 861). Eventually, Rundquist and Halila (2010) identified the risk of competence drainage.

Framework

Two papers can be assigned to this topic, which refers to theoretical frameworks and perspectives in order to study KC outsourcing. Chang et al. (2009) propose an integrated model consisting of three different theoretical perspectives (i.e. technological regime, resource-based view and transaction cost theory) as a basis for the identification of factors influencing outsourcing strategies. Cheng et al. (2010), on the other hand, describe and classify different means for knowledge transfer according to their usages and propose a means framework to integrate all the elements systematically.

Others

Two papers were assigned to this topic. Hamzah et al. (2011) who mainly studied knowledge management practices as found in an offshoring outsourcing company. Lacity and Willcocks (2013) studied Legal Process Outsourcing and mainly demonstrated the opportunities available in this new field of KC outsourcing.

5 Conclusions

The aim of this paper was to review extant research on outsourcing and knowledge competences to establish our understanding and to identify gaps justifying further research activities. We used the method of systematic literature review to identify papers. We found twelve papers that formed the basis of our analysis. The papers were published in the years 2006-2013, indicating a recent origin of the topic, and the small number of papers show that this is an underresearched field of study.

The main findings were categorised into six main themes: Consequences of knowledge competence (KC) outsourcing; Reasons for KC outsourcing; Reasons against KC outsourcing; Risk; Framework and Others aspects.

The main methods used in the papers were case studies. This calls for more variety in resource methods. Also, the analysis indicates that a stronger theoretical framework is needed for the future analysis of knowledge competence outsourcing.

Two themes are very important for future research and practical application of KO outsourcing: On the one hand, the learning potential of such outsourcing, enhancing core competence, and expanding international coverage by collaborating with other companies. On the other hand, the risks associated with outsourcing. Important research topics are risk of competence drainage, dependency on suppliers or other stakeholders,

opportunistic behavior of these stakeholders, losing touch as regards new technological opportunities for product and process innovations, and decreasing control over the outsourced functions.

Supporting eco-innovation by green HRM practices

Viktor Kulhavý

Department of Corporate Economy
Faculty of Economics and Administration, Masaryk University
Lipová 41a, Brno, Czech Republic

Structured Abstract

Purpose – To explore the conceptual links between Green Human Resources Management and Strategic Sustainable Development with the focus on knowledge management practices. The question explored is “In what ways can human resources management tools, processes and practices help to support employee participation in eco-innovation birth and at the same time be strategically moving an organisation towards sustainability?”

Design/methodology/approach – The paper uses a literature review approach. An overview of the contemporary state-of-the-art employee participation practices in the context of knowledge management is presented. Possible future integration of knowledge management tools within the Framework for Strategic Sustainable Development is being proposed.

Originality/value – The strategic aspect of human resources management and sustainability constitutes a joint connection. Scholars have been currently exploring the environmental management issues integration within the human resources research field. Knowledge management practices such as suggestion programmes or problem solving circles are one of the main measures used in continuous improvement efforts in companies. But little is known on how to use these tools strategically when dealing with environmental issues.

Practical implications – Environmental knowledge and values are reported to be predictors of employee environmental behaviours. The workers wide participation increases the business performance by sharing the knowledge of all workers within an organisation. Designing knowledge management processes in a way that will ensure the innovation tools and actions are aligned with a viable sustainability strategy can bring stronger employee engagement and better environmental performance.

Keywords – corporate sustainability, strategic knowledge management, environmental management, employee participation, FSSD

Paper type – Academic Research Paper

1 Introduction

The issue of sustainability is inherently settled on the edge of several disciplines of human understanding of the complex world. In the Human Resources research field the contemporary debate focuses on the environmental management aspects of human resources management, the so called Green Human Resources Management - GHRM (Jackson et al., 2011; Renwick et al., 2013).

According to the research studies of several authors (Rennings et al., 2001; Boiral, 2002; Rogers, 2003; Rothenberg, 2003; Jabbour and Santos, 2008b; Jackson et al., 2011) one of the most efficient means of enhancing company's environmental performance is to engage employees in environmental innovation activities (eco-innovations), i.e. to stimulate the workers to propose improvements that will lower or diminish the negative impact of company's production on the environment. Workers participation in environmental improvement enhances organization's capability for knowledge creation and is being considered as a source of competitive advantage (Rothenberg, 2003; del Brío et al., 2007). In the companies' suggestion programmes the employee tacit knowledge can be particularly used for pollution sources identification, developing preventive solutions and managing emergency situations (Boiral, 2002). However environmental tools, actions and strategies need to be deeply rooted in organisation culture - reflecting the mission, values and relating different stakeholders' interest (Fryxell and Lo, 2003; Linnenluecke et al., 2009, Renwick et al., 2013). An overarching framework that would encompass economic, environmental and social side of organisation sustainability is needed in order to move strategically towards more sustainable business models. In the sustainability field there has been a constant call for such conceptual framework. One of the approaches that have an ambition to provide such platform is the Framework for Strategic Sustainable Development - FSSD (Broman et al., 2000; Ny et al. 2006; Robèrt, 2000; Robèrt et al., 2002).

The objective of the paper is to explore the conceptual links between Green Human Resources Management and Strategic Sustainable Development with the focus on knowledge management practices. The question explored is "In what ways can human resources management tools, processes and practices help to support employee participation in eco-innovation birth and at the same time be strategically moving an organisation towards sustainability?" In order to reach the objective the contemporary

Green HRM agenda is described and knowledge management position discussed. Conceptual links between Green HRM and Strategic Sustainable Development are presented.

The core concept central to the presented paper is environmental innovation (in short eco-innovation). According to Rennings (2000) the general concept of innovation is neutral by its nature – there is no constraint regarding the direction of innovation. However, the *environmental innovation* concept is narrower – it assumes that the innovation activity will be oriented towards actions of stakeholders that will contribute to a reduction of environmental impact of organization or towards reaching given ecological objectives. This definition is somewhat broad; however there is one other aspect that should be mentioned here. Rothenberg (2003) in her case study in automotive industry points out that in reality just few innovation projects were initiated because of environmental reasons. The more common situation is that environmental benefits are just a side effect of other innovation intentions. Usually project initiation is more likely to stem from specialist staff, line level workers participate during project implementation and their role is likely such as receiving training or one time consultation.

2 Methodology

A literature review on the topic of employee involvement in environmental innovation creation has been conducted. The key words used were: employee participation; employee engagement; eco-innovation; environmental innovation; continuous improvement; corporate sustainability; green human resource management; knowledge; strategic sustainable development. A set of research articles was collected using Scopus and Google Scholar database. The most cited research articles from years 2000-2014 were reviewed and possible links between adoption of green human resources practices dealing with knowledge management area and strategic move towards corporate sustainability were examined. In order to assess green human management practices from the perspective of Strategic Sustainable Development, several questions derived from the literature review were posed (Rothenberg, 2003):

- What is the role of the workers? How they participate in the innovation process?
- What kind of knowledge content is being held by different employee groups (e.g. workers, moderators, foremen, technologists, environmental managers)?

3 Green human resources management practices

The area of green human resources management has become a research focus just in the past ten years. There are several conceptual studies that deal with the means how working with people can support corporate sustainability (Jabbour and Santos, 2008a; Jackson et al., 2011; Renwick et al., 2013) and also other studies showing the benefits of such approach in different organizational contexts (e.g. Boiral, 2002; Rothenberg, 2003; Huang and Kung, 2011; Shatouri et al., 2012 and many others).

Strategic human resources management is based on three assumptions described by Jackson and Seo (2010): 1) the primary objective of effective HRM is to improve the company's performance; 2) people management practices should be aligned with overall strategic objectives; and 3) many different practices that comprise HRM system should be interconnected (e.g. by a competency framework). According to Boudreau and Ramstad (2005) the role of human resources management in heading towards corporate sustainability is twofold. First, the strategic perspective of contemporary HRM (Jackson and Seo, 2010) supposes meeting objectives related to economic, social and sustainability objectives. Actions developed in this way should have long-term and be developed with systemic approach. As will be shown below Strategic Sustainable Development can offer such platform. As Linnenluecke et al (2009) argue the employee understanding of what sustainability in given organizational context means is moderated by existence of organizational subcultures adhering different values. Second, the challenge of globalization and need for continuous innovation require HRM to attract, develop and retain talented employees (Boudreau and Ramstad, 2005; Fernández et al, 2003).

There are specific personal processes and practices among which green practices can be distinguished, for an overview see Jackson et al. (2011) and Renwick et al. (2013). These are: recruiting and selection, staffing, training including management development and leadership, empowerment and engagement, performance management and appraisal, compensation, organization culture stewardship and knowledge management.

3.1 Knowledge management importance in Green HRM

The issue of knowledge management is found crosswise the human resources processes. Authors of research studies often stress the notion that knowledge management processes should be designed in ways that allow wide employee participation (Boiral, 2002; Renwick et al., 2013). Within formalized environmental management systems

(such as ISO14001) this might be even required and thoroughly documented – for such bureaucratic structure explicit and well codified technical knowledge (auditing, impact measurement, regulation compliance, technological solutions, statistical data analysis, administration and documentation) seem to be crucial. To distinguish the knowledge management practices from just formal training it is important to note that environmental management initiatives require the staff to acquire new techniques and knowledge regarding clean technologies implementation, learning about the causes of pollution and overall environmental management system functioning (Jabbour and Santos, 2008b). However, there is more subtle and intangible knowledge to be addressed. Formal structures can have difficulty in capturing employee experience, practices and routine behaviours that are inherently subjective, context-specific, hidden in people’s heads and therefore escaping the formal codification processes. Therefore decentralised initiatives allowing for informal learning may better suit the need for tacit knowledge exploitation. The well-known concept of tacit (implicit knowledge) and how tacit knowledge can be used to improve organizational environmental practices represent a major challenge for managers of today’s organizations. Tacit knowledge may be perceived as something that is very difficult to access, articulate, and share. The nature of tacit knowledge could be described by a “paradox of internalising” (Boiral, 2002) – it is difficult to share something that we are not aware of or that we are not convinced to be important to share with others. However the tacit knowledge cannot be separated from explicit knowledge (Boiral, 2002). Using tacit employee knowledge should be accompanied by specialist explicit knowledge providing platform for capturing, further elaborating and evaluating tacit knowledge.

Unlike the concept of explicit-tacit continuum, different categorization points out the knowledge content differentiation (Rothenberg, 2003) – see Table 1 below. It is stressed that the birth of innovation is started when the combination of employee knowledge can occur. Interpersonal trust is reported to be a crucial prerequisite for a greater level of knowledge sharing and combination (Rothenberg, 2003).

Table 1. Knowledge content classification

Knowledge Content Type	Description
Contextual knowledge	Knowledge regarding the setting in which the process of concern exists and interacts
Process knowledge	Understanding the mechanical and chemical properties at hand, as well as the performance parameters within which the process should operate

Intra-organizational knowledge	Knowledge about how the process and people involved with the process interact with other parts of the organization
External knowledge	Knowledge that resides external to the firm that is relevant to the process

Source: Adapted from Rothenberg, 2003, p. 1791

The environmental management process is often controlled by an environmental department with specialist staff and by highly skilled engineers or technologists. Its main objectives are the adherence to environmental legislative, following internal standards and dealing with pollution. On the contrary, when dealing with preventive measures the role of employees (manual workers, operators) is irreplaceable. There are several reasons for that (Boiral, 2002): 1) the employees are the ones who are physically present in the industrial process and who perform the operations which have environmental consequences; 2) employee participation in preventive measures is desirable because of greater losses avoided when environmental issues become critical (e.g. hazardous substance leakage, factory surroundings contamination); 3) employees that are observers of an environmental accident need to be prepared to react promptly.

Also it is important to recognize there are many interconnections knowledge management has with the other human resources management functions. To point out just some of them:

- Formal training programmes usually target explicit knowledge. However contemporary organizational training focuses on on-the-job training programmes which are better suited to tacit knowledge appreciation.
- Subordinate behaviour is reported to have significant influence on employee willingness to engage in continual process of implicit-explicit knowledge transformation (Ramus and Steger, 2003).
- Staff turnover may influence the retention of tacit knowledge in organization (Boiral, 2002).
- Recruitment strategy could focus on candidate dexterity rather than formal qualification (Boiral, 2002).
- The promotion of an employee idea is based on teamwork (colleagues, subordinate, environmental department) rather than on an individual suggestion.

Boiral (2002) distinguishes active and passive employee participation. The passive way treats the workers just as “repositories of knowledge” which needs to be exploited.

The active approach sees a worker as a change agent, being a natural part of the change process. The common problem of continuous improvement programmes is that the employee ideas are harvested, but the employees themselves are not involved in the idea implementation (or are involved just formally, lacking any intentional involvement or empowerment). According to the study conducted by Siebenhüner and Arnold (2007) change agents were identified to be the main influencing factor of innovation birth and innovation process continuation.

The role of individuals is also stressed by Busck (2006) using term “environmental champions”. It is referring to individuals that are deliberately offered participation in environmental initiatives with the expectation of promoting in the future. However this is corresponding to the Anglo-Saxon individualistic culture. The idea of collective sharing and cooperation is much more promoted by contemporary research literature. Nevertheless individuals play important role in influencing others through their personal networks.

4 A perspective of Strategic Sustainable Development

In the previous text it has been shown that the strategic aspect of human resources development is a generally accepted concept and represents a cornerstone of effective workforce management. Jabbour and Santos (2008a) claim that for HRM integration with organizational sustainability, human resources strategies stimulating economic, social and environmental development need to be formulated.

However it is much less clear in what ways the environmental initiatives fit the strategic notion of how the organization should be managed. For economic sustainability itself many theories, procedures, rules have been developed ensuring that the organizational existence will pay off. Common definitions of corporate sustainability often refer to Brundtland explanation of sustainability or are trying to define sustainable development through the triple-bottom line concept referred to as 3P – People, Profit and Planet. The crucial questions which are dealt by day-to-day organizational practice are:

- What does sustainability mean to us?
- Which environmental actions should be prioritized?
- What environmental goals should be set up and fulfilled?
- How to identify the most relevant environmental issues now and in the future that the organization is / will be facing?

To answer those questions an overarching sustainability framework is needed in order to provide an understanding of what sustainability is, how to set the objectives, choose actions or tools that will bring the best effect and measure the progress. Such framework could represent a guideline for knowledge management indicating what knowledge needs to be searched for, captured and retained within the organization. For planning in complex systems a unifying structure has been created (Azar et al., 1996; Robèrt et al., 2000; Robèrt et al., 2002). Sustainability is not defined as a certain state that should be reached but rather by a set of principles that should not be violated in order not to undermine the capacity of ecosystems to provide the necessary services (e.g. purification of water and air, carbon sequestration and climate regulation, recreational experiences).

The concept of Strategic Sustainable Development introduces a framework distinguishing five levels of sustainability perspective (Robèrt et al., 2001; Missimer et al., 2010) - FSSD:

1. The overall **system level** (society and ecosystems as part of the biosphere¹) – organizational surroundings are analyzed including legislative and other norms, stakeholders interests; notion of socio-economical system functioning within biosphere is taken into account (e.g. natural laws, accessibility and scarcity of natural resources).
2. The **success level** is operationalized by four distinct principles of sustainability and the backcasting approach. The organizational vision and the sustainability principles can be regarded as constraints within which the organization operates. As long as the principles are not violated, the organization socio-ecological sustainability may be reached.
3. The **strategy level** is depicting different ways of arriving to desired state. Different strategic guidelines can be used as long as they contribute to reaching defined success in the system.
4. The **actions level** is offering a range of possible actions that are in line with strategies that can be taken in order to follow the success principles and organizational vision.
5. The **tools level** is collecting the necessary methods, tools and concepts to focus on specific impacts, to monitor and measure the progress and evaluate the result

¹ This view is corresponding with the concept of ecological economics (Daly and Farley, 2010).

of actions. For example tools such as Life Cycle Assessment or Environmental management systems can be used here.

The four sustainability principles which are stated below show a direction in which organizations should manoeuvre in the socio-ecological system in order to eliminate risks that stem from behaving unsustainably. The first three principles deal with sustainability in environmental meaning, the fourth focuses on social sustainability. The economical sustainability is not captured in these principles; however it is dealt with at the success level and strategy level of the framework when seeking the return on investments.

“In the sustainable society, nature is not subject to systematically increasing:

1. ...concentrations of substances extracted from the Earth's crust,
2. ...concentrations of substances produced by society,
3. ...degradation by physical means and
4. ...people are not subject to conditions that systematically undermine their capacity to meet their needs.” (Azar et al., 1996; Robèrt et al., 2000; Missimer et al., 2010, p. 1109)

5 Issue integration and practical implications

Getting back to the question posed in the beginning, we can reflect on the ways human resources management and especially knowledge management can support employee participation in eco-innovation birth in a strategic way. Strategic sustainability perspective taken into account means that working with people in an organization does occur on all of the FSSD levels. In organizations usually the tools and actions are widely used, however their relevance to the HR strategies, overall organization strategy and organization’s sustainability strategy are weak. It is the interconnection between these three which makes the processes comprehensible for all the employee groups involved and also for other stakeholders. Competency frameworks reflecting the tight unity of strategy and HR processes can also encompass sustainability competences.

HR practices can help to make the tacit knowledge more visible; but not every tacit knowledge needs to be exploited, because the corresponding resources (time, money) has to be considered. Certain tacit knowledge which is highest importance for the organization’s operations needs to have the most attention.

In Table 2 a set of question that should be answered by management of an organization is presented. These questions were derived based on the literature review and

represent a checklist of whether human resources management practices within an organization provide strategic support for eco-innovation birth. The perspective of Strategic sustainable development is used here to structure the questions so that their relevance to the various levels of FSSD is made clear. For each question the rationale is explained and corresponding studies identified in the literature review are referenced (studies providing examples of such HR practices or defining those concepts as crucial).

Table 2. Assessment of Green HRM practices from the perspective of knowledge management and Strategic Sustainable Development (Green HRM Checklist)

Question/Area	Rationale	Research evidence
<i>SYSTEM LEVEL – what is the system the organization is operating in</i>		
<i>Who are the stakeholders of the organization?</i>	Organization's employees are an important stakeholder group. In contemporary HR management the building of relationship with employees is being stressed as a mean for building a coalition.	Del Brío et al., 2007 Fernández et al, 2003 Jackson and Seo, 2010
<i>What are the demands the legislation is posing on the organization regarding human resources?</i>	Fair treatment of employees means beyond others an adherence to legislative requirements. The basis of psychological contract needs to be settled in order to build an atmosphere of trust and cooperation.	Jackson et al., 2011 Renwick et al., 2013
<i>SUCCESS LEVEL – organizational vision, culture and sustainability principles</i>		
<i>Is sustainability defined in the organization?</i>	FSSD recommends defining sustainability by a set of four principles. These principles comprise a constraint within which organizational vision can be realized.	Ny et al., 2006 Robèrt et al., 2000 Robèrt et al., 2002
<i>Is sustainability one of the core values within the organizational culture?</i>	The sustainability commitment approach differs from a greenwashing one in a way that sustainability is regarded a core value and not just a way for building organization's image in the eyes of public.	Rothenberg, 2003 Linnenluecke et al., 2009 Fernández et al, 2003
<i>How is sustainability understood in the organization by different employee subcultures?</i>	Different understandings of sustainability might co-exist in one organization. Explaining the desired state by various means will increase the probability it will speak to various employee subcultures.	Linnenluecke et al., 2009

<i>Are the basic assumptions, values, symbols and organizational artefacts reflecting desire or necessity of company to operate in an environmentally correct way?</i>	The research studies indicate that building interpersonal trust, close working relationships, increased level of communication and access, reducing distinction power in the organization, letting managers spent time on the shop floor, eliminating fear or replacing when sharing knowledge and hands-on approach to management and especially environmental staff create an environment where employee willingness to participate is supported.	Jabour and Santos, 2008b Harris and Crane, 2002 Rothenberg, 2003 Fernández et al, 2003
<i>Is the top management demonstrating support for sustainability?</i>	Recognizing and spreading environmental dimension as a value and explaining how environmental management practices influence the day-to-day operations.	Govindarajulu and Daily, 2004 Del Brío et al., 2007 Jabour and Santos, 2008b
STRATEGY LEVEL – organizational strategy		
<i>Are principles of sustainability reflected in HR strategy?</i>	Especially fourth sustainability principle deals with social sustainability – people should be treated in such way it does not undermine fulfilling their needs. This aims at assuring fair employee treatment, building mutual trust, supporting the learning environment.	Jabour and Santos, 2008b Missimer et al., 2010
<i>Does sustainability strategy allow for prioritization of potential measures?</i>	Corporate sustainability strategy should be able to identify the “low hanging fruit”, i.e. the actions that will bring the quickest economical, environmental or social improvement.	Robèrt et al., 2000 Robèrt et al., 2002
ACTIONS AND TOOLS LEVEL – supporting HR practices		
RECRUITMENT		
<i>Are the environmental responsibilities found in the job descriptions?</i>	Job descriptions and required competencies are usually transformed into selection criteria and presented to a target group of potential candidates.	Jabour and Santos, 2008b
TRAINING AND DEVELOPMENT		
<i>Have employees received appropriate training?</i>	The employee training can be focused on general issues such as raising employee awareness, identify the problematic environmental issues, finding a best way how to solve them; or issues related to the	Govindarajulu and Daily, 2004 Jabour and Santos, 2008b

	organization operations: hazardous materials use, training on plant environmental policy, recycling, pollution prevention.	
PERFORMANCE MANAGEMENT		
<i>Are the environmental indicators used for employee performance evaluation?</i>	Performance management criteria can be stated as desired results (e.g. defined by Key Performance Indicators) and/or by desired employee behaviour (e.g. defined by competency framework).	Linnenluecke et al., 2009
<i>Are awards, recognition, praises and financial rewards linked to employee performance related to environmental management goals?</i>	Performance management system is regarded as the managerial tool for influencing the employee motivation. Financial rewards are regarded as the most important ones especially by the shop floor workers.	Wehrmeyer, 1996
<i>Are training opportunities provided for those employees who do not follow the criteria for desired results and behaviour?</i>	The performance management should be able to identify the gaps between the current competency level and the desired competency level.	Jackson et al., 2011 Renwick et al., 2013
ORGANIZATIONAL LEARNING		
<i>Is teamwork practised? (e.g. quality circles, green teams...)</i>	Knowledge combination seems to be the key mechanism for innovation birth. Small groups of people with complementary knowledge – environmental management staff, engineering staff, suppliers, factory floor workers – represent the appropriate environment for innovative thinking.	Rothenberg, 2003 Busck, 2006
<i>Is employee participation and empowerment a key approach to HR management?</i>	The shop floor workers, specialists and environmental management staff can be involved through different means such as: consultations, suggestion programmes, problem solving circles, training.	Boiral, 2002
<i>Are the processes constantly documented in order to retain the knowledge?</i>	On the one hand the documentation requirement may be perceived as a bureaucratic burden; on the other hand it remains one of the main sources of knowledge sharing in organization.	Rothenberg, 2003
<i>Is organization striving for employee knowledge capture?</i>	There are several means of deliberate endeavour for knowledge capture such as suggestion programmes, circles of quality,	Busck, 2006 Rothenberg, 2003 Boiral, 2002

	green teams, and employee consultations. The information technology provides infrastructure for such process.	
--	--	--

Strategic sustainability approach provides a necessary structure for working with people in organizations. It stresses that there are several layers of sustainability thinking. The most visible environmental actions that are taken or environmental tools that are used do not constitute the real core of sustainability awareness building and understanding. Siebenhüner and Arnold (2007) argue that sustainability-oriented learning processes are initiated and carried out in an environment where sustainability-related requirements are part of the organizational culture. This idea is further supported by the research findings of Linnenluecke et al (2009). The integration of environmental indicators into employee performance evaluation is considered to be an important element for developing an employee understanding of corporate sustainability. Linnenluecke et al (2009) found that successful implementation of corporate sustainability is preconditioned by diffusion of knowledge about sustainability throughout the organization. Therefore internal communication of sustainability should encompass various dimensions of sustainability concept in order to speak to different employee subcultures which have different conceptualizations (understandings) of it. Tailor made training programmes of new environmental knowledge and behaviours are needed for building employee sustainability awareness, explaining consequences of unwanted behaviour and usefulness of environmental management (Rothenberg, 2003).

6 Conclusions

People are said to be the most valuable asset of organizations. To energize them for participation in eco-innovation birth the meaning of such effort has to be adopted. This might be achieved if the managers of the organization have developed a deep understanding of what sustainability means for their business. The management of the organization has to be aware of the properties of the global system it is operating in, have clear definition of what they want to achieve and what are the sustainability constraints of such success. The sustainability understanding should be reflected in organizational culture, creating opportunities for innovation birth. Sustainability issue is closely interconnected with human resources management. The social side of sustainability encompasses human needs fulfilling and the environmental effects impact the health and

working conditions of employees and often of their families living in the organization's neighbourhood. Exploiting the advantage of developing sustainable organization in a strategic way may represent a major competitive advantage for the future.

Palazzo Paganowski, via Generale Parisi, 13, Napoli, 80132, Italy

Structured Abstract

Purpose – The aim of this paper is to elucidate that parliaments are seeking legitimacy as accountable and sustainable democratic institutions by managing new technologies and knowledge to design an e-parliament where stakeholders use information and communication technologies to perform more effectively their core functions of lawmaking, representation, and oversight.

Design/methodology/approach – Parliaments under increasing pressure to revisit their concept of sustainability may select different approach to policymaking and lawmaking connecting citizens to knowledge and information in the policy process. Organizations seeking greater legitimacy than better performance tend to conform to the expectations of the key stakeholders. Managing and sharing knowledge and information can help to face uncertainty and environmental complexity as the fundamental problem for organizations such as parliaments. This study is based on archival and qualitative data drawn by literature review about the use of knowledge management systems and internet technologies of information and communication within parliamentary institutions.

Originality/value – Technology has made possible greater access to the policy process enhancing quality of democratic governance if citizens are better informed and included in decision making processes. ICTs offer different scenarios to representative democracy leading parliamentary institutions to sustain public trust to survive in their current forms to cope with distrust and disengagement of people feeling unheard by politicians.

Practical implications – Parliaments embracing new technologies coherently with international standards and best practices may select different choices in order to use new technologies, managing knowledge and information in order to develop their internal workings engaging citizens in the public policy process.

Keywords – e-parliament, social sustainability, knowledge and information management.

Paper type – Academic research paper

1 Introduction

Parliaments, as the institutions through which governments are held accountable to the electorate, are designing an e-parliament keeping up with complexity of managing new technologies, information and knowledge.

The aim of this paper is to elucidate that parliaments can select different e-parliament strategies managing knowledge and new technologies of information and communication seeking legitimacy to appear as accountable and sustainable knowledge based democratic institutions engaging effectively citizens in the political process. This study is based on archival and qualitative data drawn by literature review about the use of knowledge management systems and information and communication technologies within parliamentary institutions.

Parliaments qualify as complex organizations playing a different strategic behavior and being supported by a consistent support staff. According to the Institutional view organizations tend to achieve greater legitimacy than better performance to conform to the expectations of the key stakeholders in their environments. Managing and sharing knowledge and information can help to face uncertainty and environmental complexity as the fundamental problem for organizations such as parliaments.

Knowledge management as a systematic approach to the capture, structure, management, and dissemination of knowledge has the potential to transform public sector organizations through the distribution and use of information and knowledge supported by Internet technologies sustaining citizens to participate in public decision-making and consultation in the knowledge and information society. New technologies of information and the Internet lead parliaments as open and accountable institutions to improve their internal procedures and communicate with citizens and effectively engage them in the political process through websites that make available documents and information about parliamentary activities.

2 A neo-institutional framework on change and design

Institutional theory provides an interesting lens for understanding the organizational processes of continuity and change in public sector and public administrations (Greenwood and Hinings, 1996). The primary objective of organizational change is to

achieve not better substantive performance but greater legitimacy. Ideas, values, and beliefs that originate in the institutional context and external to an organization may limit the range of available organizational designs. Organizations do not always embrace strategies, structures, and processes that enhance their performance but seek ways to accommodate pressures following external scrutiny and regulation and adapt their internal characteristics in order to conform to the expectations of the key stakeholders in their environments becoming increasingly similar. through coercive, normative and mimetic mechanisms (Di Maggio and Powell, 1983). Coercive isomorphism is dependent of an organization's pressure to conform to the cultural expectations of the large society. Normative isomorphism as a result of professionalization. Mimetic isomorphism as a response to uncertainty leading to the adoption of management practices for which there is little empirical evidence of performance benefits such as in government or non-profit organization (Ashworth and Boyne, 2009).

3 Managing knowledge, information and technologies in the public sector

Knowledge management (KM) as a systematic approach to the capture, management, and dissemination of knowledge has the potential to transform public sector organizations through the distribution and use of information and knowledge supported by new technologies. ICTs can play an important role in determining success or failure of the implementation of knowledge management systems. Organizations should translate their knowledge strategy into an organizational and technical architecture to support knowledge creation, management, and utilization processes (Zack, 1999). However, every organization may develop its own way of dealing with information and knowledge (Tseng, 2007). Organizations knowledge-based have to provide an environment favorable to knowledge creation, assimilation and dissemination (Misra, Hariharan and Khaneja, 2003). Developing the Internet and Information Technologies as dimension of KM may help to ensure excellence and improve quality (Sher and Lee, 2003). Tools and concepts of information management which are developed and implemented through technologies cannot be used to design KM systems (McDermott, 1999). While information can be captured, stored and transmitted in digital form, knowledge can exist only within an intelligent system. Information may support knowledge as the outcome of a knowledge process (Blumentritt and Johnston, 1999). Information technologies make government responsible of engaging citizen in participation and having the potential of maximizing

the knowledge of decision makers before solutions are applied (Henry, 1974). Managing knowledge in the public sector as a fundamental resource in public policy formulation implies the design and implementation of information systems improving the organizational responsiveness to social needs as to influence the political dialogue within public institutions (Gates, 1975). Transparent processes that facilitate effective two-way transfers of knowledge between public organizations and stakeholder are considered to be as fundamental for building a successful partnership to better develop sustainable policy solutions (Riege and Lindsay, 2006). Thereby, KM is still in its infancy even if technology-based KM tools are in rapid development while information management systems are well developed (Cong and Pandya, 2003; Wiig, 2002; Blumentritt and Johnston, 1999). In the public sector KM should focus on organizational culture to stimulate the sharing and use of knowledge, on processes to create and capture knowledge, on technology too to store and make knowledge accessible (Cong and Pandya, 2003). KM enhance decision making within public service; aiding the public to participate effectively in decision making and ICTs have an enabling role in leading change in the public sector (Wiig, 2002). New technologies lead to designing of flat and less hierarchical, flexible organizational structures that foster the development of information and knowledge sharing among work units (Fang, 2000) providing sophisticated means for development, management and application of information when data collected can be integrated and become resource of significance and application (Bellamy and Taylor, 1994). KM may produce effects on organizational processes enhancing information sharing as to require behaviors that influence the way the organization operates and should be fit with existing information technology infrastructure (King, Marks, McCoy, 2002). Thereby, web technology should be tested with regard to maturity of an organization to be adopted as part of the organizational knowledge sharing (Levy, 2007).

3.1 Parliament as organization. Models of parliament and parliamentary administration

Parliaments qualify as complex organizations and the institutions through which governments are held accountable to the electorate by overseeing the executive authority, performing lawmaking and policymaking. Parliament is the representative body through which the will of the people is manifested, the differences between them are debated and

negotiated, as the means through which a public interest is realized by discussion and compromise. Parliaments are considered to be as professional bureaucracies and intensive information demanding organizations able to perform their task as knowledge based organizations that use, disseminate and share knowledge establishing objectives related to social and environmental issues (Leon, 2013). Parliaments as democratic institutions perform three main functions: oversight, representation and legislation; issue and enact laws, represent the interest of voters and oversee and monitor the work of the executive branch of government, debate and define policy priorities, allocate resources, represent different constituencies and political parties. Parliamentarians acting as the operating core and knowledge workers develop their expertise in particular areas to contribute to policy formulation (Suurla, Markkula, and Mustajarvi, 2002). In any organization work staff is vital. Parliament could not perform lawmaking and policymaking activities without support of its administrative and legislative staff providing assistance and aide to the organization outside the operating work flow (Bontadini, 1983). Parliaments need their own source of information and expertise to remain independent from the government. Without its staff Congress would quickly become the prisoner of its outside sources of information in the executive branch and interest groups (Malbin, 1980). Staff structure and operations rely on strategic behaviour of the Parliament and also reflect the role of the legislature in the political system. There are different models of parliament and parliamentary support staff. Parliaments may select a strategy in terms of decisional/ratifying behaviour on policymaking in front of the executive authority and then tailor the staff structure to fit. Ratifying Parliament cannot exert any influence on policymaking. It is aided by registration staff able to ensure a merely administrative support, in terms of registration of sittings and transcript of debates. Parliaments need their own source of information and expertise to remain independent from the government. Decisional parliament as governing legislatures may play a proactive, powerful and more independent role in formulating policy and overseeing its implementation. It is supported by consulting administration knowledge oriented and able to provide technical and professional support on lawmaking and policymaking. The role of legislature is fluid over time. Mixed models of parliament and administration may develop and emerge over time (Chimenti, 1981).

3.2 Parliaments, sustainable democracy, and new technologies

Public organizations are likely to come under increasing pressure to rethink their approach to concept of sustainability moving away from absorbing simply managerial practices in managing information and knowledge about their sustainable activities (Dumay, Guthrie and Farneti, 2010). Social sustainability as life-enhancing condition and process within communities may rely on the widespread political participation and contribution of citizens in every policy area in terms of effective democratic citizenship (McKenzie, 2004) implying the development of models of democratic engagement inclusive of public participation (Gezi, 2007). The idea of citizens first should require the design and implementation of public policy as result of dialogue and shared values (Denhardt and Denhardt, 2001). E-democracy refers to the use of information and communication technologies to engage citizens, support the democratic decision-making processes strengthening representative democracy moving citizens from passive information access to active citizen participation and facilitating a way of communication between citizens empowered to hold politicians accountable and responsive for their actions (Trechsel et al., 2004). Adding a socially sustainable perspective to e-democracy let to adequately analyse social development coherently with need of inclusion, information, discussion, participation to decision-making about policies that are desired in a democratic society (Lidèn, 2012). When politicians set the agenda and citizens may be mainly included in decision-making processes or have a defined role in decision making processes ICTs should improve quality of information exchange between government and citizens (liberal democracy) or improve citizen participation and involvement in decision-making processes (deliberative democracy) (Päivärinta and Sæbø, 2006). ICTs offer to representative democracy more or less favorable scenarios (Gibson, Lusoli and Römmele, 2004): Internet technologies lead to new forms of political participation and direct democracy (erosion) reducing the reliance on intermediary representative bodies (limited erosion). Thereby, new technologies may improve the image of representative institutions that use and implement websites as marketing tool for seeking legitimacy and consensus (modernization and reform) as to permit to representative democratic institutions to use technology for performing their existing functions or reinvigorate representative institutions engaging people to participate in the political system (reinvigoration). Internet technologies permit to restructure the linkages among the institutions in representative democracies as to supplement existing channels of political communication and

information in virtue of Internet global capacity networking (Norris, 2000). Parliaments are slow to utilize the new media and tend not to have corporate communication strategies even if are likely to connect more directly citizens as to avoid to become marginalized institutions under increasing pressure to present themselves accessible, transparent and open to the public (Coleman and Spiller, 2003). Internet technologies offer new capabilities through which traditional representative arrangements can be reinvigorated and renewed (Dai and Norton, 2007) leading both representative systems to become decentralized, accessible and responsive (Zittel, 2003) and citizens to exert influence over decision-making processes (Grönlund, 2003). Thereby, only an equalized access to technologies may ensure new people to participate into democratic policy processes (Krueger, 2002). Internet technologies enhance the quality of democratic governance if citizens are better informed (Kakabadse and Kakabadse, 1999) and more likely to be involved in the political process having easily access to their representative institution. Parliaments embracing new technologies may connect to the public and inform, interact and engage with citizens to cope with the increasing disengagement and distrust of citizens feeling unheard by politicians (Lusoli, Ward and Gibson, 2006). Representative institutions should sustain public trust to survive in their current forms stimulating greater participation through e-voting, e-polling, e-consultations and e-petition (Lindh and Miles, 2007) playing a role of legitimacy of their political system promoting citizenship and accountability through their websites (Griffith and Leston-Bandeira, 2012).

4. The challenge of the e-parliament to support parliamentary functions

Democratic parliament should be representative of the diversity of the people, transparent in the conduct of its business, accessible involving the public, accountable to the electorate for performance in office and integrity of conduct and effective in the organization of business in accordance with these democratic values (World Report, 2008). Recently, parliaments have integrated the internet technologies of information and communication into their workflow to enhance primary parliamentary functions (representative, legislative, scrutiny, oversight, legitimacy, education, conflict resolution), by improving work organization and reinforcing their image in terms of communication possibilities, dissemination and management of information (Leston-Bandeira, 2007) towards the building of e-parliament that is defined to be as the use of ICTs to enhance and strengthen parliamentary core functions and operations (Oppd). An e-parliament, as

an efficient organization where stakeholders use information and communication technologies to perform their primary functions of lawmaking, representation, and oversight more effectively, is a legislature that is empowered to be more open, transparent and accountable through ICT encouraging people to be more engaged in public life by providing higher quality information and greater access to documents and activities of the legislative body. An e-parliament, through the application of modern technology and standards and the adoption of supportive policies, may foster the development of an equitable and inclusive information society (World Report, 2008). E-parliament infrastructure may provide an opportunity for parliamentarians to communicate ideas and best practices and develop common ground for model legislation that subsequently could be introduced in their national legislatures (Johansen, 2006). Citizens may be included in decision making processes through service that enable people to actively engage in interaction with Members of Parliament. E-parliament services as a supplementary venture, enable automation of parliamentary information and the tracking of decisions and documents like the stages of development of legislation, sharing of information, facilitate information exchange between parliaments and the work of parliamentarians, permit to citizens to contact their parliamentarians and give feedback, permit to parliament to attract citizens participation reinforcing participatory democracy (Papaloi and Gouscos, 2011).

Parliaments as information intensive organizations are traditionally seen as closed organizations that need to appear as transparent and accessible institutions (Leston-Bandeira, 2007) using new technologies in order to improve their communication and information capacity and connecting to people and citizens. ICTs contribute to design efficient operational process for managing documentation and information and facilitate parliamentary work by providing access to a wide range of digital information which parliamentarians can use and appreciate. ICTs can be used to help parliaments to be more efficient improving their internal workings and give a wide access to government services developing websites enabling people to acquire the advantages of information and on-line provisions of services. ICTs make parliamentarians to be more representative in front of the constituencies and contribute a new form of policies sharing and participatory democracy (Kingham, 2003). International organizations have strongly supported the development of ICT in parliaments: the International Parliamentary Union, the European Union, United Nations Development Programme (UNDP), the United States Agency for

International Development (USAID), the World Bank. The potential importance played by ICTs for parliaments is shown by developments such as the Global Centre for ICT in Parliament, a joint venture between the United Nations Department of Economic and Social Affairs (UNDESA) and the Inter-parliamentary Union (IPU) together with a group of parliaments, which aims to promote and strengthen the development of ICT in parliaments across the world treated. The Global Center has two main lines of action: promote the use of ICT as a means to modernize parliamentary processes; strengthen the role of parliaments in the promotion of the Information society through fostering ICT-related legislation by performing three tasks: information sharing and networking, analysis and research, technical assistance and advisory services; increase citizens' access to parliaments activities and documentation, thereby improving openness and accountability in legislatures; find new modalities of coordination between the international community and parliaments in supporting ICT-related initiatives.

ICTs may offer to parliamentarians support with regard to communications, information management and gathering (research) and dissemination (publishing) (Campbell, Harrop and Thompson, 1999). For instance, the Senate of the Dutch Parliament may distribute its meeting documents to its senators by tablet computer to consult and manage the complete information flow of calendars, legislative bills, correspondence and other meeting documents (World parliamentary report, 2012). ICT-based management systems significantly expand the scope of information and knowledge on a issue ensuring that the law makers are better informed about the possible outcomes of their decisions, improve parliamentary workflow increasing the speed, accuracy and flexibility and permit to parliamentarians and committees to handle pending legislation, spend more time for access to documents and consideration of proposals and recommend additional improvements making informed and responsible voting choices. Thereby, the Internet as engine of change may impact on legislative and political processes and serve as tool of control and evaluation on public policy reinforcing the lawmaking functions and operational activities of parliamentary assemblies (De Rosa, 2010). In the European Parliament the e-parliament is designed to modernize core parliamentary information system and ensure the use of the most appropriate ICTs tools and applications to support legislative and administrative parliamentary processes enabling the institution to perform its duties in an effective way and better support the work of its Members. The e-parliament implantation should follow two phases: in the first phase the focus is on

parliamentary text management and changes in related processes; in the second phase the attention is oriented to activity/process dealing with the optimization of the text production processes and supporting workflows (World Report, 2012). In the young Scottish Parliament ICTs daily entrenched within parliamentarians' activities support legislative and oversight functions of representatives linking the work of the operating core and the staff or parliamentary administration with regard to: legislative and oversight functions, in terms of access to legislative, committee, government and administrative documentation, and communication with internal and external actors; representation function, in terms of access to party and local office documentation, communication with constituents, lobby groups (Smith and Websters, 2008). Parliaments, by using Internet technologies to manage legislative documents and internal information resources are able to build a knowledge resource in order to operate efficiently, legislate effectively providing the public with relevant and accountable information (Oppd). ICTs offer an effective way to gather legislative document, prepare verbatim account and summaries integrating it with other legislative information to provide a complete picture of legislative actions. Through databases, intranets, and digital libraries parliamentarians have access to resource relating to legislative documents (bills and proceedings) and legislative committee reports on line to monitor legislation in process and under debate. ICTs can support for plenary session activity on legislation needs to be another component for managing and tracking legislation. Effective document management systems permit to manage documentation in digital formats and make parliamentary operations more efficient and support transparency. KM as systematic location, processing, storage and distribution of knowledge, competence and expertise within an organization should enhance the Parliament's routine work efficiency and its capability to react to environmental changes. ICTs support extensively parliamentary basic functions and data processing have become integrated as to provide new opportunities for KM (Suurla, Makkula and Mustajarvi, 2004).

The publicity of political decision making is a central element of representative democracies. Technology may enable parliaments to realize the value of transparency, openness, accessibility and accountability developing information and communication flows with voters and public opinion to legitimize public policies (Hoff, Coleman, Filzmaier and Cardoso, 2004) and making available to citizens: information about parliamentary process; issues debated and ability for participation through petitions;

communication with committees and parliamentarians (Missingham, 2001). The practice of e-parliament is related to the concept of e-democracy that enables citizen participation in the policy-making and requires that parliamentary records have to be available to be viewed and discussed by citizens through websites that provide greater access to its parliamentary documents and make available a growing amount of information about legislative process. The Inter-Parliamentary Union (2009) proposed some guidelines for structuring parliamentary websites that include: access to parliament (information, diagram, organization of the website); history and role; functions, composition and activities; data and pictures of Presiding Officers, Vice-Presidents, powers and prerogatives; information about committees and committees' work; members of parliament, party groups, electoral systems, general links to websites; general information about legislative, budget/public financing and oversight activities. The goals of parliamentary websites concern: providing basic information about the history, the functions, the leadership, and the membership of the legislature; providing copies of official texts of proposed legislation, then the verbatim accounts of debates and summaries of plenary actions and copies of committee documents. Parliamentary website as a virtual face of the parliament and digital bridge between parliaments and citizens constitute an important way for citizens to learn about their legislature providing a central accessible source for disseminating information about the current legislative activity, and administrative acts increasing the chances of ex ante and ex post public scrutiny of legislatures (Setälä and Grönlund, 2006) becoming the primary means by which parliaments make their work known to citizens and an important tool for the parliament to 'market' itself to the citizens in order to appear as accountable voice in front of the executive authority and government (Dai and Norton, 2007). The website of parliament must be no partisan providing a focus on the institution collectively but also on the individual Members of Parliament. The website should be easy to understand and use, and be freely accessible to all, well managed and supported so that it can respond to the growing needs of both citizens and parliamentarians coherently with the objectives of transparency, accessibility, accountability. Websites should require mindset change on the part of both parliaments and the citizens, leading to change of practices and procedures increasing the internal efficiency through reengineering of lawmaking processes and strengthen legislatures-citizens connections by establishing a close communication between parliamentary institution and citizenry (Sobaci, 2010). Quality and completeness

of information and availability can be very different in terms of transparency and accountability. Websites are conceived as an important tool for parliaments seeking to stimulate deliberation, discourse and active citizenship (Taylor and Burt, 1999). Parliaments improving their websites to meet internationally recognized standards and best practices are advanced in using social media to improve communication and interaction than in implementation of their websites (Griffith and Leston-Bandeira, 2012). Building a website that fails to offer current, comprehensive and reliable data because the parliament lacks a document management system can actually be counterproductive to the goal of keeping citizens well informed and engaged with their parliament (Oppd, 2010). Parliaments are engaging citizens in discussing and participating actively in social issues making their voice heard (Papaloi and Gouscos, 2011). Thereby most of Parliaments are in the phase where one-way access of information is the main use of parliamentary websites even if there are initiative for promoting feedback and participation from the public (Undp, 2006). Parliaments should facilitate a two-way interaction and accountability in terms of information and communication meaningful and relevant for citizens in everyday life: representatives should interact with citizens that may express their concerns for engendering a meaningful dialogue (Marcella, Baxter and Moore, 2002; Papaloi, Ravekka Staiou and Gouscos, 2012).

5. Discussion and conclusions

Parliaments are embracing digital and internet technologies to develop more efficient internal operations connecting people to information and knowledge. Thereby, institutional and political differences play an important role in terms of nature and independence of legislature from the government that may have an effective impact on the means and extent to which parliaments may decide to provide citizens with information and documents (Leston-Bandeira, 2007; Griffith and Leston-Bandeira, 2012). Decisional parliament should search for the effective support of citizens, restoring the relationship of confidence, by sharing knowledge and information encouraging citizen participation or behave as accountable, open and transparent legislature being supported by a registration staff. Ratifying parliament should play a role of seeking legitimacy in front of the electorate or providing general information about its activity.

The e-parliament concept is fruitful of opportunities for increasing the internal efficiency through reengineering of processes and procedure, managing the parliamentary administration overcoming bureaucratic obstacles avoiding the transformation of

traditional bureaucracy into an infocracy (Zuurmond, 2005). Parliaments should design the support staff coherently with strategic choices. Parliamentary staff take most of the day-to-day decision on the management of parliamentary affairs (Leston-Bandeira, 2007). ICTs make parliamentary staff as gate-keeper able to play a relevant role in the process of gathering, selecting, interpreting information and require organizational innovation within design of administrative and legislative staff structure by developing professionalism in order to incorporate and absorb technology advent and pervasiveness (Dai and Norton, 2007; Leston-Bandeira, 2007; Mulder, 1999).

Thereby, within parliaments the introduction and implementation of ICT as difficult and complex process should imply both relevant technological, procedural and cultural change (Leston-Bandeira, 2007). Thereby, with ICTs being embedded in parliamentarians' activities parliamentary core functions seem to be unchanged. The high levels of use and positive orientation towards new technologies of parliamentarians and the emergent ICT culture may contribute to improve lawmaking and policymaking activity enhancing the relationship between citizens and representatives (Smith and Webster, 2004). Websites, that seem not to involve the citizens as a partner into the processes of legislative and policy formulation (Sobaci, 2010), stressing the classical view of parliament (Norris, 2000), can be used as a platform to conduct polls on policy matters via online-surveys can be equipped with e-mail addresses and discussion boards to deliberate with citizens (Zittel, 2003) strengthening the committee's role with regard to information, consultation and dialogue (Bosch, 2003; Leston-Bandeira, 2007).

There is no one way towards the design and implementation of an e-parliament infrastructure. Even if international standards and best practices drive the introduction and implementation of ICTs within parliamentary, the role of parliament in the constitutional arena, the relationships between political actors (parties and parliamentary groups), the work organization and structure of parliamentary staff can influence on management of technologies, information and knowledge (Leston-Bandeira, 2007). Parliaments may select different choices in order to use new technologies, knowledge and information for enhancing their internal workings and engaging citizen participation in the public policy process by integrating different forms and mechanism of direct, mediate and participatory democracy (Anttiroiko, 2003). Parliaments may develop knowledge or information management systems supported by technologies designing different typologies of e-parliament (fig. 1).

Figure 1 – Designing e-parliaments

	Managing Knowledge	Managing Information
Enhancing internal workings	Knowledge Based E-Parliament	Basic E-Parliament
Engaging citizen participation	Sustainable E-Parliament	Accountable E-Parliament

The future of democratic sustainability in terms of effective legitimacy of parliaments within democratic governance may rely on capacity to integrate the building of a knowledge management system supported by technologies, stimulating citizens contribution and participation to the policy process. ICTs capabilities that merely mimic existing communication systems support good management than good democracy (D’Agostino, Schwester, Carrizales and Melitzki, 2011). Most of parliament providing high degree of transparency do not use opportunities of ICTs for increasing participation (Berntzen, Healy, Hahamis, Dunville and Esteves, 2006). Parliament as sustainable knowledge organizations (Leon, 2013) may develop technological and organizational structure, and practices that encourage creation, dissemination and use also strategic of knowledge for social and economic issues regarding community and society, strengthening forms of political dialogue with citizens in terms of knowledge and information sharing and creation about planning and implementation of public policies. Parliaments connecting to public should follow some issues: what information is of citizen’s interest, whether the information published will be used for gathering citizens’ feedback, how to manage negative comments (Papaloi, Ravekka Staiou and Gouscos, 2012). Without involving citizens to participate in the public debate the focus on internal processes supported by use of knowledge or by information management systems may permit to parliament to make more efficient internal workings. Parliaments using technologies as support to information management may appear as accountable and accessible institutions connecting to the public and seeking legitimacy in front of the executive authority. This study is descriptive. Future research should investigate the relationship between e-parliaments and e-participation in terms of seeking the areas of convergence and symbiosis or conflict.

Structured Abstract

Purpose – For decades, Vietnamese universities have been criticized for producing low quality training and research outputs. This study tries to investigate the influence of organisational culture, leadership style, human resource practices, technology support and job characteristics on the knowledge sharing behaviour of academic and administrative staff in Vietnamese universities. Findings from this study are expected to help university management understand better the enabling factors of knowledge sharing behaviour in universities and therefore can develop relevant policies to promote knowledge sharing among lecturers/researchers to advance the quality of teaching and research activities in universities.

Design/methodology/approach – Six research hypotheses related to the relationships between culture, leadership style, HR practices, technology support, job demands and knowledge sharing behaviour were formulated in this study. To test the hypotheses, the

authors developed the measures based on the works of previous researchers as well as on their own reflections. The sample used for this study consists of 123 lecturers and supporting staffs working in ten universities in Hanoi. A multiple regression was applied to investigate the relationships between the six independent variables and the dependent variable (knowledge sharing behaviour). Age, job category, position, gender, working experiences were used as control variables in the regression analysis.

Originality/value - This study reveals some interesting results related to the non-significant association between culture, reward and the knowledge sharing behaviour of individuals in university context. This unexpected finding is however consistent with the results of some studies in the existing literature which also failed to prove the influence of culture and reward on knowledge sharing. The role of leadership style and IT support on the knowledge sharing behaviour of individuals in organisations is confirmed by this study, however when only lecturers are considered as research sample, leadership style loses importance in terms of its influence on knowledge sharing behaviour.

Practical implications – Findings from this study suggest that job demands; training and development; and technology support are the strongest drivers for the knowledge sharing behaviour of lecturers in universities. University management should therefore pay due attention to these aspects to promote knowledge sharing among lecturers/researchers, thus enhancing the “intelligence” of the university. For example, by providing lecturers with regular training opportunities and access to a strong IT system/knowledge base of the university, the later will demonstrate a stronger knowledge sharing behaviour.

Keywords – Knowledge sharing behaviour, Culture, Leadership, HR practices, Technology

Paper type – Academic Research Paper

1 Introduction

University is a type of organization which is aimed to produce students being “knowledge intensive products” to the society. Although KM over the past few decades has evolved as the most prominent field of research in management science, KM in education sector has more or less remained a little-explore domain (Vashisth *et al* 2010). There are two main categories of employee in universities: i. *academic staffs or lecturers* whose main job is teaching and ii. *supporting staffs* who perform non-academic functions in such areas as administration, organization and personnel, planning and finance, etc. These two personnel categories are different in some aspects such as work type, work process, work output and therefore, are expected to experience different KM practices.

For decades, Vietnamese universities have been criticized for producing low quality training and research outputs. For instance, each year, the number of publications by Vietnamese universities in international journals is far low compared to that in

neighboring countries in the regions such as Thailand, Malaysia. A question emerges here is whether poor KM leads to poor training and research performance in Vietnamese universities?

Knowledge sharing is widely recognized as the most important step or activity in the KM process. By sharing information and knowledge, individual employees can learn from others' know-how and work experience (Kang, Kim, Chang 2008). It's widely recognized that knowledge sharing is influenced by the organizational, cultural and technological contexts in which individuals are working and interacting with each other.

This empirical study tries to investigate the relationship between different organizational, cultural and technological factors and knowledge sharing performance in the university context. The paper first presents a review of contextual literature, discusses the methodology used by the authors, proposes some hypotheses to be tested using data collected from selected Vietnamese universities, mentions the implications for university managers and finally ends with summary and conclusions.

2. Literature Review & Problem statement

Tacit vs explicit knowledge

According to Michael Polanyi (1954), knowledge in any organizations exists in two types: explicit knowledge and tacit knowledge. The former is knowledge asset that can be codified, documented and transferred among members in organization. In the context of universities, written working procedures, training manuals, information of students, etc can be seen as explicit knowledge. The later is personal, contextual, exists in the form of know-how, skills, institution,... and normally can not be easily formalized, codified or documented for sharing purpose.

This classification of knowledge is later further studied and developed by Nonaka et al, who in their famous SECI model, explains the ways knowledge transforms from explicit to tacit form and vice versa to create organizational intellectual asset.

Knowledge sharing. Knowledge sharing is known as one of the most researched topics in the field of KM and being the most used key word according to a review of 235 papers published over the past 10 years in the journal Knowledge Management Research and Practice (Ribiere & Walter, 2013).

Knowledge sharing is more than transferring knowledge but creating it (Van den Hooff, 2009). Riege (2005) posits that purposeful sharing of useful knowledge translates into accelerated individual and organizational learning and innovation. Social Capital Theory explains that knowledge sharing occurs because it provides social benefits for both the sharer and the organization (Nahapiet and Ghoshal, 1998). Bock et al (2005) emphasize that the movement of knowledge across individual and organizational boundaries is ultimately dependent on employees' knowledge sharing behaviour and that even with the codification of knowledge, knowledge objects remain unexposed to others until the knowledge owner makes the objects available.

In practice, many large consulting firms such as Ernst and Young, KPMG, McKinsey have invested in robust KM system to foster the sharing of knowledge, ideas, best practices among individuals or groups (Cabrera & Cabrera, 2002).

Organizational culture and knowledge sharing. Organizational culture is defined as a system of shared assumptions, values and norms (Schein, 1985). Organizational culture influences the way individuals interact and share information with each other in the organization. An organizational climate where people are free to express their ideas or opinions, are encouraged to challenge others' perspectives is believed to facilitate the sharing of knowledge and information. Organizational climate, demonstrated in the form of shared value, beliefs and work atmospheres plays an essential role in shaping employees' behaviors and influencing their perception of knowledge management (Chen & Lin, 2004). The relationship between organizational culture and knowledge management has been analyzed by several scholars. Nahapiet and Ghoshal (1998) proved that individuals are more willing to engage in cooperative behaviors, such as knowledge sharing behavior, when a relationship is characterized by a high level of trust. Kim and Lee (2006) pointed out that employees who are attached to each other by social networks will demonstrate higher level of knowledge sharing.

De Long and Fahey (2000) suggest that while trust and cooperation may lead the employees to share knowledge, a working climate which encourages individual power and competition may result in knowledge hoarding behaviors among individuals.

Hypothesis 1. Knowledge-centered culture positively influences the knowledge sharing behavior of individuals in organization

Job demands and knowledge sharing. Lecturer and supporting staff in universities differ in their working approaches. The former mainly works at home or in the class. In

addition, lecturers are not obliged to go to school every day, therefore they have limited chance for formal interaction and for sharing knowledge with their colleagues and their managers. Riege (2005) identified “lack of time to interact and share knowledge” as one of the barriers to knowledge management. Although lecturers’ physical working environment may not be conducive to knowledge sharing, the demand for sharing knowledge seems to be higher for lecturer than for supporting staff in universities. It’s therefore expected that the more the job holder is required to share knowledge with others, the better his or her knowledge sharing behavior. So far, very few studies in the existing literature have been carried out to examine the relationship between knowledge-oriented job demand and knowledge sharing.

Hypothesis 2. There is a positive association between job demands and the knowledge sharing behavior of individual s in organization

Knowledge- centered HR practices and knowledge sharing. Knowledge-centered HR practices include a set of HR initiatives such as staff performance appraisal, reward, training, job rotation, coaching & mentoring, etc which encourage and foster knowledge sharing behavior in organizations. Numerous studies have been conducted with findings leading to a positive interaction between KM activities and HR practices.

McDermott and O’Dell (2001), in their study of five “best practice” knowledge sharing companies, showed how sharing knowledge is included in the company performance appraisal system. Cabrera and Cabrera (2005) posit that firms can create an environment that was conducive to KM by using practices such as team work, team performance appraisal, compensation and reward systems. Kim and Lee (2006) proved that performance-based reward can foster knowledge sharing in organization. Armbrecht et al (2001), Riege (2005) argue that the lack of appropriate rewards, incentives and recognition systems is one of the barriers for KM implementation in organizations. Training and development is an important mechanism to foster knowledge sharing in organization (Cabrera and Cabrera, 2005; Kang et al, 2003).

Hypothesis 3. Knowledge-centered HR practices positively influences the knowledge sharing behavior of individual s in organization

Knowledge-oriented leadership and knowledge sharing. There have been several empirical studies conducted to examine the relationship between different leadership styles and knowledge management. Yang (2007) pointed out that when leaders play the

roles of “innovator”, “mentor” or “facilitator”, knowledge sharing in organizations will be enhanced.

Many scholars (Bryant, 2003, Srivastava et al, 2006) also proved that KM is positively influenced by transformational leadership style which is characterized by empowerment, promotion of trust and commitment.

Singh (2008) suggested that the best form of leadership style for managing knowledge in organization is the delegating style wherein employees are given adequate power, authority and responsibility. Xue et al (2010) found out that team climate and empowering leadership significantly influence individuals’ knowledge-sharing behavior by affecting their attitude toward knowledge sharing. Donate and Guadamillas (2011) defined knowledge-oriented leadership as the style whereby leader plays the role of knowledge facilitator, role-modeling; recognizes and rewards knowledge sharing; promotes trust and learning; and put emphasis on staff empowerment.

This study tries to confirm the findings from existing literature that knowledge-oriented leadership will positively influence individuals’ knowledge-sharing behavior.

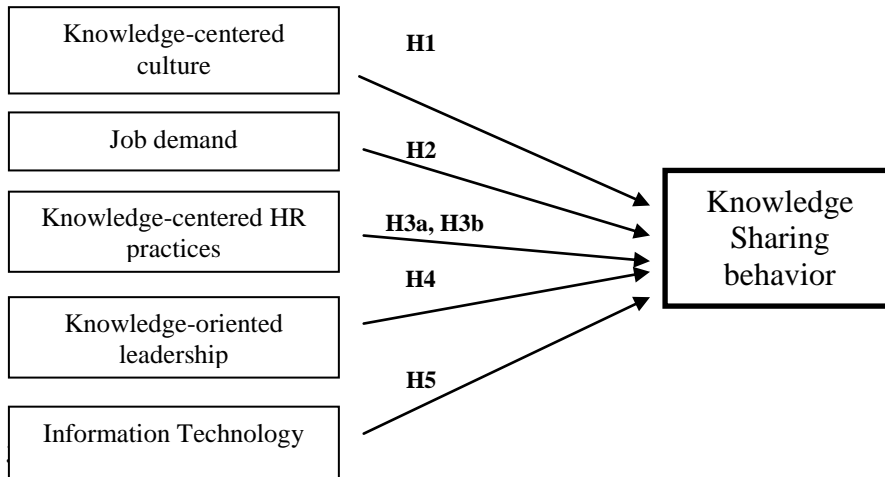

Hypothesis 4. Knowledge-oriented leadership positively influences the knowledge sharing behavior of individuals in organization

Technology and knowledge sharing. Thank to the rapid development of information technology, organizations can create and make use of different tools from sophisticated ones such as groupware, intranet, knowledge base to simple ones like email to foster knowledge sharing and knowledge acquisition. ICT enables knowledge management activities for collaborative decision support, information sharing, organizational learning and organizational memory (Yoo & Kim, 2002).

In recent years, ICT is increasingly considered merely as an enabling tool for KM activities and no longer as a determining factor for the success of KM programs in organizations. Bock et al (2005) recognize that individual’s knowledge does not easily translate into organizational knowledge despite the implementation of knowledge repositories because of the tendency to hoard knowledge. Soliman and Spooner (2000) also posit that KM is about people, not about technology. Lecturers in universities due to their limited face-to-face interaction, tend to rely heavily on ICT to exchange information and knowledge with their colleagues.

Hypothesis 5. The use of information technology positively influences the knowledge sharing behavior of individuals in organization

Figure 1. Research model

3.1 Data Collection

Data for this study was collected from ten different universities in Hanoi. A close ended questionnaire was developed and distributed to both lecturers and staff working in those universities. 143 questionnaires were returned out of nearly 200 questionnaires sent to ten universities located in Hanoi Capital, 123 questionnaires are usable for data analysis.

3.2 Sample Characteristic

Table 1. Sample statistics

	Variables	Frequency	Percent %
Gender	Male	36	29.3
	Female	80	65.0
	Missing	7	4.1
Age	20-30 year old	40	32.5
	31-40 year old	62	50.4
	41-50 year old	14	11.4
	above 50 year old	7	5.7
Seniority	under 2 years	32	26.0
	2-5 years	26	21.1
	6-10 years	26	21.1
	11-20 years	22	17.9

	above 20 years	6	4.9
	Missing	11	8.9
Job	Lecturer	59	48.0
	Staff	63	51.2
	Missing	9	99.2
Position	Manager	26	21.1
	Non-manager	97	78.9

About 48% of the participants in this study are lecturers and 51% are supporting staffs. The majority of the participants are non-managers (78.9%) and only 21.1% are managers of functional departments or faculties in university. 50.4% of the participants are between 31 and 40 year old and up to 32.5% are less than 30 year old. Female participants account for 65% of the sample while male account for only 29.3%. In terms of number of years working in the university, 47.1% of the participants have worked in their universities for less than 5 years, 21.1% of them have worked from 5 to 10 years in their current organization, and 22.8% of the participants have had more than 10 years of working in their current organization

3.3 Measures

In order to examine the relationship between different organizational factors and knowledge sharing behavior, the authors used the five point Likert scale for all items constituting the constructs as shown in the theoretical model proposed by this study.

Table 2. Scale items for independent and dependent variable	Source
Knowledge-centered culture	
Cul1. I see my working unit as a “big family”	Adapted from Bock <i>et al</i> (2005)
Cul2. We consider the problems of my organization our own problems	Self developed
Cul3. I trust my colleagues and share with them job related information	Adapted from Kim & Lee (2006)
Knowledge-centered HR practices	
Hr1. The more I contribute ideas/initiatives to my organization, the better chance I have for job promotion or salary increase	Self developed
Hr2. The ability to work well in team is one of the criteria for staff performance appraisal	Adapted from Donate & Guadamillas (2011)
Hr3. We are given many opportunities to attend training courses to improve knowledge and skill	Adapted from Donate & Guadamillas (2011)
Hr4. We are encouraged to teach different courses or to	Adapted from Donate &

perform different tasks	Guadamillas (2011)
Hr5. Old staff is responsible to provide on the job training for new staff	Adapted from Cabrera & Cabrera (2005)
Knowledge-oriented leadership	
Ld1. Leader of my unit praises or gives compliment whenever a staff has a new idea or initiative to contribute to the organization	Adapted from Donate & Guadamillas (2011)
Ld2. Leader plays the role of advisor and welcomes all opinions, perspectives from staff	Adapted from Donate & Guadamillas (2011)
Ld3. Leader encourages teamwork	Adapted from Donate & Guadamillas (2011)
Ld4. Leader encourages staff to seek information, knowledge from outside	Adapted from Donate & Guadamillas (2011)
Ld5. Whenever a staff makes mistakes in work, leader encourages him or her to draw lessons from those mistakes	Adapted from Donate & Guadamillas (2011)
Ld6. Leader always creates an open and exciting working atmosphere	Self developed
Technology support	
Tec1. Work related information and knowledge are stored, classified and updated in a scientific and regular manner	Self developed
Tec2. The organization's IT system provides valuable and useful information/data for my work	Adapted from Lee & Choi (2003)
Tec3. The organization's IT system facilitates the sharing of knowledge and information among members	Adapted from Lee & Choi (2003)
Job demands	
JobD1. My job requires me to coordinate, interact and share information regularly with my colleagues	Adapted from Casimir <i>et al</i> (2012)
JobD2. Sharing knowledge is a part of my job	Adapted from Casimir <i>et al</i> (2012)
JobD3. Knowledge, information related to my job are easy to understand, describe and to transfer to others	Self developed
Knowledge Sharing behavior	
Ks1. I often participate in seminars, workshops at my university to share knowledge or learn from colleagues	Self developed
Ks2. I often express my thinking or ideas in meetings at my university	Self developed
Ks3. I often share information and knowledge I have with colleagues in my unit	Adapted from Van den Hooff and de Ridder (2004)
Ks4. I am ready to share understanding, know-how, institution gained through work with colleagues in my unit	Adapted from Suppiah and Sandhu (2011).
Ks5. Whenever I learn something new from training activities, I see in it that I have to share that new learning with colleagues in my unit	Adapted from Van den Hooff and de Ridder (2004)
Ks6. I am not reluctant to share success stories and failure lessons with colleagues in my unit	Adapted from Suppiah and Sandhu (2011).
Ks7. I feel responsible to mentor and coach new staff/colleague who has little work experience	Adapted from Suppiah and Sandhu (2011).

Independent variables

The scale for knowledge-centered organizational culture include three items related to values that should support and promote KM activities in organization, including the promotion of trust (Kim and Lee, 2006), affiliation of employee to the working unit (Bock et al, 2005), and affiliation of employee to the organization.

This study uses a five item scale for knowledge-centered HR practices. This scale is largely based on the works of Donate and Guadamillas (2011), Cabrera and Cabrera (2005). It emphasizes that relevant HR practices such as knowledge-based reward and evaluation policies, job rotation, training and development, mentoring should be in place to encourage knowledge sharing among individuals in organization.

Knowledge-oriented leadership was measured through a six item scale adapted from prior research on KM and leadership, especially from the work of Donate and Guadamillas (2011). These authors developed a scale for knowledge-oriented leadership with items related to encouraging and rewarding employees to share knowledge (Pan and Scarbrough, 1999), leading by example (von Krogh et al, 2011), and creating an environment conducive to KM.

Information Technology scale consists of three items, among which two are referred to the role of IT in providing useful knowledge for the work of university employees and in fostering knowledge sharing among the later. The last one is referred to the role of IT in codifying the university's explicit knowledge. This IT-related scale is largely adapted from the work of Lee and Choi (2003) and Gold et al (2001). Job demand scale consists of three items, which are largely based on the scale used by Casimir et al (2012).

Dependent variable

A seven item scale for knowledge sharing behavior was developed for this study. This scale was adapted from previous scales developed by Van den Hooff and de Ridder (2004), Chang Lee et al (2005), Suppiah and Sandhu (2011). Knowledge sharing behavior, as conceptualized in this study, includes not only the act of sharing knowledge but also the willingness or intention of individuals to share knowledge with others. By willingness, it recognizes that knowledge owner will share his/her information, knowledge, know-how, or skills with others whenever he or she has the chance to do it.

In addition, as knowledge exists either in tacit form or explicit form, this scale also considers the sharing of codified information or data (explicit knowledge) and of know-how, skill, best practices, institution (tacit knowledge) among individuals in organization.

4. Empirical study results

Factor analysis

A principal components analysis was conducted on the items selected to measure knowledge-centered organizational climate, knowledge centered-HR practices, Knowledge-oriented leadership, job demand, and knowledge supporting technology. Table 2 below provides the result of a six component varimax solution with a cut-off value of 0.4 for item loadings.

Item loadings table reveals the following:

- All three items used for knowledge-centered organizational culture loaded satisfactorily
- All five items related to knowledge-centered HR practices loaded satisfactorily into two separate components. Hence, the scale for HR practices should be broken into two separate scales, namely *i. knowledge-centered reward and evaluation* and *ii. training and development* and two hypotheses related to HR practices (H3a & H3b) are formulated accordingly.
- All six items related to knowledge-oriented leadership loaded satisfactorily.
- All three items related to technology loaded satisfactorily
- All three items related to job demand loaded satisfactorily

Table 3. Rotated Component Matrix

% Explained variance	14.63	13.05	11.43	10.79	10.77	9.83

Notes: Loadings above 0.40 are shown. Kaiser-Meyer-Olkin test = 0.831, Bartlett's Test of Sphericity = 1085.645, Significance = 0.000. Total explained variance of six components is 70.5%

Internal consistency of measures

To assess the internal consistency reliability of all measures, the famous Cronbach's alpha was used. Knowledge-centered culture measure has an acceptable consistency ($\alpha = 0.71$). HR practices measures were split into two separate measures and the consistency level of these two new measures are also acceptable for analysis ($\alpha = 0.67$ for HR1; $\alpha = 0.76$ for HR2). Consistency level is highest for leadership measure ($\alpha = 0.86$), followed by IT support measure ($\alpha = 0.84$) and knowledge sharing measure ($\alpha = 0.82$).

A correlation matrix of all variables is shown in Table 4, along with means, standard deviations and Cronbach alpha for both independent and dependent variable. This study used a multiple regression analysis with six different models to test the different hypotheses presented in previous section. The first model includes five control variables: job category, age, gender, position of respondents and the size of the unit where they are working. The two variables job category and position were created in the form of dummy variable with 1 equals lecturer, 0 equals staff and 1 equals manager, 0 equals non-manager.

In the second model, two independent variables Culture and Reward were first added, ruling out the effect of other independent variables. In the third model, all remaining independent variables were added so that direct effect of each independent

variable on the dependent variable can be measured controlling for all other variables. Models 4a, 4b and models 5a, 5b examine the effects of control and independent variables on the knowledge sharing behavior of lecturers and supporting staffs respectively.

Results of multiple regression

All three models: 1, 2, 3 are significant. The position of the participants in this study has a positive influence on knowledge sharing behavior across the models 1-3. This indicates that managers do a better job in knowledge sharing than their staff. Job category has a negative influence on knowledge sharing behavior in model 2 & 3, as job category has been coded as lecturer = 0, staff = 1, this could mean that knowledge sharing behavior is stronger for lecturer than supporting staff in university context. Other variables in the control model such as unit size or number of staff, age and gender of respondents don't have any effect on knowledge sharing behavior.

The second model is significant (adjusted R² = 16.9) and R² is increased by 9.7%, mainly due to the effects created by the two independent variables: reward and culture. Both these two independent variables show a positive significant relationship to the knowledge sharing behavior of respondents. However, as this 2nd model does not control for other important variables such as leadership style, training, IT support,..any conclusions drawn at this stage could be misleading.

(%) Increase in R ²		12		9.7		29.4
Change in F		3.164		7.05		16.58

In the 3rd model, when all the independent variables were entered, R2 is improved by 29.4% and this model explains 46.3% of the variance of the knowledge sharing behavior result. All the newly added variables (i.e. job demand, leadership style, IT

support, training) have positive and significant relationship to knowledge sharing behavior whereas the two variables (reward and culture) previously entered in the 2nd model lose importance in terms of their relationship to knowledge sharing behavior.

Model 4b is highly significant and explains 60.7% of the variance of the knowledge sharing behavior result. Only three out of the six independent variables, i.e. job demand, IT support and training show a direct and significant relationship to knowledge sharing behavior. Leadership style doesn't have a significant effect on knowledge sharing behavior in this model, suggesting that the leadership style of faculty manager does not play an important role in deciding the knowledge sharing behavior of lecturer and the knowledge sharing behaviour of the later is rather influenced by other aspects such as IT support and training.

Model 5b is also significant and explains only 33% of the variance of the knowledge sharing behavior result. Among the six independent variables, only Job demand has positive influence on knowledge sharing behavior for both sub-groups. Similar to the 3rd model, there are no direct relationships between the two variables: culture and reward and the knowledge sharing behavior of both sub-groups: lecturer and staff.

Notes: Dependent Variable: Knowledge Sharing; *Significant p < 0.1; **Significant p < 0.05; ***Significant p < 0.01

Knowledge-centered leadership has a strong direct positive effect on the knowledge sharing behavior for staff ($\beta = 0.48$, $p < 0.01$), but not for lecturer. This can be explained by the fact that faculty leaders don't interact with lecturers on a daily basis, thus the former doesn't have strong power over or influence on the working behavior of the later.

IT support has a significant influence on the knowledge sharing behavior of lecturer ($\beta = 0.29$, $p < 0.01$), however it doesn't have any influence of knowledge sharing behavior of staff. This could be logical as lecturers nowadays should rely heavily on the information technology, especially on the internet to constantly look for updated professional knowledge and to share knowledge with their colleagues on a regular basis.

Notes: Dependent Variable: Knowledge Sharing; *Significant $p < 0.1$; **Significant $p < 0.05$; ***Significant $p < 0.01$

Training also has a significant influence on the knowledge sharing behavior of lecturer ($\beta = 0.257$, $p < 0.05$), but doesn't have a direct effect on the knowledge sharing behavior of staff. Training obviously is a very important channel for lecturers to upgrade their knowledge and to share knowledge with others in class.

5. Discussion

Findings from this study have shown that most demographic information such as the size of the working unit, age and gender don't have any effect on the respondents'

knowledge sharing behavior. Job category (lecturer vs staff) has a significant negative association with knowledge sharing behavior. The position of the respondents (manager vs non-manager) does have a significant positive relationship to knowledge sharing behavior. In university context, the need for knowledge sharing is therefore more important for lecturer than for staff. Similarly, the knowledge sharing behavior of managers is better than staffs in universities.

Culture has been widely considered as a catalyst for knowledge management in organizations. However, this study shows that culture values including trust, affiliation to the organization and affiliation to the working unit don't have a direct effect on the knowledge sharing behavior of employees in universities. This finding contradicts with the results from a number of studies in the existing literature, for example Lee and Choi (2003) and Alawi et al (2007) have identified a positive relationship between trust among employees and knowledge sharing in organizations.

In the same manner, this study could not point out a direct relationship between knowledge-oriented reward policy and knowledge sharing behavior. This is not contradictory as some previous studies in the existing literature also pointed out that extrinsic reward did not have a positive influence on knowledge sharing. Bock et al (2005) found out a negative effect of extrinsic rewards on knowledge sharing attitude while Chang, Yeh and Yeh (2007) assert that outcome-based rewards do not foster knowledge sharing among team members. This study shows that reward lose its importance in terms of its effect on knowledge sharing behavior in the presence of other predictors such as leadership, training and job demand. It could be suggested that the relationships between culture, reward and knowledge sharing behavior seems to be controlled by other factors such as leadership, job characteristic, technology support, etc.

Knowledge-oriented leadership has a significant positive effect on the knowledge sharing behavior for individuals in universities. This is consistent with the results of a number of previous studies showing that appropriate leadership style would foster knowledge management. For example, Srivastava et al (2009) argue that leadership style focusing on empowerment positively influences team efficacy and knowledge sharing. However, when only lecturers are taken into account as research sample, the relationship between leadership style and knowledge sharing behavior is no longer significant. Hence, the role of leadership in fostering knowledge sharing may be contingent on the frequency of interaction between leader and staff, i.e. when individuals don't interact with their

leader on a daily basis like in the case of university lecturers, leadership does not have a significant effect on knowledge sharing behavior.

Technology support is positively associated with knowledge sharing behavior in both model 3 and model 4b. This study points out that more the IT system of the university facilitates the work and communication of lecturers, the better the knowledge sharing behaviour of the later. This result confirms the findings from previous studies which suggest a positive and direct effect of technology on knowledge sharing. Information technology is undoubtedly a vital tool for lecturers to enrich their knowledge and to share knowledge/information with their colleagues. Adel Ismail et al (2007) argue that information systems together with other organizational factors such as trust, communication, organizational structure are positively related to knowledge sharing in organizations. Cabrera and Cabrera (2005) suggest that one of the best ways to reduce the perceived cost of sharing knowledge is to have well designed, user-friendly technological tool that simplifies the tasks and reduces the time necessary for sharing one's ideas with others.

Training also has a positive and significant influence on knowledge sharing behavior in both model 3 and model 4b, thus suggesting that training and development is an effective HR practice to foster knowledge sharing among lecturers in universities. Cabrera and Cabrera (2005) emphasize that when training and development help to increase self-efficacy among organizational employees, the later will feel more assured of their abilities and will be more willing to exchange knowledge with others. Training place is not only an ideal environment to foster knowledge exchange but also is where employees from different divisions can socialize and build trust. The relationship between training and the knowledge sharing behavior of staffs, however is not found in model 5b. One explanation could be that staffs in universities are given fewer training opportunities compared to lecturers, hence training is not perceived by staffs in university as a facilitator for their sharing knowledge with others.

Knowledge oriented job demand has a positive and significant association with the knowledge sharing behaviour of university employees, including both lecturer sub-group and staff sub-group. This implies that the knowledge sharing behavior is much driven by the extent to which a job itself requires the job holder to share knowledge with others. The findings from this study show that the more a job requires the employee to interact and share knowledge with others, the stronger his or her knowledge sharing behavior.

This study has practical implications for university management in order to promote knowledge sharing. First, knowledge oriented leadership style is vital to foster knowledge sharing in universities. Leaders in universities should be trained on how to encourage lecturers and staffs to acquire knowledge from inside and outside organization, to share knowledge with others, and to learn from mistakes. Leaders of faculties or professional departments in particular should try to create frequent interaction among and with lecturers. By meeting and talking to lecturers more frequently, faculty leaders will strengthen their influence on the knowledge sharing behavior of the lecturers. Training and development has been proved in this study as an effective HR practice to foster knowledge sharing among lecturers, as such, lecturers in university should be given frequent training and job rotation opportunity so that knowledge is effectively shared among individuals in university and the intelligence of the university as a whole is built up. In addition, universities should place priority on developing a strong IT system that enables knowledge to be easily stored, acquired, and shared among lecturers. Lastly, human resources manager in university may consider to institutionalize knowledge sharing as a duty or responsibility specified in the job description of both lecturer and staff as the findings from this study has shown that the more a job requires knowledge to be shared, the better the knowledge sharing behavior of the job holder.

6. Limitations of this study and suggestions for future research

This research presents several similar limitations as found in common organizational behavior research. First, the cross-sectional nature of the research design in this study does not allow causality to be inferred. Second, data related to all constructed was collected using a single questionnaire, findings were based on self-reports of respondents, thus the issue of common methods variance cannot be avoided. Third, a single liker five point scale was used for all constructs, as a result, some of responses seemed to be deliberately replicated and had to be rejected. This study only focused on the main effects of organizational and technological aspects on knowledge sharing behavior and did not consider other aspects moderating these relationships. Also, in this study, knowledge sharing behavior was treated as the “final outcome” of organizational and technological factors, not as an intermediate outcome to reveal its moderating or mediating role in the relationships between those organizational antecedents and organizational or individual performance. Future research may investigate how knowledge sharing leads to improved

organizational performance of universities that could be justified by the number of international publications, ranking of university, post graduation employment rate , etc. Future research may also examine how the organizational, cultural and technological factors interact internally or with knowledge management strategies (codification verses personalization) to influence on the organizational performance of universities.

Infrastructure for Knowledge Sharing in Universities and Research Centres in Iran

Leila Nemati-Anaraki

Iranian Research Institute for Information Science and Technology
(IRANDOC), Tehran, Iran
Enghelab Street, Conjunction of Felestin Street, No. 1090, 1315773314

Structured Abstract

Purpose – Nowadays, knowledge sharing has become a strategic source of gaining and preserving competitive advantage and collaboration between universities (centers of science) and research organizations (centers for practice). So, knowledge sharing between different organizations, is the cause of their retain in today's competitive environment and providing the necessary platforms and infrastructure is must in this process. Accordingly, the purpose of the present study is to investigate the technical and infrastructural factors that influence knowledge sharing process in medical universities and research centers in Iran, and then identify the most effective platforms, methods and channels of inter- and intra knowledge sharing.

Design/methodology/approach – The method of this paper is mixed and applied research (a combination of library and Delphi method) that was conducted in 2013. The study population considered of the faculty members of medical universities and research centres in Iran which by use of stratified sampling 423 samples selected. According to the statistical results around 17 percent of professors considered the organizational structure as acceptable. There was also a sharing of knowledge and experience of faculties in the 48/2 percent somewhat faculty teaching and research within their organization more than other organizations. From the view of faculties, conferences and forums, with an average rank of 4/93 and personnel exchanges with the average 4/24 are the most effective ways of sharing.

Originality/value – A few attempts have been made to investigate success factors for inter- and intra-organizational knowledge sharing empirically or even theoretically, but this is the first of its kind that provides role of infrastructures for the knowledge sharing in medical science collaborations. It serves as a useful starting point for those interested in knowledge management. So, it can serve as a roadmap of significant knowledge sharing research for researchers, designers, and managers considering their options for fostering knowledge management.

Practical implications – The outcomes of the application will provide empirical basis for planning and implementing knowledge sharing mechanisms.

Keywords – Knowledge Management, Knowledge Sharing, Information Technology, Faculty Members, University

Paper type – Academic Research Paper / Practical Paper

1 Introduction

Today, it seems that many countries have recognized the importance and role of higher education in knowledge production and transferring it to the research society as a section of general process of knowledge management and thus have provided the grounds to align the academic research to the research centres' priorities (Hasanzadeh and MohammadKhani, 2010). In other words, the survival of education and research is interdependent. The faculty members and the employees of these centres are main capitals for knowledge sharing. Cooperation and participation of human resources need sharing the effective knowledge in and out of the organization and management of the activities, as stated by Kim and Ju (2008) if the necessary conditions, infrastructures, and the grounds are provided for faculty members, they can share their knowledge and thus help the organization succeed. So, this critical knowledge flows when the infrastructures, grounds and channels of knowledge sharing are regarded by the organizations.

One of the best methods of improving the knowledge sharing is the recognition of current conditions and moving towards the favourable conditions, therefore studying the current circumstances and the points that need promotion are feasible through using the most important technical factors effective on knowledge sharing and continuous assessment of universities and research centres. Therefore, the present research is aimed at studying the technical and infrastructural factors effective on knowledge sharing process among the faculty members of universities and the research centres all over the country in the field of medicine while identifying the most effective grounds, methods and channels of knowledge sharing.

2 Literature Review

The tendency of countries to admit globalization along with development of information and communication technology, have developed powerful tools to create global networks of education and research (Abel et al., 2007). Activities of the universities in modern days have affected the sole mission of knowledge production and have turned universities into problem solving service institutes for local, national, and global problems. This significant issue duplicates the responsibility of universities on qualitative and quantitative promotion of knowledge sharing. The research and education organizations that utilize the knowledge sharing concepts manage and reinforce their

human and organizational capitals through sharing the effective and useful knowledge and promote their knowledge-based capabilities (Hsu, 2008). Knowledge sharing involves a set of common understandings that are created through accessing the organizational information and leads to utilization of knowledge-based networks inside the organization (Hogel, Parboteeah, and Munson, 2003). Several factors are considered in the research conducted to study the factors effective on knowledge sharing. These factors are generally divided in two groups of individual and organizational. On the other hand the applied studies demonstrate that human and organizational factors and a large number of modern technologies are related to the knowledge sharing process (Huang, Luther, and Tayles, 2007).

KhatamianFar (2007), in his thesis, studies the condition of knowledge sharing, its infrastructures, grounds and knowledge sharing methods in Astane-Qodse-Razavi. The research findings demonstrated that the general infrastructural condition of knowledge sharing is rather suitable in the related organization. Alvani, ZareiMatin and Pashazadeh (2009) identified in their research effective factors in knowledge sharing. One of the factors they identified was technology that involved existence of capabilities of information technology and the amount of utilization of each one of the related tools. In ShamiZanjani`s research (2010) all the interviewees in the research recognized leadership and solutions as the most important infrastructural weak points of knowledge sharing in the State Tax General Plan. Trusting the management and high concentration were also recognized as the next important infrastructural weak points in that place. In a research conducted by Rofova (2011), the human infrastructures included the (ability to conduct a teamwork and communication interpersonal skills), the process infrastructures involved (attitude, support by manager, guidelines, structure, culture of the organizations), and the technology infrastructure as the third infrastructure studied in the research. The results of the research demonstrated that the infrastructures of knowledge sharing in these companies were of a medium quality condition. Among the subject infrastructures, the process infrastructures had the best condition and the human infrastructures had the weakest. In the results of the research conducted by Brennenraedts, Bekkers and Verspagen (2006) the most usable channels were arbitration in scientific publications and books, conferences and workshops, participation in the organizations' expertise councils, social networks and the networks based on friend finding, projects participation, simultaneous activity in teaching and industry, thesis advisor, information sharing,

productions and facilities and industry. The results of Han and Anantatmulas' research (2007) showed that regarding the accessibility and applicability of information technology, around 95 percent of individuals confirmed accessibility to the technologies such as the internet, intranet, email, telephone, fax, video conferencing and telephone conferencing. The research of Sondergaard, Kerr and Clegg (2007) focused on the leadership, organizational, and individual factors effective on knowledge sharing. Studying the technical infrastructures were considered as a part of organizational factors and indicated that the technical factors were not effective on knowledge sharing, however they were required to exist and correct application of technologies was confirmed by the interviewees. Bekkers, Maria and Freitas (2008) conducted a research titled as "analyzing the knowledge sharing channels among the universities and industries". The results generally demonstrated that the activities of industrial factories did not have remarkable difference regarding the significance of a large variety of channels. However, the difference relied in the disciplinary origin, the specifications of the knowledge and in characteristics of the researchers producing such knowledge (that is the individual traits) and the environment where knowledge is produced and applied (organizational characteristics). The findings of Cheng, Ho and Lau (2009) indicated that 60 percent of the individuals, who took part in network knowledge sharing, identified their activity as a result of being mandated by management, while they wouldn't participate in the activity if they were free to participate in network voluntarily. Also, as viewed by knowledge recipients, Share Net cannot be suitable source for faculty members in related university.

Jansen VanVuuren (2011) studied the dynamic role of ICTs and also the interactions they undertake in the process. The main output of this research was development of a conceptual framework that can support the cooperation and knowledge sharing among the universities and other involving groups. This framework included 6 important factors as the way of cooperation, the role of leadership, facilitation of using the information technology, the profitability of using the information technology, individuals' capability and skills and eventually the individuals' commitment. The findings showed that the official or unofficial knowledge sharing activities were different in organizations and their existence was different in various communities, for example some of the knowledge sharing activities was conducted in reports, documents, emails, and telephone and in four cases. While the organized meetings and face to face and unofficial activities were used only in some of the communities. In addition, physical approximation had direct relation

to the amount of interactions and knowledge sharing. Results of the research conducted by Ali *et al.* (2012) showed that although all the respondents used information technology, they most used it for sharing the documents and not much for direct communication with the experts. Interlocution through remote conferencing, video conferencing and emailing were used more than interlocution through social media technology, weblogs, and online discussion groups. Also the results showed that there were significant relations between publications and accessibility to documents, using the cell phone and using the video conferencing, publications and finding small expertise information. Fullwood, Rowley and Delbridge (2013) recognized the role of management, organizational structure, and also the information and communication technology not effective on knowledge sharing. Also, Yuan *et al.* (2013) concluded by their research that although information technology supports the knowledge sharing, there will be a large gap by using the social software between the modern information technologies and the older ones. It can be concluded from the conducted researches that until 2009 more attention was paid to reviewing the literature rather than deep analysis and empirical researches (Wang and Noe 2009). On the other hand, the applied studies have shown that the human and organizational factors and a large range of modern technologies are related to the knowledge sharing processes.

3 Aims of the Survey

1. Determining the condition of technical and infrastructural factors in the universities and research centers in intra/inter organizational knowledge sharing
2. Determining the effect of each one of the grounds, channels and methods in sharing the knowledge and experience among the faculty members of medicine
3. Determining the most effective method in sharing knowledge and transferring the experiences as regarded by the medicine faculty members

4 Research methodology

4.1 Sample and procedure

In the first stage, qualitative and quantitative investigations were used for extraction and formulation of theoretical model. In the second stage, questionnaire survey was carried out to collect data to test proposed hypotheses. In qualitative part of the research, the combination of library and Delphi method was used which was applied method. For

quantitative part, a Delphi-developed questionnaire was used to collect the required data for analysis and also a single cross-sectional study was used where the required data has been compiled from April until the end of September 2012.

The faculty members of medical universities and medical research centers supervised by the Ministry of Health Treatment and Medical Education of Iran constituted the population of the research. The statistic population consisted of 3430 persons employed as full-time faculty members at medical research centers and 12,428 persons employed as full-time faculty members of medical universities. Because the extent of the population, sampling techniques were used to collect the data needed to select the best sampling and according to the type of the universities and research centers, which “stratified random sampling” was used and a minimum required capacity of 423 people were provided. In order to perform sample capacity sufficiency, Bartlett and KMO’s test were used.

4.2 Data collection and measurement development

In this study, data were collected using a validated method of face and construct validity. Therefore, after studying the scientific literature and library studies, items associated with infrastructure factor based on the conceptual model of the research components were extracted. For the implementation the second phase of the Delphi study, the experts were asked to agree or disagree to statements intended to express for any factors. By analyzing the results of the second round Delphi study, besides confirming the conceptual model, the face validity of the questionnaire was reviewed and approved. To evaluate the construct validity of questionnaires using factor analysis and construct validity was confirmed based on a framework designed. Questionnaire survey was carried out to collect data. About 500 questionnaires were distributed to faculty members and a total of 450 questionnaires were received. 50 incomplete questionnaires were excluded due to missing values or double-checked items. In all, 425 questionnaires were valid. For descriptive analysis SPSS statistical software 15 was used and the output was analyzed. Kolmogorov–Smirnov test was used before selecting the type of tests to make sure that the data were normal and to determine the type of tests.

Pearson’s correlation coefficient was used for the amount of relation between knowledge sharing and each one of questionnaire’s aspects in order to evaluate the amount of internal harmony questionnaire’s various aspects and the results demonstrated that the knowledge sharing component (as the dependent variable) has significant

correlation to its dependent variable such as infrastructures. Moreover, there are significant relations among the independent components which show high levels of internal harmony of questionnaire's aspects. It should be noted that by conducting a pilot study and distributing the questionnaire to 15 medical faculty members, its reliability was examined. As a result, Cronbach's alpha for technical factors was equal (0.908), because it is greater than 0.7 thus the reliability of the questionnaire was confirm.

5 Results

Analyzing the demographic factors demonstrated that 73 percent of the respondents were men and 27 percent were women and out of the total, 43.3 percent of professors were engaged in biomedical basic sciences and 56.7 percent were engaged in clinical fields. To answer the question determining the condition of technical and infrastructural factors in the universities and research centers in intra/inter organizational knowledge sharing, the research findings demonstrated that out of various locutions, teaching the way of using information and communication technology to the faculty members took 37 percent and also the way professors get to know the latest changes and decisions made by other organizations through unofficial channels took 35 percent of the total as two most important amounts. The locutions of tools and technologies for knowledge and experience sharing can conform to the individual needs by 36.9 percent, designing the process plan of activities in organization as a software system by 35.8 percent, knowledge sharing through official channels by 34.8 percent and also the favorability and accessibility to the knowledge banks by 34.6 percent as the top to average level among all cases. Generally, around 17 percent of professors evaluated the technical infrastructures as suitable; around half of them (43 percent) evaluated it as rather suitable and around 40 percent regarded it as unsuitable.

To answer the second question of the research determining the effect of each one of the grounds, channels and methods in sharing the knowledge and experience among the faculty members of medicine, this is to state that knowledge sharing among faculty members of organizations can be implemented through various methods, tools and channels. They are generally divided into six categories including the publications and technologies, conferences and associations, transaction of human resources, performing common projects and consultation on research and development programs, sharing the facilities and equipment and cooperation in training and transferring the experiences.

Totally 23 cases were proposed to study the amount of effectiveness of publications and technologies and accordingly the table 1 below is concluded from analyzing the accumulated data from the professors:

Table1 .Frequency distribution of effectiveness amount of publications and technologies on knowledge sharing to other faculty members

Locutions	Too few		Below Average		Average (To some extent)		Above Average		Very Much		Total	
	Quantity	Percent	Quantity	Percent	Quantity	Percent	Quantity	Percent	Quantity	Percent	Quantity	Percent
Internal publications of organization and reports	64	15.1	182	42.7	129	30.4	42	9.9	8	1.9	425	100

Telemedicine	59	13.9	94	22.1	131	30.8	90	21.2	51	12	245	100
The amount of effectiveness of publications and technologies on knowledge sharing	1	0.2	65	15.3	288	67.8	71	16.8	0	0	245	100

From among the publications and technologies, technologies had the largest portion of effect on knowledge sharing. From among the publications, the effect of news bulletins and electronic notification boards by 12 percent and the internal publications and reports of the organizations by 11.8 percent were very much effective. Regarding the other cases the effect of organization's intranet (internal network of the organization)

by 40 percent, action groups such as discussion forums by 37.4 percent, personal computers by 36.5 percent and digital library by 34.8 percent, yellow pages of the organization (network of specialists) and the knowledge resources in organization by around 33 percent, was average. It was also generally observed that 16.8 percent of the professors viewed publications and technology very much effective and more than half of them recognized it averagely effective on knowledge and experience sharing among faculty members.

To study the amount of effectiveness of conferences and associations in knowledge sharing, generally 4 cases were proposed whereby the analysis of professors' opinions showed that around 66 percent of the professors recognized exhibitions, conferences and seminars or the common scientific meetings very much effective, around 48 percent of the professors recognized training workshops in organization for acquiring knowledge and experience very much effective, 60 percent of them (that is above average) recognized the training workshops out of organization for acquiring knowledge and experience (national and international) very much effective, around 71 percent of them recognized personal communications via membership in professional and scientific associations very much effective and 21.9 percent of them recognized the last case averagely effective on knowledge and experience sharing among faculty members . From among the above factors, individual communication via membership in professional and scientific associations was the most effective one on knowledge sharing. It was also generally observed that around 61 percent of the professors viewed the conferences and associations very much effective and 35.5 percent of them recognized it averagely effective on knowledge sharing among faculty members and 3.5 percent of the viewed it ineffective.

To study the effectiveness of exchanging human resources on knowledge sharing, 4 choices were proposed and the data analysis showed that around 61 percent of the professors considered simultaneous activity and occupation in university, medical centres and research centres very much effective, half of the professors in viewed cooperation with other centres in specialty field or related to the field very much effective, around 48 percent of the professors considered passing the supplementary courses in national and international organizations very much effective and 29.6 percent of the considered the same as moderately effective on knowledge and experience

sharing among faculty members and around 8 percent of them evaluated it as ineffective.

To investigate the amount of effectiveness of common projects and consultation on research and development programs on knowledge sharing, 6 choices were proposed and the related data analysis demonstrated that more than half of the professors considered the research cooperation and common projects with other centres very much effective; around 59 percent of them stated common cooperation in guiding the student theses very much effective while 32.7 percent of them considered it moderately effective, 56 percent of the professors considered the common publications among other organizations very much effective; 47 percent of the professors stated participation in research priorities transaction meetings in presence of university professors and research centres very much effective and around half of them (47.5 percent) considered participation at meetings on cooperation development and utilizing the mutual capacities (Cooperation network) as very much effective; around 40 percent of the professors stated the participation in research and development plans very much effective in knowledge and experience sharing among the faculty members. It was also generally observed that half of the professors viewed common projects and consultation on research and development programs very much effective and 38 percent of them considered it moderately effective on knowledge and experience haring and around 11 percent of them evaluated it as ineffective.

In order to investigate the amount of effectiveness of common facilities and equipment on knowledge sharing generally 3 choices were proposed and the related data analysis demonstrated that around 24 percent of the professors recognized sharing the laboratories and sample purchasing as very much effective; around 13 percent of the professors considered the science and technology parks as very much effective; around half of them (around 41 percent) stated the utilization of research and training centres facilities as very much effective and around 40 percent of them considered it moderately effective on knowledge and experience sharing among faculty members. It was also totally observed that around 22 percent of the professors evaluated facility and equipment sharing very much effective and around half of them (around 47 percent) considered it moderately effective on knowledge and experience sharing among faculty members and around 31 percent of them evaluated it ineffective.

With respect to the effectiveness amount of cooperation in training and transferring the experiences, it was observed that cooperation in research centres for training by 56 percent, professors' lectures in universities and research centres by 53 percent and cooperation in scientific and non scientific under the titles (chief editor, editor, editorial board, ...) by 44 percent, were the most effective factors among others. It was also generally observed that around 39 percent of the professors evaluated the training and experience transfer very much effective and half of them considered it moderately effective on knowledge and experience sharing among faculty members and around 11 percent of them evaluated it ineffective.

Since there are six methods and channels used in this research on knowledge and experience sharing, we should realize if the methods have equal effects on knowledge and experience sharing. In case the answer is no, what would be the most effective method on knowledge and experience sharing from the view of faculty members? To answer these two questions, the Freidman's Nonparametric Test was used and the related findings showed that the significance level of Chi Square test (0.000) is smaller than the test level ($\alpha=0.05$) and therefore this is to express by 95 percent of certainty that there is a significant difference between the effectiveness level of each method and channel for knowledge sharing among the faculty members of universities and research centres (table 2).

Table 2.Freidman's Test with respect to the amount of effectiveness of methods and channels of knowledge sharing.

Number of respondents	Statistics of Chi Square Test	Level of Freedom	Significance level
425	829.195	5	0.000

With respect to the differences among each method and channel of knowledge sharing, the rankings of the methods were offered (Table 3).

Table 3.ranking of the methods and channels effective on knowledge sharing among the faculty members

Methods and channels of knowledge sharing	Average (Ranks)	Priorities
Conferences and associations	4.93	1
Exchanging the man power	4.24	2
Performing common projects	4.8	3
Cooperation in training and transferring the knowledge	3.36	4

Publications and technologies	2.28	5
Sharing the equipment and facilities	2.02	6

Based on faculties' opinions, the conferences and associations by average rank 4.93 exchanging the man power by average rank 4.24 and implementing the common projects were the most effective methods in knowledge and experience sharing among the faculty members. However, Freidman test (Table 4) demonstrated (regardless of a particular categorization for methods and channels effective on knowledge sharing) that the significance level of Chi Square test (0.000) was smaller than test level ($\alpha=0.05$) therefore this is to state by 95 percent of certainty that there was a significant difference between the effectiveness level of each tool for knowledge sharing among the faculty members of the universities and research centres.

Table 4.Freidman's test with respect to the significance level in methods and channels of knowledge sharing

Number of respondents	Statistics of Chi Square Test	Level of Freedom	Significance level
425	3951.974	46	0.000

The ranking of each one of the methods and tools of knowledge sharing is offered according to their different effectiveness levels. Noticeably, as regarded by the professors, respectively:

Establishing personal relations via membership at the professional and scientific associations; common exhibitions conferences, seminars or scientific meetings; organization's exclusive website; training workshops out of the organization to obtain national and international knowledge and experience; simultaneous activity and occupation in the college, medical centres and research centres; common cooperation in guiding the student theses; exclusive email of the organization; cooperation in research centres for training; offering lectures in mass media including radio and television; common publications in cooperation with the other organizations were the most effective methods and tools for knowledge and experience sharing among the faculty members. By contrast, the gray texts including the patent registration license, technical and industrial reports, rewarding systems, guiding booklets, manuscripts and instructions, science and technology parks and the internal publications of the

organization and the reports were comparatively less effective on knowledge and experience transferring among the faculty members.

Table 5. Ranking of methods and channels effective on knowledge sharing among faculty members

Methods and tools of knowledge sharing	Average	Priority
Establishing personal relations via membership at the professional and scientific associations	33.58	1
common exhibitions conferences, seminars or scientific meetings	32.61	2
organization's exclusive website	32.12	3
training workshops out of the organization to obtain national and international knowledge and experience	31.06	4
simultaneous activity and occupation in the college, medical centres and research centres	30.50	5
common cooperation in guiding the student theses	30.21	6
exclusive email of the organization	29.81	7
cooperation in research centres for training	29.58	8
offering lectures in mass media including radio and television	29.42	9
common publications in cooperation with the other organizations	29.39	10
offering lectures in universities and research centres	28.97	11
Social networks, weblogs, wikis, ...	28.65	12
Electronic discussion groups	28.37	13
Research cooperation and performing common projects with other centres	28.26	14
Cooperation with other centres in specialty field or related to the specialty field	28.04	15
Teleconferences, telephone conferences, videoconferences, ...	27.70	16
Passing the supplementary courses in national and international organizations	27.41	17
Training workshops in organization for obtaining knowledge and experience	27.40	18
Attending at the meetings of research priorities exchanging participated by professors of universities and research centres	26.50	19
Attending at meetings to develop cooperation and to utilize the mutual capacities	26.50	20
Virtual seminars and webinars	26.15	21
Cooperation in scientific and non-scientific publications of chief editor, editor and editorial board, ...	25.76	22
using the facilities of the research and training centres	25.18	23
Promotional and on-the-job trainings	24.96	24
Short messages, RSS, Alert, ...	24.52	25
(Organization's extranet), network out of organization used for organization's internal services	24.07	26
Cooperation in research and development plans	23.95	27
Participation at retraining courses for professors in and out of organization	23.79	28
Knowledge resources in organization database of articles, research plans and books, ...	23.30	29
Cooperation with retired faculty members for training and transferring the experiences	22.62	30
Action groups like think tanks or consultation chambers for increasing the cooperation)	22.14	31
Virtual training spaces	21.78	32
Study and work opportunities	21.33	33
Continuous asking and answering systems	20.97	34
Telemedicine	20.08	35
Digital library	19.90	36
Story telling	19.07	37
Personal Computer	18.92	38
Organization's intranet, internal network of organization	18.22	39
Yellow pages of the organization, network of specialists	17.89	40
Laboratories and purchasing the samples	17.89	41
News bulletins and electronic notification boards	14.96	42

Internal publications and reports	14.78	43
Science and technology parks	14.78	44
Guidance booklets, manuscripts and instructions	13.25	45
System of recommendations	12.61	46
(Gray pages), patent registration license, industrial and technical reports, ...	9.07	47

6 Conclusions

With respect to analyzing the first question, this is to state that many universities try to required information banks, however there are limits and obstacles in providing the data banks accessibility because of increased prices of annual subscriptions of data banks and in some cases the lack of awareness of professors regarding the existence of such banks or the way to use them so the libraries and authorities should be aware of the issue and solve them as much as possible. Around 34 percent of the professors expressed that modern technologies (hardware and software) existed in organization to a very large extent for knowledge and experience sharing with professors inside the organization. Around 18 percent of the professors expressed that modern technologies (software and hardware) existed to a very large extent for knowledge and experience sharing with the professors out of the organization. The cause of this discrepancy may be lack of awareness of authorities on necessity of interactions among professors of various organizations. Another reason may be the lack of fund for purchasing and mobilizing the technical infrastructures therefore many activists in the field try to primarily solve the organization's internal problems and then purchase the hardware and software needed for communication to the sections out of organization. That is because, the knowledge management is based on three principles of individuals, process and technology and attention to principle of individuals as the infrastructure of knowledge management is of a greater significance than technology. This is also noticeable that technology may become an inhibitor rather than an enabler if it is not adequately regarded. Libraries and research deputies play the main role in this regard and are bound to take responsibility of establishing various training workshops and also accurate informative affairs and this aim depends on the amount of awareness and expertise of the libraries authorities on establishing the necessity to establish the training workshops, using the technologies and knowledge sharing. Around 25 percent of the professors declared that they are informed about the latest changes and decisions of other organizations to a very large extent via official channels, while around 35 percent of the professors stated that professors receive the information about the latest changes to a very large extent through unofficial

channels. Unofficial channels are used generally for being easily communicated and less time consuming. This can also be due to existence of trust and reliability among the co-workers. Thus, the authorities can provide suitable grounds such as co-operational groups, free discussion meetings, forums on lunch break...to increase exchanging the news, knowledge and experience. Totally, around 17 percent of the professors considered the technical infrastructures suitable and 43 percent of them considered it averagely suitable. According to Brennenraedts, Bekkers, and Verspagen (2006), one of the most common unofficial methods of transferring and sharing knowledge is social networks and interaction among individuals on various levels.

It seems by studying the literature that existence of information and communication technologies in organization alone do not suffice and training the way to using such tools plays a significant role on using them. The results obtained by the research conducted by Alvani, ZareiMatin and Pashazadeh (2009) indicate that existence of information technology capabilities is one of the effective factors in effective knowledge sharing. Technologies are accounted as a ground that facilitates accessibility and emission and providing such ground and basis is useless without the capability to utilize technologies (Yang and Chen 2007). The research conducted by some researchers show that the ability of personnel to utilize information technology and the systems based on them can be accounted as important and effective variables on individual's ability to share personal and group knowledge sharing (Gouza 2006; Gao 2004; Hooff and Husman 2009). In this regard, the research of Yang and Chen (2007) demonstrated that the more individuals are skilled in using the information technology, the more they will be interested in knowledge sharing. The results of a research recently conducted in England demonstrate that the role of ICTs is neutral in knowledge sharing (Fullwood, Rowley and Delbridge 2013).

From among various proposed methods, around 52.5 percent of the professors highly exchanged knowledge and experience with other faculty members of the organization regarding the new educational needs of the students. The next ranks were 49 percent for external conferences and the way to attend at them and also around 47 percent for the internal conferences and eventually 46 percent on introducing the new resources, books and publications for knowledge and experience sharing compared to other methods. As you observe, the methods most used by faculty members inside the organization for knowledge sharing were on the students' educational needs and introducing the resources and books and this shows that the professors did put their utmost endeavours on sharing

the affairs that could promote knowledge for advising and training the students, so they tried to use the experiences of other teachers to succeed in this regard. Although knowledge sharing with other organizations' professors was fewer than the intra-organizational knowledge sharing as a total, inter-organizational knowledge sharing was most common in cases as: 16.5 percent of the professors averagely introduced internal conferences and the way to attend at them in knowledge sharing with the faculty members of other organizations. Around 15 percent of the professors exchanged information to a large extent with the faculty members of other organizations on the new educational needs of the students. We can conclude that the faculty members used various methods to share knowledge and experience. As an instance, to share the knowledge inside the organization they used introducing the foreign conferences to a large extent more than other methods probably because value can be added to the origin organization through notification on foreign conferences and even conferences held abroad by any faculty member as a capital of the organization, because under such conditions there will be more communication to the world outside the organization, resources become more up to date and knowledge (intentionally or unintentionally) is exchanged more and this is because individuals are involved in various phenomena and the occupational output of the individuals is increased after returning back to the organization and offering a travel report to be added to the organizational resources. The least significant cases where faculty members shared knowledge with other faculty members in the organization were information related to the welfare and recreational affairs by 16 percent, administrative information and also transferring the scientific experiences of industrial environment, medical equipment and business by around 19 percent. One can concluded by this section that the research and educational professors in the field of medicine are so much engaged in their profession to cure patients and discover new medicines and therapeutic methods and run short of time for the administrative and recreational affairs.

Regarding how effective is each one of the grounds, channels and methods on knowledge and experience sharing, the results of analyzing the faculty members' opinions showed that from among the publications, the internal publications, reports electronic bulletin and news boards of the organization were the most effective ones on knowledge and experience sharing and from among the technologies, the organizations' exclusive website (65 percent), delivering lectures in mass media (60 percent), social networks and electronic discussion groups (59 percent) and also e-mails (59 percent) were respectively

the most effective ones on the process. Low rank of the publications and technologies is associated by two interpretations; first, these tools and publications were not important motivators as viewed by the individuals; second, faculty members could not consider a rank for them because organizations did not care enough to introduce them and train the faculty members to learn them, so the organization should try to alleviate or solve these issues. Aligned with the results of this research, in the research conducted by Jafarzadeh-Kermani (2011) the highest average rank was confirmed for specialty publications (3.46). Accordingly, the research results obtained by Nedjat *et al.* (2008) the article publication in journals and offering the articles and research results at conferences were known among the most effective factors on knowledge sharing activities. These results show that publications and conferences can be a suitable ground for knowledge sharing activities. Accordingly, the research results obtained by Brennenraedts, Bekkers, and Verspagen (2006) similarly demonstrated that as viewed by the researchers, conferences, training workshops and scientific publications (books and magazines) had the highest ranks as the significant channels and foundations for transferring and sharing knowledge at the biomedicine engineering department. Specialty publications existing in the profession and the internal publications and reports of the organization can be regarded and studied in this section. As we know, publications are considered as a basis to emit written and objective knowledge and provide the grounds for scientific activities publications. Therefore, it seems universities and also the research centres can facilitate knowledge sharing through establishing an internal publication than can also facilitate publishing the faculty members' articles and also subscription of specialty scientific magazines (printed or electronic) and providing the conditions for accessibility.

Regarding the significance of training workshops on obtaining the knowledge and experience, this is necessary to provide the suitable circumstances for participation of faculty members. It also seems that training workshops are appropriate environments where younger faculty members can take advantage of more experienced individuals' subjective knowledge who has obtained too much knowledge through many years of teaching and researching; the knowledge that is so volatile and can easily be lost when they retire or lay off. The workshops held in or out of the organization, service location, universities and research centres have already been expensive and therefore they can be established by participation. Moreover, in order to utilize more of the training workshops, providing the equal conditions for all and providing timely utilization, we can establish

such workshops electronically because the faculty members may sometimes be away from such meetings and workshops and cannot attend at them in presence. It seems that the site of specialty and professional associations or the site of the universities and research centres may be suitable for such affairs.

The effect of exchanging the human resources is another method of knowledge and experience sharing as stated by 61 percent of the faculty members the simultaneous activity and occupation in university, the treatment centres and research centres as effective factor on improving the process. The results showed that the respondents were generally the members who were engaged in activities at the treatment and educational hospitals and then simultaneously at universities and research centres or hospitals and as we stated before the simultaneous engagement led in expansion of individuals' views on the problems and weaknesses in the knowledge sharing process and confrontation with the patients add to the necessity of the process among the training and research personnel. On the other hand, individuals, by simultaneous engagement at two or several organizations, can transfer the knowledge and experience from one environment to another and the individuals themselves will become the factors of transferring knowledge and experience and turning the implicit knowledge to the explicit knowledge.

Common projects and consultation in programs can provide the grounds to promote the participating individuals in projects because the individuals are demandingly exposed to the knowledge and experience of the other professors or do their best to accomplish the responsibility they have undertaken and consequently their knowledge is increased by accompanying the knowledge and experience of the colleagues. The research findings obtained by Brennenraedts, Bekkers, and Verspagen (2006) aligned with the results of present research and they introduced the common projects and consultation on research and development programs as one of the suitable provisions for transferring knowledge and sharing experiences. As regarded by the professors, sharing the facilities and equipment of the research and training centres among other factors, were the most important factors in effective knowledge sharing. From among the effective factors on cooperation for training and transferring the experiences, more than half of the professors (around 56 percent) regarded cooperation in research centres for training effective on knowledge and experience sharing. In this regard, we can state that many professors learn the theoretical sciences through books and articles and studying the experiences of others to be up to date, however turning the theoretical into practical science requires

laboratories, hospitals and research centres clinically; therefore sharing the facilities and equipment and participation at the common affairs should be supported and encouraged by authorities.

Generally, by the said factors we can conclude regarding the differences among effectiveness of methods and channels that, considering the professors opinions, the conferences and associations by average rank 4.93, exchanging human resources by average rank 4.24 and performing the common projects by average rank 4.18 were the most effective methods on knowledge and experience sharing among the faculty members. Aligned with this research, in the research conducted by Jafarzadeh-Kermani (2011), the results of Dunkan's test that categorized the grounds into 12 groups show that by the opinions of the faculty members, the grounds of emails, training workshops, seminars and scientific meetings and specialty publications were similarly the most significant ones regarding the suitability for knowledge sharing, and the grounds of scientific parties, forums, weekly or monthly meetings with the group and electronic boards were the least significant ones as viewed by the faculty members regarding suitability for knowledge sharing. The significance of grounds like specialty publications, books, training seminars, scientific congresses and meetings as viewed by the faculty members, showed that the universities should endeavour to provide such grounds. The necessary conditions should be arranged for participation of faculty members in internal and external conferences as lecturers or learners in order to let individuals acquire knowledge and also provide the suitable atmosphere for interaction and knowledge exchanging to emit and share knowledge by co-workers. Sometimes the faculty members face problems in scientific seminars such as lack of time, lack of facilities to attend at seminars (Financial problems, accommodation, ...), lack of adequate support exerted by universities and research centres in this respect, unsuitability of the lecture subject to the faculty members' interests, useless subjects of some presentations, therefore organizations should find solutions and alleviate the problems.

The present research explains that some tools of web and technologies and network facilities observed here and regarding which we consulted by the faculty members, were reposed to the lowest rank with respect to knowledge and experience sharing. This fact demonstrates that this is not sufficient to provide the bases and grounds for knowledge sharing, but it is also necessary to pay attention to the way to use them. Providing the atmosphere of trust and cooperation and settling the culture too. Also the universities

need to provide the necessary infrastructures in advance (such as accessibility to high speed internet, hardware and software facilities for each professor including computers, tools and solutions required for controlling the messages, ...).

It is concluded by studying the results related to technology that around 59 percent of the professors considered the social networks (weblogs, wikis, ...) effective on knowledge and experience sharing and moreover around 57 percent of the professors recognized electronic discussion groups; 55.5 percent of them considered teleconferences (telephone conferences, video conferences, ...); around 50 percent of the professors considered virtual seminars and webinars; and around 33 percent of the professors considered telemedicine the most effective factors on the process. As approved by the research results obtained by Chai and Ki (2010), weblogs should provide an environment replete with trust for the users and their weblog administrators should secure the privacy and safety of their users to increase their trust and this knowledge sharing, otherwise individuals cannot be expected to exploit this facility suitably for knowledge sharing. These results are contrary to the results obtained by Cheng, Ho and Lau (2009) because faculty members had mandatorily subscribed in the network and although 60 percent of the respondents had declared they had participated in the knowledge sharing network of the university, only a few of them would participate in the network if they could subscribe voluntarily. Therefore, we can conclude that this is not possible to encourage individuals to use them through providing modern technologies and demanding them to use the facilities. This aim can be achieved only through motivation in a participatory cultural environment for the employees.

Structured Abstract

Purpose – In today's society, knowledge is the most important capital and it is difficult to control. Knowledge is increasingly obtained outside the company. Social networks have taken the lead because they allow the exchange of information in real time. The aim of this study is to determine if the exchange of knowledge in the professional social network LinkedIn group for Java affects the overall knowledge gain for professional work, depending on the socio-demographic characteristics of respondents, regional affiliation and professional requirements, further motivation and frequency of use of the network and the way they perceive the amount of their knowledge.

Design/methodology/approach–Research is performed as follows: the survey was designed and performed on LinkedIn, the biggest global professional network, among participants of Java programming language professionals. We collected N=448 valid questionnaires from the respondents from India 37.7%, 30.9% from North America, 18.6% from Europe and other regions (12.8%), that properly represent the whole population of these group members. Data analysis (descriptive statistics) and data mining was performed. Data mining models by applying knowledge trees and linear regression were made and gave more insight into patterns.

Originality/value–This research represents the most comprehensive research of knowledge sharing in professional social networks, because others have focused only on particular subgroups of variables covered here. We have conducted research, for the first time, on the gains obtained by knowledge sharing between professionals, while additional value is provided by identification of the most important factors in this process. Research provides an insight into how global processes of knowledge sharing work in the

professional social network, how processes are affected by the socio-demographic data. Research has given an answer to the question of who has the highest benefit from this process.

Practical implications–Technical skills and culture of knowledge sharing of Java technology groups on the LinkedIn social networks is a pioneering process that will be developed for other professionals in future decades. The participants’ region had very little influence on the benefits gained, so these networks contribute to globalization. Gains are influenced by the intensity of use and the quality of knowledge, giving directions to the social networks service providers. Satisfaction with certain services on this professional network, compared with the satisfaction with other (non-professional) social networks is lower, which indicates the potential of this domain and need for development and research.

Keywords–knowledge management, professional social networks, knowledge sharing and knowledge gain.

Paper type – Academic Research Paper

1 Introduction

Knowledge has been described as the “only meaningful resource”, a resource which increases the capacity of an entity for effective action (Drucker, 2001). It has been explored from both the individual and social perspective. Papadopoulos et. al. stated that knowledge is an object that could be stored, operated and reused for current and future situations or the outcome of interaction and sharing within communities of practice (Papadopoulos, Stamati and Nopparuch, 2013.). Knowledge sharing is defined as provision of task information and know-how to help others and to collaborate with others to solve problems, develop new ideas, or implement policies or procedures (Wangand Noe, 2010). A lot of previous research has confirmed that knowledge sharing significantly improves competitive advantage (e.g. Papadopoulos, Stamati and Nopparuch, 2013) and individual learning. Recent research in this field investigates and emphasizes the significant role of technology in knowledge sharing. There are numerous technology tools available to facilitate knowledge sharing, such as forums, e-mails, blogs, as well as social networking sites. Social networks were found as one of the most important factors impacting knowledge sharing (Chowand Chan, 2008).

Knowledge sharing between individuals and firms through social networks has just recently started attracting attention among researchers (Rejeb-Khachlouf, Mezghani and Quélin, 2011). However, knowledge sharing through social networks is highly present

and even specific knowledge is shared. The main reason for this lies in the fact that knowledge and information are flowing more easily in a social network than outside (Østergaard, 2009). The most famous social networks are Facebook, MySpace, Twitter and LinkedIn. The latter stands out because it is a social network of professionals who use this social network to achieve business contacts and create new job opportunities. Professional social networks connect large numbers of experts and provide mutual discussion on particular problems, create new ideas, help in problem solving, improve presentation skills. They allow users who need knowledge to obtain useful information from professional experts. Social media enable the exchange of information and discussion on topics in real time, regardless of location and time (Papadopoulos, Stamati and Nopparuch, 2013).

This article examines globally the current state of these technologies and processes on the example of a typical advanced professional social network. LinkedIn is the most advanced professional social network with over 161 million users, at the moment when research was conducted (Skeels and Grudin, 2009).

As of April of 2014, LinkedIn reports more than 300 million of registered users in more than 200 countries and territories (LinkedIn, 2014).

There are several groups of professionals in the LinkedIn network whose area of interest centers on Java programming. The Java programming language, since its inception as a dominant Open Source technology, connected people who share knowledge, and who also have great knowledge of information and communication technologies. This is potentially a very interesting group of social network users. Since these participants are experienced ICT specialists and are triggers of certain trends, their behavior on social networks could hint toward possible trends in the future for other groups of users.

Online social networking is having a great impact on knowledge sharing through online interaction. Therefore, the purpose of this paper is to explore how knowledge flows in specialized groups that are part of online social networks and which factors play an important role for knowledge gain in the social learning context using online social networking. In addition, the paper will explore what types of knowledge users share and the types of benefits that they obtain through this activity. The methodology of this study is novel, namely in the fact that data mining techniques have been applied.

The paper is organized as follows. In Section 2 we review the theoretical background serving as a basis on which we built our research. Section 3 deals with research methodology and outlines data collection among participants of four groups regarding Java programming in the professional social network LinkedIn. In section 4 we explain data analysis: the application of data mining techniques on our data. Finally, in section 5 we point out concluding remarks.

2 Theoretical background and research hypothesis

Knowledge sharing refers to the provision of task information and know-how to help others and to collaborate with others to solve problems, develop new ideas, or implement policies or procedures (Cummings, 2004.). From the perspective of knowledge management, a social group is a place that can contain a large amount of knowledge, and thus it is a place of great interest. Today, social groups appear in a social network as its subsets. Jeff Weiner, Executive Director of LinkedIn, in a discussion on the topic of "Web 2.0. Summit ", argues that the social networks are developing in two directions: a) social networks that are used for entertainment and b) professional social networks (Hadzic, 2010). Network theory suggests that the formality of the network structure may result in different types of knowledge diffusion (Dyer and Nobeoka, 2000). Thus, this paper focuses on professional social networks since their social groups contain specialized domain knowledge and knowledge sharing behaviour of their members and knowledge flow may be different. In order to integrate and extend existing views, this paper develops theoretical model and performs an empirical investigation to examine relationship between the sources of knowledge and other patterns of knowledge sharing behaviour.

2.1 Research model

Social exchange theory suggests that individuals evaluate the perceived benefits of certain action and base their decisions on the expectation that it will lead to some kind of rewards (Emerson, 1981). Participating in knowledge sharing in an online community also assumes some kind of benefit. In general, knowledge sharing practice has been found to be related to increased internal satisfaction, perceived obligation to reciprocate the knowledge gains from the forum, enhanced professional reputations and helping advance the community. Previous research seems to suggest that knowledge sharing is more

strongly related to participants beliefs that their shared knowledge is useful to others than the personal benefits they gain, especially in a professional network (Siemsen, Balasubramanian and Roth, 2007).

However, there are no research papers that explore the knowledge flow or the perceived benefits of knowledge sharing in social groups within social networks. In this chapter we are exploring previous work regarding knowledge sharing in order to prove the claim and identify elements important for knowledge sharing to set up our research model.

When characterizing benefits of knowledge sharing, demographic characteristics are the one to start since the younger generations are substantially influenced by recent trends. The knowledge they possess is the result of their demographic characteristics and sources from which they acquire it. Their behaviour in the group is the result of their demographic characteristics and the level of knowledge they possess. Finally, the benefits of technology are the result of demographic characteristics, sources of knowledge and group behaviour.

A small part of earlier research comprised investigations on various characteristics of members in the knowledge sharing process. The results of these studies suggest relationship between demographic characteristics and knowledge sharing. For instance, Ojha showed that members who considered themselves a minority based on gender, marital status, or education were less likely to share knowledge within group (Ojha, 2005). Sawng et al. found that teams in large organizations with higher female–male ratios were more likely to engage in knowledge sharing (Sawng et al., 2006).

Furthermore, some of the previous studies suggest the influence of national, cultural and regional characteristics in knowledge sharing process. Chow et al indicate that participants from the Chinese culture tended to share information for the good of the organization even when sharing was potentially personally disadvantageous (Chow et al., 2000). They also found that Chinese participants were less likely than American participants to share knowledge sharing with someone considered out of their group.

Despite all of the above, none of the previous studies examined the effects of these factors on knowledge gain and knowledge flow in a professional social network, which is the focus of this paper.

Richness of knowledge sources has a positive influence on individuals' attitudes toward knowledge sharing. Foss and Pedersen have investigated the relationship between

sources of knowledge and the transfer of that knowledge to others (Foss and Pedersen, 2002).

Their results lead to the conclusion that all knowledge sources have a significantly positive influence on knowledge transfer. Furthermore, they proved that not all knowledge is transferred to the same extent, and that the sources of knowledge seem to be a good indicator for the extent to which knowledge is actually transferred. This is because the sources of knowledge are determining the characteristics of knowledge (Foss and Pedersen, 2002).

One of the most important factors which influence knowledge sharing, according to Rus, Lindvall and Sinha, is the fact that there is a culture of knowledge sharing (Rus, Lindvall and Sinha, 2001).

Many studies in the field of knowledge management have proved the importance of studying motivations, and motivation has been one of the most studied factors in knowledge management (e.g. Papadopoulos, Stamati and Nopparuch, 2013). Knowledge sharing especially cannot be forced and it is more likely to occur when people are motivated. Thus, participants' motivation is considered to be important factor. Knowledge sharing is highly influenced by the participants' willingness to be included in the process.

Members of social networks differ in their interaction frequency. The more participants are involved in the activities of the group the more knowledge they will share (Østergaard, 2009). It is expected that frequent visits to social networks and inclusion enhances the levels of participation in groups' discussions. Therefore, participation in activities in social network may influence behaviour of social network users. They can share information and experience to achieve group participation.

Despite the fact that motivation has been recognized and emphasized in the knowledge sharing literature (e.g., Davenport and Prusak, 1998; Goodman and Darr, 1998; Hansen, Mors and Lovas, 2005), traditional motivation theories (e.g. expectancy theory) have not been used as often in knowledge sharing research. Expectancy theory states that the intensity of a tendency to perform in a particular manner is dependent on the intensity of an expectation that the performance will be followed by a definite outcome and on the appeal of the outcome to the individual. In line with this theory, our model assumes that, the more rewards and enjoyment social network members perceive to be associated with their knowledge sharing, the more they will be inclined to participate

in such activities. Therefore, social network members` intentions to share their knowledge strongly depend on individual motivations.

Different levels of participant`s knowledge lead to different degrees in contribution of knowledge sharing within group. The perception of social network participant`s expertise helps increase participation in knowledge sharing. Some of the previous research examined relationship between estimated level of knowledge and intention for knowledge sharing. For instance, Wasko and Faraj did not find individuals' self-rated expertise to be related to knowledge sharing (Wasko and Faraj, 2005). However, knowledge sharing does appear to be contingent on individuals' confidence of sharing useful knowledge with others. Several studies have shown that individuals who are more confident in their knowledge and ability to share useful knowledge are more likely to share knowledge and report higher levels of engagement in knowledge sharing (e.g., Cabrera et al., 2006; Lin, 2007). Participants with higher expertise are more likely to share useful knowledge when other participants asked. On the other hand, Bordia et. al. found that anxiety based on fear of negative evaluations has been found to be negatively related to knowledge sharing (Bordia et al., 2006).

Our model assumes that the role of resources embedded in network relationships somehow determines knowledge exchange and knowledge sharing activities.

The key factors in the process of knowledge sharing are presented through the model in the figure below (Figure 1).

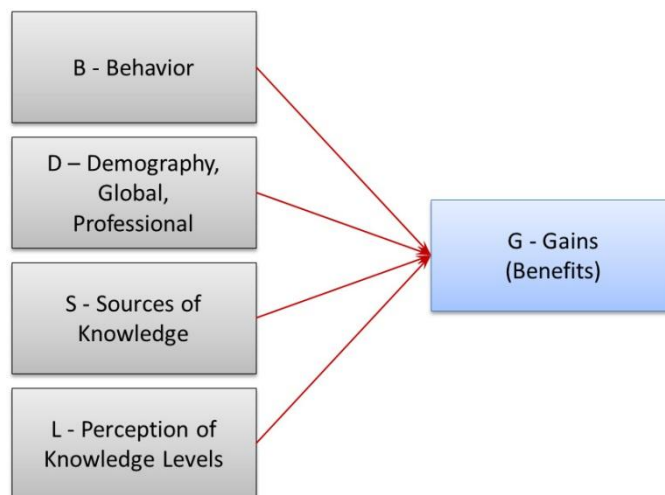

Figure 1. Research model: gain (benefits) dependency of the group of variables.

Figure 1 displays dependencies and relationship between key factors that influence gains (benefits) of knowledge sharing among members of professional social network.

According to the model presented in figure 1, gain (benefits) of knowledge (G) is assumed to be the function of the group of variables listed below with the following dependencies:

- Demography, global, professional (D)
- Behaviour(B)
- Sources of knowledge (S)
- Perception of knowledge levels(L)
- Gain (benefits), $G = g(D, B, S, L)$.

The group of variables include socio demographic, regional and professional characteristics (Demography, global, professional - D), behaviour in social network groups (Behaviour- B), sources of knowledge used to learn and solve the problems (Sources of knowledge - S) and perception of personal and other member`s knowledge level (Perception of knowledge levels - L).

In table 1, particular variables, included in the model, are given with their affiliation to one of the aforementioned groups.

Table 1. Description and grouping of variables in the model.

Group of variables	Variable	Description
Demography, global, professional (D)	AGE	Age
	REGION	Geographical region
	LVL_EDUC	Level of education
	SOFT_EX	Experience in software development
	PRO_FIELD	Professional field
	EMP_PRIM	Primary line of business
	JOB_FUNC	Principal job function
Behaviour(B)	COMM_AVE	Communication intensity
	FOLLOW_TRENDS	Follow new trends
	SEARCH_FOR	Search for a job
	PROVE_MY	To prove myself
Perception of knowledge levels (L)	SHARE_KN	Share knowledge
	KL_PER	Personal knowledge
Sources of knowledge (S)	LEVL_OTH	Level of others knowledge
	GAIN_INT	Gaining knowledge on Internet
	GAIN_LOC	Gaining knowledge local
	GAIN_SEM	Gaining knowledge on seminars
	GAIN_SL	Gaining knowledge by self-learning
Total gain (G)	GAIN_LIB	Gaining knowledge in library
	GAIN_TOT	Total gain from sharing knowledge in social group

3 Research methodology

The research model, shown in figure 1, aims to identify the factors affecting gains on the professional social network. To test the proposed research model, we use data of an online survey conducted in October 2009 by the authors of this article. Most of the variables in the questionnaire were developed following phases of knowledge audit method (Cheung et al., 2011; Burnett, Illingworth, Webster, 2004; Perez-Soltero et al. 2006). Questionnaire is presented in table A of appendix. The survey URL was posted to the four groups found at the professional social network LinkedIn. Total population of social groups in which research was conducted are, according to the LinkedIn group statistics on 21st October of 2009: 1) J Architect with 16,119 members, 2) Java Developers with 49,889 members, 3) the Java EE Professionals with 29,588 members, 4) Java/JEE Enthusiasts with 9,167 members. These groups are overlapping (many members of one group belongs to some of other groups).

3.1 Sample

The respondents are individuals who have experience and have participated in projects to develop application programs. Respondents were qualified to make valid judgments in the questionnaire about professional social networks usage for the purpose of knowledge sharing on global level. Total sample of participants who completely filled out the questionnaire is $N_1=524$, reduced to sample $N = 448$ in the process of data preparation. This later data sample, $N = 448$, is used for descriptive and data mining analysis, described later.

Participants were asked ten general questions relating to their basic characteristics: age, country of origin, level of education, years of experience, years of experience in participating in the projects of development of application programs, issues of employment and their current position at the work. Furthermore, a set of twenty questions related to the motives for group membership and activities in the group, communication channels, assessment of knowledge in the group and its importance, identification of sources of knowledge were asked.

The aggregation of input variables is performed with the aim to reduce the dimensionality, to increase the interpretability of the model and to achieve more preferable statistical distributions important to the performance of analyses.

Considering high correlation between certain variables, confirmed by principal component analysis PCA, they were integrated into new, aggregated variables. Following aggregated variables were created:

- variable COMM_AVE indicates the intensity of communication within the group, is obtained as follows:

$$\text{COMM_AVE} = (\text{QA_PART2} + \text{IM2} + \text{MAIL2} + \text{DISCUSS2})/4.$$

COMM_AVE thus indicates intensity of communication in the interval of 1 (low) to 5 (high), aggregated from intensity to other group members via *questions & answers* (QA_PART2), *instant messages* (IM2), *email* (MAIL2) and *discussions* (DISCUSS2).

- variable KL_PER indicates average perceived level of personal knowledge (perceived for KL_SDK and KL_SPMK), is obtained as follows:

$$\text{KL_PER} = (\text{KL_SDK} + \text{KL_SPMK})/2.$$

KL_PER thus indicate personal knowledge level in the interval of 1 (low) to 5 (high), aggregated from *software design knowledge* (KL_SDK) and *software project management knowledge* (KL_SPMK).

- variable LEVL_OTH, indicates perceived level of knowledge of others, is obtained as follows:

$$\text{LEVL_OTH} = (\text{EXPER3} + \text{KNOW3} + \text{LEVL_SDK} + \text{LEVL_SPMK})/4.$$

LEVL_OTH thus indicate knowledge level of other members, in the interval of 1 (low) to 5 (high), aggregated from *experience* (EXPER3), *knowledge* (KNOW3), *software design knowledge* (LEVL_SDK) and *software project management knowledge* (LEVL_SPMK).

- variable GAIN_TOT, indicates total gain is obtained as follows:

$$\text{GAIN_TOT} = (\text{GAIN_SDK} + \text{GAIN_SPMK} + \text{MEMB_PROBL} + \text{MEMB_QUICK} + \text{MEMB_PERF} + \text{MEMB_USEF} + \text{MEMB_REACT} + \text{MEMB_DECS})/8$$

GAIN_TOT thus indicate total gain for a person obtained from these professional social groups in the interval of 1 (low) to 5 (high), aggregated from *software design knowledge* (GAIN_SDK), *software project management knowledge* (GAIN_SPMK), *helped me solve problems* (MEMB_PROBL), *enabled me to accomplish tasks more quickly* (MEMB_QUICK), *improved my job performance*(MEMB_PERF), *is useful in my job overall* (MEMB_USEF), *enabled me to react more quickly to changes in business* (MEMB_REACT) and *improve decision making* (MEMB_DECS).

The aim of this study is to determine if the exchange of knowledge in the professional social network LinkedIn group for Java affects the overall knowledge gain for professional work, depending on the socio-demographic and professional characteristics of respondents, regional affiliation and professional requirements, motivation and frequency of use of the network and the way they perceive the amount of their knowledge and knowledge to exchange on the social network.

By means of a decision tree, model of dependencies was tested, described above:

$$G = g(D, S, L, B).$$

By applying this model we want to establish the influence of individual variables to knowledge gain in social networks and achieve high-quality models that will explain with sufficient reliability these phenomena.

4 Data analysis

Respondents answered questions about age, country, level of education, and obtained information on current employment.

The average age of members of the groups was 34.65 years, with 23 as youngest and 64 as oldest participants.

Most of the respondents are from India 37,70%, following 30,89% from North America (USA and Canada) and 18,59% from Europe. Other regions together make up less than 13% of the sample. Qualifications-wise, most respondents have a Master's degree 50.67%, followed by 4-year study 36.55%, 5.41% of the respondents have initiated studies and 2.51% of them had a completed 2-year university programme. Other groups of respondents according to education are represented about 2% or less. According to years of professional experience most of the respondents (34.35% of them) has 2-5 years of experience, then the respondents with 6-10 years of experience (31.87% of them), followed by respondents with less than 2 years of experience, (12.98% of them). There were 11.07% respondents with 11-15 years of experience, and 9.73% with more than 15 years of working experience.

Table 2. Descriptive statistics for variables included in the model.

Variable	Min-Max value (continuous) Values (nominal or ordinal)	Mean/stddev Distribution (Probability)
AGE	23-64	34.39 ±7.58
REGION	AF (Africa) AS (Asia/without India)	0,01116 0,05580

GAIN_SEM	0 (min) – 1 (max)	0,25 ± 0,33
GAIN_SL	0 (min) – 1 (max)	0,7 ± 0,35
GAIN_LIB	0 (min) – 1 (max)	0,21 ± 0,41
GAIN_TOT	1 (min) – 5 (max)	3,18 ± 0,70

In the second part of the questionnaire, group members were asked about the culture of knowledge sharing, motives for knowledge sharing, communication channels and barriers to the communication.

When asked about motives for knowledge sharing, respondents expressed two most influential motivators: monitoring trends and knowledge sharing. Respondents stated that the acceptance of their knowledge and experience played an important part in communication with other members of the group. They also expressed their perception of knowledge of other group members. Most of them ranked other members as possessing above average knowledge.

When analysing the answers regarding climate and communication in the group we can conclude that there is a high awareness of knowledge sharing.

Communication in the group is "one to many". Respondents positively evaluated the accessibility of the group's shared pool of knowledge, good communication, and enthusiasm of the group members and help in solving problems.

Third part of the questionnaire was focused on two basic skills that are needed in the development of application programs. The main conclusion drawn from the analysis of this part of the questionnaire is: Internet is the first stop when in search for knowledge.

Furthermore, respondents ranked their knowledge contribution to the group. The entire population has an average level of knowledge gained in the design of application programs. Group members gain a part of the rest of member's knowledge, which directly contributes to the personal knowledge of each member. The following table gives descriptive statistics for variables included in the decision tree model.

4 Research methodology

Previous research studies engaged in identifying principles in knowledge sharing process have used traditional methods such as descriptive statistics (e.g. Dahl and Pedersen, 2004.), correlation analysis (Michailova and Minbaeva, 2012) and regression analysis (Yang, 2008, Michailova and Minbaeva, 2012). In both regression models, coefficient of determination R^2 (R squared) was used as an indicator of success. Coefficient of determination R^2 is a measure of the proportion of the total variance explained by the fitting model. Yang presented a model of individual attitudes and organisational knowledge sharing with R^2 value of 0,54 (Yang, 2008), whereas Michailova and Minbaeva achieved R^2 of 0,22 for their model of organizational values and knowledge sharing (Michailova and Minbaeva, 2012.). This paper seeks to achieve more reliable models and get better explanation of knowledge sharing process by applying decision trees.

4.1 Decision tree modelling

Decision trees are very powerful and popular techniques for modelling classification and prediction problems. The attractiveness of decision trees lies in the fact that they offer data models in a 'readable', comprehensible form.

Decision trees are models based on a recursive partition method. Their goal is to divide the data set using a single variable at each level (Mantas and Abellan, 2014.). Their knowledge representation has a simple tree structure. It can be interpreted as a compact set of rules in which each tree node is labelled with an attribute variable that produces branches for each value. Decision trees are built using a set of data referred to as the training data set. A different set, called the test data set, is used to check the model. When we obtain a new sample or instance of the test data set, we can make a decision or prediction on the state of the class variable by following the path in the tree from the root to a leaf node, using the sample values and tree structure (Mantas and Abellan, 2014).

Data is partitioned according to a relationship between the dependent and independent variable values, creating a tree of partitions. Sets of cuts or groupings of independent variables that best predict a dependant variable are then found. This is achieved by exhaustively searching all possible cuts or groupings. These splits (or partitions) of data are done recursively forming a tree of decision rules until the desired fit is reached. This is a powerful platform, because it chooses the optimal splits from a large number of possible splits. A precise mathematical description of the algorithm can be found in SAS JMP 11 help.

In order to determine the explanatory power of the model, coefficient of determination R^2 was used: larger value of R^2 indicates better explanatory power (Wixom and Watson, 2001.).

In our analysis, the SAS JMP 11 data mining tool was used, and algorithms applied in this analysis are described in the tool's manual, so we will only mention parameters of analysis.

This study hypothesizes that the differences in benefits of knowledge sharing between social network members exists due to their socio-demographic and professional characteristics and behaviour, the perception of level of knowledge they possess and sources of their knowledge.

According to the model described in the table 1, and shown in the figure 1, a decision tree to predict total social network member gain (benefits) from knowledge sharing was

developed by total gain (GAIN_TOT) as a dependent variable and 19 characteristics as predictor variables. By using a decision tree, it is possible to examine the relationship among variables and to pick the most important variables for predicting a knowledge gain, because these variables are chosen for splitting high in the tree. N=448 valid responses were applied to train the decision tree.

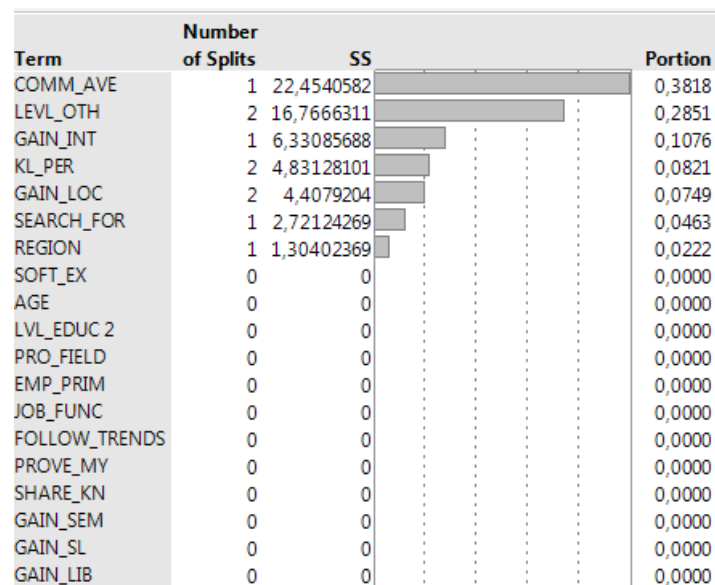

Figure 2. Variable contribution in decision tree model

The analysis shows that in the decision tree model, by far the most important variable is COMM_AVE (average communication in social group), followed by: LEVL_OTH (knowledge level of others), GAIN_INT (knowledge gain through internet) and KL_PER (perception of personal knowledge).

The following are the rules extracted from the decision tree with the aim to explain the profiles of social network members with the highest and the lowest benefits of knowledge sharing. The rules of the tree are formed as:

If A then GAIN_TOT (R).

This means that the samples which satisfy condition A, have total gain of R.

Here we list the main rules of the tree, sorted in a descending order by knowledge gain.

Leaf Label	Mean	Count
COMM_AVE>=3,75&LEVL_OTH>=3,25	4,29333333	15
COMM_AVE<3,75&GAIN_INT>=1&LEVL_OTH>=3&KL_PER<25	3,59090909	11
COMM_AVE<3,75&GAIN_INT<1&SEARCH_FOR(0)&GAIN_LOC<1&GAIN_LOC>=0,5	3,45833333	12
COMM_AVE<3,75&GAIN_INT<1&SEARCH_FOR(1)	3,41724138	29
COMM_AVE>=3,75&LEVL_OTH<3,25	3,40681818	88
COMM_AVE<3,75&GAIN_INT<1&SEARCH_FOR(0)&GAIN_LOC<1&GAIN_LOC<0,5&KL_PER<1,5	3,3	21
COMM_AVE<3,75&GAIN_INT>=1&LEVL_OTH>=3&KL_PER>=2,5®ION(IN, EU)	3,16111111	18
COMM_AVE<3,75&GAIN_INT<1&SEARCH_FOR(0)&GAIN_LOC<1&GAIN_LOC<0,5&KL_PER>=1,5	2,8	10
COMM_AVE<3,75&GAIN_INT>=1&LEVL_OTH>=3&KL_PER>=2,5®ION(AS, NA)	2,76875	16
COMM_AVE<3,75&GAIN_INT<1&SEARCH_FOR(0)&GAIN_LOC>=1	2,76153846	26
COMM_AVE<3,75&GAIN_INT>=1&LEVL_OTH<3	2,64230769	78

Figure 3. Rules extracted from the tree, describing GAIN_TOT as a function of input variables.

According to the above rules, we can see COMM_AVE, LEVL_OTH, and KL_PER are the most powerful variables. COMM_AVE reflects average intensity of communication in social group. The higher this value, the more probable higher value of total gain of shared knowledge. LEVL_OTH is the perceived level of knowledge of other members of social group. The benefit of each member of a professional group depends on the knowledge which is in the group. KL_PER indicates personal knowledge level.

The decision tree model indicates the profile of the social network participant with a higher knowledge gain (GAIN_TOT = 4,29) thus: a participant who communicates very often (COMM_AVE > 3,75), perceives knowledge shared by others in the network as high quality knowledge (LVL_OTH >= 3,25). The profile of the social network participant with the lowest gain is as follows: low level of communication with others, use of other knowledge sources (Internet) and low perceived knowledge in the group (LVL_OTH < 3) and according to that, no need to use the social group as source of knowledge (GAIN_TOT = 2,64).

Most of these rules are consistent with fact. The model reflects real professional knowledge sharing process objectively. These results will not only help individuals to improve their knowledge through communication in a social group but also develop company strategies. For example, an organization knows those individuals using intensively social group for communication with groups or individuals of high level of knowledge will help them improve their business. The rules also tell us that the more other sources the social network member uses, the less willing he is to seek and give knowledge in a social group.

Table3. Model verification

	RSquare	RMSE	N	Number of Splits	AICc
Training	0.414	0.5073958	324	10	504.831
Validation	0.342	0.584507	124		

The best model based on the decision tree is the model with reliability of 0.414 for training data, and 0.342 for validation data. It indicates that 41.4% of the variability is explained by the model.

4.2. Linear regression

Conducting a sensitivity analysis and an analysis of significance of variables enables further enhancement of both models in a way that would only conserve significant variables, and leave out the less significant. Thus, linear regression is performed on significant variables to identify direction and intensity of their relationship with gained knowledge.

Linear regression, which is a widely used statistical modelling technique, could be used to build a model with a continuous outcome and has been proven as a powerful algorithm (Lee et al., 2006). In order to find the power of different variables, we build models with 8 most important (continuous!) variables from the decision tree model.

We build a model with most significant variables to examine the power of a different kind of information. The result of the model is displayed in Table 2. Beginning with the univariate analysis for each of the predictor variables, table 4 shows the statistics and the corresponding *p*-values of the likelihood ratio tests for each predictor variable.

Due to their very low *p*-values, the variables COMM_AVE and LEVL_OTH were recognized as variables with the greatest weight effect on the output variable in the model. Furthermore, there were significant differences in the knowledge gain between the social network member persistor for the variable SOFT_NUM, KL_PER, GAIN_SEM and GAIN_INT at the 0.05 significance level.

Table 4. Regression analysis results

Term	Estimate	Std Error	t Ratio	Prob> t
Intercept	1.4399959	0.178535	8.07	<.0001*
COMM_AVE	0.3324329	0.032976	10.08	<.0001*
KL_PER	-0.06162	0.027702	-2.22	0.0266*
LEVL_OTH	0.3817212	0.050151	7.61	<.0001*
GAIN_INT	-0.300292	0.058876	-3.20	0.0015*
GAIN_LOC	0.0446043	0.068545	0.70	0.4831

The selected variables have shown that the socio-demographic information makes little contribution to knowledge prediction. The behaviour information, the knowledge source and the knowledge level information work very well in the model.

Since the values of variables are not normalized we cannot make conclusions about differences in weight of the impact, although we can see direction of the impact. Variables COMM_AVE, LEVL_OTH and SOFT_NUM have a positive impact on knowledge gain, whereas KL_PER, GAIN_SEM and GAIN_INT have a negative effect on knowledge gain.

At the 0.05 significance level, variables from every group identified in our research model were not dropped without sacrificing a significant amount of variance explained by the model.

4.3. Results discussion

Participant's openness to experience and willingness to communicate was found to be positively related to an individuals' knowledge gain. These participants are more likely to use knowledge sharing as an opportunity to deepen their own understanding and find a better way to organize and explain the knowledge before they share it. Results suggest that individuals with high ratings in openness and frequency of communication with other members of group tend to have a high level of motivation resulting in knowledge benefits.

The fact that the variable concerning prior software experience of the social group member, SOFT_NUM, has a positive influence on knowledge gain, corresponds to the fact that employees with longer work experience and higher number of projects are more likely to share their expertise, have positive attitudes toward sharing and have more benefits from it. Individuals with higher absorptive capacity are more likely to experience the benefits of knowledge sharing resulting in more positive attitudes toward knowledge sharing.

Different sources of knowledge have been suggested to be related to knowledge sharing. Results of our research indicated that both seminars and self-learning contribute negatively to knowledge gain in communication in a social group. The extent to which an individual uses different types of channels to learn and obtain knowledge contributes to the extent to which an individual gains knowledge. The abundance of sources for

knowledge gain, as competitive sources of knowledge, has a negative influence on an individual's benefit from knowledge sharing.

Furthermore, the variable that indicates perception of personal knowledge level was shown to be important. Perceived knowledge level is important because social network member`s level of knowledge is influenced by the extent to which knowledge sharing occurs between members.

The benefit of each member of a professional group depends on perception of the quality of knowledge that is contained in the group. Perceptions of the quality of their personal knowledge and the intensity of use of other, competing sources of knowledge, negatively affect knowledge gain. Thereby, the benefit it is not only in the accumulated knowledge, but also in improving other competencies of group members and usefulness for business. The above stated benefits significantly distinguish them from other sources of knowledge on the internet (articles, encyclopaedias).

Although there has been only a small number of cross-cultural studies conducted to date, the results suggest that we need to pay close attention to cultural characteristics in knowledge sharing practices that will facilitate knowledge flow, i.e., there is not a single, universal set of practices that can be used to facilitate knowledge sharing in global. For example, we need to make adjustments to the type of incentives provided to fit the cultural contexts (Voelpel et al. 2005). Contrary to that research, the variable in our model, which indicates affiliation to certain region (Europe, United States of America, India, and others), was revealed as not significant for knowledge gain. We can conclude that globalization has been achieved and there are not any great differences, detected by our model, regarding the way the process of knowledge sharing works and the total gain from professional social network among different regions.

7 Conclusion

In this paper, we have addressed the issue of knowledge gain and knowledge flow in social networks in a novel manner. Our study focuses on the factors affecting total gain in a social group within a global professional social network. We developed a decision tree model for predicting whether or not benefits from knowledge sharing would be successful for a specific type of participant. The prediction accuracy and reliability of the suggested model was found to be on a high level, which brings us to conclude that the decision tree is quite a valuable approach. Furthermore, linear regression was performed with the aim

to identify which of the variables identified as important in the decision tree affect knowledge gain positively and which ones affect it negatively.

This study is one of the first empirical investigations that deal with knowledge and total gain in the knowledge sharing process. It is also the preliminary study investigating the success of data mining methods in this field. Hence, this study provides several meaningful insights into the characteristics that increase the gain in knowledge sharing in professional social networks. The results show that communication frequency, perceived quality of group knowledge and participants experiences are key factors for knowledge gain to be achieved. Besides the above three factors, sources of knowledge (e.g. seminars, self-learning from different sources) and perception of own level of knowledge are also factors that are selected as criteria when determining benefits. The findings provide a guide for those who want to gain knowledge in social network group. Besides, decision tree model is suggested from the findings and can be used for predicting knowledge gain.

The information provided in this paper is significant in that it gives researchers and online service providers a better understanding of knowledge sharing process in professional social networks and benefits it produces.

Structured Abstract

Purpose Tourism is one of the largest industries in the world subject to strong innovations in the last years essentially due to globalization and availability of new ICTs. In a tourism destination operate autonomous entities whose business is related to the sector and whose aim is the tourism destination growth. We introduce the *Collaborative Network Organization (CNO)* model to reach both competitiveness for the destination and sustainable development for the territory and local operators. In particular, we propose:

- a model to highlight forms of collaboration in the tourism sector;
- a characterization of supporting ICT services and mobile applications.

Design/methodology/approach – After identified two kinds of short term CNOs in a Tourism Destination: the *TEE -Tourism Extended Enterprise*, and the *TVO - Tourism Virtual Organization*, we use a methodology made of 3 steps:

- Characterization of the CNOs in a TBE: the TEE and TVO models;
- modelling the coalition's types that can be recognized within a CNO on the basis of the different levels of integration among members
- characterization of the ICTs that support each coalition type, with a focus on different functional classes of networking information services and mobile applications that are currently adopted in a CNOs

Originality/value – Scholars approach the issue of collaboration in tourism from different points of view: social benefits and sustainable development (Graci, 2013; Jamal and Stronza, 2009), organizational supports for collaboration (March & Wilkinson, 2009), characteristics of ICTs tools (Buhalis & Law, 2008; Zach et al., 2008; Ndou & Petti, 2007). The originality of this study consists in composing different perspectives in literature to propose an original framework to characterize forms of CNOs in tourism, taking into account the effects of ICT in reengineering the sector.

Practical implications – First results of the study highlights the importance of setting CNOs within a tourism destination in order both to answer to the new demand of personalized tourism, and to give local tourism players an opportunity to reach economy of scale, competitiveness and sustainable development in the effort to overcome limits of

touristic organization's size and contrast big players power. The original framework we propose aims to support the operationalization of the collaboration concept in the tourism sector and the setting up of CNOs in a tourism destination at different level of collaboration

Keywords – Tourism breeding environment, Collaborative Networks, Tourism Extended Enterprise, Tourism Virtual Organization, ICT.

Paper type – Academic Research Paper

1 Introduction

Tourism is one of the largest industries in the world subject to strong innovations in the last years (Craig Wight, 2013; Wan Lee & Brahmasrene, 2013; Mihajlović, 2012). Main changes are due to the availability of new technologies and in particular to the spreading of the mobile ones, which directly connect tourists among them and with service providers, and to the always more personalized supply of tourism experience (Polo Peña et al., 2013; Buhalis & Law, 2008; Zanker et al., 2008).

Since nineties, several case studies and conceptual models highlight the increasing importance of partnerships in many industrial sectors, assessing new organizational forms and identifying key factors in successfully initiating of sustainable development (Volpentesta & Ammirato, 2013; Lerro & Schiuma, 2009; Romero et al., 2009).

Scholars highlight that such innovations can be exploited as drivers of development by local tourism operators only if they are able to reorganize the tourism offer around structured patterns of collaboration (Erkus-Otzurk & Eraydin, 2010; Jackson & Murphy, 2006; Plummer et al., 2006). In the tourism sector, the diffusion of collaborative network models is often related to the marketing of alternative forms of tourism experiences (Cabiddu et al., 2013; Vainikka, 2013; Wang & Fesenmaier, 2007; Selin & Myers, 1998). In many regions characterized by niche tourism vocation (e.g.: historical, business, sport, cultural, rural, religious etc.), or localized in developing countries, or simply where some organizations decided to create “alternative” development paths, local tourism operators have started organizing themselves spontaneously in tourism networks in order to create aggregate tourism offers able to compete with big tourism operators thus transforming regions with potential and vocation in real tourism destinations (Robinson et al., 2013; Brown, 2010; Gursoy et al., 2010).

Recent years have been characterized by an extensive transformation of the tourism sector, due also to evolution in ICT industry (Ndou and Petti 2007). In fact, ICTs have

innovated considerably Tourism Sector in operational workflows, management and marketing of tourism packages and new paradigms in tourism experiences (Polo Peña, Frías Jamilena and Rodríguez Molina 2013). From the business side, ICTs provide significant opportunities for internal business process re-engineering (back-office systems, reservation systems, etc.) and e-business (B2B and B2C), at the company level, while, at the supply chains level, ICTs allow communication and information exchange with partners, integration of information flows from a wide spectrum of suppliers, and new patterns for the customer care (Stamboulis and Skayannis 2003). Changes are also evident at the industry level; indeed the Internet is changing the tourism industry structure by altering barriers to entry, minimizing switching costs, revolutionizing distribution channels, facilitating price transparency and competition, as well as enhancing production efficiency (Mills and Law 2004). From the tourist side, the breakdown of geographical and cultural barriers is a result of international cooperation/exchange agreements and fast advances in transportation and electronic communication. New and cheap transportation marketing policies, reductions in custom duties and on limitations to cross-countries tourism, allow people to easy consuming tourism products (Cabiddu, Tsz-Wai and Piccoli 2013). E-commerce developments enable tourist to interact directly with tourism services providers, allowing travelers to retrieve reliable and accurate information in a fraction of the time, cost and inconvenience required by traditional tools, moreover disintermediating players of tourism market such as travel agencies and tour operators (O'Connor 1999) (Mihajlović 2012). Tourists are becoming increasingly selective using the web to choose tourist operators offering services that more closely match their needs. Furthermore, the customer insights and reviews, provided by people through social media, represent important sources of information for travelers in helping choose tourism services (Volpentesta and Felicetti 2012).

In this paper, we propose an original cross-sector analysis of the scientific literature on the topics of sustainable tourism, organizational models for sustainability and ICT evolution in order to introduce:

- a model to highlight forms of collaboration in the tourism sector;
- a characterization of supporting ICT services and mobile applications.

The paper is organized as follows. In section two, a characterization of the typologies of collaborative networks within a tourism destination is proposed followed, in section 4, by a discussion about the evolution of ICT for tourism sector. A classification of the different

levels of integration among networked members of a tourism destination and supporting ICT is presented in section 5. Section 6 holds the conclusion of the study.

2 Collaborative Networks in a tourism destination

In a tourism destination, live and operate autonomous entities whose business is related to the sector. While these entities can be heterogeneous in terms of their operating environment, culture and goals, they all aim to achieve the common goal of local tourism development and to increase the general competitiveness respect to other geographical areas and global competition (Akoumianakis, 2014).

The service providers operating in a tourism destination can be grouped into the following categories:

- *Hospitality Services Enterprises*: companies that offer overnight accommodation (e.g. hotels, B&B) and meal provision (e.g. restaurant).
- *Transportation Services providers*: public and private companies that provide services of people transportation (i.e. buses, taxis, airplanes, trains, etc).
- *Event Management Services*: public and private companies dealing with the organization of events (e.g.: conferences, concerts, exhibitions, sport events).
- *Tourism complementary goods and services providers*: e.g. local shops, museums, excursion services, sport & leisure facilities, handicrafts.
- *Destination Marketing Organizations*: that promote incoming tourism and Tour operators that purchase/book services to combine and resell them.

When some of the service providers decide to reinforce collaboration, they can set stable agreements in the forms of Touristic Associations or Touristic Districts, adhering to a base long term cooperation agreement, and adopting common operating principles and infrastructures. Each agreement is characterized by an own organizational form in terms of structure of membership, activities, definition of roles of the participants, governance principles and rules (Ammirato and Felicetti, 2014). We name each of such agreements as a ***Tourism Breeding Environment (TBE)*** (Zach et al., 2008) i.e. a Breeding Environment in tourism sector whose members share values, culture and infrastructures and have the potential and the will to cooperate in order to pursue the general long-term objectives of territory development and competitiveness (Volpentesta et al., 2013). In a TBE, each member competes with the others and with players outside the TBE in searching for new business opportunities in the global market. When a business opportunity is identified, a

subset of the TBE members can be rapidly selected to become part of a short term *Collaborative Networked Organizations, CNOs*, oriented to catch the opportunity. Two kinds of short term CNOs are most evident in a TBE:

- ***Tourism Extended Enterprise (TEE)***: it refers to a tourism operator that “extends” its business boundaries by involving all or some of its suppliers in the product packaging and delivery in order to offer customers possibilities to a more complete tourism experience.
- ***Tourism Virtual Organization (TVO)***: It represents a temporary alliance of private and public organizations that come together to share skills or core competencies and resources in order to better respond to business opportunities, and whose collaboration is supported by computer networks. A TVO is established in a short time to respond to a competitive market opportunity; it has a short life cycle dissolving when the short-term purpose of the TVO is accomplished (Volpentesta and Ammirato, 2013). ICT advances enable tourists in customizing services on the basis of their own specific tastes (Ammirato 2010). Availability of systems for tourism packaging enable tourist to (self) compose a personalized tourism product choosing a subset of services provided by TBE members.

3 The ICT revolution and the *augmented tourism experience*

The rise and diffusion of CN models all around the world is strictly related to the availability of networking ICT, web based and mobile, which enable operators to develop original ways to manage the tourism supply chains, the destination marketing and relations with customers. Actually, ICTs have been transforming tourism globally; their developments have undoubtedly changed both business practices and strategies as well as industry structures (M. E. Porter 2001). E-tourism is part of the electronic trade, which encompasses the fastest developing technologies, such as communication and information industry, hospitality and management/marketing of strategic planning industry. The specific activities of e-tourism must rely on tourism operators, tourism agencies and other organisms directly interested in virtual tourism using a specialized website. The e-tourism concept includes all business functions (i.e., e-commerce, e-marketing, efinance and e-accounting, eHRM, e-procurement, eR&D, e-production) as well as e-strategy, e-planning and e-management for all sectors of the tourism industry, including tourism, travel, transport, leisure, hospitality, principals, intermediaries and public sector organisations.

Hence, e-tourism bundles together three distinctive disciplines: business management, information systems and management, and tourism (Buhalis and Law, 2008).

From a business perspective, since the mid-nineties, the tourism sector adopted the Internet as a advertising medium as well as new distribution channel, providing the basis for the development of new systems linking consumers and CRSs/GDSs, leading to a lowering of entry barriers (Werthner Klein, 1999). ICTs improved the efficiency and effectiveness of tourism organizations and the way to manage businesses within the marketplace, as well as how consumers interact with broker organizations (Buhalis and Law, 2008), facilitating operations, business transaction and networking with partners among operators in the tourism industry (Hjalager, 2010).

From a tourist perspective, e-tourism provides specialized websites and software applications able to reduce time and costs of the tourist preparatory activities, making easier the process of booking or renting a car or help planning the trip and making a decision. Tools such as fare aggregators and meta search engines, enabling users to compare prices, further transformed the role of ICTs in Tourism (Kracht and Wang, 2010). The emergence of social networking platforms have profoundly influenced the way tourist interact with other tourists. The "social web environment" enables new mechanisms of interaction, cooperation and "social experience" among tourists (Volpentesta and Felicetti, 2012), fostering the spread of electronic word-of-mouth communication, opinions about places, services and tourism operators. The possibility to taste in advance a trip (thanks to videos, photos, opinions and storytelling of other users), the opportunity to compare thousands of offers from around the world, the immediate delivery of a set of tourism services (e.g. reservation or booking, payment, etc...) are among the features that make the Internet&tourism an absolutely winning combination.

The provision of new informative services supporting all tourist activities, always available through mobile technologies, made the conventional tourism experience enriched in each phase of it. Given its suitability with ICT, tourism has emerged as one of the most well suited sectors for mobile applications. Today's tourists expect to get personalized access to tourism information at anytime, from anywhere with any media. Mobile technologies have challenged existing theoretical frames of information access and use by transforming the spatial and temporal context by providing users with an ubiquitous access. Ubiquity offers new opportunities and challenges in terms of *time-aware*, *location-aware*, *device-aware* and *personalized services* which can be achieved by

using *customization*, i.e., adapting an application towards the current context (Schwinger, et al. 2005). Mobile applications are capable of enhancing the tourist experience at every stage of the tourism experience life cycle, creating a paradigm shift in how information is accessed and digested, and transactions performed. (Karanasios, Burgess e Sellitto 2011). Travel mobile applications are the seventh most popular category of apps being downloaded. According to TripAdvisor, 60 percent of smart phone users have downloaded travel apps and of those individuals, 45 percent plan to use the apps in the firsts phases of the tourism experience life cycle for research and travel planning. Furthermore, 55 percent of travel apps are purchased within 3 days of travel or while travellers are at the destination, which helps demonstrate how important mobile apps are in influencing tourists' decision-making along all the tourism experience life cycle. (Kennedy-Eden e Gretzel 2012). We can name this paradigm shift as *augmented tourism experience*.

4 Levels of collaboration in a Tourism Breeding Environment

Tourism operators may interact in different way in a TBE. Four coalition's types can be recognized within a TBE, each of them represents a different level of integration among considered groups of actors: *networking*, *coordination*, *cooperation*, *collaboration*; "as we move along the continuum from networking to collaboration, we increase the amounts of common goal-oriented risk taking, commitment, and resources that participants must invest into the joint endeavor" (Camarinha-Matos and Afsarmanesh, 2006). In what follows we propose the four levels highlighting, for each of them, goals and characteristics of interactions and of supporting technologies.

Level 1 - Networking. It involves communication and information exchange for mutual benefit of TBE. Each TBE actor involved in the relationship can benefit from the information shared but there is not necessarily a common goal influencing individual contributions as well as there is no common generation of value. At this level, it's not possible to highlight the presence of CNOs within the TBE. A TBE offer to each tourism operator a way to grasp opportunities that current demand of tourist flows is producing. In particular, individual actors may benefits from integrate communication and promotion activities performed by the TBE. It represents a local brand that propose a diversified tourism offer, contributing to local tourism development and to increase the local

competitiveness respect to other geographical areas. This is the case of a Touristic Associations that aim to promote tourism activities in a specific territory and offer to tourism operator a “showcase” in order to promote their own services. While a TBE promotes a common brand, a slogan, a symbol, etc., individual operators are responsible for the accuracy and the correctness of the information provided about offered services.

At Networking level, it is possible to identify a set of ICT solutions representing a valid support for promoting a tourist destination and give the right services to customers for an authentic augmented tourism experience:

- *Inspiration Portals*: websites promoting the sharing of multimedia content among users by allowing them to get a preview of territories, places, cultures and type of vacation that will inspire potential tourists.
- *Tourism services comparators*: web portals that allow travelers to compare tourism services offered by different providers. Travelers have the possibility to compare services providers and chose the offer that best suits their needs.
- *Tourism social networks*: collection of individuals who share information, opinions and contents about tourism in an online setting over the internet.
- *Mobile and immersive technologies*: technologies that harness the potential of mobile devices to provide information, geolocation, and augmented reality services; information about the surrounding real world becomes interactive and digitally manipulable.

Level 2 - Coordination. In addition to communication and information exchange, more organizational commitment is evident at this level. Coordination involves aligning/altering activities so that more efficient results are achieved; nevertheless each networks member might have a different goal and use its own resources. At the coordination level, ICTs are intended to support automation of inter-organizational business process. In addition to the tools typical of the networking level, at this level technologies need to support tourist to take advantage of integrated offerings. Examples of such technologies are the *Destination Management Systems (DMSs)*, i.e. systems that gather into a single portal a variety of tourism services provided by heterogeneous tourism operators and related to a specific geographical area. DMS attempt to utilize a customer centric approach in order to manage and market the destination providing strong destination related information, real-time reservations, destination management tools and paying particular attention to supporting small and independent tourism suppliers.

Level 3 - Cooperation. In addition to level 2, it involves knowledge and resources' sharing for achieving compatible goals of TBE. In this case the aggregated value is the result of the addition of individual "components" of value generated by the various participants in a quasi-independent manner. A common plan exists which in most cases is not defined jointly but rather designed by a single entity. Participants' goals are compatible in the sense that their results can be added or composed in a value chain leading to the end-product or service. At this level it is desirable to use web and mobile based systems which enable consumers to build their own tourism package made of flights, accommodation, and other tourism services instead of purchasing a predefined package from a catalogue. This kind of technologies are known as *Tourism Dynamic Packaging Systems, TDPS*, whose characteristics are: full automation through online applications; real-time update of travel product information; single price for an entire tourism package. From a process automation point of view, distributed business processes management tools are required in order to allow integration and communication processes between individual information systems adopted by tourism each operator.

Level 4 - Collaboration. At this level, all entities share information, knowledge, resources and responsibilities to jointly plan, implement and evaluate a program of activities to achieve a common goal. It implies sharing risks, resources, responsibilities, and rewards. Tourist operators committed in collective decision process have common values and visions. The TVO becomes a self-organizing system with global properties that cannot be predicted from the properties of the economic actors who are directly involved in it. At this level the inter-organization process planning and management regards many operative and supporting processes which are managed in a common way. The CNOs can be supported by a form of *Enterprise Resource Planning* technologies for tourism networked organizations also known as a *Cloud-Based Business Network* that connects and coordinates the ERP of each networked tourism operator on a common platform.

5 Conclusions

The importance of setting a TBE is related both to the necessity to answer to the request of personalized tourism offer, in line with the new demand trends, and to the possibility to give sustainable development to local tourism players in the effort to

overcome limits of touristic organization's size and reach economy of scale and competitiveness in contrast to big players. The availability of organizational models and ICT supporting solutions make possible the operationalization of the collaboration concept in the tourism sector and the setting up of CNOs in a TBE at different level of collaboration, in line with the territorial development strategies and tourism operators' propensity to risk taking.

Structured Abstract

Purpose – In the time of globalization, growing uncertainty, ambiguity and change, traditional ways of doing business are no longer sufficient for sustainable competitive advantages. Nowadays, it is more and more important to consider non-conventional collaborations, methods, approaches and initiatives to release and apply creativity in order to facilitate and develop organizational innovation capacity. Cultural and Creative Industries (CCI) in this prospect can represent a source and resource of critical and creative thinking as well as a set of processes to be deployed in order to foster and support innovation. In this view, the collaboration between CCI and traditional businesses can represent a strategic and operational approach to develop cross-innovations enhancing organizational value creation capacity.

Sharing the assumption that the adoption and the integration of creative processes can produce positive impacts on organizational processes and business performance, this paper provides the results of a scoping study exploring how traditional businesses can engage or deploy culture and creativity in order to support the development of their innovation capacity. Focusing on a sample of Italian companies, we have investigated the forms and practices of collaborations between CCI and traditional businesses as well as the scope of these collaborations.

Design/methodology/approach – The paper is based on a practical exploration of projects, practices, initiatives aimed to improve innovation capacity of the organizations addressing collaboration between creative and culture industries and traditional business in the Italian context. Using a sample of Italian organizations, we draw first insights about their awareness, perception and orientation to identify, adopt and integrate creativity-based processes and collaboration with the creative and culture organizations to foster their innovation capacity, and to qualitatively identify a feasible set of new approaches

and practices potentially driving performance improvement. In particular, the empirical research aimed to find Italian companies within the manufacturing and service areas whose primary business is not to provide experience products and services, but who could benefit from adopting and integrating creative and experience economy in their traditional business activities. In order to derive and test theories, trace causal pathways, explore hypotheses generated by research, researchers have designed and implemented qualitative research methods and conducted investigation mainly based on web-available data, archives and interview-based information.

Originality/value – This paper represents one of the first attempts to investigate at practical level the collaboration of CCI and traditional business. The case examples of relevant Italian companies – such as Illy, Unicredit, Furla, Zegna – effectively provide evidences of the impact and modalities of adopting initiatives to shape a creative environment capable of sparking, fostering and developing human potentials and innovation capacity.

Practical implications – The investigation of a sample of Italian companies suggests that the focus is mainly on the adoption of creative processes as a way to support the performance achievements of one or more dimensions of the organisational value chain. It appears that most of the attention is focused on collaborations aimed to reinforce company image and reputation, to develop corporate social responsibility and to improve brand recognition. Particularly, great attention is paid on the deployment of creative- and culture-based activities and/or relationships as a marketing and communication approach as well as a way to add intangible value into products and services; while, there is a lack of attention and understanding on the use of the relationships with CCI as an instrument to support organisational development and learning.

Keywords – Cultural and Creative Industries; Traditional Business; Innovation Capacity; Management Models; Italy

Paper type – Academic Research Paper

1. Introduction

Nowadays different global trends are transforming the competitive environment and forcing organisations to develop new capabilities. Increasingly, organisational value creation capacity is not only linked to the definition of efficient and consistent organisational systems, as traditionally postulated by modern management, but it is increasingly tied to the establishment of adaptable and resilient systems that are able to meet changing market demands and continuously emergent business problems (Hamel, 2007). In the new business age, companies need to be more and more flexible, agile, intuitive, imaginative, resilient, and creative in order to face the increasing complexity, turbulence, and pace of change of the competitive environment (Schiuma, 2011).

These dynamics are connected with the increasing organizations' needs to do business in different ways. In fact, nowadays, the traditional rational- and efficient-based way of managing business is no longer sufficient to guarantee profits and sustainable competitive advantages: it is more and more important to consider the ability to use creativity for supporting innovation capacity and performance improvements as well as the capacity of catching and anticipating emerging needs in the society. In this prospect, in order to get access to creative processes business organisations can build relationships of various natures with CCI. Specifically, although CCI can be considered as part of the business economy, they are distinguished from traditional business sector by the products and services they offer.

In order to foster innovation capacity and performance improvements, change and transformation, businesses can collaborate and learn from CCI. For this reason, this paper presents the results of a scoping study exploring the feasibility of fostering innovation capacity through collaboration between CCI and traditional businesses. This involves the understanding of the potential benefits and impacts that could be generated from such collaborations as well as a practical exploration of projects, practices, and initiatives aimed to improve organizational innovation capacity by deploying creativity and culture. The focus of the explorative fieldwork is the Italian business context.

First, the conceptual background of this scoping study is presented. Second, a brief overview of the creative industries is introduced, highlighting specifically the different sectors and related peculiarities and their main challenges. Then, the insights collected from a qualitative empirical investigation are discussed. The on field investigation has been based on the selection of a sample of Italian firms. They have been investigated using a combination of semi-structured interviews and information gathered through desk analysis. Finally, some final remarks are outlined.

2. Background

The twenty-first century business landscape appears more and more scattered with ambiguities, uncertainties, dynamism, and unpredictability, that call for a renew interpretative perspective of the organisation and management systems (for an in-depth understanding of the conceptual pillars of this paper see "The Value of the Arts for Business" by G. Schiuma Cambridge University Press). In today's new business age,

organisational success cannot be considered as the mere ability to define and manage technical efficiency. Organisations are challenged to develop a continuous tension for change and innovation and acquire new capabilities to survive and prosper. In particular, they have to become agile, intuitive, imaginative and resilient to changes. This requires an interpretation of the organisation as a living-based system and an understanding of the employees within the organisation as innovation actors fully engaged to give the best of them and to exercise their creativity in order to solve existing problems, promote changes and generate new valuable business opportunities. Creativity has been traditionally recognized as relevant source for innovation and fundamentally as a precondition of innovation processes. For this reason some researchers and practitioners have argued about the role of *creativity-based innovation* as a driver for innovation and performance improvements, highlighting the potential impacts of the adoption and integration of creativity-based processes in the competitive strategies of businesses

For the scope of this paper we see cultural- and creative-based processes related to CCI as a potential catalyst and leverage or driver to enhance organisational innovation capacity. In other words, they can be seen as an instrument for improving organisational business performance. In this view, we approach cultural- and creativity-based processes as devises for cross-innovation, i.e. as mechanisms that using the creative and cultural contents and practices can inspire and support managers to develop management innovation, frame new organisational and business models, and draw on new approaches and instruments to tackle emergent business challenges.

In particular, we see the culture and creativity as cross-innovation devises, i.e. as an instrument to impact on people's engagement and commitment in organizational issues as well as a way to transform organizational infrastructure both tangible and intangible in nature. So, cultural- and creativity-based processes can be adopted, for example, for shaping workplaces, for communicating culture, identity and image of the organisation, for emotional-driven design of facilities, equipments and products, and so on.

The power of the cross-innovation devises can be analysed through their twofold role. On one hand, they represent vectors to shape and influence organizations' dimensions. This first perspective considers creativity and culture as an instrument to support individual and organizational learning mechanisms both by transferring or developing creative skills that are useful in the business context and/or by shaping an experiential and igniting organizational atmosphere which can spur critical and innovative thinking and

engage people with their emotions and energy. In this perspective creativity-based processes can be deployed as a learning platform aimed to transform human capital.

The activated learning mechanisms support the competence development of employees both at individual and group level. This may also produce a positive impact on the internal and external organizational relationships dynamics as well as on the development of organizational and business models valuing emergent coordination, distributed wisdom, full engagement of people and distributed authority.

On the other hand cross-innovation devices can be used as managerial vectors to transform business dimensions and properties, in particular, influencing and transforming tangible and intangible organisational infrastructures and products. This is the case of the use of cultural- and creative-based processes as a way to shape workplaces that can be inspiring and capable of affecting people's mindsets of absorbing external changes in accordance with an adaptive approach as well as by nourishing internal transformational processes in order to proactively project and induce changes in the firms' operations and in the external environment. The cross-innovation devices as instruments to enhance organisational innovation capacity are particularly relevant for transforming intangible elements of an organisational capital such as culture, values, identity and image. These dimensions can be made visible, more understandable and emotive through the use of cultural- and creativity-based means that represent and communicate them.

The adoption of culture and creativity - either as a learning platform or as a managerial vector to influence organisational dimensions create a frame of references in which emotive and rational organizational characteristics are put in conversation and are integrated to foster organizational innovation capacity. Taking into account the above rational it is important to acknowledge the fundamental role that culture and creativity can play in order to foster and support the development of organisational innovation capacity. This calls for the understanding of the forms and contents of collaborations and partnerships between CCI and traditional business sectors as a new fruitful strategy to develop organisational innovation processes.

3. The creative industries

The term "creative industries" has relatively recent origin. While there are obvious connections to and continuities with cultural industries, the designation marks a historical

shift in approach to potential commercial activities that until recently were regarded purely or predominantly in non-economic terms (Andersen et al., 2000; Smagina and Lindemanis, 2012). The concept emerged in Australia in the early 1990s, but was much wider exposure by policy makers in the United Kingdom (UK) in the late 1990s, when the Department for Culture, Media and Sport (DCMS) set up its Creative Industries Unit and Task Force. In the process, the DCMS moved the understanding of the concept of creativity a long way from its common association with activities having a strong artistic component, to any activity producing symbolic products with a heavy reliance on intellectual property (UNCTAD, 2004).

Defining “creative industries” is a matter of considerable inconsistency and disagreement in the academic literature and policy circles as well as among practitioners, especially in relation to the parallel concept of culture and cultural industries. Sometimes, a distinction is made between the creative and the cultural industries; sometimes the two terms are used interchangeably.

Despite some criticism concerning definition of the creative industries, the most widely accepted are the ones set by UK DCMS and UNCTAD. UK DCMS in its “Creative Industries Mapping Document” (1998, revised 2001) define creative industries as *“those industries which have their origin in individual creativity, skill and talent and which have a potential for wealth and job creation through the generation and exploitation of economic property”*. In the “Creative Economy Report”, UNCTAD (2008) defines creative industries as *“the cycle of creation, production and distribution of goods and services that use creativity and intellectual capital as primary inputs. They comprise a set of knowledge-based activities that produce tangible goods and intangible intellectual or artistic services with creative content, economic value and market objectives”*.

The structure of creative industries is continually evolving and differs country by country. However, they traditionally include four main domains identified as: *Heritage, Arts, Media, and Functional Creations* (UNCTAD, 2008). Heritage domain has as subgroups: *Traditional Cultural Expressions* (arts and crafts, etc.) and *Cultural Sites* (cultural and recreational services, library services, archives services, museum services, botanical and zoological garden services, amusement parks). Arts domain comprises *Visual Arts* (antiques, painting, photography, sculpture, collages and decorative materials), *Performing Arts* and *Music*. The Media domain has as subgroups *Publishing*

and *Printed Media* (books, newspapers, other printed matters, publishing services), *Audiovisual* (cinematographic film, radio and television related services) and *New Media* (recorded media, video games, business and creative software, interactive leisure software, digitalized creative contents). Finally, the domain of the Functional Creations has as subgroups *Design* (interiors, fashion, toys, graphic, jewellery), and *Creative Service* (advertising, market research and public opinion services, architectural and other technical services, trade fair and exhibition organization services, cultural and recreational services).

The specific interest of this scoping study is the notion of cross-innovation, i.e. how culture-based and creative-based processes can contribute and foster the development of an organisation innovation capacity particularly in the context of traditional business sectors. Our basic proposition is that the intersection of culture and creativity with traditional businesses can trigger and support the development of new innovation processes. Thus, we envisage the collaboration and integration of culture and creativity into organisational life and the exploration, identification and definition of new approaches, frameworks and tools that can drive the deployment of culture and creativity as instruments for enriching the value creation capacity of an organisation. Then, we are interested to understand the possible relationships between the CCI and traditional business sectors.

Our fundamental assumption is that traditional businesses can potentially collaborate with CCI with the scope of deploying what we see as the 4Ps of culture and creativity for innovation capacity: ‘people’, ‘practices’, ‘principles’ and ‘products’. Traditional businesses can enhance their innovation capacity by deploying the 4Ps and exploiting them as catalysts and drivers for change and transformation.

In Figure 1 it is presented the conceptual framework explaining the contribution of the 4Ps for enhancing the innovation creation capacity of an organisation and in turn its ability to deliver better performance and higher value propositions for stakeholders. Adopting a knowledge-based view of the innovation processes, organisation can produce innovations by developing their competence domains that affect how organisational processes are executed and then how business performance achieved. Knowledge assets represent the building blocks of an organisation’s capacity of being innovative. In order to enhance an organisational innovation capacity it is relevant to develop, renew and manage the knowledge base of an organisation.

The 4Ps provide mechanisms to support such mechanisms. In particular, people coming from the CCI can bring into organisations and share with employees their skills and knowledge in order to support the refinement and development of the organisational soft competences. This equals to consider the people as vector of new knowledge tapped from the culture- and creative-based domains. Practices denote all those methods and processes that are typical of the cultural and creative world and that can be useful for traditional businesses in order to do ‘things’ in a different way in comparison to what they normally do. Principles are related to the human-centric view that usually distinguishes CCI as a driver for sustainable value creation focusing in particular on experiential and emotive-base economic features. Finally, products denote the use of the outputs of the CCI as a way to increase the value added of traditional businesses as well as a way to shape working environments as symbols and vectors of meanings.

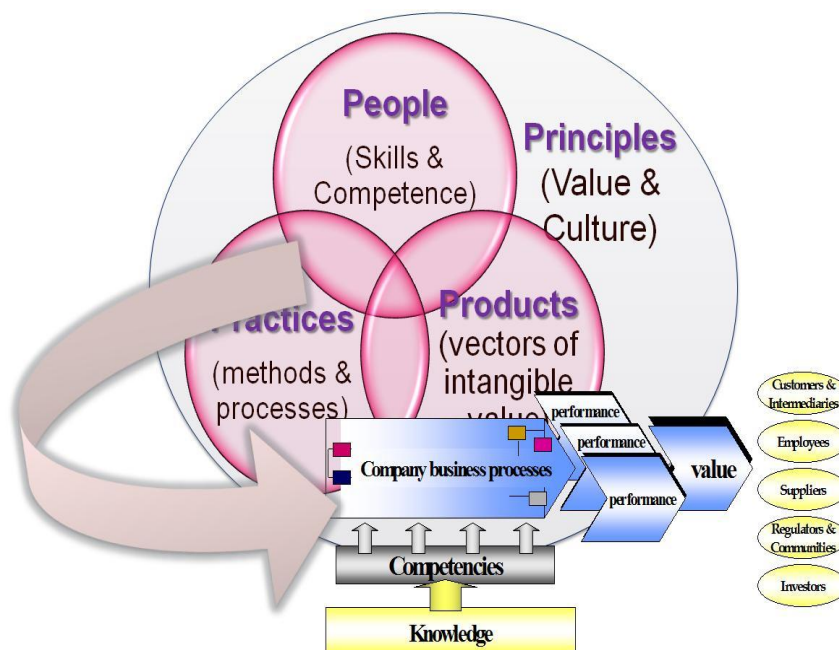

Figure 1. How the culture and creative industry can support organisational innovation capacity and business performance improvements by providing the 4Ps.

4. The empirical research

4.1 Data and methods

This section presents a series of concrete business results and elements of innovation and competitive advantages focused on the collaboration between cultural and creative industries and traditional business sectors. The attention is paid on the Italian business context with the scope to extract some relevant insights from the Italian state of the art of the use of culture and creativity in the organisational business models in order to support innovation capacity and value creation. In particular, the empirical research has been carried out with the aim to identify some possible trends of Italian companies in terms of adoption and/or integration of culture and creativity in the organisations' value creation chain.

The key investigated question is: *How do Italian firms operating mainly in traditional businesses engage with culture and creativity in order to enhance innovation processes and get competitive advantages?*

This is a scoping study with the aim of identifying the benefits related to the adoption and integration of creative- and cultural-based processes in traditional businesses. In order to derive and test concepts, trace causal pathways and define new hypotheses, we have designed and implemented a qualitative investigation combining semi-structured interviews enriched with the collection of available secondary data. Specifically, we solicited more than thirty Italian companies and sent emails to these companies describing the research project and inviting senior managers to participate in the explorative study. Out of the population, 24 companies have been included in the sample that we have analysed. In Table 1 the list of the investigated companies building the sample are listed together with the indication of the sectors that they overall represent.

<i>Companies building the investigated sample</i>

Benetton Group; Brem; Brunello Cucinelli – Fondazione Cucinelli; Cartiere del Garda; Ceretto Vini; Diesel; Elica; ENI; Favero-Milan Ingegneria; Ferrero – Fondazione Ferrero; Furla – Fondazione Furla; Gobetto Resine Speciali; Gruppo Euromobil; Gruppo Industriale; Tosoni; Illy; Italcementi Group; Ridea – Heating Design; Santa Sofia Vini; Telecom Italia; Teseco – Fondazione Teseco per l'arte; Trussardi – Fondazione Trussardi; Unicredit Group; Zegna – Fondazione Zegna

Services/Commodities & Waste Management – n. 1
Textile/Dressing/ /Shoes/Fashion – n. 7
Services/Banking – n. 1
Utilities (oil&gas, telecom) – n.2

Table 1. Italian companies included in the investigated sample.

The empirical research has investigated some relevant issues with the aim to collect information about the kind of relationships Italian companies are engaging with the CCI. In particular, below the main investigated matters are outlined.

- The existence of collaborations with the companies and organizations operating in the cultural and creative sectors;
- The sentiment/feelings of Italian companies about these collaborations;
- The strategic objectives that the companies wish to achieve through the collaboration with organizations operating in CCI;
- The main projects and specific initiatives that have been developed in the last few years;
- The business areas, departments and processes more interested and involved in shaping collaborations with cultural and creative organisations;
- The main obtained or expected results and/or impacts derived from such collaborations;
- The main enabling and hampering factors and obstacles for the development and the effectiveness of such collaborations.

4.2 Main evidences

The fieldwork investigation has revealed different and interesting insights about the collaborations between traditional businesses and CCI. The first evidence shows a limited but increasing awareness of the relevance to develop collaborations with the creative industries as well as of adopting cultural-based and creativity-based processes for

improving innovation dynamics and competitiveness in the traditional businesses. However, Italian companies have not structured connections with creative organizations. Most of the relationships tend to be stand-alone and not structured but rather emergent in nature. There is a general interest and feeling of the role and relevance that culture and creativity can play for company competitiveness. In other words executives have the intuition that organisations could benefit and tap into CCI as a way to enhance innovation capacity and deliver better value to stakeholders. Nevertheless, they lack of frameworks and clear understanding of how this can be achieved and governed in practice. In addition, the actual economic recession, which is strongly affecting the economic performance of Italian firms puts managers in the difficult position of experimenting new approaches and tools that could turn into failures without generating return on investments. In this prospect a structured investments in the relationships with culture and creativity is seen highly risky and not capable of producing clear benefits for firms' bottom line results.

The main declared objectives to be reached through the collaboration with CCI are mostly related to reinforce company image, brand and reputation and to develop corporate social responsibility. Further dimensions of benefits are: product differentiation; the contribution to add intangible value to traditional products and services; the capacity of driving product innovation mechanisms. While, little attention is associated to the role that culture and creativity can play as drivers for organizational development and particularly as managerial approaches to support human resource development and engagement.

From the empirical analysis it is possible to infer the nature of the relationships that can be established by businesses with CCI. In particular, it is possible to discern three fundamental profiles of companies corresponding to three archetypes of relationships that describe the approaches adopted by businesses in engaging with culture and creativity: Observer, Adopter and Integrator. They respond to a different strategic view of the position of culture and creativity as a resource and source of business performance.

The Observer considers culture and creativity as a 'diverse world' from business, something very much distant from the everyday business challenges and needs. Then, accordingly the fundamental view is that CCI has not really much to offer for company competitiveness and the kind of relationship to be established is mainly aimed at supporting the cultural and creative sectors. This view is predominant in very traditional

sectors that have not experimented and explored the benefits that culture and creativity can offer for business-related purposes.

The Adopter represents the profile of those businesses that clearly identify the potential contribution that CCI can provide to support, improve and develop organisational value chain and in turn business performance. Accordingly, businesses engage with some specific dimensions of the CCI looking for extending, completing or enhancing one or more components of their value creation chain. Thus, the fundamental idea is to plug in some competences and value creation capacity from CCI. This is the position of most of the Italian companies considered in the investigated sample. They acknowledge that culture and creativity can enrich and enhance their value creation capacity and for this reason they adopt some specific cultural and creative dimensions.

From the empirical investigation has emerged that Italian companies establish relationship with CCI in order to respond to three fundamental purposes as listed below.

- Corporate social responsibility (CSR);
- Marketing, branding and communication;
- New value for products and services.

Many Italian organisations are developing relationships with CCI as part of their CSR strategy. The focus is on delivering value propositions for stakeholders and particularly to create value for communities, society at large and indirectly for environment by deploying cultural-based and/or creative-based activities and projects. The fundamental mechanism through which organisations operate to build a relationship with CCI and deliver their CSR initiatives is the sponsorship

Actually, sponsorship is the traditional and quite common approach of interaction between culture/the arts and business. Through sponsorship the companies assume the role of patron to an artist, an artwork and/or an artistic process and even art and cultural institutions such as museums and galleries. This is done for multiple reasons, including ethical and cultural motivations, getting the attention of institutions, strengthening ties with the local community, creating an opinion and an identity of the organisation both internally and externally, and for increasing brand awareness and enhancing reputation. Cultural sponsorship and co-sponsorship can take different formats. Usually, organisations sponsoring cultural and arts productions and events get marketing benefits, such as credit on television and print advertising as well as credit on all cultural event

related materials including banners, posters, performance programmes, and ticketing options.

Corporate social responsibility, marketing, branding and communication involve all the delivering of a company's "message" to its customers and stakeholders in a renewed way. *Unicredit* represents a good example of Italian company that have shaped its relationship with CCI as a CSR initiative. Unicredit is an international banking group which is successfully exploiting sponsorship as a way to create and deliver socio-cultural value to stakeholders. The basic idea moving *Unicredit* sponsorship is to support talents to emerge and to have success through the reinforcement of the relationships among artists, arts lovers, galleries, critics and specialized magazines. Specifically, *Unicredit* has established relationships with: "Castello di Rivoli" a contemporary art museum, the MACRO - contemporary art museum based in Rome, the MAMbo - contemporary art museum based in Bologna, the MART - contemporary art museum based in Trento and Rovereto, the Museum der Moderne of Salzburg. In addition, *Unicredit* is greatly involved in sponsoring music and opera. It actively promotes, through the support of orchestras, the attention and the promotion of the classic music engaging audience at large. It is partner of the "Teatro alla Scala" of Milan, the "Arena di Verona", the "Filarmonica '900" of the "Teatro Regio" of Turin, the "Teatro Massimo" in Palermo, the "Teatro dell'Opera" of Rome. At international level, through its controlled banks such as Bank Austria and HypoVereinsbank (HVB), *Unicredit* also supports respectively the Filarmonical of Wien in Austria, and the Opera of the Bayern in Germany as well as it promotes relevant regional events in Bayern such as the Rheingau Music Festival, the Mozart Festival at Würzburg the Richard Strauss Festival at Garmisch-Partenkirchen., the Opera Academy at Gut Immling and its programme "Jugend Kulturell". A further case example of Italian company pursuing CSR through the development of relationships with CCI is *Telecom Italia*: a company operating in the telecommunication sector. They are supporting culture as part of their CSR strategy by partnering with "Galleria Borghese" based in Rome, the "Accademia Nazionale di Santa Cecilia" of Rome as well as sponsoring the "Mostra Internazionale di Architettura" of Venice and the MAXXI Museum of Rome. In addition, they are partner of the "Salone Internazionale del Libro" of Turin, and of the RomaEuropa WebFactory - the web community dedicated to multimedia artists. Along the same approach stands *ENI*, one of the major Italian oil and gas corporations. ENI supports actively the cultural life of the territories in which

operates, particularly through the support of artistic initiatives and by sponsoring renovation projects of heritage assets.

It is worth to point out that the main way of establishing and managing the relationships with CCI is performed by means Foundations. Indeed, the analysis of the relationship developed by the Italian companies with CCI has revealed that most of the organisations have created a Foundation, see for example, *Fondazione Ermenegildo Zegna*, *Fondazione Nicola Trussardi*, *Fondazione Cucinelli* and *Fondazione Ferrero*. It is important to note that the attention to establish relationships with CCI for CSR purposes is not a prerogative of Italian multinationals, but it characterises also SMEs. In particular, *Favero-Milan Ingegneria*, operating in the engineering field, and *Cartiere del Garda*, operating in the paper production, support cultural initiatives in region of Trentino and collaborate effectively with cultural associations, institutions and foundations.

Marketing, branding and communication denote the second fundamental strand of collaboration between Italian businesses and CCI. In this case, the fundamental purpose of establishing a relationship with CCI is aimed at creating, communicating and protecting company's identity, brand and reputation. The scope of this kind of relationship is mainly to impact on customers and intermediaries, but also more generally affect the perception of a company from the point of view of its different stakeholders. One of the key example of Italian company that has traditionally used creativity and culture as a way to build its brand and reputation is *Benetton*. Among others, it is worth to mention the initiative named "Fabrica". Fabrica - founded in 1994 - is the Benetton Group's communication research centre in which a group of creative young people of various nationalities work together with the aim of developing ideas and potential inspirational creative-based projects that can be valuable for promoting and marketing the company worldwide.

Other examples of Italian companies that are deploying and exploiting the relationships with CCI for marketing and branding purposes are: *Gruppo Euromobil* (home furniture), *Teseo* (facilities and waste management), *Diesel* (fashion), *RossiModa* (textile), *Gobetto Resine* (materials for the construction sector), *Gruppo Tosoni* (engineering) and *Santa Sofia Vini* (wine production).

The attempt to provide new value for products and services is the third strand of collaboration between Italian traditional businesses and CCI. The basic idea grounding this approach is that creative partners can contribute to the idea and development of new

products. Product and/or service experience can be strengthened by working with its sensuous qualities, aesthetics and design, or by involving the consumer in the development process. Accordingly, design, culture, arts represent important 'value added vectors' to increase the value incorporated into products and services. From a business perspective, the idea is to infuse the artful energy into products and services. The attention is focused on increasing the economic value of a product by incorporating aesthetic dimensions.

At practical level, creative collaborations can contribute to product and service innovations in various ways. In this perspective Italian companies have been traditionally particularly effective in differentiating themselves and their products in the market by embodying cultural and creative features into products and services with the result of creating embedded intangible value. For example, *Ridea* and *Brem*, two Italian leader companies in the design and production of heating products have linked their market success to the ability to offer heating systems and solutions that incorporates aesthetic and design features. The focus is on finding a continuous advanced balance between functionality and elegance, utility and aesthetic, high technology and environmental sustainability. The value proposition is to deliver to the market not only an object that heats but also real furnishings objects that can be integrated perfectly in the home atmosphere contributing to create a living house.

Furla represents a further example. Giovanna Furlanetto, owner of Furla, has stated: "*The arts have delivered to the world a very different perception of my company*". Furla is an interesting case example since it experiments on its core-products (i.e. the female bags) the work of young creative people sponsored by the Furla Foundation as well as it exploits the talents of young filmmakers to reinvent communication through new "stories" in which the bag becomes input, fetish object to be transformed and even destroyed and desecrated. For example, the project "*#candycool*" has been an open laboratory in which creatives have been invited to re-interpret the Candybag playing with fantasy and unusual components such as chains, textiles pieces and even biscuits. More recently, on 2007, this approach has been institutionalized through the so-called Furla Talent Hub, a centre for the promotion of the new young talents of the fashion design that offers to them the chance to design a complete collection. A further Italian case example of a company that is using the relationship with CCI as a way to create intangible value embedded into products is *Italcementi Group*. This company represent one of the major

actors in the cement industry at international level. Nowadays, the cement offers high performance very difficult even to think till some years ago and this determines the great relevance of the deep collaborations that *Italcementi* develops with customers, designers, architects and building community. Among these dimensions great attention is paid to the architecture as a means to impact on the sustainable transformation of territories. This feeds collaborations with architects in order to develop relevant projects able to be symbols of innovative and sustainable use of cement. This view is resulted in the development of projects with famous architects such as Nervi, Ponti, Meier, Perrault, and Cucinella. In order to make this kind of collaboration more stable and structured, *Italcementi Group* has launched since the end of '90s an initiative named "Incontri Millenium" which is aimed at developing conversations with Italian faculties of architecture through workshops and events.

An Italian company that has been able to leverage on cultural and creative dimensions to transform a commodity such as coffee into a product with high value-added is *Illy Caffè*. Among the different initiatives put in place by *Illy*, one of the most significant is the so-called "Illy Art Collection": it is a series of 70 little cups for coffee limited in number, designed by famous artists, such as Michelangelo Pistoletto, Marina Abramović, Sandro Chia, Julian Schnabel, Robert Rauschenberg, Jeff Koons, Kiki Smith, Joseph Kosuth, James Rosenquist and a lot of young emergent talents. This was one of the very first examples of collaborations with the CCI launched by the company. As result of this project the little cups for coffee became real porcelain sets through which the arts and the aesthetic dimensions were linked to the sensorial pleasure of the coffee, promoting at the same time brand management and enriching customers' experiences.

Since 2006 *Illy* largely adopted the idea of using art as a means to enrich the value incorporated into products with the vision of making art accessible and applied to common objects. In this perspective, a further example of application of creativity and culture is the creation of another iconic *Illy's* product: the "250g" box of the coffee named "Barattoli d'Autore" (authored coffee boxes). According to a number of famous contemporary artists, such as James Rosenquist, Michael Lin, Michelangelo Pistoletto, Tobias Rehberger, and Sebastião Salgado, the box provides a new symbolic message interpreting the surface of a box and transforming it in a circular and infinite picture. To underline the relevance and the exclusivity of the artistic boxes, they are limited in number and available only twice in a year. The above are examples of how culture and

creativity can be deployed to increase the value added of products and differentiate them in the market. Apart the use of culture and creativity as a way to enrich the value incorporated into products another important use of the relationship with CCI as a way to generate intangible value is represented by the deployment of CCI as an instrument for shaping better workplace.

Among others companies, this is the vision that has inspired *Ceretto Vini* which has established a collaboration with the creative industries with the aim to 'beautify' the work environments. They see the workplace design as one of the major factors affecting the performance of workers and of the overall organisation. Their fundamental assumption is that the physical setting and the workplace environment have measurable effects on building relational capital, social life and organisational context, which in turn influence work. Workers are more productive when working within a positive, stimulating and enjoyable environment. Accordingly, arts are used as an instrumental means to create a space and an intangible aura within and around the organisation, with a positive impact on people, by stimulating a constructive emotional and energetic state. They have designed and built facilities in a such a way that they embed symbolic meanings so that they positively shape and affect the workplace.

The integrator depicts the third archetype of relationship between the traditional business sectors and CCI. The Integrators are those companies that fully recognised the value of the relevance of culture and creativity and pursue an integration of such dimensions into the 'DNA' of the organisation.

In this case, the companies are keen in adopting culture and creativity as an instrument that permeates the overall organisation rather than been just an added dimensions as in the case of adopters. A key success example of Italian company that act as an integrator is *Elica Group*. Elica is a world leader in the kitchen hoods business and represents a benchmark for understanding how collaborations with creative industries can drive a real transformation of the organization, opening up the organization and its people to a new consciousness and supporting continuous organisational changes and evolution.

5. Final remarks

Increasingly 21st century business landscape will challenge organisations to exploit new forms of innovation to guarantee sustainable value creation capacity. The traditional view of the organisation as an efficient system to be steered towards planned and

designed directions fails to meet these requirements. For this reason, the collaborations between the creative world and the traditional business acquire great relevance. In this perspective the collaboration with CCI can be seen as a managerial approach to shape new organisation's competences and capabilities. The empirical scoping study about a sample of Italian companies has pointed out that there is an interest on developing collaborations with the creative industries and understand how to better integrate culture and creativity into business models; however there is still a lack of strategic understanding about how this can be carried out. The existing collaborations with creative industries do not respond to a structured strategy and are mainly the result of emergent relationships generally driven by the personal interest of the entrepreneur and its family or in other cases of the top management. From a practical point of view, the collaborations tend to be developed with single professionals/artists and consultants (for example curators) rather than to be based on structured relationships or partnerships with cultural and/or creative organisations. It is also worth to mention that there is a lack of attention on the assessment of the impacts/benefits produced by the relationships with the cultural and creative sectors.

Finally, the study has allowed to show that the most important enabling factor for the development of effective relationships between businesses and CCI is represented by the commitment of the entrepreneur and/or top management. While, the most significant barriers for the engagements of culture and creativity into the business models are: the reluctance of employees to be engaged into cultural- and creative-based processes; the difficulty in forecasting the benefits that such kind of relationships can generate for business; the lack of structured offer from cultural and creative providers of potential services cultural- and creative-based to enhance company competitiveness.

We call for more in-depth and extensive research investigations that could shed light both on the empirical practices and on the conceptual frameworks of how cultural- and creative-based processes can generate cross-innovation and benefit organisational value creation capacity.

Structured Abstract

Purpose – Eco-Industrial Parks (EIPs) are defined as industrial clusters wherein a community of firms linked in a network of collaborative relationships exploit new business opportunities so as to increase their economic performance, by minimizing the environmental impact and creating benefits for the local community (Côté and Cohen-Rosenthal, 1998). A number of EIPs have recently spread in both developed and developing countries, with specific features and various degrees of success. Despite such a variety, the common driver for these initiatives is the awareness that industrial symbiosis on materials and energy may be beneficial for both the companies and the environment (Yang and Lay, 2004). The aim of this paper is to characterize EIPs and identify specific typologies for them. For this purpose we propose a framework based on relevant literature and articulated in three dimensions, namely organizational, environmental, and social.

Design/methodology/approach – To apply the framework, we consider a number of heterogeneous initiatives of EIPs, located in Europe, North America, and developing countries, and characterize them in accordance with the developed framework. In particular, assessing the variables of the framework we describe the organizational structure of EIPs as well as the adoption of practices related to the environmental sustainability and social responsibility. Once we have characterized these cases, we apply the cluster analysis to group them according to the organizational dimension: we identify the emerging clusters as specific types of EIPs. Then, we repeat the cluster analysis on the other dimensions to assess the way environmental and social practices are implemented.

Originality/value – Although there are several examples of EIPs in developed countries as well as in emerging economies, and the attendant literature provides some guidelines for the establishment of EIPs, to our knowledge there is a lack of studies that aim at assessing possible linkages between the organizational structure of an EIP and its environmental and social practices. This study is a first attempt to address this issue.

Practical implications – The research findings can support the policy makers in defining the organizational characteristics of EIPs that allow to foster the environmental and social performance of EIPs.

Keywords – Eco-industrial parks, industrial symbiosis, industrial ecology, organizational structure, cluster analysis.

Paper type – Academic Research Paper

1 Introduction

Since the seminal paper of Frosch and Gallopulos (1989) an extensive body of research has flourished, leveraging on the analogies between natural and industrial ecosystems. As industrial ecosystem we mean “a community or network of companies and other organizations in a region who chose to interact by exchanging or making use of byproducts and/or energy” (Gertler, 1995) so as to get benefits from the systemic reduction in the use of virgin resources and in the waste to be disposed, as well as from the increase in variety and amount of outputs that have market value.

Ayres and Ayres (2002) remark that several aspects of industrial networks mimic distinctive phenomena of biological systems, such as the cycling of materials, nutrients, and energy, or the interactions among individuals playing the role of producers, consumers, or decomposers (Liwarska-Bizukojc *et al.*, 2009). According to this research stream, which is usually called industrial ecology (Allenby and Graedel, 1993; Ehrenfeld, 2004; Gibbs and Deutz, 2007), rather than emphasize the independence and competitiveness of companies studies should stress their collaborations and interdependence (Côté and Cohen-Rosenthal, 1998). These characteristics, indeed, move the focus from monadic individuals to their interconnectedness, which is considered crucial in assuring the resilience of industrial ecosystems and giving them efficiency and persistency over time.

Moreover, in the last decades studies on industrial ecology have been also spread due to the increasing prominence gained by the concept of sustainability: scholars and strategic consultants have stressed that greening production processes is a key factor for single companies and local networks of firms to gain competitive advantage (Shrivastava, 1995; Tudor *et al.*, 2007). In addition, the promotion of sustainable development has been the focus of many governmental policies and international initiatives. In 2012, the United Nations Conference on Sustainable Development “Rio+20” have reaffirmed the interlinkages between environmental and social goals in building an economically, socially and environmentally sustainable future (United Nations, 2012).

Several researchers (Roberts, 2004; Korhonen *et al.*, 2004) have pointed out that unsustainable industrial systems might turn to sustainability by borrowing the nature's model of material recycling and energy cascading, wherein there is little or no waste. Nonetheless, some other observe that the character of most of the research on industrial ecology is speculative: rather than "offering concrete solutions and practical measures for policy makers and business managers" (Korhonen *et al.*, 2004) to promote a disruptive innovation in production processes (Hawken *et al.*, 1999), its main contribution seems to be, sadly, the mere description of materials and energy flows. Therefore, Gibbs and Deutz (2007) question whether the approach commonly adopted by scholars for addressing the topic of industrial ecology is effective for moving traditional industries toward the principles of industrial ecology and helping them to build synergies that mutually improve their effectiveness in a win-win scenario.

At the opposite, the concrete realization of industrial ecology principles is more frequently referred to as industrial symbiosis. Chertow (2000) defines it as "engaging traditionally separate industries in a collective approach to competitive advantage involving physical exchange of material, energy, water, and by-products". She claims also that symbiotic relationships are more complex than the usual two-side exchanges occurring between companies (Chertow, 2007); as a rule of thumb, she proposed to define industrial symbioses only those relationships that involve at least three different actors sharing at least two different resources. According to her, the pillars that underpin the establishment of fruitful industrial symbioses are geographical proximity and the existence of a collaborative approach among business actors. Both pillars, indeed, enhance the opportunities for companies to reuse by-products, share utilities and infrastructures, and arranging a common provision of services.

Roberts (2004) stresses that "the clustering of firms with similar waste and by-product streams create opportunities [to] encourage the co-location of firms that can reprocess waste material", to promote new synergies and efficiency gains and, ultimately, to create "value for individual firms and collective industry business". This is the basic intuition of eco-industrial parks (EIPs). The latter can be defined as industrial clusters wherein a community of firms linked in a network of collaborative relationships exploit new business opportunities so as to increase their economic performance, by minimizing the environmental impact and creating benefits for the local community (Côté and Hall, 1995; Martin *et al.*, 1996; Côté and Cohen-Rosenthal, 1998). As pointed out by Roberts (2004),

industrial symbiosis can be implemented at different scales, and EIPs are just one of them, namely the intermediate level between the micro-level of single plants and the macro-level of a global network of companies and regional clusters applying the principles of circular economy (Andersen, 2007; Su et al., 2013). Compared to them, however, at the same time EIPs can reach the economies of scale that cannot be obtained at a firm-level and exploit geographical proximities which are difficult to exploit in dispersed networks.

A number of EIPs have recently spread in both developed and developing countries, with specific features and various degrees of success (Shi *et al.*, 2010; Sakr *et al.*, 2011; Bai *et al.*, 2014). Some of them have been promoted as governmental initiatives, whereas other have resulted from spontaneous processes carried out by companies (Behera *et al.*, 2012). Despite such a variety, the common driver for these initiatives is the awareness that improvements in circulation of materials and energy may be beneficial for both the companies and the environment (Yang and Lay, 2004). Simultaneously, the topic of EIPs has received a growing attention by scholars, who slightly have moved from individual case studies and assessments of single EIP programs, to cross-country analyses of EIPs as well as of governmental policies aimed at promoting their establishment (Shi *et al.*, 2010).

Although the literature provides guidelines for the establishment of EIPs, to our knowledge there is a lack of studies that aim at assessing possible linkages between the organizational structure of an EIP and its environmental and social practices. The goal of this paper is to characterize EIPs and identify specific features for them. To this aim, we first develop a framework based on three dimensions, namely organizational, environmental, and social. For each dimension a number of variables are identified from literature. This framework is then applied to a number of heterogeneous initiatives of EIPs, located in Europe, in North America, and in selected emerging economies (China, India, and Brazil). Such initiatives are then characterized and a value associated to each variable included in the framework. Finally, data are combined to derive some insights.

The framework is described in the next Section: three dimensions of analysis, and the attendant variables, will be considered, derived from a desk analysis of the extant literature (Sections 3 to 5). In Section 6 we will present the set of EIPs and characterize them in accordance with the developed framework. By cluster analysis, these EIPs are grouped with reference to each dimension so as to identify specific types/common

patterns of EIPs and investigate the relationships among the three dimensions (Section 7). Finally, Section 8 summarizes result and present limitations and suggestions for further research.

2 Framework

To address the goal of this paper, a framework to investigate the features of EIPs is proposed, based on an extensive literature review on EIPs and related concepts, such as industrial ecology and industrial symbiosis. Peer-review scientific journals in English with management focus have been scrutinized, so as to identify the features that describe EIPs. The framework, that is extensively presented in the following Sections, is composed by three dimensions, namely organizational, environmental, and social. For each dimension, a number of variable are provided, each related to a peculiar aspect of EIPs.

The first dimension investigates the organizational features and uses nine variables to describe how they are formed and managed. Specifically, as to the origin of the EIP this dimension discusses whether it emerges spontaneously or is intentionally promoted by an initiator, if it grows around an anchor tenant and if it counts on governmental support. Heterogeneity of companies that participate to the EIP is also considered to characterize the organizational structure of EIPs, as well as the existence of cooperation with external subjects, such as companies, research centers, and governmental agencies. Other variables explore the existence of shared information systems and the commonality of support services among the EIP participants.

Table 1. Dimensions and attendant variables included in the framework.

Dimension	Variable
Organizational	– Top-down development process
	– Existence of an anchor tenant
	– Governmental support
	– Heterogeneity
	– Cooperation among companies
	– Cooperation with universities and research centers
	– Cooperation with governmental agencies
	– Shared information system
	– Commonality of support services
Environmental	– By-products exchange
	– Sustainable use of resources
	– Adoption of Best Available Techniques

	<ul style="list-style-type: none"> – Eco-design – Environmental management systems – Green procurement – Sustainable goods transportation management – Sustainable people transportation management – Landscape protection
Social	<ul style="list-style-type: none"> – Service provision – Human resource training – Public awareness and stakeholder participation – Promotional events and symposia

The second dimension relates to environmental aspects of EIPs, and is composed by two focal points, enucleated in nine variables. At first, the production processes adopted within the EIP have been investigated: these comprise the byproducts exchange, the sustainable use of resources, the adoption of Best Available Techniques, and the sustainable design of products. This dimension includes also other variables, dealing with the management practices that companies belonging to the EIP carry out to address the environmental goals: these variables explore the adoption of environmental management systems, the recourse to green procurement, the arrangement of sustainable transportation for goods and people, and the landscape protection.

Finally, the social dimension relates to the linkages existing between the EIP, or its single participants, and the local community wherein the park is located. Such linkages are detailed by four variables, namely the provision of services for workers and their families, the human resource training on sustainability, the elicitation of people's sustainability awareness and the stakeholder participation, and the organization of promotional events and symposia on these topics.

The dimensions, and their attendant variables, are listed in Table 1. In the following sections, all of them are described and positioned in the literature.

3 Organizational dimension

3.1 Development process

The literature mentions two different development processes for EIPs, namely spontaneous and planned. The former, which Chertow (2007) calls self-organizing symbiosis, is typical of EIPs arising from a spontaneous initiative of a company willing to achieve efficiency, cut costs, or expand its business by leveraging on resource exchange

with other organizations. In other terms, the intuition that, by promoting symbiosis among companies, win-win conditions can be obtained makes the EIP unintendedly emerge (Baas and Boons, 2004, Behera *et al.*, 2012). If such transactions prove to be effective in achieving the expected goals, they may become the core of a more complex network of exchanges that gradually will enlarge and involve further organizations. The spontaneous development of EIPs based on companies acting on their behalf mimics the way natural ecosystems arise: such a model is in fact considered the most frequent (Chertow, 2000; Jacobsen, 2006) and successful (Heeres *et al.*, 2004; Gibbs and Deutz, 2007).

Nonetheless, in several cases EIPs are developed thanks to an exogenous promoter, called initiator (Brand and de Bruijn, 1999). This can be a local or central government agency, as well as an association of companies or entrepreneurs, a trade union, or another player acting as institution *de facto* (Heeres *et al.*, 2004; Chertow *et al.*, 2007). The external stimulus for exogenously planning the development of an EIP can be the need to compel with stricter environmental regulations, reduce pollution, reconvert abandoned industrial estates, or support companies located in a given area in facing toward competitors from abroad (Seuring, 2001; Desrochers, 2004; Tudor *et al.*, 2007). This kind of genesis for EIPs is not necessarily in contrast with the metaphor of natural ecosystems, which suggests the spontaneous rise of EIPs: it has been claimed that the role of the promoter is to overcome market failures, which otherwise would impel the development of symbioses among business actors (Tudor *et al.*, 2007). By contrast, several analyses (Gibbs *et al.*, 2003; Chertow, 2007) on projects funded in 1996 within the U.S. President Council of Sustainable Development, have shown the low success rate of EIPs arisen through deliberate planning. Nonetheless, some positive exceptions exist, mostly located in the Far East wherein the governmental role in driving economics is prominent (Zhu *et al.*, 2007; Zhang *et al.*, 2010; Behera *et al.*, 2012). To reduce the risks of failure associated to a top-down development process, Costa and Ferrão (2010) describe a mixed approach that combines governmental directives and business initiatives.

3.2 Existence of an anchor tenant

In the context of regional studies, a major company located in a specific area, heavily committed in R&D activities, and having, at least a partial absorptive capacity in a given technological area (Agrawal and Cockburn, 2002) often plays a key role in promoting the emergence of self-organizing enterprise networks and, specifically, in sustaining the

establishment of an EIP. The benefits that such an organization – which scholars define anchor tenant (Lowe, 1997; Côté and Cohen-Rosenthal, 1998; Chertow, 1998; Korhonen, 2001; Heeres *et al.*, 2004), magnet (Tudor *et al.*, 2007), or initiator (Brand and de Bruijn, 1999) – gives to the EIP is twofold. First, the anchor tenant is a major manufacturer that either may ensure a continuous waste stream (which can be potentially used by third parties in their manufacturing processes), or it is able to turn information about the existence of some waste materials or by-products into business opportunities. Secondly, thanks to its reputation and capability (Lowe, 1997), the anchor tenant has many links with several satellite enterprises involved in treating wastes and supporting its production processes (Côté and Cohen-Rosenthal, 1998); therefore, it contributes to the EIP development by allowing new companies to arise or existing ones to move into the park. According to Behera *et al.* (2012), the anchor tenant may drive the development process of an EIP also by recruiting potential partners through a formal selection process.

3.3 Governmental support

Whatever is the EIP development process, namely spontaneous or planned, there is a general consensus on the importance of the role of institutions in favouring its growth and success (Heeres *et al.*, 2004; Park *et al.*, 2008). Often, bureaucracy is a strong obstacle for companies in arranging such exchanges of waste and by-products to build industrial symbioses. Rather, policies should be designed so as to provide political, coordinative, educational, and infrastructural support to EIPs (Chertow, 2007; Gibbs and Deutz, 2007; Taddeo *et al.*, 2012). Liu *et al.* (2012) stress that, even when the EIP moves from the spontaneous initiative of a company, government is crucial in breaking the sectorial boundaries, thus allowing the earlier spontaneous network to evolve in a regional cross-industry ecosystem. In some specific cases, the support offered by government includes the definition of appropriate coordination mechanisms to encourage companies to manage waste streams (Brent *et al.*, 2008), the dictation of prices for specific items or materials (Zhu *et al.*, 2007), or the rewarding of individual actions that generate environmental benefits (Shi *et al.*, 2010). More commonly, and in addition to possible specific initiatives, the governmental support includes direct or indirect subsidies to the companies that take part to the EIP formation.

In their extensive review, Jiao and Boons (2014) scrutinize the governmental policies to promote industrial symbiosis and assert that it is often difficult to distinguish whether

these policies have been the true initiator or just an influencing factor for the EIP development. Moreover, they outline that programs implemented and their evolution over time are country-specific, and observe that the nature of their impact, and specifically their effectiveness, differs per cases: as a guideline for policy makers, they emphasize the importance of taking the specific context into account.

3.4 Heterogeneity

Some EIPs include companies involved in diverse industries, other ones seem to be more focused on a single sector. This feature of the EIP is usually called diversity or heterogeneity (Côté and Smolenaars, 1997; Sterr and Ott, 2004; Taddeo et al, 2012). According to the technical memorandum by Martin *et al.* (1996), heterogeneity is considered key to distinguish an EIP from other kinds of businesses aggregations.

Heterogeneity may also involve the kinds of materials that flow among the companies within the EIP. According to Pellenbarg (2002), the existence of complementary materials may improve the chances of success for an EIP, whereas Cohen-Rosenthal (2004) stresses the need to examine all the material flows for ensuring the EIP success. Sterr and Ott (2004) argue that heterogeneity and the attendant redundancy in input-output relationships may facilitate the establishment of symbiotic transactions within an industrial site. In fact, several case studies on successful EIPs show their intrinsic heterogeneity (Elabras Veiga and Magrini, 2009; Shi *et al.* 2010; Sakr *et al.*, 2011; Behera *et al.*, 2012). At the opposite, a low level of diversity among firms in an EIP reduces the variety of material exchanges, thus it may cause instability of the park, which tends to be dependent on single flows (Côté and Smolenaars, 1997).

3.5 Cooperation

As other forms of businesses aggregations, EIPs imply a dense network of collaborations. These include, but are not limited to, linkages among the companies that are located in the EIP. In many cases, such inter-firm linkages are due to the existence of exchanges for goods and energy, either in form of wastes or by-products or not; in other cases, they are based on from the existence of an information exchange system that ensures a tight connection among all the companies belonging to the park. Different forms of collaborations should also be considered, and are specifically considered through this variable. For instance, a company belonging to an EIP usually collaborates with

several business entities outside the park boundaries, such as suppliers or customers, and exchanges information with universities and research centres, which often act as information sources to identify the possible use of by-products and the attendant synergistic relationships among companies. Another critical factor is the existence of relationships between companies in an EIP and governmental agencies. Finally, it should be emphasized the existence of relationships that single companies, or the EIP as a whole, have with stakeholders, such as institution, local communities, environmentalists, labour representatives, which are all interested in shaping the development of the park. Heeres *et al.* (2004) include the active participation of the above stakeholders among the success factors for EIPs.

According to Gibbs and Deutz (2007), trust and cooperative relations among EIP tenants are of key importance in the early phases because they reduce “the mental distance among companies”. Moreover, although such a positive approach is not enough to improve the companies’ environmental performance, it gives a guidance for changing their behaviour and promotes the necessary cultural change.

In the followings, this variable is investigated by distinguishing three sub-variables, namely: cooperation with companies, cooperation with universities and research centres, and cooperation with governmental agencies.

3.6 Shared information system

To effectively take part to an EIP, a company should share all information that is potentially relevant to other companies and, conversely, should have access to the one in the hands of its counterpart. This could be the case of the kind, the amount, the timeliness, the quality, and the other characteristics of wastes and by-products generated by a company, as well as its energy needs. Moreover, the existence of an EIP implies the activity of monitoring and managing data, inherent to that site, which cannot be directly associated to any of the actors (e.g. air pollution, traffic, etc.): the knowledge of these data, indeed, let companies to better arrange their needs by exploiting symbioses and identify possible rooms for improving their performance.

The importance of an information gathering for an EIP has been stressed by Heeres *et al.* (2004) and Tudor *et al.* (2007): according to them, a number of issues should be held, including products manufactured and services provided, material and energy streams,

actual and potential markets, purchases, companies' present resources and capabilities, their future plans, collaborations, and needs.

3.7 Commonality of support services

This variable encompasses the existence of a variety of services that the EIP tenants manage in common. Such services range from basic utilities (such as security, maintenance, or transportation) to more complex ones, e.g. energy management, waste treatment, or regulatory/legal consulting support. Chertow *et al.* (2007) enumerates the existence of such common services among the basic symbiotic transactions that occur in EIPs, the other ones being the exchange of by-products and the cooperation in training and sustainability planning. According to Heeres *et al.* (2004), the management of common services is a pre-requisite for other initiatives in an EIP.

4 Environmental dimension

4.1 By-products exchange

The most common way to develop an industrial symbiosis is to exchange by-products between two companies (Park and Behera, 2014). Such by-products can be in form of physical waste, energy, water, or air and, in default of symbiosis, would be disposed upon payment, or at least in change of some environmental cost. But when the symbiosis occurs, the company producing such by-products can give them to another company that is able to use them as raw materials or, more generally, as factors of production. This exchange opens a room for savings that are beneficial for both parties involved, therefore they are considered the "kernel" of EIPs (Chertow, 2007).

Several papers describe the nature of the exchanges that occur in EIPs, as well as the attendant economic and environmental benefits. For instance, with reference to the South-Korean EIP in Ulsan, Behera *et al.* (2012) enumerate 40 symbiotic relationships, thirteen of which being actually in operation and the remaining ones in negotiation stage or under feasibility investigation. Such relationships cover a wide spectrum of material and energy exchanges, ranging from recycling of waste oil to incineration of industrial or municipal waste supplying steam, from reuse of waste aluminium chips to conversion of high strength ammonia containing wastewater to a nutrient for microorganisms. Shi *et al.* (2010) address the TEDA EIP in Tianjin (China), isolating 81 symbiotic exchanges, 33 of

which among companies both located within the boundaries of the EIP, whereas the other ones involve an internal company with another that does not belong to the park: most of these transactions relate to materials, but there are several occurrences of symbiotic exchanges for water and energy. Liwarska-Bizukojc *et al.* (2009) conduct a similar analysis for the EIPs in Hartberg (Austria) and Schkopau (Germany).

4.2 Sustainable use of resources

This variable mainly relates to the quantity and the quality of natural resources involved in the production processes of the EIP. Within the scope of this assessment, natural resources are defined as: (1) non-renewable or slowly renewable resources that are available in nature in a limited amount and are adopted by the EIP as a whole, or any of its actors, for producing goods (e.g. soil, forest, oil, fish stocks, minerals, rare-earth elements); (2) resources that can be directly or indirectly derived from any of the previous ones (e.g. energy, wood, plastics); and (3) environmental compartments (e.g. air, soil, fertile ground, water basins) intentionally adopted as sinks to absorb emissions and dispose waste generated in the EIP processes, or depleted because of them.

To assess the amount of resources used by an EIP, it should be taken into account the existence of bilateral exchanges of materials and energy among the companies that belong to that EIP. Thanks to such interactions, the overall amount of resources is less than the sum of resources that each company uses in its production processes.

Park and Behera (2014) propose an indicator to measure the economic and environmental performance of industrial symbiosis in an EIP. It is based on the concept of eco-efficiency, namely the ratio between the product or service value and the environmental influence (Verfaillie and Bidwell, 2000). The latter is evaluated as weighted sum of raw material consumption, energy consumption and carbon dioxide emission.

4.3 Adoption of best available techniques

The concept of best available techniques (BATs) has been defined as “the most effective and advanced stage in the development of activities and their methods of operation which indicate the practical suitability of particular techniques for providing in principle the basis for emission limit values designed to prevent and, where that is not practicable, generally to reduce emissions and the impact on the environment as a whole”

(IPPC, 1996). Other organizations and country-specific laws and guidelines have adopted similar definitions of BATs, both referred to their general meaning and applied to specific contexts, e.g. as in the 2001 UNEP Stockholm Convention on Persistent Organic Pollutants (UNEP, 2001). In determining BATs, it should be considered: the consumption of natural resources, the use of less hazardous substances; the adoption of technologies able to minimize the amount and the dangerousness of waste and emissions, as well as to further recovery and recycling of wastes produced in other processes, and the prevention of accidents.

4.4 *Eco-design*

To comply with the sustainability goals, companies located in an EIP should re-think their products and services so as to reduce the attendant environmental impact along their entire life cycle. This principle can be adopted by adopting techniques and methodologies such as life cycle assessment (LCA) (Guinée and Heijungs, 2005) or, for manufacturing companies, design for disassembly (Bogue, 2007).

Mirata and Emtairah (2005) argue that, by establishing industrial symbioses, companies are oriented toward a collective definition of problems, promote an environmentally-oriented culture of inter-organizational collaboration and foster environmental innovation. Mattila *et al.* (2010) use LCA approaches to quantify the environmental impact of a Finnish forest industrial symbiosis and suggest priorities to make processes more sustainable. Liu *et al.* (2011) adopt LCA to assess the impact of an EIP in the Shanghai area.

4.5 *Environmental management systems*

In most countries and for many industries, companies must follow laws and regulations on emissions and pollution control, waste management, and other environmental issues. Beyond these compelling duties, companies may voluntarily adhere to standards, such as ISO14001 or EMAS (Eco-Management Audit Scheme) (Shi *et al.*, 2010; Taddeo *et al.*, 2012). These schemes help companies in building a comprehensive environmental management system that explicitly indicates goals, milestones, procedures and processes to be followed, as well as who is responsible for their fulfilment.

4.6 Green procurement

According to the Commission of the European Community, green procurement is the procurement of “goods, services and works with a reduced environmental impact throughout their life cycle when compared to goods, services and works with the same primary function that would otherwise be procured” (CEC, 2008). Several guidelines have been given for public institutions to promote procurement practices that take into account sustainability issues, in the European Union as well as in the USA (EPA, 1999). More recently, similar initiatives have been extended to companies and business organizations for specific sectors: Uttam *et al.* (2012), addressing the construction sector, analyse the ties between green procurement and environmental impact assessment. Routroy and Pradhan (2011) provide a framework for green procurement in manufacturing. Blome *et al.* (2014) investigate the impact of green procurement on supplier performance and show that the adoption of green procurement practices drives green supplier development (Bai and Sarkis, 2010) and is a pillar for green supply chain management (Srivastava, 2007; Diabat and Govindan, 2011).

4.7 Sustainable goods transportation management

Companies belonging to an EIP are typically interested in three types of material flows, i.e. incoming (e.g. for raw materials and components), outgoing (e.g. for finished products and wastes to be disposed outside the park), and internal to the EIP (e.g. flows of products, by-products, and waste materials that are processed by other companies within the EIP). To arrange these flows and make them more efficient, effective, and sustainable, various initiatives can be pursued in an EIP, such as building a shared transportation management system that coordinates the disperse transportation demand of the companies (Côte and Cohen-Rosenthal, 1998) and leverages on freight consolidation (Bellantuono *et al.*, 2013), or promoting the adoption of intermodality (Tudor *et al.*, 2007), so as to increase the adoption of means of transportation having a lower environmental impact.

4.8 Sustainable people transportation management

Another source of sustainability is the promotion of alternative means of transportation for people, especially for the workers' journey to work (Bakker *et al.*, 1999; Tudor *et al.*, 2007). By managing such programs at the park level, substantial economies of scale can be achieved.

To this aim, some initiatives that the EIP as a whole can promote are: building infrastructures for mass transportation means (e.g. a railway station) or sustainable transportation (e.g. bike lanes and tracks), subsidizing mass transportation networks (e.g. bus lanes within the park or between it and the nearest cities), arranging a car pooling management system, granting workers that switch to more sustainable means of transportation or imposing fees for the private vehicle entrance in the park area.

4.9 Landscape protection

Landscape protection is the combination of actions and initiatives aimed at preserving the natural environment and favouring the integration of human activities with it. The United Nations Environment Programme, in its technical report on industrial estates (Francis and Erkman, 2001), indicates the establishment of landscaping plans as crucial in designing new industrial parks and reconverting existing ones. The concept is relevant especially for EIPs, which are characterized by the strong leanings toward the environment.

However, for EIPs landscape protection does not consist in a mere attempt to disguise plants so as to not deface (or to limit the defacing of) the natural landscape: rather, based on the Forman's (1999) postulate of the existence of a dynamic relationship between landscape structure (namely the arrangement of natural and urban elements) and the landscape function (namely the ecological flows and processes), Yang and Lay (2004) suggest the adoption landscape ecology principles in designing EIPs to reduce the negative ecological effects of urban and industrial development. Often EIPs are the evolution of previously existing industrial parks, built with no regard to the environment, thus another key issue for them is the landscape regeneration, namely the definition of some targeted initiatives for restoring, at least partially, the natural ecosystem that has been already compromised .

5 Social dimension

5.1 Service provision

The existence of a EIP let companies to jointly provide some services – e.g. canteen, nurseries, sports facilities, language schools, dentistry, or tax consultancy offices – specifically addressed to workers in the EIP. The benefits arising from the existence of

such services, accessible for free or at discounted prices, goes beyond the economic advantage, and involves the people's quality of life. Co-locating such services nearby the work place, indeed, reduces their mobility needs, as well as the attendant time that is requested for making use of them. Moreover, it is possible to open the access to the above services to people who do not directly work for the companies belonging to the EIP, thus reinforcing the positive externalities that the park gives to the neighbour wherein it is located.

The above kind of initiatives goes beyond the usual practice to share utilities or access to common services, which Chertow *et al.* (2007) include among the symbiotic transaction and therefore consider a pillar in EIPs.

5.2 *Human resource training*

Sometimes, companies belonging to an EIP arrange conjoint human resource training about the topics that are not company-dependent, such as safety, or environmental protection. Beside the economies of scale assured by centralizing the training activities at a park level instead of at a company level (Roberts, 2004), the aim of these initiatives is twofold: at first, they contribute to the spread knowledge among workers about the importance of a sustainable behaviour, both at an individual and at an organizational level; in addition, they allow the shaping of a shared culture, a common language, and similar abilities. So doing, these initiatives strengthen the ties between companies, favour their mutual collaborations and foster the development of new strategies (Côte and Cohen-Rosenthal, 1998). In other terms, they provide a foundation to build business and social change. Lambert and Boons (2002), shaping a social science framework to scrutinize local industrial ecology, stress the importance of learning processes. As better pointed out by Boons *et al.* (2011), although the acceptance of a superficial social change is relatively easy for companies, in default of a genuine, deep change in their mind-sets, in the long term they tend to fall back to their old patterns of behaviour.

5.3 *Public awareness and stakeholder participation*

There is a common belief that dealing with waste, scraps, by-products, and recycling is always a source of problem for local communities, rather than an opportunity (Taddeo *et al.*, 2012): especially if people are informed on scandals that have involved such a kind of activities, they are reluctant to agree on the establishment of an EIP in their

surroundings. At the opposite, the change in value systems is beneficial for the establishment of an EIP (Roberts, 2004). The creation of a suitable cultural background among stakeholders is crucial especially in countries wherein citizen activists and non-governmental organizations can be effectively affect the strategic planning process of companies and institutions.

To bring about such a background, and in general to build good public relations (Pellenbarg, 2002), actors in the EIP should elicit public awareness by promoting initiatives aimed at disseminating information locally (Lowe, 1997; Shi *et al.*, 2010), and stimulate the participation of stakeholders in the decision making processes of the EIP (Heeres *et al.*, 2004; Mirata and Emtairah, 2005). Their participation is key especially in building a climate of trust and collaboration and in convincing on the technical and economic sustainability of the processes that companies belonging to the EIP carry on. Moreover, stakeholders can play as gatekeepers (Milchram and Hasler, 2002) in collecting information on the opportunities offered for supporting the EIP development.

On the other hand, in most cases discovering the real needs and worries of local communities and providing them with convincing answers is difficult for companies. Therefore, awareness and collaboration is promoted by establishing ad hoc agencies within the EIP (Schwarz and Steininger, 1997; Milchram and Hasler, 2002; Ashton, 2009; Taddeo *et al.*, 2012).

5.4 Promotional events and symposia

To enhance the participation of local community, EIPs may organize seminars, meetings, and conferences, as well as training courses and similar public initiatives on environmental protection. Among these, a particular focus is given to educational programs addressed to schoolchildren or students. The effects of such a kind of initiatives is twofold: first, it spreads the sustainability concept among new generation and, through them, to their families; second, it shines a light on principles of EIPs and benefits that arise from their diffusion, and increases the community compliance toward them. This actions are also helpful in overcoming, or attenuating, the possible neighbours' objections or oppositions to the development of industrial areas, commonly considered a factor that negatively affects their quality of life.

6 Characterizing EIPs through the proposed framework

We applied the framework on a set of 17 well-known EIPs. The set has been defined so as to cover different experiences of EIPs variously located around the world: nine of them are in Europe, more specifically two in Scandinavian countries (Denmark and Sweden), two in UK, three in Central Europe (Austria, France, and Germany), and two in Southern Europe (Italy and Spain). Other five EIPs are located in North America (one in Canada and four in the United States) and the remaining 3 in developing countries, namely Brazil, China, and India. Table 2 lists the EIPs and summarizes their main features and the reference adopted for the analysis.

By desk analysis, we assess the characteristics of the EIPs included in our sample and retrieve the value that each variable assumes for each of them. The analysis has been mostly based on peer-review literature, and complemented with information retrieved by analyzing the EIPs' web-sites and other web sources. Tables 3, 4, and 5 relate to organizational, environmental, and social dimensions, respectively. The tables indicate if an EIP has or lacks the features described through the variables that are included in the proposed framework. For all the variables, indeed, we assumed two possible values only.

Table 3. Classification of the analyzed EIPs according to the organizational dimension.

Organizational dimension	Kalundborg	NISP	Crewe Business Park	Value Park	Vreten	Lopez Soriano	Hartberg Eco Park	Arbois Mediterranée	Environment Park	Burnside	Brownsville	Cape Charles	Fairfield	Devens	Santa Cruz	TEDA	Naroda

Shared information system				✓		✓			✓		✓						
Commonality of support services	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓

7 Cluster analysis

With reference to each dimension of analysis, Tables 3 to 5 show the heterogeneity of EIPs. This evidence suggests to address the questions whether there exist different types, or models, of EIPs, each having its own characteristics and, in case, which are the characteristics that define these models.

To investigate the existence of homogeneous patterns, cluster analysis was adopted. It includes a family of techniques that use algorithms based on the concepts of similarity and dissimilarity to decompose a set of elements, each described by a number of variables, in two or more subsets mutually disjointed, named clusters. Basically, the underlying concept of this aggregation is to maximize the similarity among elements that are included in the same cluster, while maximizing the difference within every couple of them that belong to different clusters (Kaufman and Rousseeuw, 2009). Instead of other techniques (e.g. discriminant function analysis), in cluster analysis the features that define the clusters are not pre-determined, rather they emerge from the clustering itself. This requires to give an ex-post interpretation of the clusters obtained, which often urges scholars to trade-off between the number of clusters considered and the homogeneity among the elements included in the each of them.

Of the 17 EIPs instances, we did separate cluster analyses for organizational, environmental, and social dimension. We considered all the variables included in the framework, as listed in Table 1, and assumed two possible values for each of them, according to the binary scheme depicted in Tables 3, 4, and 5. The analysis has been conducted on IBM SPSS software, selecting the Euclidean quadratic distance as a measure of dissimilarity, and making use of a hierarchic aggregation method. The latter consists in aggregating elements into a progressively sloping number of clusters: at each step, the clusters obtained in the previous one are compared and the more similar of them amalgamated. To aggregate clusters, the unweighted pair-group average rules is adopted.

Table 4. Classification of the analyzed EIPs according to the environmental dimension.

Table 6 summarizes the results of the cluster analyses that have been separately conducted on the three dimensions. For each dimension, two clusters have been assumed.

Table 6. The resulting clusters for each dimension of analysis.

Organizational dimension	Environmental dimension	Social dimension
<i>Cluster ORG-1</i> – Kalundborg – NISP – Crewe – Arbois Mediterranée – Environment Park – Burnside – Devens – Santa Cruz – TEDA <i>Cluster ORG-2</i> – Value Park – Vreten – Lopez Soriano – Hartberg – Brownsville – Cape Charles – Fairfield – Naroda	<i>Cluster ENV-1</i> – Kalundborg – NISP – Value Park – Vreten – Lopez Soriano – Hartberg – Arbois Mediterranée – Brownsville – Cape Charles – Fairfield – Devens – Naroda <i>Cluster ENV-2</i> – Crewe – Environment Park – Burnside – Santa Cruz – TEDA	<i>Cluster SOC-1</i> – Kalundborg – NISP – Value Park – Vreten – Lopez Soriano – Hartberg – Environment Park – Burnside – Cape Charles – Fairfield – Devens – Santa Cruz <i>Cluster SOC-2</i> – Crewe – Arbois Mediterranée – Brownsville – TEDA – Naroda

As for the organizational dimension, it should be preliminarily observed that in all the EIPs common support services are provided, and cooperation with companies exists: therefore both these variables are not suitable to distinguish the clusters. At the opposite, cooperation with governmental agencies is observed in all the EIPs included in the former cluster (which we call ORG-1), and in none of them included in the latter one (named ORG-2). The patterns for the development process of the EIP and the governmental support are, to some extent, similar: as to the former, a top-down development process is identified in six EIPs, all included in the cluster 1; as to the latter, the institutions give support to the EIP in seven cases, six of which are included in the cluster ORG-1 and only one in the cluster ORG-2. Vice versa, all the EIPs wherein the heterogeneity among firms is attested are included in the cluster ORG-2. These results let us label the cluster ORG-1 as composed by EIPs whose development has been planned by institutions, that collaborate and are strongly supported by them, and the cluster ORG-2 as composed by spontaneous, self-organized EIPs, possibly driven by an anchor tenant that is able to aggregate heterogeneous companies.

As for the environmental dimension, the sustainable use of resources is common to all the EIPs, and the adoption of best available technologies as well as the byproducts

exchange are carried out in 15 of 17 parks. These variables, all pertaining to the sub-dimension that describe the production processes, are thus ineffective to classify EIPs in two clusters. According to the results of the analysis, the main difference between the two clusters ENV-1 and ENV-2 is in the extent to which EIPs recur to the management practices for the environment protection: namely, the 5 parks included in the cluster ENV-2 adopt these practices more extensively than the ones included in the cluster ENV-1; the unique exception is the existence of sustainable transportation management systems for goods and people, which are slightly more frequent among the EIPs belonging to the cluster ENV-1.

Finally, from the cluster analysis applied to the third dimension it is possible to distinguish a group of EIPs, wherein the adoption of initiatives in the social field is quite common (cluster SOC-1), from another smaller group (cluster SOC-2) that is formed by EIPs that seldom implement this kind of initiatives. Moreover, within the former cluster, the most common variable is the elicitation of public awareness and stakeholder participation: it seems to be the first and most important step that EIPs should accomplish to take initiatives in the social field.

Table 7. Organizational and environmental dimensions.

		Environmental clusters	
		ENV-1	ENV-2
Organizational clusters	ORG-1	4	5
	ORG-2	8	0

Table 8. Organizational and social dimensions.

		Social clusters	
		SOC-1	SOC-2
Organizational clusters	ORG-1	6	3
	ORG-2	6	2

Furthermore, we have investigated whether a relation exists between the organizational structure of EIPs and the adoption of environmental or social practices.

At first, we have analyzed the clusters comparing the organizational against the environmental dimensions (Table 7): this comparison shows that all the elements belonging to the cluster ORG-2 also belong to the cluster ENV-1. It means that the self-organized EIPs are less likely to adopt the management practices in the field of environmental protection than EIPs developed thanks to top-down initiatives. This insight is consistent with the different organizational nature of the two kinds of EIPs and the peculiarity of these practices: the adoption of environmental management practices relate to the EIP as a whole rather than a single company, which is more likely to require a higher coordination effort. We believe that this is hardly achievable without the presence of an “external” actor, e.g. an institution or an association of companies or entrepreneurs. Such an actor can play a key role for the EIP coordination, e.g. by prompting the park establishment itself, or by subsidizing activities, arranging a framework of norms.

We have then compared the organizational and social dimensions: data in Table 8 do not show any correlation between the two dimensions.

8 Conclusions

This paper has investigated Eco-Industrial Parks (EIPs), namely networks of companies and other actors located in the same area, which establish collaborations and exchange byproducts to exploit new business opportunities and increase their economic performance, by minimizing the environmental impact and creating benefits for the local community. Even though this topic has been extensively addressed in the literature, to our knowledge there is a lack of studies that aim at assessing possible linkages between the organizational structure of an EIP and its environmental and social practices. This paper is a first attempt to cover this gap.

We have proposed a framework that characterizes EIPs along three dimensions of analysis, namely organizational, environmental, and social. Every dimension has in turn been decomposed into several variables. We have then applied our framework to a set of EIPs located in diverse geographic areas. A cluster analysis has been carried out based on the value assigned to all variables characterizing any EIP: for each dimension, two

clusters have been obtained and described according to the identified features. The analysis shows that some variables (organizational features as well as environmental practices) are common to all the considered EIPs, or at least to the majority of them. Such a set of variables could then be considered as fundamental for the EIP's establishment. On the other hand, the remaining variables (organizational features and practices that occur less frequently) could be used to assess the differences among existing EIPs. Finally, the clusters related to the analyzed dimensions have been compared so as to investigate the existence of possible patterns. We have compared the EIP organization against (i) environmental and (ii) social practices. In particular, EIPs promoted or supported by governmental initiatives apply environmental practices more extensively than EIPs which emerge as spontaneous initiatives and have limited public support. This result suggests that even for self-emerging EIPs, an "external" actor playing a coordination role might help adopt the environmental practices not strictly related with production processes.

Though our study is exploratory, we stress some possible limitations. First, in our analysis we consider a limited set of existing EIPs. Second, data have been retrieved by desk analysis (based on previous literature and complemented by the website analysis), which, being based on indirect information, might involve some inaccuracy. Further research would then move from the preliminary insights to formulate research hypotheses and test them by means of an extensive survey.

Structured Abstract

Purpose – The aim of this paper is to propose a model to assess the maturity level of companies' organisational, managerial and technological levers for Virtual communities of practices (VCoP). The proposed model serves as a benchmarking tool in order to analyse an industry sector performance in the management activities of VCoP.

Design/methodology/approach – The methodological approach was divided into two main stages: (i) the development of the VCoP Maturity Assessment Model, and (ii) an application of such model to different realities (benchmarking). The model proposes the assessment of eight key elements to measure the company's organisational, managerial and technological maturity in order to find a correlation with the performance and business impact of the VCoPs. On the other hand, the performance of the VCoP is evaluated based on four main criteria: utility, trust, contribution and sense of belonging. After the development of the model, we carried out an application of it in a benchmarking study of six of the major Oil & Gas global companies focusing on the Exploration & Production sector of such companies.

Originality/value – The main contribution of this paper is that an assessment carried out by the proposed model provides an overview of the strengths and weaknesses of the VCoP management system, and the opportunity for comparison with other organisations. Moreover, the assessment also enables the identification of a series of potential actions that can be undertaken in order to improve the current status of the virtual communities.

Practical implications – Our benchmarking study put in evidence the usefulness of the proposed model. Companies were compared and ranked in terms of the performance of VCoP management. Such results helped companies to have a clear vision of their own state in management practices. Moreover, the assessment helped in identifying the best

practices to be shared in order to improve the overall usage of VCoPs within the Oil and Gas industry.

Keywords – Communities of Practice, maturity assessment model, Oil & Gas industry

Paper type – Academic Research Paper

1 Introduction

The concept of Communities of Practice (CoP) was introduced by Wenger and Leave in the early years of 1990 (Leave and Wenger, 1991). Basically, it consists on group of people that share knowledge, problems, solutions, information and news about a specific issue, helping to extend the group learning by means of people interaction (Wenger et al., 2002).

At the beginning, CoP used to be built by means of a personnel interaction among members, but this changed with the advance of technologies. Today, there are also Virtual CoP (VCoP), which is referring to a group of people who interact, learn together and build relationships through specific social media, potentially crossing geographical and political boundaries in order to pursue mutual interests or goals, developing a sense of membership and reciprocal commitment (Leave and Wenger, 1991; Kowch and Schwier, 1997; Wenger et al., 2002; Jeon et al., 2011). VCoP is the community approach that is attracting more interest in the business environment, mainly in large companies. This is because it helps to bring near experts from different sectors and regions, enabling them to build a common base of knowledge among people dispersed in different places (Song et al., 2007; Montoya et al., 2009).

Following such approach, VCoP have become a common knowledge management practice in Oil & Gas companies. In this sector, VCoP are seen as one of the most powerful knowledge management tool (Corso et al., 2009), since the teams and the experts are frequently dispersed in other units from other countries that need to be integrated. Thus, VCoP are a way to reduce displacement costs of experts that traditionally should be physically present in order to help solving a specific problem. Moreover, VCoP are considered a way to share best practices adopted by some experts that achieved a successful result, aiming to standardize the organisational processes based on the most successful practices and tools used. In the Oil & Gas industry there are different approaches for VCoP. Some companies have adopted models oriented toward individual initiatives, without a centrality of the VCoP management functions. Other companies have adopted

structured models for VCoP, in which member activities are coordinated by a central management team. Consequently, there is not a single strategy to address VCoP in this sector, which changes according to the company's characteristics (Corso et al., 2012). Some prior research have studied the particularities of the VCoP in this sector (e.g. Edmonds, 2002; Scarso et al., 2009) and it is noted that there is a lack of standardization and systematization of the best practices used for VCoP in this industrial sector. Moreover, such a lack of systematization of best practices drives to another problem, which consists in measuring the maturity level of VCoP management in a specific company of this sector when compared with its competitors.

Thus, the aim of this paper is to propose a model to measure the maturity level of companies' organisational, managerial and technological levers for virtual communities of practices (CoP), based on best practices proposed for VCoP management. The proposed model serves as a benchmarking tool in order to analyse an industry sector performance in the management activities of VCoP. The main contribution of this paper is that an assessment carried out by the proposed model provides an overview of the strengths and weaknesses of the VCoP management system, and the opportunity for comparison with other organisations. Moreover, the assessment also enables the identification of a series of potential actions that can be undertaken to improve the current status of the VCoP.

2 Models to evaluate VCoP

There are several perspectives in which the CoP are evaluated. The academic literature has proposed some models, frameworks and domains that should be considered for a community evaluation. Basically, Wenger et al. (2002) identify three common characteristics of CoP that should be considered: (i) Domain (the area of interest); (ii) Community (relationships and the development of a sense of membership and reciprocal commitment; and (iii) Practice (the shared repertory of competences and common resources that members have developed). Based on these principles, some authors have developed different models for CoP evaluation. For instance, Kim et al. (2012) developed a diagnosis framework that help identifying the current knowledge sharing activity status in a CoP. Lee et al. (2010) proposed an evaluation of CoP based in an evolutionary process. Bertone et al. (2013) presented a conceptual framework for CoP assessment in health policy; while Loyarte and Rivera (2007) proposed a model for CoP cultivation. Chu and Khosla (2007)

proposed index evaluations for CoP. Probst and Brozillo (2008) studied the success and fails of CoP, aiming at identifying best practices for CoP management. Such works help to identify several factors and characteristics that should be considered in order to provide a clear understanding of weaknesses and strengths of a CoP. These models present different perspectives, since some of them look at CoP assessment from a perspective of growing, and others from a perspective of index that should be implemented. Both point of views help us to build an assessment framework that help for a benchmarking in the Oil & Gas industry, aiming at evaluating companies' best practices and performances in the use of VCoPs.

3 Research Method

The methodological approach was divided into two main stages: (i) the development of the VCoP Maturity Assessment Model, and (ii) an application of such model to different realities (benchmarking).

First, the maturity model was developed based on the study of international literature and the analysis of implementations of knowledge management systems and communities. Several CoP characteristics and best practices were analysed from Kim et al. (2012), Lee et al. (2010), Bertone et al. (2013), Loyarte and Rivera (2007), Chu and Khosla (2007) and Probst and Brozillo (2008), Corso et al. (2009). Based on these characteristics for CoP assessment, we developed a model based on the main common issues mentioned in such works. Complementary practices and characteristics cited only by few works were also added. The model proposes the assessment of eight key elements to measure the company's organisational, managerial and technological maturity in order to find a correlation with the performance and business impact of the VCoPs. These eight VCoPs' key elements are: culture, sponsorship, architecture alignment, development, management, policy, technology and community assessment. On the other hand, the performance of the VCoP is evaluated based on four main criteria: utility, trust, contribution and sense of belonging.

After the development of the model, we carried out an application of it in a benchmarking study of six of the major Oil & Gas global companies focusing on the Exploration & Production sector of such companies. In order to meet the benchmarking objectives, the collection and analysis of data were conducted using different methodologies: (i) an online survey of 22 multiple-choice questions addressed to 14 KM Managers with

the aim of assessing the VCoP maturity level considering the above mentioned key elements; (ii) an in-depth interview to validate the data collected and to identify the most relevant initiatives supporting the VCoPs management; and (iii) a collection of documents and presentations describing the Knowledge & Community Management System. The benchmarking panel includes some of the major global companies, comparable in terms of size (number of employees) and internationalization level. In particular, the analysis is focused on the use of Knowledge & Community management in the Exploration & Production Unit of Oil & Gas companies.

4 Results

3.1 A model to assess the maturity of VCoP

Our model (Figure 1) proposes the assessment of eight key elements to measure the company's organisational, managerial and technological maturity in order to find a correlation with the performance and business impact of the VCoPs. These eight VCoPs' key elements are: culture, sponsorship, architecture alignment, development, management, policy, technology and community assessment. On the other hand, the performance of the VCoP is evaluated based on four main criteria: utility, trust, contribution and sense of belonging. Following, we describe these elements showed in Figure 1.

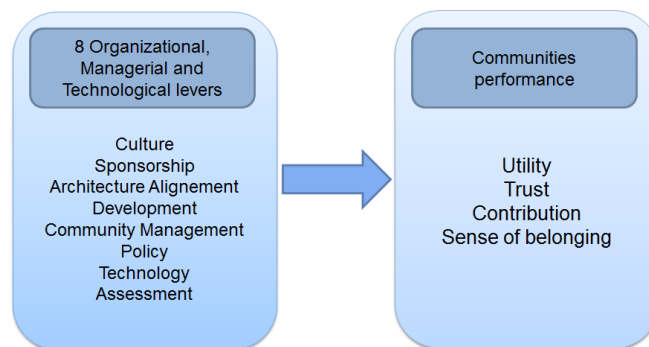

Figure 1 – VCoP assessment model

Assessment of VCoP performance

The performance of the VCoP is evaluated through 4 variables: (i) Utility: users believe in the utility and effectiveness of the communities for their own activities; (ii) Trust: there is strong sense of trust between the members of a community; (iii) Sense of belonging: members have offline relationships and connections among themselves, and a strong

sense of belonging to the community; (iv) Contribution: members participate in the community in a continuous and systematic manner.

Assessment of VCoP Levers

The KM Maturity Assessment Model considers 8 variables in order to evaluate the company's organisational, managerial and technological maturity:

(i) Culture: attitude of top management, middle management and employee towards knowledge sharing behaviours. The analysis of the "culture" evaluates the attitude of top management, middle management and the employee towards the following organisational behaviors that support Knowledge & Community Management: a) *Emerging collaboration* (cross-functional and independent of predefined hierarchies) between people and internal experts; b) *Openness* to knowledge-sharing with actors in the company's extended network (customers, partners, suppliers, consultants, etc.); c) *Co-creation*, creation of broad participatory content and knowledge by people to foster widespread innovation; d) *Sociality*, enhancement of interpersonal relationships and stimulation of the creation and management of extended networks of contacts; e) *Transparency* and opportunity to communicate freely in a climate of trust and belonging to the organisation; f) *Flexibility to change*, capacity and speed of process and activity changes in response to shifts in business needs and context.

(ii) Sponsorship: management, countries and business units support in development and use of the communities. Regarding the management's sponsorship of the VCoP, the analysis considers two different dimensions: a) *Top and Middle Management Involvement* (i.e. sponsorship toward the development and use of communities); and b) *Top and Middle Management Commitment in Communities* (i.e. whether there is or not a widespread participation by managers in the launch, promotion and change management activities; and in contributing to the communities).

(iii) Architecture alignment: definition of objectives and long-term development plans for the communities, and analysis of the target needs and methods of interaction. The analysis in this category considers two different dimensions: a) *Target-needs alignment*, i.e. domain of the VCoP (common themes and problems, expertise of potential members, tools and language to be used, etc.), the needs of the target users, the methods of interaction and the informal networks of the target users (e.g. organisational network analysis); the company objectives and the needs of community members, identifying shared goals;

b) *Business alignment*, i.e. long term development plans with objectives that are aligned with corporate strategy; a clear mission for each community defined and communicated (e.g. technical improvement, process innovation, training, etc.); top and middle management involvement in the community concept definition (goals, scope, domain, etc.).

(iv) Development: approach for the development of the communities in terms of design, activities, roles, people and country involvement, technology tools and change management. Regarding this construct, the analysis considers two different dimensions: a) *Open and cross-organisational participation*, including people with expertise in communications, organisational and business process, in addition to technical roles; identification and involvement of internal “champions” in the development phase of the community (i.e. users with some experience in the use of community tools and promoters of change); collection and acceptance of independent initiatives by employees for the creation of new communities; and various countries involved in the definition and design of the communities. b) *Structured roles and activities* defined with a team dedicated to the technical development of community tools and a launch and change management plan for each community established.

(v) Community management: regarding the management of the communities, the analysis considers two different dimensions: a) *Animation and Incentive activities*, like strategies to promote the community (promotional videos, communication campaigns), activities to involve the community members and to stimulate contributions (editorial plans, contests), specific communication and engagement activities defined for the various countries, offline Meetings and events organised for community members (workshops, conventions, etc.), open and free policies of use are established (free access to community, contributions without moderation, etc.), activities for training and support on community tools; economic incentives tied to user participation and contribution in the communities (e.g. bonuses, benefits, MBO); formal recognition tied to participation and contribution in the communities (e.g. awards, contests, visibility in the community, etc), organisational policies and procedures to increase user participation (ex. evaluation workflow of business application, request; b) *Structured roles and activities*, like community manager and/or a central team (KM Team) that coordinates the various initiatives, the roles and the coordination mechanisms that regulate the management of the community (e.g. community leaders, facilitators, process owners, KM champions and area experts), adequate training and enough time to dedicate to VCoP management activities, use of

tools and initiatives for sharing best practices among the people who manage the communities, and monitoring of the evolution of the community over time.

(vi) Policy: regarding community use policies, the analysis considers two different dimensions: a) *Accessibility*, i.e. all employees can obtain access to any community through a simple registration process; and b) *Trasparency*, i.e. users may freely express their own opinions within the boundaries of corporate etiquette.

(vii) Technology: the technological assessment considers 3 main categories of IT tools: a) *Social Network & Community (SN&C)*, which supports in managing and creating relationships between individuals through tools promoting discussion, the exchange of ideas and involvement in networks of extended acquaintances, including those beyond company borders (blogs, forums, social network tools, expert research, advanced user profiles, etc.); b) *Unified Communication & Collaboration (UC&C)*, which supports in managing each type of communication and collaboration both within and outside the company, uniformly and independently of the media adopted to transmit contents (web, landlines, mobile, TV) through specific infrastructures and tools audio/web/videoconferencing, instant messaging, VoIP, etc); c) *Enterprise Content Management (ECM)*, which provides support in managing contents and documents within and outside an organisation through tools that improve accuracy, accessibility and integrity.

(viii) Assessment: regarding the monitoring of community activities, the analysis considers two different dimensions: a) *Monitoring, which considers the use of a measure of community access and use* in a systematic way; an appropriate KPIs and success metrics; executive reporting carried out in a systematic manner; and an analysis of utilisation levels for the redefinition of the strategy for the development of the communities. b) *Analysis of the benefits and business impact*, which considers standard organisational tools and mechanisms established to identify the benefits and the business impact of the community system; benefits and business impact of the community system identified in qualitative terms (e.g. qualitative descriptions, indicators, etc.); benefits and business impact of the community system identified in quantitative/economic terms (time/cost reduction, increased quality, increased production); and evidence of the benefits and success stories provided to community stakeholders.

3.1 Applying the VCoP maturity assessment model in the Oil & Gas industry

Our proposed model was applied in four leading Oil & Gas companies in order to evaluate their VCoP management performance. First, Figure 2 presents the results of VCoP performance, which was measured by utility, trust, contribution and sense of belonging through the answer provided to an electronic survey confirmed by a set of case studies.

Figure 2 – Assessment of VCoP performance

After evaluating VCoP performance, the eight VCoP management levers were also evaluated, based on the items presented in previous section. Figure 3 shows the main result about such levers.

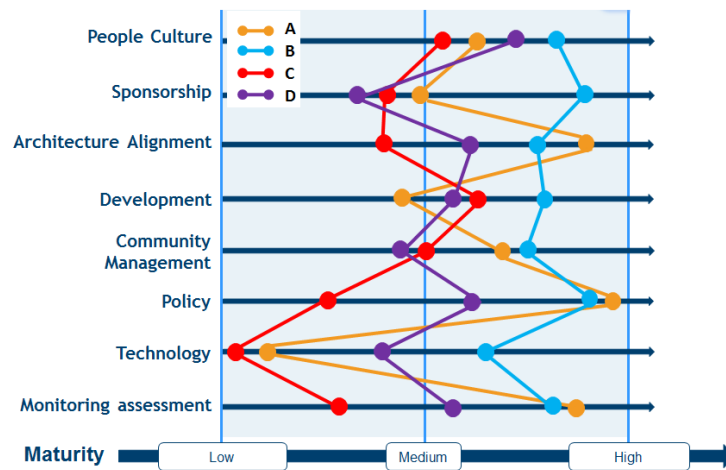

Figure 3 – Assessment of VCoP levers of maturity

As expected by our maturity assessment model, the company that presented the best performance in results showed in Figure 2 (Company B) was the same that showed the best condition in terms of levers maturity in Figure 3. The same happens with the company with the worst VCoP performance in Figure 2 (Company C), which is the company that presented the lowest maturity in the evaluated levers (Figure 3), especially in policy, technology and assessment monitoring.

It is also worth to note that all companies presented higher scores to the utility and sense of belonging of VCoP, and that the most important problems associated to VCoP performance are related to the lack of contribution of the members and the lack of trust among communities members (Figure 2). On the other hand, when considering the levers (Figure 3), technology appears as the most critical lever in which VCoP are still in a very low maturity stage. In this sense, we collected information about the most used technologies in the companies analysed. Figure 4 presents such results.

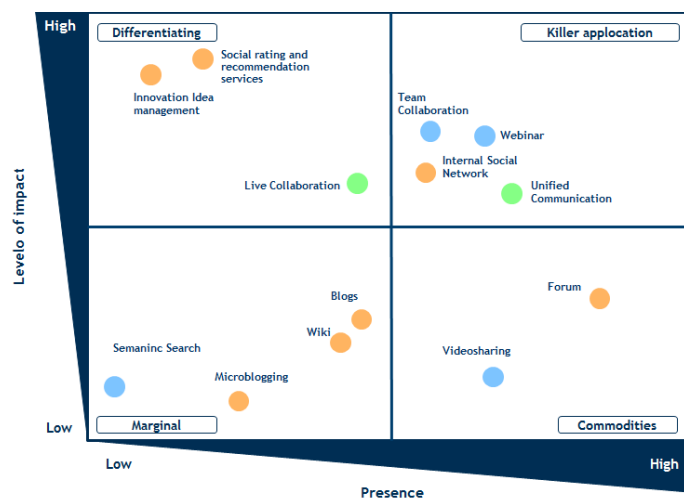

Figure 4 – Technological tools used in VCoP of the Oil & Gas companies

Based on the in-depth interviews we carried out with KM managers, we classified VCoP technologies using two axis of scores (Figure 4). The first axis shows the level of presence or use of a specific technology in the VCoP studied. The second axis shows the level of contribution or impact of such a technology for VCoP in the Oil & Gas sector. We classified these technologies based on the two axes in four quadrant: marginal, commodities, differentiating and killer applications. The first two quadrants have a low con-

tribution for VCoP, according to the interviewees. On the other hand the differentiating and killer applications are the most powerful technological tools for VCoP in this industrial sector. Technologies in blue colour are those related to enterprise content management, in orange are those related to social network, and in green color the related to unified communication and collaboration. The differentiating quadrant of Figure 4 presents tools that are used few in such communities but have a high potential of contribution for VCoP.

5 Conclusions

This paper presented a model to measure the maturity level of companies' organisational, managerial and technological levers for virtual communities of practices (CoP). The proposed model serves as a benchmarking tool in order to analyse an industry sector performance in the management activities of VCoP. The main contribution of this paper is that an assessment carried out by the proposed model provides an overview of the strengths and weaknesses of the VCoP management system, and the opportunity for comparison with other organisations. Moreover, the assessment also enables the identification of a series of potential actions that can be undertaken to improve the current status of the virtual communities.

Our benchmarking study put in evidence the usefulness of the proposed model. Companies were compared and ranked in terms of the performance of VCoP management. Such results helped companies to have a clear vision of their own state in management practices. Moreover, the assessment helped in identifying the best practices to be shared in order to improve the overall usage of VCoPs within the Oil and Gas industry.

Structured Abstract

This paper discuss how regional economic renewal can be achieved within a region that is highly dependent on a traditional low value added industry with relatively low technology level and the competitiveness of which has declined, over a short period of time, to a level where economic viability is questionable. The approach is built around government intervention to reduce the information asymmetry between local players and global state-of-the-art whilst simultaneously instigating a culture shift enabling cluster development for the implementation of identified transformation pathways.

The project involved the establishment of a policy framework with a balanced supply side tool, information provision and demand side tool portfolio. This was then followed by a mapping of the local value network and its participating actors to identify their present status as compared to world best practice. Following on from this, there was construction of alternative strategic technology roadmaps which differed on the raw material lenses used, time lines, competence levels and investments. In parallel with this there was communication and engagement processes to enable a self-organised cultural

shift towards a situation conducive to initiating industry led clusters. The early successes are identified as well as indicators for the desired trajectory being followed.

Purpose – The purpose of the research is to capture a novel approach to regional economic renewal through the application and synthesis of approaches from several different domains. The theoretical lens, the tools, the process and the outcomes are described.

Design/methodology/approach – The approach taken was descriptive with the roadmaps adding prescriptive conclusions, and hence the studied project is in its own right was both descriptive and prescriptive. The methodology is a triangulation of theory and literature review, empirical data collection, qualitative and quantitative analysis as well as observation of outcomes.

Originality/value – This methodology puts in evidence of integrating methodologies from foresight, strategy, social science, policy science, innovation studies, cluster studies and Schumpeterian economics¹. The combination of methods adds to the current innovation management and industry renewal theory.

Practical implications

The main outcomes of the project are (a) the changed attitude among the value chain participants, (b) the identified renewal trajectories, (c) the identified and verified balance of policy tools for economic renewal, and (d) the acceptance of cluster development as an industry led route to success.

The combination of these methods adds to the current innovation management and industry renewal theory and generates, at least, three implications. Firstly, the integration of company assessment, value chain analysis and identified renewal trajectories created new opportunities, but also new challenges, on both the micro and meso levels. Secondly, the future-oriented, lens specific, global view was a new approach among the regional players that formed a cornerstone in raising awareness about the needs to collaborate and form a joint strategy and it also provided an educational input for policy makers dealing with regional industrial development in a new way. Thirdly, the project also had a strong policy perspective that focused on the interaction between path dependency and path creation in a technologically very dynamic domain and within an agglomeration economic and Schumpeterian framework.

The project had both practical and managerial implications: Firstly, the company assessment identified domains where individual firms had weaknesses as well as where the group as a whole lagged global best practice. Secondly, the value chain analysis showed strengths and weaknesses of the present industrial structure in the region, but also delineated the necessary components to be developed in order to move towards higher

¹ Schumpeter, 1934.

value added production. Thirdly, the renewal trajectories identified the present and future operational frontiers in advanced cellulose fibre-based industries, and made possible a successful positioning of the Green Triangle region, the regional industry and the individual firms for future success. Fourthly, the project has generated a high level of international interest resulting in several high-value adding cellulose fibre related firms approaching the region for potential relocation.

The study contributed to the creation of a future-oriented strategic agenda for the Green Triangle region on the macro, meso and micro levels. The integrated approach created in the project will also benefit innovation, industry and innovation policy, and industry and regional transformation and renewal scholars. Individual companies can apply the assessment framework and key transformation trajectory findings in their own strategy work.

It can be concluded, as evidenced in the main text, that the project is a clear success at this point in time but it remains to be seen what trajectories the path creation in the Green Triangle will take into the future.

1 Introduction

Australia has a long period behind it as a relatively low cost environment to operate in, especially in domains of low value adding to local raw materials where Australia has a traditional comparative advantage on the primary industry side e.g. mining, natural gas, agriculture, forestry and marine. This changed very rapidly around 2008 when the mining boom created a Dutch disease problem for Australia and the industries linked to the above areas suddenly found that they operated in a high cost environment where they could no longer compete on price doing what they did and they had no tradition in developing their

business into producing high value for money offerings at a relatively high cost (Prime Minister's Manufacturing Taskforce, 2012; Roos, 2012; 2013b; Roos & Kennedy, 2014).

Being exposed to this rapid shift resulting in very poor financial performance combined with a lack of experience and capability around how to move to a more successful basis for competing in a high cost environment many of these firms were rapidly facing a risk of going under (see e.g. Kettle et al., 2012). Many of these firms were stuck with low value add products, outdated production technology and eroding competitiveness. With insufficient capacity to innovate and adopt new technologies firms, sectors and entire regions can fall into a vicious circle of economic decline having negative effect also on other firm's profitability, their supplier industries, local employment and all of the local communities.

At this point policy makers can chose between three options: Firstly, they can allow the force of creative destruction to take its toll by letting uncompetitive sectors dwindle and hope more productive and competitive operations will grow to replace them. This laissez-faire approach, favoured in the neoclassical view of the world, has a high short term economic and social cost. In spite of what the neoclassical economic theory states, it provides no guarantee that more productive and competitive businesses will emerge to replace the disappearing ones, especially if the industrial commons¹ surrounding a key natural resource is being reduced. As a consequence, large stocks of local natural and human capital may become redundant. Secondly, they can start providing economic support to the threatened sector in order to improve its viability and its ability to maintaining its current operations. While this option might be politically attractive in order to save jobs, a key objective in the neo-Keynesian view of the world, it is very expensive and holds no guarantee for success in the long run. If anything, it delays the necessary transformation thus making it even harder to deal with the inevitable changes at a later stage. Numerous examples e.g. the ship building crisis in Europe during the 1970s, illustrates the futility in pursuing this approach. Thirdly, they can take an active role in instigating and facilitating transformation towards a new technological trajectory with a view to developing higher value add products for emerging markets. This is a challenging

¹ *The industrial commons is normally defined as the embedded knowledge, technology capabilities, specialised equipment and specific co-specialised assets that enhance the efficiency, effectiveness and productivity of the proprietary capital and labour that use it. This industrial commons does not reside in one organisation but is spread out over a large group of organisations and individuals but normally within a limited geographic domain (Pisano & Shih, 2009).*

task for policy makers. Governments are notoriously ill equipped to identify opportunities with long term prospects. They are also not in a favourable position to direct industry towards new pathways. Nonetheless, correctly executed so that information is presented for industry to act upon and in that an environment can be created in which winners can emerge, as identified in the neo-Schumpeterian and evolutionary world view, this option tends to provide better outcomes than the other two options.

In this paper, we present an approach taken to achieve regional economic renewal through structured knowledge development using a combined foresighting and roadmapping approach to identify future development trajectories (see e.g. Kostoff et al., 2001; Phaal et al., 2001; Petrick et al., 2004; Phaal et al., 2004; Walsh, 2004; ICS Ltd., 2009b; Phaal & Muller, 2009; ICS Ltd., 2010a; 2010b; Walsh & Linton, 2011; Bok et al., 2012; Kerr et al., 2012; Voros et al. 2012). These trajectories are aimed at higher value added activities and will require innovation. Innovation will have to encompass both value creating innovations and value appropriating innovations (see e.g. Roos & Pike, 2009; Chung et al., 2010; Roos, 2011a; 2011b; 2011c; 2013c; Burton et al., 2013; Roos et al., 2013). The approach also facilitates a cultural shift (see e.g. Valdivielso, 2010) aimed at enabling collaborative activities such as cluster formation to benefit from the agglomeration economic effects when a whole industrial commons is moved to this new level.

The paper looks at the case of the forestry processing industry located in the South Australian part of the “Green Triangle”. The forest and wood products industry and associated value chain have experienced a very difficult time due to the issues outlined above. This development combined with internal factors such as a lack of investment, aging equipment and poor management decisions have resulted in a significant reduction in industry profitability and a loss of employment opportunities that have combined to create an atmosphere of doom and gloom in the crisis situation that existed when the process was initiated in the second half of 2012.

The Regional Development Australia Limestone Coast has met this challenging situation by pursuing an agenda of economic diversification to broaden the economic base of the South East through the initiative of The Limestone Coast Economic Diversification Forum. The South Australian government based on both the findings and recommendations of the 2012 Adelaide Thinker in Residence “*Manufacturing into the Future*” report and the Department for Manufacturing, Innovation, Trade , Resources and

Energy's "*Manufacturing Works*" strategy where the cellulose fibre domain was identified as one of the priority areas for smart specialisation requiring forward thinking and the acquisition of knowledge about new markets and opportunities, emerging technologies and partnerships between industry, government and the research sector turn (DMITRE, 2012, p. 9 & pp. 42-44), acted by implemented these recommendations. The implementation included both a fund providing investment grants to industry as well as the project discussed in this paper.

A central tenet of the smart specialisation argument is that governments should focus their knowledge investments in activities– not in sectors in per se – that reflect areas where a region or country has some comparative advantage (specialisation) or emerging areas where entrepreneurs could develop new activities (diversification). This connection between specialisation and technological diversification in the context of regional development and growth has been highly influential as it demonstrated that the smart specialisation as policy framework is very well suited for dealing with the problems of place-based growth (McCann, P. & Ortega-Argiles, R., 2013a; 2013b; 2013c; 2013d; 2013e).

Smart specialisation differs from traditional innovation and industry policy in that it is focused on the 'entrepreneurial discovery process' or 'self-discovery' which is the process through which an entrepreneur realises that a good or activity, that may or may not already exist in other regions, can be produced locally, with some variations and possibly at lower cost (Rodrik D., 2004). The entrepreneur is able to identify new activities by combining existing scientific and technical knowledge with the industrial resources and capacities in the region that can lead to new economic opportunities. This new process of identification will also hopefully lead away from imitation and me-too strategies that characterised many regional innovation strategies in the past decade. In order to do so the firm must have a large stock of intellectual capital and the entrepreneur must be able to combine these stocks into an effective transformation system (see e.g. Marr & Roos, 2005; Roos, 2005; Roos et al., 2005; Roos & Roos, 1997; Peng et al., 2008; Pike & Roos, 2008; Peng et al., 2011; Roos & Pike, 2011; Peng et al., 2012; Roos et al. 2012a), including access to appropriate research results (Roos et al. 2012b). Furthermore, empirical evidence shows that despite similar endowments, countries and regions may specialise (through the identification process – for example by applying the same technology to the local conditions) in very different activities (Sabel Charles et al. 2010).

It is clear that strategic roadmapping plays a key role in enabling the entrepreneurial identification process which is core to the smart specialisation strategy. Table 1 outlines the rationale for a smart specialisation strategy (OECD, 2013).

Table 1: Rationales for smart specialisation (OECD, 2013, pp. 24-25)

		Policy intervention	Examples of existing and new policies/initiatives
	<ul style="list-style-type: none"> • Low ‘self-discovery’ activity • Low information exchange flows. • Lack of <i>intra-</i> and <i>inter-</i> regional interactions that restrict the knowledge spillovers. 	<ul style="list-style-type: none"> • Incentives to reward entrepreneurs who discover new domains. • Incentives to involve non-traditional actors. • Creation of platforms and mechanisms to facilitate – <i>intra</i> and –<i>inter</i> regional interactions. • Public policies can assist further this process by providing key infrastructures (e.g. information about emerging technological and commercial opportunities and constraints, product and process safety standards for domestic and export markets, and external sources of finance) 	<ul style="list-style-type: none"> • Prizes for inventions and discoveries, fiscal incentives, IPRs • Incentives for public sector innovation (e.g. procurement) • Public web consultations • Regional workshops • Innovation Vouchers • Internationalisation support services

The project discussed in this paper was implemented with the assistance of VTT Technical Research Centre of Finland, as experts in the forest product value chain, who developed grounded pathways for the renewal of the sector, both in the short (3–5 years), medium (5–10 years) and long-term (greater than 10 years), through a roadmap exercise. The objective of this roadmap project was to provide the region with a information input underpinning a strategy to renew the cellulose fibre value chain and its associated industrial commons. The project was funded by Department of Manufacturing, Innovation, Trade, Resources and Energy (DMITRE) and led by VTT Technical Research Centre of Finland (Ahlqvist et al., 2013a, 2013b).

2 Sector transformation policies and Strategic roadmapping

2.1 Foresight based policy change

Foresight has increasingly been identified as a practice and process for enabling industry transformation and associated policies. Foresight is an ability, a process and a set of tools to anticipate future developments, manage uncertainty and come up with responses to identified future challenges (see e.g. Rohrbeck, 2011; Slaughter, 1997; Miles et al., 2008). It is used in identifying opportunities and challenges, exploring alternative futures, gaining a better understanding of the current situation and its development and creating strategies and plans for coping with changing environment (Martin, 1995; Rohrbeck & Schwarz, 2013; Day & Schoemaker, 2004). In the context of strategic management, foresight contributes to different value creation forms (Rohrbeck, 2012, p. 441) and it has also been deployed to develop new business fields for companies (e.g. Heger & Rohrbeck, 2012; Rohrbeck et al., 2013; Battistella et al., 2012; Kraatz et al., 2012).

Foresight studies can be executed with different time scales, different spatial scales, different sector focus, different technology width and depth. On the micro level it could e.g. focus on the strategic options for one firm and the development and implications of one technology. On the meso-level it could e.g. focus on strategic options for groups of firms or whole sectors and the development of related technology portfolios. On the macro level it could focus on strategic options for complete innovation systems and their development given trajectories in complete technology portfolios.

This project involves foresighting on the meso level and on this level there are two important aspects: stimulation of systemic capacities and anticipation of potential system failures. Foresighting stimulates systemic capacities through providing actors with information and signals originating outside the actor's immediate environment and therefore help actors to identify potential opportunities and threats. Foresighting also facilitates new linkages that both facilitates the flow of information as well as the value add to this information which in turn enables the formation of new social structures (see Ahlqvist et al., 2012a). Foresighting assists in anticipating potential system failures by identifying and preventing rigidities and mistakes of innovation agents" and "a lack of linkages and fragmentation between innovation actors" (Georghiou & Keenan, 2006, p. 763), which otherwise lead to system failures.

The policy practice is of course influence by the policy process and Weber et al. (2009, p. 955) argue that policy processes have gone through a conceptual shift in which a linear model of policy-making has been replaced with a more learning based cyclical model. Here, foresighting is a process that aligns expectations and builds a "self-fulfilling prophecy". Foresighting can thus be viewed as "an integral element of networked and distributed policy making". This is realized through three functions of foresighting: informing, strategic counselling and facilitating (Weber et al., 2009, p. 956).

There are different reasons for using foresighting in policy making. Georghiou & Keenan (2006, p. 766) distinguish three rationales: Firstly, the provision of policy advice by accentuating the long-term perspective; Secondly, the building of advocacy coalitions. This outcome is achieved by foresighting creating an "interaction space" through enabling new networks and communities to form around a common vision; Thirdly, foresighting provides a "hybrid forum" between public and private actors enabling strategic reflection that broadens the range of participation on policy issues.

The policy process relating to a complex system, like a complex sector with its associated and underpinning industrial commons, becomes very much a question of policy design. Policy design, as the adaptive and experimental approach in which a portfolio of selected policy instruments are implemented in some simultaneous or sequential combination. The specific instruments selected and the specific way in which they are combined and implemented is a function of the complex system that the policy is to operate on. The most common characteristics of the system that impacts these choices are: the volume, variety and type of actors in the system; the relevant technologies; the

relevant infrastructure; the time horizon of the system, the change velocity of the system; the spatial coverage of the system; the cultural and behavioural characteristics of the system.

Foresighting is strengthening policy design in providing six functions: Generating grounded views on potential futures i.e. informing policy design; Increasing the capacity for change in the policy community i.e. facilitating policy implementation; Make policy-making more participatory; Converting foresighting insights into policy practice i.e. assisting in the definition of policy; Re-orienting the policy system towards a more long-term perspective; Creating a co-created ground for policy (Da Costa et al., 2008, p. 369). This augmentation of the policy design with a foresighting process generates a forward-looking policy design (Ahlqvist et al., 2012b).

2.2 Meso-level foresighting using strategic roadmapping to generate forward looking sectoral policy design

Strategic roadmapping can be considered both as a strategic thinking approach and as a collaborative process methodology. Teece et al. (1997) defined “dynamic capability” as: “the firm’s ability to integrate, build, and reconfigure internal and external competences to address rapidly changing environments” (Teece et al., 1997, p. 516). Dynamic capabilities are linked to managerial processes, strategic position and organisational path. Thus, the notion of dynamic capability provides a theoretical basis for organisational transformation by linking the transition to a contextual historical understanding. From a strategic management perspective, foresight contributes to different value creation forms (Rohrbeck, 2012, p. 441). This can be exemplified by the different roles (initiator, strategist, opponent) foresight can have within innovation management (Rohrbeck, 2012, p. 442). An extension of the initiator role is when foresight is deployed to develop new business domains within firms (e.g. Heger & Rohrbeck, 2012). The literature within organisational strategy crafting (e.g. Whittington & Cailluet 2008; Heracleous & Jacobs, 2008), argues that strategies should not be viewed as locked-in paths to some pre-determined goal, but rather as organic schemes that are always partially open and available for alternative options, multiple instruments and “side-schemes”.

Roadmapping is a continuous and transparent process that can be used as a foresighting practice. Part of its methodological strength rests in that it combines different modes of knowledge with specific activity layers (Kostoff & Schaller, 2001; Phaal et al.,

2004). Roadmaps also allows for combining and synthesising organisational knowledge that may be difficult to combine or synthesise using other strategic methods (see e.g. Petrick & Echols, 2004, Phaal et al., 2006). Roadmaps are used in two different ways: Firstly, as a normative instrument to identify relevant emerging technologies and to align them with explicit product plans and related action steps (see e.g. Phaal et al., 2001). Secondly, as a dynamic and iterative process that produces weighed visual narratives of an organisation's long-term vision, and short- to medium-term strategies to realise this vision, using the roadmap's ability to convey the most critical paths of future developments (Phaal & Muller, 2009). The visual form of roadmaps enables formulation of strategies and visions¹ with explicit linkages across time scales (present, medium term, long terms) and within and across key layers (e.g. drivers, markets, actors, technologies) as illustrated in Figures 10-13. This enables the use of roadmaps as strategy charts that open simultaneous macro- and micro perspectives (see Blackwell et al., 2008), especially since roadmapping is an adaptive process-based methodology well suited for systemic context (see Ahlqvist et al., 2012b).

Knowledge spillovers, shared input markets, and other linkages that form part of the industrial commons exist and have an impact on the performance and location of companies (Lindqvist et al., 2013). There is also agreement that locations do significantly differ in their specialisation profiles, and that individual groups of related industries tend to be concentrated in a narrow set of locations (Chatterji et al., 2013). Specific groups of interlinked players underpinned by an industrial commons tend to be called clusters and exist at all levels of economic development and work largely as a multiplier that enhances the benefits of business environment conditions rather than being a substitute for weaknesses (Lindqvist et al., 2013). While the direct effect of co-location in clusters might thus be limited – many estimates suggest an elasticity of cluster wages to specialization at around 2-3% - there leverage effect can be substantial (Lindqvist et al., 2013). Given this, a vision of a single firm that is shared between geographically bounded economic and political actors may provide a risk reducing mechanism for the firm by aligning development activities of interdependent organisations. Given the existence of local externalities, there is an in principle case for policy to address the market failures

¹ *Visions should be understood as objectives that are systematically verified and re-formulated, either based on the outcomes of the organisation's strategy cycle or when an unanticipated event takes place that impacts the existing objectives.*

that these externalities create (Lindqvist et al., 2013). Cluster policies thus fit as one policy in the group of New Industrial Policies (Rodrik, 2008), and from the above it can be seen that strategic roadmapping as a foresighting tool can provide useful insight into the formulation of such a cluster policy.

Strategic roadmapping has both a cognitive and collaborative component. The cognitive element provides a method for producing and analysing insight grounded in information pertaining to the current economic situation, foresight on markets and technologies, and policy options in a temporally sequenced representation with systemic linkages between the elements. The collaborative element provides a process for mobilising relevant stakeholders to initiate transformation processes. Information alone is a weak tool for initiating change, but when combined with collaborative processes involving the sector, its underpinning industrial commons and other key participants of the regional innovation this information becomes a powerful instrument to assist participants in arriving at a shared understanding of potential future pathways.

Strategic roadmapping can be applied towards creating a common vision which contributes to embedding the long-term objectives and enhances the commitment of the participants towards achieving this long-term goal. Strategic roadmapping can also be applied towards identifying existing or emerging societal needs (frequently termed “grand challenges”), consumer and business needs that create a potential demand for new products and services and hence can underpin a systemic change. This role is important when working with sectors where large cumulative investments have been made in existing technologies and infrastructures leading to the sector risking to become locked into technological solutions which are suboptimal from an emerging need point of view. This lock in is frequently evidenced by the sector rejecting demand signals from the marketplace. Under these conditions a transformation process can be set in motion by a well grounded public policy implemented with high precision. Strategic roadmapping can play an important role in grounding this public policy as well as in preparing the sector and its underpinning industrial commons for the necessary change envisioned by the public policy. Strategic roadmapping can also link the identified needs with specific policy instruments (Wieczorek & Hekkert 2012).

Strategic roadmapping can also play a role in identifying when and how demand could develop in conjunction with the emergence of a new market. There are many reasons why a market for new offerings cannot be taken for granted: Adopting new

technologies can be very slow due to high switching costs (David 1985, Arthur 1989); The market may not develop due to pricing mechanism for any benefits being absent (Faber & Frenken 2009). A well executed strategic roadmap can capture purchasers' and suppliers' common understanding of future societal and market needs (Georghiou & Cassingena Harper 2011). A strategic roadmap also enables insights into the required boundary conditions and likely time lines for technology push and demand pull to match. This allows for the development and implementation of an appropriate portfolio of policy tools in response to the opportunity created by this match. A strategic roadmap can also be used to identify specific innovation objectives relating to a specific technology or to a specific development over time. When the economic logic of the business environment adheres to that of a value network rather than that of a value chain or value shop (see Stabell & Fjeldstad, 1998 for a discussion of the three logics and Roos et al., 2012 for a detailed discussion of their drivers and their managerial implications) it is important that all elements and linkages are identified (Adner & Kapoor, 2010) and hence the inclusion of the industrial commons that underpins the sector to ensure that potential partners for achieving the identified innovation objectives. Value networks consist of organisations that cooperate with each other to benefit of all network members (Valkokari et al., 2011). Value network describes the competitive environment: the power structures, alliances and conflicts (Heger & Rohrbeck, 2012). Value network analysis aims at generating a comprehensive picture of how value is generated in the network (Peppard & Rylander, 2006). The main focus is on the present situation, although it can be and has been applied in exploring possible future value chains (e.g. Ahokangas et al., 2012; Wessberg et al., 2013). The analysis focuses on the roles or functions of the nodes of the network (e.g. saw mills) and not in specific organisations; therefore it does not explicitly assess the competences of individual companies.

Dufva et al. (2013) states that there are two major challenges when applying roadmapping in the context of a regional industry sector. The first is the tension between the local and the global, which roadmapping does not explicitly address. There is a risk that roadmaps focus too much on the local present situation and therefore are not able to create a compelling picture of a radically different desired future and the path towards it. On the other hand, focusing only on the global developments and available technology may lead to the results being unconnected from the reality of the region. Therefore it might be useful to distinguish explicitly between the local situation and the global state-

of-the-art. The second, challenge is that roadmaps are seldom able to capture the dynamics of the actors in the region. This is usually postponed to the more detailed action planning phase that is based on the roadmapping. However, understanding the actors, their interactions and the value creation dynamics might be useful already when exploring the strategic pathways or the desired future (see e.g. ICS Ltd., 2009a; 2009b; 2010a; 2010b).

2.3 *Regional Economic Renewal or Transformation*

Spoehr (2014) in his review of economic renewal finds that industrial rejuvenation and urban/regional regeneration are intimately linked and when intelligently integrated they are mutually reinforcing with the potential to significantly improve both the social and economic prospects of areas experiencing industrial decline, closures and a legacy of underinvestment in social and physical infrastructure. The key elements of a complete approach are found to include (Spoehr, 2014, pYY):

- integration of economic, industry, workforce, social and urban policy and program agendas
- responsiveness to place, economic, political, historical and cultural needs and circumstances
- agile and responsive collaboration, governance processes and structures
- developing high quality leaders and diffusing leadership
- authentic engagement, trust building and collaboration
- effective communication of vision, strategic responses and progress
- new trans-disciplinary institutional spaces for design thinking, problem solving and action
- early assessment of the full range of potential impacts of sectoral decline or disinvestments and closures to provide an evidence base prior to them occurring
- economic, workforce and social modelling of potential and actual impacts
- scenario planning of alternative responses to large scale retrenchments with particular attention to short and medium term demand side solutions
- ensuring that the social and economic costs of industry adjustment are mitigated or minimised for employees, families and communities through early intensive

assistance appropriate support or pathways to appropriate employment made available to all those affected by restructuring, retrenchment or closure

- building and sustaining a robust regional innovation system
- developing viable pathways for transitioning from mass production to knowledge intensive, high value goods and services
- transforming existing industries and enterprises to make them more resilient in the face of domestic and global pressures
- fostering and supporting the growth of new and more resilient firms/sectors to respond to the decline of others
- investing in high performance workplace systems
- facilitating and sustaining robust and outward looking industry clusters and networks
- fostering and investing in a culture of creativity and innovation sustained by design thinking processes and institutions
- identifying early infrastructure development priorities that help to boost employment in the short term and productivity over the medium term
- improving the quality of civic amenity as a foundation for improving morale, well-being, population/workforce attraction and retention
- modernising housing and transport infrastructure to improve well-being and reduce travel to work times
- Ongoing monitoring, evaluation and adjustment as appropriate of response strategies.

This aligns well with the actions found by Power et al. (2010) to be taken by cities that are successfully recovering from having suffered multiple problems caused by profound economic restructuring. On the meta-level these cities have been found to take actions aimed at (Power et al., 2010, p. 271):

- overcoming their structural problems;
- adapting to the requirements of changing political and economic conditions;
- alleviating the worst consequences of the crisis;
- implementing successful regeneration strategies;
- improving the overall quality of life;
- creating a path towards a sustainable future.

The specific actions taken can be gathered under the following headings (Power et al., 2010, p. 283-284):

- Strategic response to population losses
- Focus on deprived neighbourhoods
- Specific skills / qualification initiatives targeting skills mismatches
- Efforts to integrate ethnic-migrant population
- Creating stronger linkages between higher education and local businesses
- Investment in higher education
- Focus on specific economic sectors, e.g. cluster strategy
- Creation of economic development / inward investment agencies
- Investment in high-profile physical projects
- Investment in / promotion of high-profile events
- Revitalisation of city centre
- Regeneration through culture
- Strengthening of the retail function of the city (centrality)
- Upgrading of housing
- Investment in accessibility: long-distance transport infrastructure ('hub functions')
- Investment in public transport
- Environmental sustainability on the political agenda
- Actions taken to improve the environment, e.g. land, water, air decontamination
- Public administration made more efficient
- Benefit from devolved powers
- Coherent strategy guiding the recovery actions (for different tiers of government)
- Metropolitan level cooperation

From our previous discussion it is clear that strategic roadmapping as a foresighting tool can be useful in providing input enabling some of the actions identified by both Spoehr (2014) and Power et al. (2010) as necessary actions to achieve economic renewal and / or transformation. It is also clear that agglomeration economics forms an underpinning for some of the actions identified e.g. cluster formation, strengthening of the industrial commons, strengthening of the regional innovation systems both in terms of actors and linkages.

The agglomeration economic lens builds on the joint effects of economies of scale and network effects. As firms with related activities cluster their cost of production declines due to greater specialisation and division of labour, competing multiple suppliers,

economies of scale and scope in the underpinning industrial commons, economies of learning in the regulatory environment, labour pooling, larger number of customers attracted, increased opportunities for communication between participants increasing the learning and innovation, etc. (Faggio et al., 2014).

The key benefits of these proximities are best articulated by Döring & Schnellbach (2006): “Networks of regionally clustered businesses and institutions, therefore, offer two broad opportunities: formal exchanges of knowledge through market relationships, where proximity allows the establishment of closer ties; and the informal exchange of knowledge in social networks of individuals”. Those beneficial aspects of close proximity which firms cannot control or achieve in any other way than through close geographical and specialisation proximity have been named untraded interdependencies by Storper (1995; 1997).

One of the key agglomeration economic policies is known as cluster policies. These cluster policies have continued to evolve and presently EU member states are encouraged to put more emphasis on the smart specialisation of their regions by concentrating resources on a few key priorities and addressing their particular strengths rather than by spending investment thinly across areas and business sectors in order to contribute to knowledge and innovation based economic growth (European Commission, 2010).

The efficiency and effectiveness of Cluster’s have been shown by research in this domain. The findings show that firms that are members of agglomerations, e.g. clusters, have higher productivity as well as higher productivity improvements than firms that are not members of any agglomeration (Jaenicke et al., 2009; Garanti & Zvirbule-Berzina, 2013). Typical benefits are fourteen percentage points higher value added growth, seven percentage points higher profitability growth and two percentage points higher wages per employee (a proxy for productivity) to the advantage of firms in clusters vs. those not in clusters (Extracted from Table 2, page 30 in Sölvell & Williams, 2013). Companies participating in a cluster are far more likely to become innovative than (other companies. Statistical analysis shows that companies participating in clusters increase their probability of being innovative by a factor of 4.5 compared to a control group of companies with similar characteristics (Danish Agency for Science, Technology and Innovation, 2011)

Clusters can be used at both the design and the implementation phase of smart specialisation strategies. In the design phase, they can be used to identify the industrial

strength and assets in a region, to contribute to set strategic priorities and to make the right political decisions. In the implementation phase, clusters can be used as efficient platforms that can focus on and quickly contribute to the objectives of smart specialisation. In particular, by fostering cross-sectoral cooperation, clusters can contribute to implement thematic-based strategies by addressing new society challenges and creating new competitive advantages in a region (European Commission, 2012). From this the importance of using the strategic roadmapping based foresighting as an input into a cluster policy becomes clear.

2.4 Cluster development and path dependency

A path dependent system is a system where the outcomes evolve as a function of the systems' previous states. (Martin & Sunley, 2006). There are three common views in conjunction with path dependency: Firstly, that technological systems has an inherent tendency to become locked in a single development trajectory – so called technological lock-ins. Technological lock-in has been the subject of study since the mid 1980's (see e.g. David, 1985; Arthur, 1989; Cowan, 1990; Liebowitz & Margolis, 1995; Unruh, 2000; Unruh, 2002; Yarime, 2009; Floch et al., 2012). One reason for technological lock-ins is that the nature and direction of technological advance is strongly shaped by the cognitive framework of actors. These frameworks are sometimes called technological regimes (Neleson & Winter, 1977) and sometimes technological paradigms (Dosi, 1982). These frameworks provides boundaries for the thoughts and actions perceived possible by members of a specific technological community and hence limits the efforts to advance the performance of a given technology by only focussing on opportunities that build on past achievements, ideas and knowledge. This means that technological opportunities and solutions that lie outside this dominant framework are rarely explored. Hence, the tendency of technological change to proceed incrementally along certain trajectories rather than radically in discontinuous leaps (Dosi, 1982). Secondly, that path dependent system adheres to the logic of increasing returns. This means that one dominant path in a system gets continuously stronger due to positive feedback loops. This can be observed when two or more technologies are competing for market share. The presence of increasing returns leads to the option securing an initial lead in adoption goes on to dominate the market (David, 1985; Arthur, 1989). This effect may lock the market into an inferior solution since choice during the early stages of competition is characterised by

uncertainty and ignorance about the respective qualities and properties of various options, and hence generate market failure. A lock-in outcome can be generated by a combination of four mechanisms. The first three mechanisms (Economies of experience, economies of scale, economies of learning) have been empirically well documented. The effect of these three mechanisms is normally strengthened by the fourth mechanisms, adaptive expectations, whereby increased adoption reduces uncertainty about the performance, reliability and durability of an offering or a technology (Perkins, 2003). Secondly, that path dependent organisational and social systems has a tendency to self-replicate and grow and thus generating a high degree of self-reliance which does not necessarily reflect the relevant practices that ought to be taking place in the system – this is sometimes known as institutional hysteresis (Martin & Sunley 2006).

The theory of path dependency can be coupled with a theory of path creation. Schienstock (2007) suggests that path creation could be approached as a process of mindful deviation by people who have an understanding of the opportunities that a new paradigm offer, which to a great extent depends on the engagement of social pioneers such as scientists, politicians and entrepreneurs prepared to initiate and conduct anticipatory institutional change. Thus envisioning an industrial transformation which can be viewed as a creative act that aims to build a new path, including a new vision, new structures for collaboration and a new institutional basis.

Gáspár (2011) states that path dependency and path creation are both conditioned by historical trajectory and future images made in the past, but also the future visions made in the present. In his model, path dependency provides the “prognostic power” to explore the future. Thus, path dependency forms the context and the perspective that enables the strategic vision. Path creation represents the potentiality of the future, the openness to make new decisions and take new actions. Gáspár (2011) asserts that path dependency and path creation require each other in order to produce meaningful and actionable strategies to transform something. Path creation is a social practice that should engages the key actors in a creative collaboration (Schienstock, 2007; Gáspár, 2011).

The above argument can also be applied to clusters and other agglomerations (see e.g. Keeble & Wilkinson 1999; Bathelt 2005). According to Sölvell (2008), the emergence of clusters can be explained through two causal factors. The first is the natural factor advantage, which can relate to traditional natural factors, such as soil, climate, ores, logistic position, or forests. The second causal factor is a historical accident, in which

some entrepreneur has started a business, and in a period of time, this has led to spill-over effects, such as emergence of supporting industries, services, and eventually towards cluster structures. Sölvell (2008) stresses that many clusters have a hero whose emergence can be traced back to the initial phases of cluster formation. When the cluster is growing, it needs a specialised sort of social resources. The most important ones are social capital, formal and informal networks, personal and corporate networks, and organizations to foster collaboration. The cluster requires also specific configurations including sophisticated demand, competitive strategies, related industries, infrastructure and R&D to develop further- many of these fall under the concept of industrial commons. These specific assets can also be fostered through policies, such as national and regional level policy instruments (see Ahlqvist 2013).

2.5 *Multi-criteria assessment as a tool*

In our framework the assessment of companies is based on Multi-Criteria Decision Analysis (e.g. Belton & Stewart, 2002) and especially Multi-Attribute Value Theory (e.g. Keeney, 1993) whilst adhering to the fundamental requirements of measurement theory (Pike & Roos, 2004; 2007; Roos & Pike, 2007; Pike & Roos, 2010). The basic idea behind this approach is to include multiple criteria, which are weighted according to their relative importance (see e.g. Fletcher et al., 2003). Different alternatives, or in our case companies, are evaluated with respect to each criterion. The result is an overall value for each alternative, which reflect both the performance of the company against each criterion as well as the relative importance of the criteria expressed in the weights. Assuming that the attributes are mutually and preferentially independent (Keeney, 1993), the overall values can be calculated by using an additive value function.

There are three main aspects in the assessment: criteria, scores and weights. The criteria give the framing for the assessment and determine what is taken into account. These criteria draws on the resource-based view of the firm (Wernerfelt, 1984; Prahalad & Hamel, 1990; Peteraf, 1993; Wernerfelt, 1995; Granstrand, 1998; Barney, 2001) and discussion about firm's internal/external capabilities (including technological capabilities) and dynamic capabilities to exploit opportunities as outlined in Figure xx where the firm's or actor's embeddedness in networks and the surrounding environment is illustrated. At the actor level, e.g. resources, capabilities, knowledge and trust between actors influence the formation of networks that enable opportunity exploitation and at the institutional

level, which usually appears regionally as well as nationally (Lundvall, 1992; Cooke et al., 1997; Rosenfeld, 2002; Hekkert et al., 2007; Cooke, 2008a; Cooke, 2008b; Linton & Walsh, 2008; Asheim, 2011; Morgan, 2012; Simmie, 2012; Varis et al., 2012; Henning et al., 2013; Klitkou, 2013 there are e.g. economic, political, legal, social and technological factors which provide impulses or blockers for opportunity exploitation.

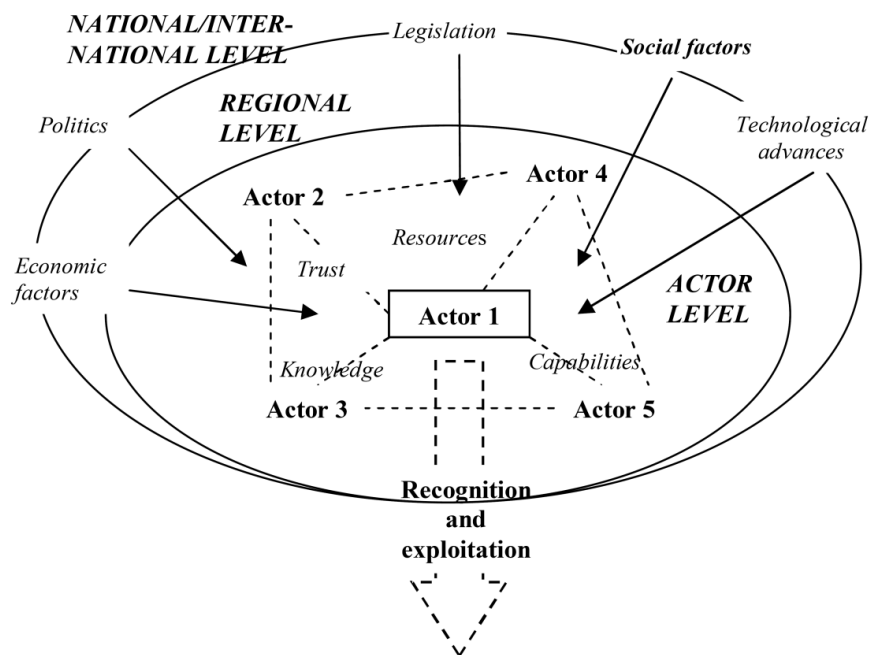

Figure 1: Opportunity recognition and exploitation (Lehtovaara et al., p. 200)

Scores represent the performance of the companies against the criteria. Finally the weights represent the viewpoint taken in the assessment in that they determine what is deemed most important, and how important are other criteria relative to the most important one.

3. The case of the cellulose fibre value chain in the Mt. Gambier region of South Australia

The Green Triangle, incorporating South Australia's Limestone Coast region and adjacent parts of Western Victoria is Australia's premier wood production region. The softwood (SWD) plantations yield 3.2 million m³ of logs annually, approximately two-

thirds saw logs and one-third pulp logs. In Green Triangle, there is a well-established forest and wood products industry cluster developed to grow, harvest and transport, and process these logs. However manufacturing capacity has been declining with notable facility closures in the last several years. Chronic underinvestment for most facilities has left the majority of the remaining industry relatively uncompetitive versus state-of-the-art domestic or international competitors. This sector has experienced poor markets for key products, especially low-grade sawn wood, residual chips and surplus round wood. Consequently, the whole value chain has struggled to generate adequate returns. Increasing SWD log exports are an outcome, as growers seek to re-balance log demands with the log mix produced from their forests.

The hardwood (HWD) plantations produce mainly pulpwood logs. The plantations were developed by ad-hoc planting during the last decade by Managed Investment Scheme (MIS) promoters, many of which have gone into receivership. The estimated volume of logs to be yielded from these plantations will exceed 4 million green metric tonnes (GMT)/year by the middle of this decade. Significant volumes of HWD pulpwood supplies will be available for the following 10 years. Aside from chipping, there is no domestic processing of these logs. Chips are currently exported destined for Asian pulp mills. Export of HWD round wood logs is a recent and growing phenomenon. Infrastructure will limit HWD chip exports to approximately 3.4 million GMT/a.

Asian markets are currently oversupplied with HWD chip and pricing is well below the level required to deliver adequate returns to growers. Consequently, industry observers expect around half of Australia's current HWD plantation estate will not be replanted. This will include plantations in the Green Triangle. The area replanted will affect the HWD pulpwood volumes available beyond 2025.

In addition to the supply of SWD and HWD logs, the region can also generate an estimated 500,000 m³/a of woody biomass. This material comprises the tops and branches of trees left after harvesting.

The HWD pulpwood supplies yielded from the region represent a globally significant volume of high quality, certified fibre. The current owners of these plantations are actively looking to diversify uses away from the current low paying export chip markets. In addition, Australia is the only region with a long term surplus of cellulose.

Few of the current players had initiatives in place to address either the fundamental problems in the existing sector, or to capture the region's unique opportunities (For a

discussion around the challenges and opportunities for the industry see e.g. Roos et al., 2013; Roos, 2013).

3.1 Methodological framework for the Strategic Roadmap

The strategic roadmap framework used for the project is based on two dimensions. The first dimension is the level of analysis, and the second one is the temporal-spatial scale. To assess the companies in regional industry system three functional layers were defined (Figure 2) based on the layers in roadmapping and the levels in the Multi-Level Perspective (MLP) (Geels, 2002).

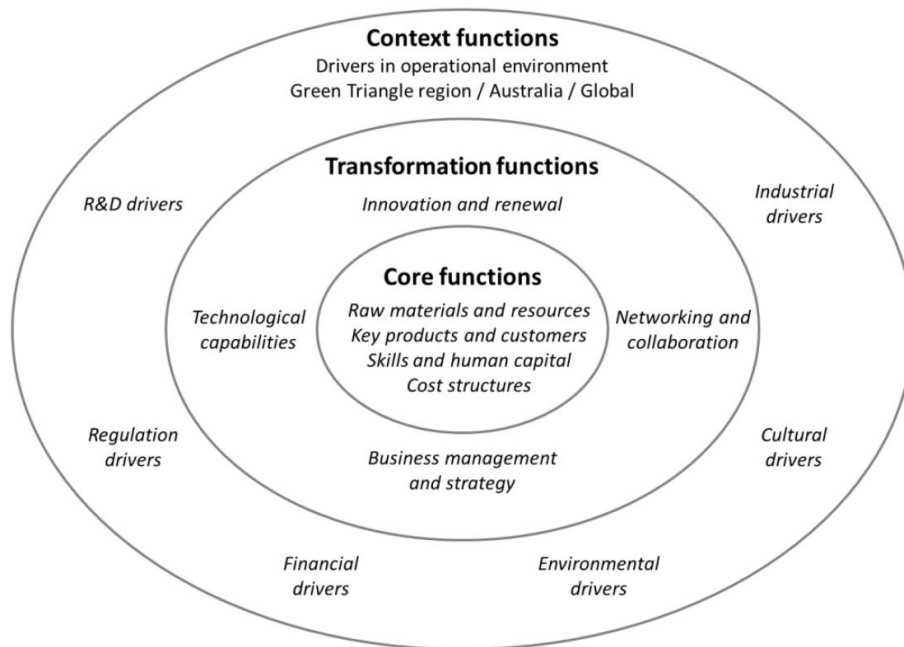

Figure 2: Functional layers used in the assessment of the companies (Dufva et al., 2013, p. 6)

The functional layers describe the key functions of the company in the context of the drivers. The first layer is the core functions that gather the most elemental issues for a (cellulose) company. The core functions are divided into raw material and resources, key products and customers, skills and human capital, and cost structure and finances. This layer is focused specifically on assessing the key business processes of the company.

The second layer aspires to gaining two crucial insights: firstly, it aims at assessing the capacity of the company to transform and renew, and, secondly, it endeavours to identify the core components required for the regional transformation of the cellulose industry in South Australia. The first component is innovation and renewal that focuses on the potential of the company in innovation-fostering activities and, through these, the renewal (see e.g. Roos, 2007; Roos, 2014a). The second component is networking and collaboration that aims at identifying the capacity of the company to form linkages and in finding useful channels for the development of its business. The third component is business management and strategy that aims to recognising the company's capacity in strategy crafting and in constructing and realising feasible targets for future business development (for details see e.g. Roos et al. 2014). The fourth component is technological capabilities, which is used for evaluating the company's competencies in adoption new production technologies as well as technology sourcing competence.

The third layer is called context functions. This layer consists of drivers in operational environment at the regional (Green Triangle region), national (Australia) and global levels. The aim of this layer is to understand, on the one hand, how the company is embedded in the regional structure and, on the other, how the company perceives the possibilities to exploit key drivers of change in national and global domains. The drivers were analysed in six categories: industrial, cultural, environmental, financial, regulation, and R&D.

The time dimension is explicitly defined in roadmapping, and the developments in e.g. technology and markets are considered also with a time scale. A commonly used time scale ranges from the present to the desired long-term future with one intermediate step. The spatial dimension, on the other hand, is not explicitly considered. However, it becomes especially important in the case of a regional sector behind the global developments, because in that case there is a clear mismatch between the local present situation and the global state-of-the-art. The challenge then becomes to map a path through the state-of-the-art and further into the desired future state.

In this project a three-step temporal-spatial scale was defined and used: the local present situation, the global state-of-the-art and the local desired future embedded in the global context. The local present situation focuses on the competences, knowledge, technology, markets, networks and interactions in the region. It represents the starting point with the local historical links. The state-of-the-art focuses on leading edge

technology, global market situation and opportunities, top knowledge centres and global networks. It represents the “external world” with which the regional industry has to cooperate and compete in order to survive.

Aiming only at the state-of-the-art would lead to a never ending catching up situation. It would also disregard the local special characteristics. Therefore the aim should be further in the future, in a vision for the regional industry, specialised and prospering in a global economy. This vision is based on both the local present situation and the global state-of-the-art but goes beyond both.

The methodology framework for the project is outlined in figure 3.

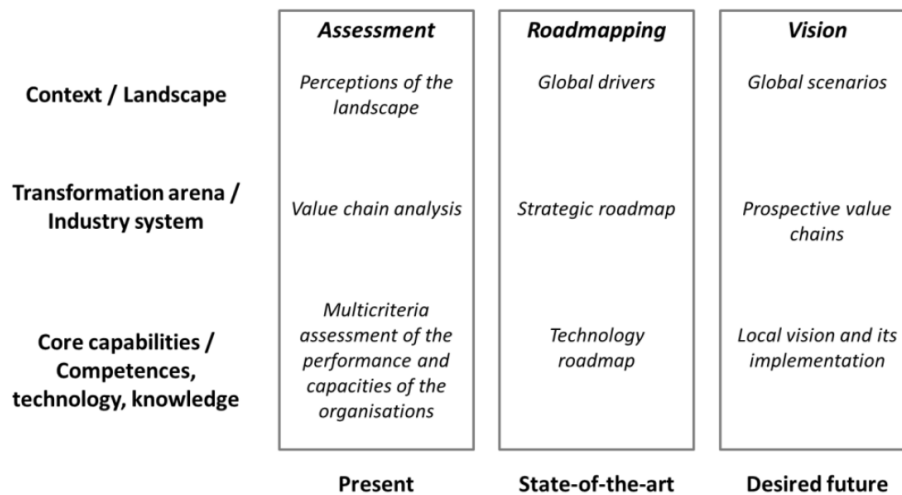

Figure 3: Methodology framework for the case (after Dufva et al., 2013, p. 8)

The process used in the case project consisted of: company assessment (steps 1 and 2 in figure 4), value network analysis (steps 3 to 5 in figure 4) and roadmapping (steps 6 to 8 in figure 4). As can be seen from figure 4, the process meanders across both axis, which illustrates the reflection between the global context and the local situation. We present the process as a sequence of methods, although in reality it was far more iterative and overlapping.

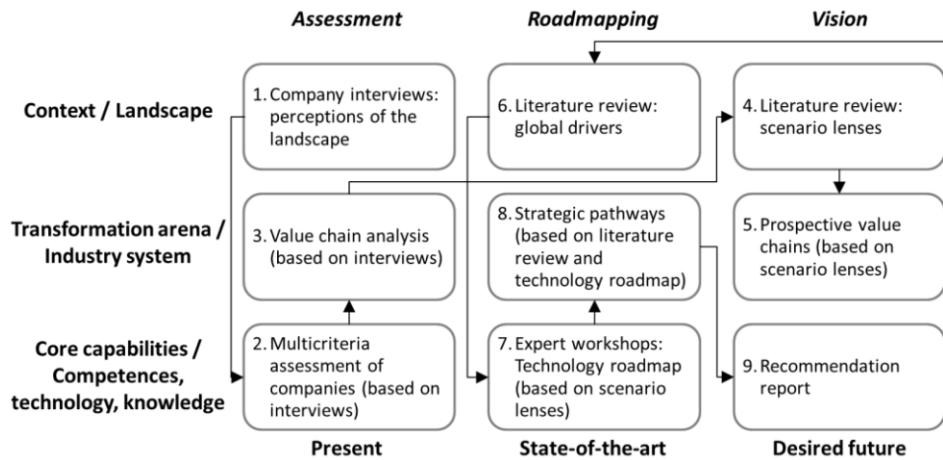

Figure 4: Project process presented in the methodology framework (after Dufva et al., 2013, p. 9)

Another view of the same approach can be seen in figure 5.

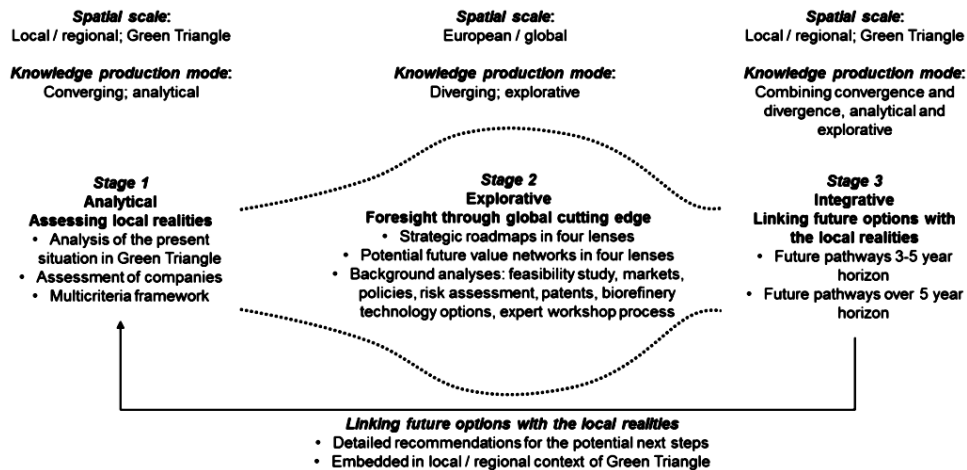

Figure 5: Spatial scales, knowledge production modes and stages in a project aimed at strategic industry renewal (Ahlqvist et al., 2013c, p. 5)

The strategic roadmapping process, adopted a so called “lens-based” approach. The future of the forest and wood products industry was analysed through four lenses (figure 6) as suggested by the chair of the steering committee. The idea of lenses was to get a grip of the global cutting edge in the forest industry development, and build strategic roadmaps on the assessed state-of-the-art.

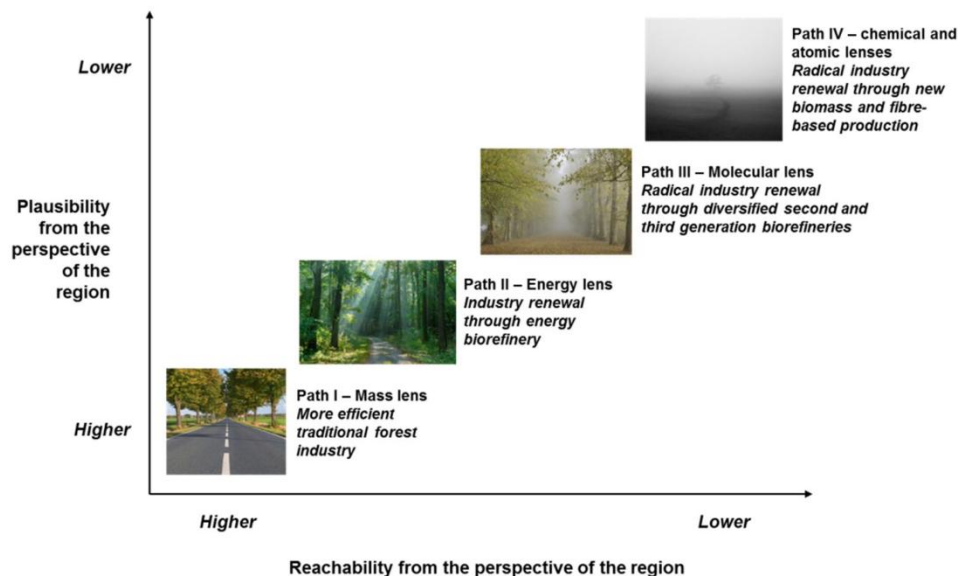

Figure 6: Strategic Roadmap lenses and their connection to the regional knowledge base (Ahlqvist et al., 2013c, p. 8)

The first is a mass lens: it emphasise more efficient traditional forest and wood products industry. Basically, the question was about making the existing type of forest and wood products industry more efficient by forming strategies for how to modernise the old technology and how to make the production processes more efficient. This is the lens that underpins the present traditional logging, wood chip, timber and wood based construction elements sector in Australia. The mass lens represents a lowest level of value adding and varies from very vulnerable to only somewhat vulnerable in a high cost operating environment.

The second is an energy lens. This lens focuses on the potentials of industry renewal through energy. It focus especially on the how much energy can be obtained from the forest production side streams, like branches, bark or excess chips. This lens also underpins the existing and emerging industries that focus on heat and energy generation, as well as ethanol and biodiesel production (normally via a first generation bio-refinery). In the lens, there are pockets of high value opportunities such as biodiesel, bioethanol and aviation fuel.

The third is a molecular lens, emphasising radical industry renewal through diversified second and third generation biorefineries. This is the lens that shows emerging opportunities that have the potential to replace existing chemical production based

industries. The lens could include specialty chemicals that are recyclable such as bioplastics for soft drinks bottles.

The fourth is an atomic lens, with a focus on radical industry renewal through new biomass and fibre-based production. This lens is high value-added and requires exceptional technological understanding and R&D. The lens enables the production of a wide range of new or modified materials such as biodegradable lightweight cellulose nanocrystals (CNCs) with a tensile strength exceeding that of steel or cellulose foams as insulators for the construction industry, and transparent paper replacing petroleum-based materials, like plastics.

3.2 Data Sources for the strategic Roadmapping

The data of the SA project included 23 interviews with South Australian companies, 6 steering group meetings, and 3 strategic workshops, where technology experts in forestry, biotechnology and cellulosic fibre industries crafted strategic technology roadmaps for the region. Massive amount background data was collected and analysed. In addition, a simulation model was constructed to evaluate the flows of biomass in the regional system as well as a model to assess the productions costs of different bioenergy routes.

3.3 Key Findings

The initial phase of the project was an evaluation of the status among key actors in the region. They were evaluated using several criteria and the overall findings are shown in figure 7.

Figure 7: The aggregate scores of core, transformation and context functions (Alqvist et al., 2012c)

From figure 7 it is clear that there is a large variation in the status of the different actors in the region.

The typical outputs for Green Triangle’s large and small sawmills are contrasted with a hypothetical Australian best practice mill sawing the same logs (as available to the large sawmills) (Table 2). The hypothetical mill employs curve or shape sawing technologies and state-of-the-art scanning technologies that allow such sawmills to generate higher yields of product and a higher proportion of structural product than either of the typical mill types in Green Triangle. The best practice mills typically have lower labour and energy costs per unit quantity of timber produced. The present average labour use in large sawmills is one FTE per 800 m³/a.

Table 2: The typical large and small Green Triangle sawmills benchmarked against hypothetical Australian best practice (Ahlqvist et al., 2013a)

Output Component	A typical Large Green Triangle sawmill (>500,000 m ³ log input/a) Av 42.0% dry dressed recovery	Hypothetical Australian best practice large softwood sawmill (>500,000 m ³ log input/a) Av 47.0% dry dressed recovery	A typical Small Green Triangle sawmill (<100,000 m ³ log input/a) Av 48.0% green sawn Recovery = <40% dry dressed recovery
Structural grades (MGP 10 or better)	29%	35%	5%
Non-structural boards	7%	6%	26%
Non-structural core wood	6%	6%	17%
Woodchips	28%	25%	28%
Shavings/dockings	18%	17%	10%
Sawdust	11%	11%	15%
TOTAL	100%	100%	100%
Bark	7%	7%	7%

Figure 8 presents the principle present forest industry value network in the Green Triangle forest and wood products industry (a major part of the industrial commons). Two key functions of the present value network can be divided into the activities of forest owners and supporting actors, notably actors in breeding and genetics, machine suppliers, and data analysis providers that all provide inputs for utilisation and renewal of the resource base in the region, mainly formed of pine and eucalyptus plantations. This set of activities forms the first loop of the value network and act as an input to the second loop i.e. from hauling and harvesting to the downstream sawmills. The key present products of Green Triangle sawmills are sawlogs, pulp logs, roundwoods, woodchips, sawmill and

wood residues and barks. Important external inputs for this second loop are skilled labour and cost-related factors such as electricity and fuel.

In the third loop, the sawmills act as providers to different customer industries, the first of which is direct exports of woody materials such as logs and woodchips, mainly to Asia. Some of this material is later imported back to Australia as value-added products. The second is the declining traditional pulp and paper industry in the Green Triangle region. The pulp and paper industry uses mainly pulp logs and wood chips as material for the production of cellulosic pulp and, subsequently, paper products. The third customer industry is the construction and building industry that produces sawn timber, panels, engineered wood products, posts and treated timber. In addition, the industry produces furniture, fencing and other products. There are also residual products, like mulch and potting mix, but these do not contribute significantly to the present value network. On the basis of the analysis, the side streams are currently under-utilised and provide a clear opportunity for the region.

In the current value network, the functions of the four actor groups in the study (forest owners, hauliers, sawmills, specialised suppliers) can be summarised as follows. The core business of forest owners is to take care of the renewal of basic resources, production of timber (softwood and hardwood), and the core functions related to this. The hauliers and harvesters persevere with their core business of hauling, harvesting and transport. The sawmills produce processed timber, generally at low levels of added value. The specialised suppliers provide services and products both for business-to-business and business-to-customer. There are currently services, for example, in breeding and genetics, machine supply, data analysis and geoinformatics, but their potential in the present Green Triangle forest and wood products industry is not fully realised because there is a lack of advanced demand and demanding customers.

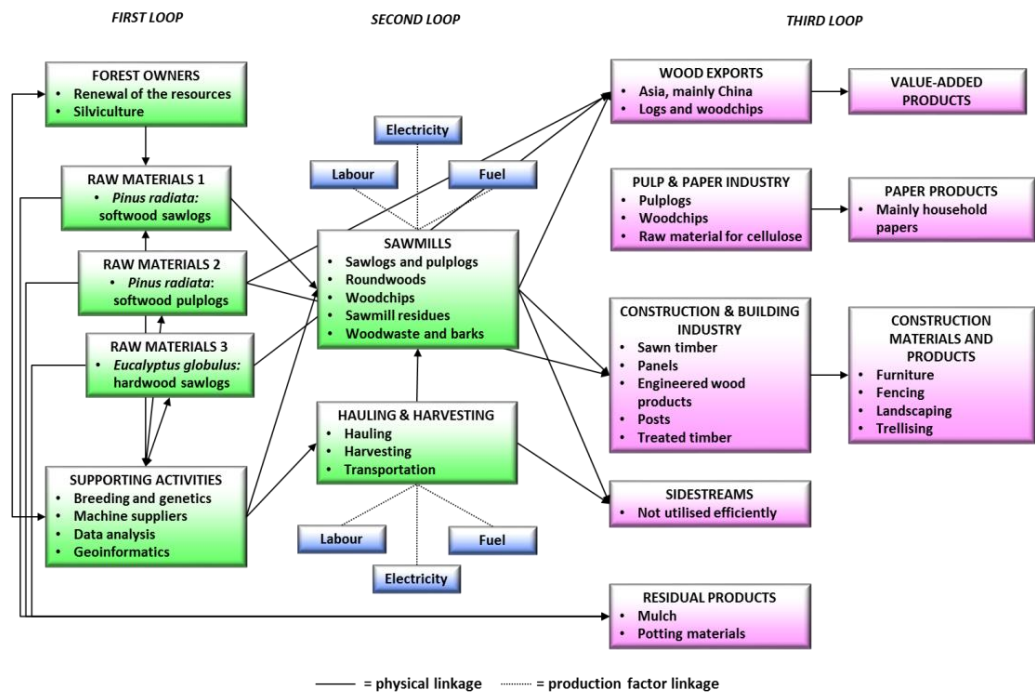

Figure 8: Representation of the forest and wood products industry value network in the Green Triangle region. The shaded green colour depicts the key functions in the value network, the shaded purple depicts key output directions, and shaded blue colour designates key external inputs (Ahlqvist, et al., 2013a, p.70)

The actual wood flow in the green triangle is outlined in figure 9.

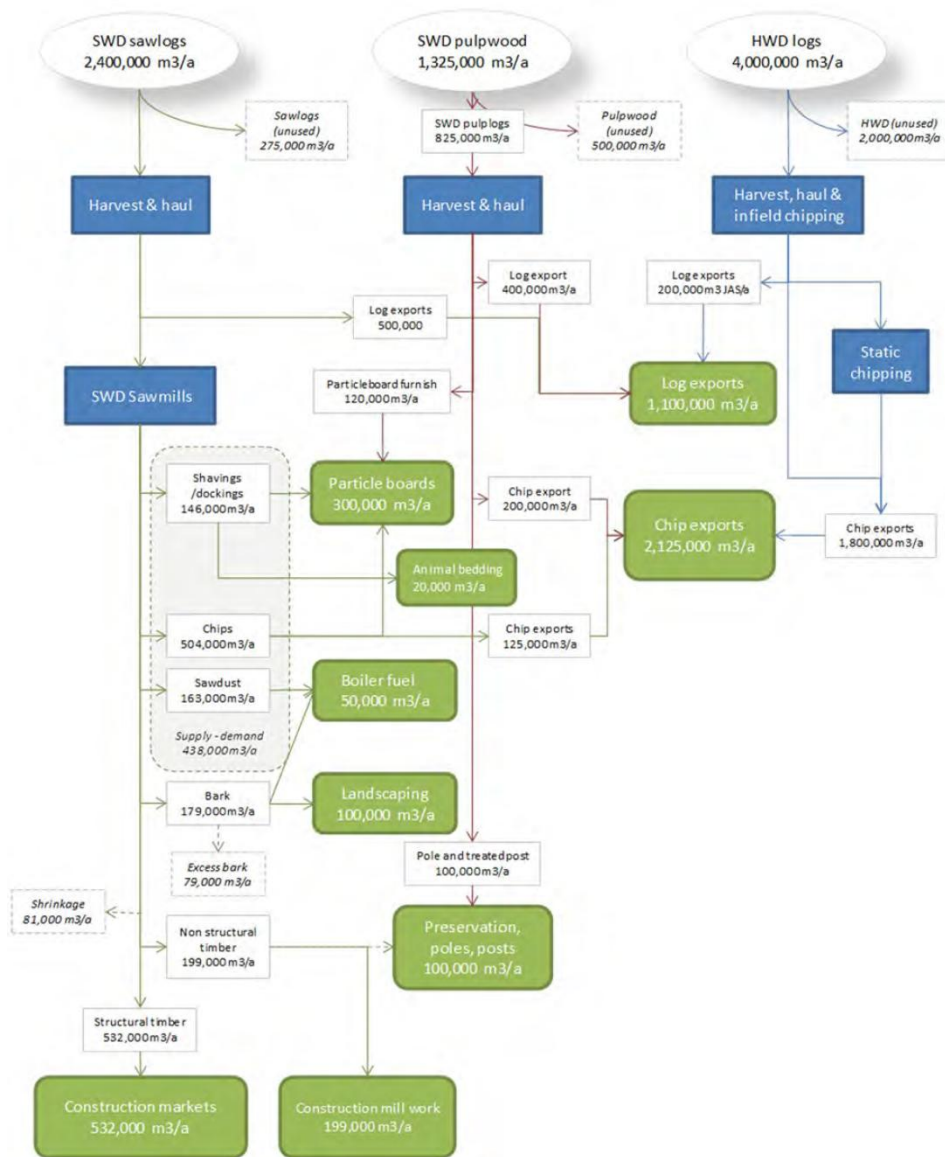

Figure 9: Wood and forest products flows in Green Triangle – current situation. Flows are presented in m³/a. White ellipses – feedstocks, Blue boxes – processing, Green rounded box – applications/demand, dashed boxes – balance/loss. (Ahlqvist, et al., 2013a, p.61)

The roadmaps using the four lenses that were developed in the project are shown in Figures 10-13.

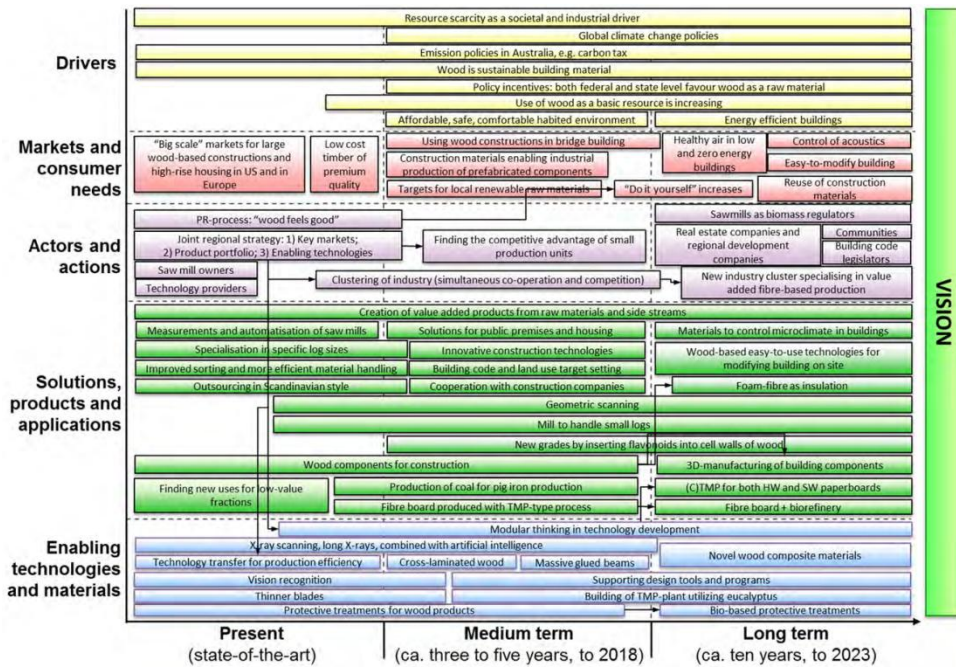

Figure 10: Mass lens roadmap: more efficient traditional forest industry (Ahlqvist, et al., 2013a, p.74)

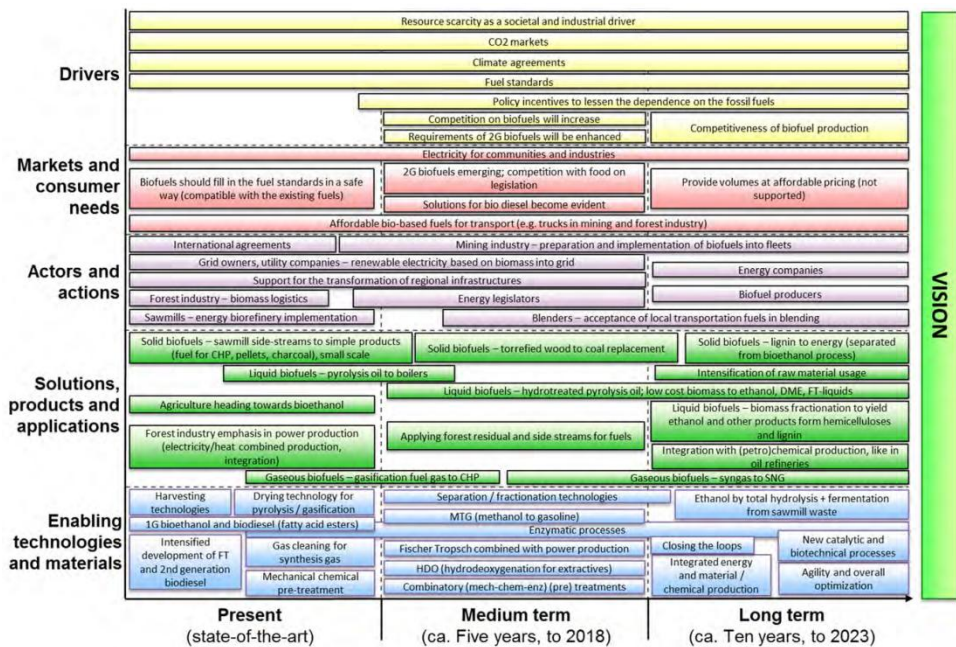

Figure 11: Energy lens roadmap: industry renewal through energy biorefinery (Ahlqvist, et al., 2013a, p.78)

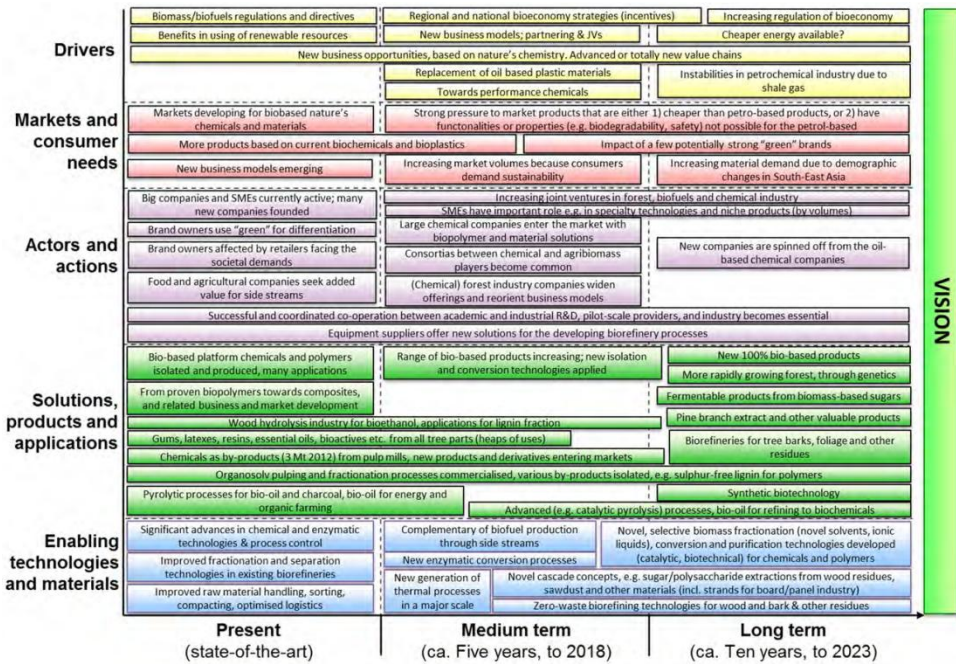

Figure 12: Molecular lens roadmap: radical industry renewal through diversified second and third generation biorefineries (Ahlqvist, et al., 2013a, p.82)

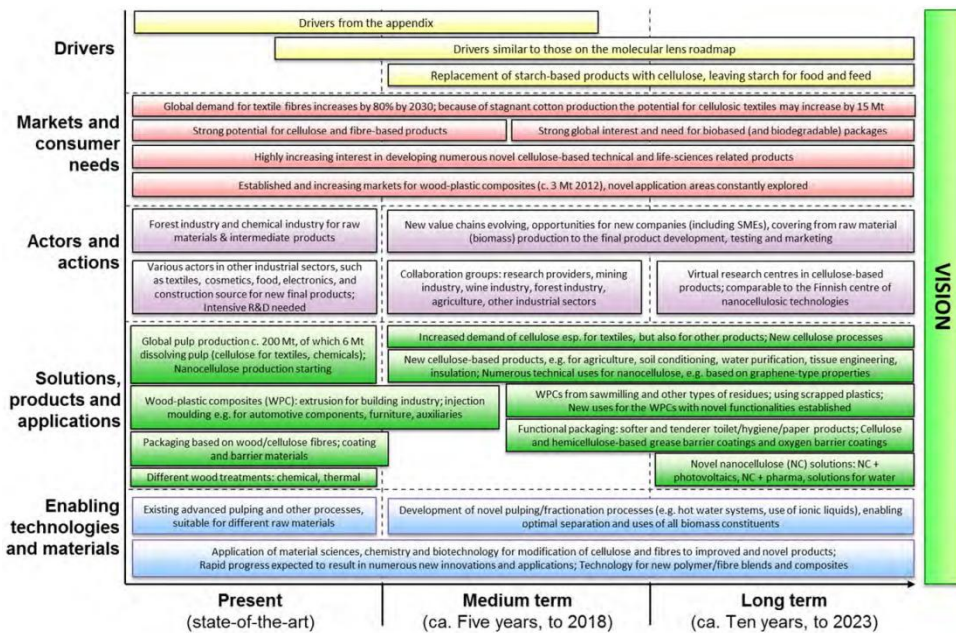

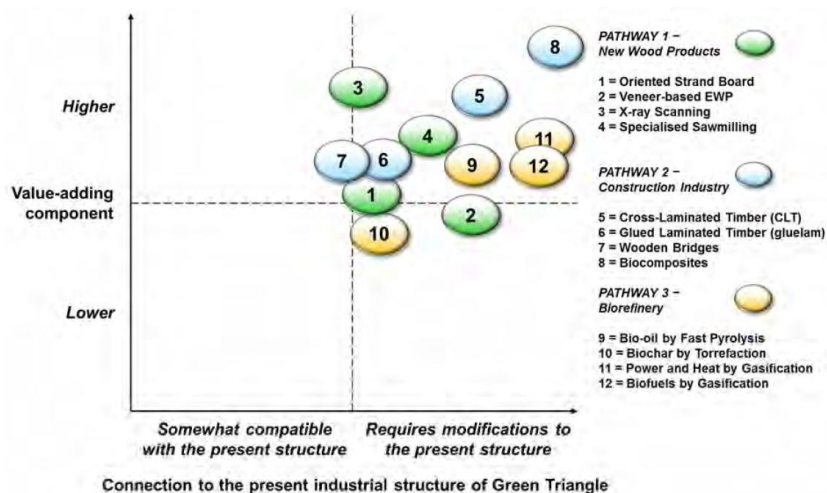

Figure 13: Atomic lens roadmap: radical industry renewal through new biomass and fibre-based production (Ahlqvist, et al., 2013a, p.86)

Grounded in the above four roadmaps a set of recommendations were provided. These are summarised in the table 3 and then in figure 14.

Table 3: Recommendations from the roadmaps with a 3-5 year time horizon (Extracted from Ahlqvist, et al., 2013a, pp.6-10)

	Mass Lens	Energy Lens	Molecular Lens	Atomic Lens
Action recommendations	<p>New wood products from underutilised Green Triangle log supplies:</p> <ul style="list-style-type: none"> • Oriented Strandboard (OSB) manufacturing • Veneer-based Engineered Wood Products (EWP) • Improved sorting and better yields by X-ray scanning • Specialised sawmilling (using smaller logs for sawmills) <p>Opportunities in construction industry using existing outputs:</p> <ul style="list-style-type: none"> • Cross-laminated timber (CLT) and high storey houses • Glued-laminated timber (Gluelam) • Wooden bridges • Biocomposites 	<p>Opportunities for underutilised wood fibre and residues:</p> <ul style="list-style-type: none"> • Bio-oil by fast pyrolysis • Bio-char by torrefaction • Power, heat and biofuels by gasification 	<ul style="list-style-type: none"> • Development of adsorbents and membranes for local opportunities • Cellulose fibres in textiles • Bio-based chemicals and polymers 	<ul style="list-style-type: none"> • Opportunities in nanocellulose

Following on from this a hypothetical future scenario was developed and is shown in figure 15.

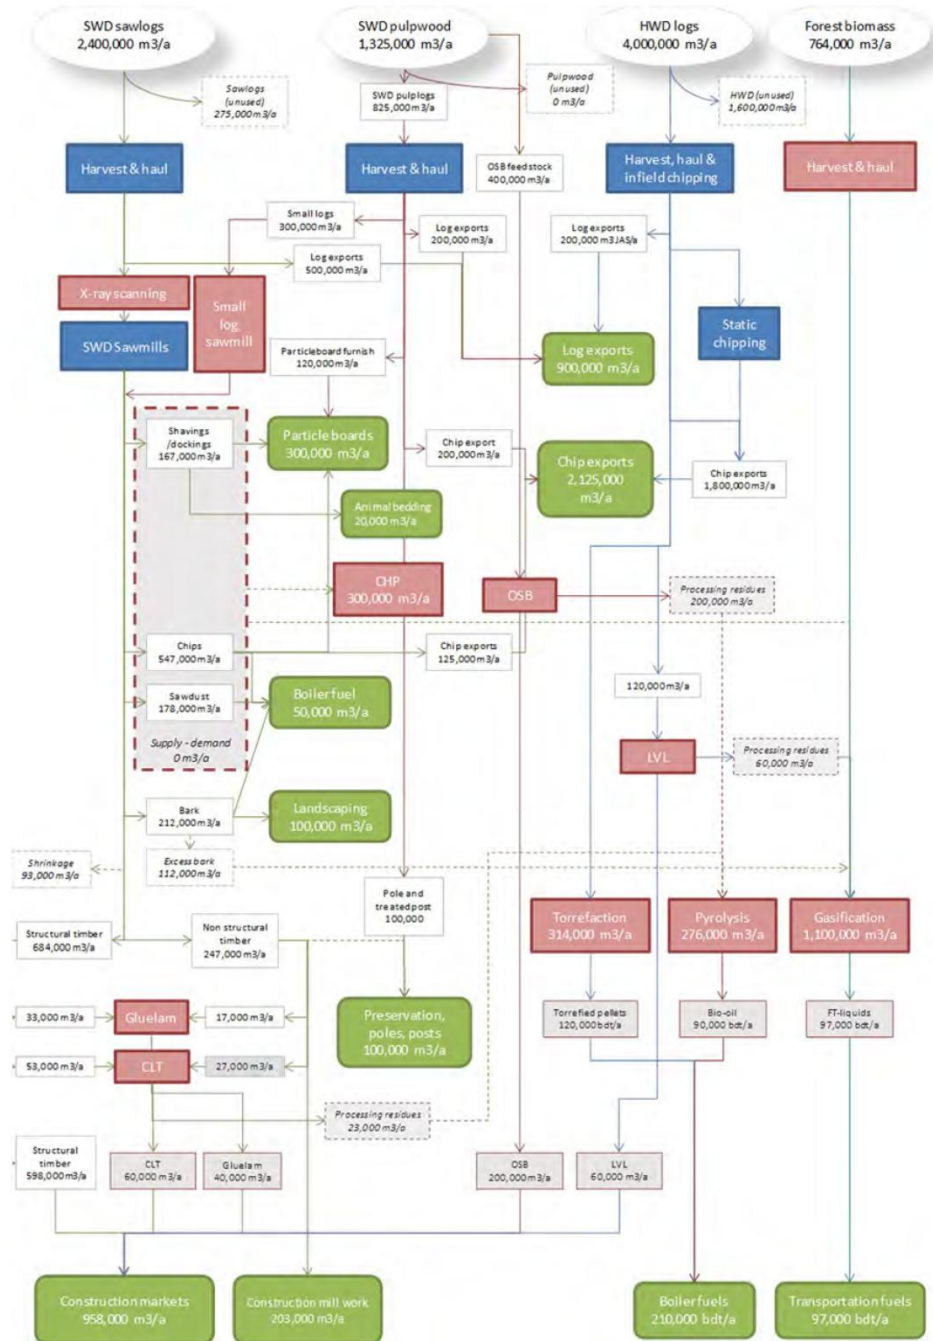

Figure 15: Wood and forest products flows in Green Triangle – hypothetical future scenario. White ellipses – feedstock, Blue boxes – processing, Green rounded box – applications, dashed boxes –

balance, Pink – new processes/product flows. X-ray scanning, small log sawmills, CLT, Gluelam, OSB, LVL, pyrolysis, torrefaction with pelleting and gasification plants implemented. HWD logs used for LVL production and SWD pulpwood for OSB production. All processing residues, excess SWD pulpwood, HWD logs and forest biomass used as feedstock to the energy biorefinery processes, totalling 2,000,000 m³/a biomass used in all biorefineries. Part of timber products is used for CLT and Gluelam production. (Ahlqvist, et al., 2013a, p.62)

4 Conclusions

The Strategic Roadmap executed in the South Australian part of the Green Triangle have through the actions initiated during the roadmapping process and following on from the roadmapping process generated a trajectory (in the form of a pattern in a sequence of actions) that is well aligned with that of a smart specialisation strategy:

The objectives of the strategic roadmapping project on the sectoral level were to enable entrepreneurial discovery of new opportunities that could maximise the value economic returns from the local cellulose raw material, either directly or indirectly.

The objectives of the strategic roadmapping project on the firm level was to minimise the information asymmetry between the firms in the region and global best practice in order to facilitate an entrepreneurial discovery process enabling differentiation of the product-service-system offered as well as the capabilities existing within the firm. In addition the project wanted to instil a mindset that would broaden the resource that the firm could put to use around the waste streams or expressed in the words of the Chair of the steering committee: “there is no such thing as waste – there is only raw material for which you have yet to find a value creating use”.

The objectives of the strategic roadmapping project on the industrial commons level was to provide an entrepreneurial discovery process that would be different across the industrial commons but would have an equally high commitment independent of the individual actor in the industrial commons.

The outcomes so far has been several instances of modernisation of existing firm activities by following the recommendation in, primarily, the mass lens part of the roadmap as well as in the waste use part of the roadmap. There has also been initiation of a sectoral transition by feasibility studies being initiated as well as external investment interest shown as relates to the other three lenses of the roadmap.

The objectives of the strategic roadmapping project on the regional level were to improve the broader linkages in the region as well as injecting a positive view of the future. This has been shown with a clear shift in tone from a negative, defeatist and non-

cooperative tone at the initiation of the roadmap project to one of positive, up-beat, can-do attitude that permeates the region presently. The project has also engendered interest among firms outside the region to potentially migrate or establish activities within the region. This interest is primarily in the more advanced domains identified through the mass, energy and molecular lenses. As the project progressed the interest in participating also grew as well as interest in continuing competence development around the relevant actors activities (e.g. competence development around business models on both the firm and the local government level). This has resulted in new synergies in the region that are showing early indications of new activities. Some of the inward investments will bring with them opportunities to enter new domains in e.g. the chemical lens of the roadmap.

All in all the project is judged, so far, to have been a major success which has made the state government decide to do similar exercises in other regions and other sectors.

Abstract

Cities are perhaps the most effective basis for innovation, as urban societies have well-established mechanisms of feedback, amplification, and selection to support creative production from their vast resources of human and intellectual capital. Throughout history, cities have been a natural pool of inventions and ideas. Especially in the case of social innovations, urban societies play a central role. This paper asks: How can inventions that originate from within a society effectively evolve into innovations for the respective society as a user and recipient? The model called USIP (“Urban Social Innovation Process”) put forward in this text defines “Social Innovation” from a comprehensively social perspective: it places society as an active player (inventor) already at the beginning of the process, and then introduces “innovation adolescence” and “diffusion” as subsequent key mechanisms. The paper shows central deficits of innovation discourses due to their limitation to economic processes, and how in favour of market absorption, social absorption had been widely neglected. The article concludes with a set of hypotheses how urban social innovation can be empirically investigated in order to derive applications for urban and economic development.

Keywords – Social innovation, urbanity, innovation adolescence

Paper type – Research Paper

1 Innovation

From business to society

Innovation research has drawn some clear dividing lines, the distinction between economic, or business-oriented innovation and social innovation is one of them (Rogers 2003, Fontan et al 2004). Another distinction separates closed from open innovation approaches (Chesbrough 2011). Further there is the opposition of incremental innovation (continuous improvement of existing qualities and goals) versus "radical" or "disruptive innovation" (Christensen 2011), defining the latter as the establishment of fundamentally new qualities and values. In the search process for a contemporary innovation paradigm, the boundaries between these distinctions, however, blur and dissolve.

Business innovation. Classic economic and business oriented innovation theory has argued that only when creative idea ("invention") successfully enters the market it can be considered an innovation (Drucker 1993). On other words: When enterprises and entrepreneurs have established their innovation with users and customers and made it "socially acceptable" (Schumpeter 1991). In order to organize and optimize this process, innovation management was established and introduced to the corporate world. Key motivation for the implementation of innovation processes in companies and institutions was the strategic minimization of the risks and uncertainties of invention. The idea of innovation management, before all, attempts control over the creative process, and to make it an object of planning and organization. This idea has resulted in the well-known models of "innovation funnels" which tacitly assume that innovation is predictable, directed, and goal-oriented (Fig.1, left).

Fig.1 Left: Innovation funnel; right: Open Innovation (Source: H. Chesbrough, 2005)

Commonly, innovation funnels are characterized by a high number of idea input (inventions), the majority of which gets successively disabled through a cascade of systematic evaluation and selection ("stage gates") to eventually reach a certain goal: successful market entry (Cooper 1990). Certainly, a broad basis of ideas must be tested and assessed in order to accomplish a breakthrough innovation in the end. This basis is the creative capital or invention capacity of a company or institution in question. Here, the intellectual input may be provided by the genius of company leaders (one may call it the "Steve Jobs-Model"), the inventiveness of R&D sections ("Xerox PARC-Model"), or the collective creativity of employees ("3M-Model").

Open and User driven innovation. The newer so-called Open Innovation approaches bring the potential of larger communities into focus. They expand the creative base of the innovation funnel to larger "ecosystems" of the local or regional business environments, as well as to larger societies and networks (Chesbrough 2011; Hippel 2013). Open Innovation basically views the environment as an active agent for innovation processes. A larger innovation ecosystem forms when, for example, innovators do not refrain from emitting own (unselected) ideas to the environment, but simultaneously have the capacity to integrate "alien" ideas taken from the environment into their own practice (Fig. 1, right). This leads to two effects: 1) The basis, or creative capital, upon which innovation processes are set, is drastically expanded. 2) A fertilized, rich innovation environment is created which – just like the Silicon Valley – develops complex diffusion systems of intellectual products and property.

Problem 1: Overmanaging Innovation. Management concepts – including open innovation approaches – are still overestimated in their capacity to organize the pursuit of invention and innovation (Porschen 2012, Hermann et al 2007). Studies of R&D in business practice have shown that without any management self-reliant and self-governing innovation processes may emerge that are highly effective. What is more, research on user-driven innovation has demonstrated that apart from developers and producers, customers and end-users themselves possess effective invention potential which may be activated through "participatory design" (Hippel 1995). The user's recognition of inoperability, system weakness, or design failures makes them a rich source for new solutions (Fricke 2009). Innovations that emanate from personal experience are, however, difficult

to integrate into the narrow funnel of conventional innovation management (Christensen 2011). These findings, and many of others, indicate in sum the need for post-tayloristic work and business organization that go beyond the managerial thinking that has originated from mechanical industrial production (Pink 2010, Wolf 2011, Hage 1999, Burns and Stalker 1994).

Problem 2: Innovation as business. A second major deficit in innovation discourse was its limitation to the economic and business sphere. Targeting at market absorption of marketable products or services, other innovation goals and absorption processes had been neglected. To define economic survival as the major criterion of innovation ignores the possibility of innovations targeting at other kinds of public fora, before all their implementation in social realms like education, healthcare, or political systems (Rogers 2003). Eventually, the innovation discourse was extended when the notion of social innovation emerged, referring to new forms of human intercourse accepted and absorbed by communities, not markets (MacCallum et al 2009). Here, innovation success cannot be defined in economic measure; it rather relies on ethical terms and socio-cultural settings.

Social Innovation. Social innovation has been defined as the development and diffusion of new organizational forms of personal interactions that support the achievement of common goals (Mumford 2002). If coexistence within traditional social systems is frail, the inclination of social systems towards change rises and social innovations emerge as a necessary cultural development (Csikszentmihalyi 2007, MacCallum et al 2009). By now, much attention has been given to the different forms of acceptance and diffusion of social innovation; also the processes of implementation and absorption have been carefully described (Rogers 2003). Noteworthy is that the processes of diffusion and absorption are considered part of the general innovation process: Innovations and innovators cannot be identified solely on the basis of their creative work, but emerge only when improvements find acceptance in society.

Moreover, the process of innovation itself has become social. In the digital domain, open innovation was established as a collective practice by way of crowdsourcing interactive platforms and networks (an example is German co-innovation community Hyve, www.hyve.de). Here, the advantages of a broad idea input combines with the network and

marketing potential of a digital community. Close social interaction and feedback is possible, yet social innovation as “innovations for society” has become a business itself.

Convergence. There are convergences and correspondences of business innovation and social innovation. It is the acceptance at the backend of the process (market; society) that defines what an innovation is, and what is not. Also, the start condition is identical: Models of social as well as business innovation depart from a multitude of inventions to progress towards successful innovation. Despite such similarities, there are significant differences in regarding the organizational resp. managerial nature of the process in-between, the roles and numbers of the actors involved, and the scope of the involved environment.

The critical stage: Adolescence of Innovation

Studies in the field of Knowledge Architecture have indicated that the path from invention to innovation requires a period of “cocooning” that brings about social retreat, wild experimenting, and radicalization of concept (Diedrich et al., 2009, Noennig and Jannack 2013). To describe this critical transformative phase oscillating between ideation, social reflection and implementation, the notion of "Innovation Adolescence" was introduced (Noennig et al, 2014). In the context of social innovation, this period of radicalization and a-socialization but becomes problematic due to its profound disregard of social environment. To support and foster radical social innovation - despite its problematic “adolescent” nature – poses profound difficulties to most societies.

In the field of technology, the problem was solved by the notorious start-up garage: The garage-type setting is an environment that provides for maximum experiment and interaction among innovators, while staying in touch with society (Gridneva and Noennig 2013). Another solution has emerged in the creative industries: so-called co-working spaces establish micro-societies of free-lance knowledge workers, artists, and designers in urban hotspots, usually open to everybody to enter, yet with a special address towards the “creative class” (Brenn et al 2012b).

Both types – technology-based start-up garage as well as creative co-working space – usually do neither integrate with, nor depend on, the broad range of society. Although it is understood that information and ideas necessary for innovations may diffuse best in strongly networked groups, these are in turn often highly redundant. On the other hand, it

was demonstrated that open groups in turn have advantages in finding valuable ideas and information, yet they are less quick and effective in communication and exchange (Granovetter 1973). A remarkable finding on “social mobility” but shows a potential way out: The more people move between closed and open groups or societies, the higher the probability of successful innovation is (Ziemer 2013). Such dynamics are based to a large extent on emotional values and soft factors which are difficult to control or manage within organizations or institutions (Ziemer 2013). Yet there are other structures that naturally provide such qualities: cities.

2 Cities as Innovation Systems

Urban (social) innovation. Cities can be regarded natural innovation ecosystems. Although the ongoing process of urbanization is ever more associated with losses in life quality and the perception of cities as places of accelerated marketing and consumption (Lefebvre 1972), their creative potential seems unbroken (Florida 2006, Krätke 2012). Cities certainly differ in their inventiveness and innovation capacity. In urban history, there were pinnacles like Hellenist Athens, Renaissance Florence, or Paris of the 19th century: places of unmatched creativity and innovation. But any city is an astonishing device for the production of knowledge. Wherever people meet and live together, there will be an abundance of thinking and ideas; inventions will inevitably occur. In fact, with the population of a city its productivity and innovation increases, following scaling effects (Bettencourt and West 2010). The inherent dynamics, heterogeneity, and complexity of cities, plus their large number of actors and social interactions make them an excellent arena for invention and the diffusion of ideas (Jacobs 1992, Florida 2006). Yet for describing the crucial role of urban context for the emergence of knowledge there are few systematic analyses (Bettencourt and West 2010, Bade et al 2012). Despite the obvious capacity of urban societies to innovate on all kinds of levels, substantial innovation models were not presented until now. With the new demand for social innovation as a guarantor of balance, prosperity, and growth, urban society should be seriously taken into consideration as a central resource. It was in urban communities, before all, that social innovations have emerged, very often triggered by social disruptions (MacCallum et al 2009; Johnson 2010). But also here: the mechanisms how social innovation in urban societies diffuse and spread are far from being clear. The processes how they are broadcasted, accepted and absorbed remain vague. Clear is only that the emergence of social innovation

cannot be reduced to the inventiveness and personality of individual innovators or knowledge workers. Mostly it is the result of complex social dynamics and the self-organization processes of the population that is confronted with new demands of community life: social innovation in cities is “crowd-sourced”.

Enriched environment. Current attempts to describe the creative capital of cities assume an “intellectual matter” which is metaphorically spread over places of interaction and exchange (Krätke 2012). Environments with such enrichment are characterized by qualities such as serendipity, impulse density, high tolerance, variety of spaces and technological affordance (Florida 2006). The very potential of creative cities lies in the evolution and promotion of intellectually enriched environments, in the generation of knowledge from the collaboration and co-learning of crosslinked knowledge workers. The interplay of actors and activities across different spatial, organizational, and value levels is conditional for vital innovation ecosystems (Gridneva and Noennig 2013).

City as amplifier and trigger. Creative invention as the initial step towards innovation is a complex learning and synthesis process which interweaves private and personal experience with external knowledge (Csikszentmihalyi 2007). In the urban context, intensified exchange thus leads to accelerated idea sophistication and innovation (Bettencourt and West 2010). The social transfer of ideas works like an impulse trigger: Upon stimulation, associations, alternative views and opinions will be quickly evoked in a number of people, which in turn will add evolutionary momentum. Social innovations will be adopted and accepted, if there exist a shared knowledge base and social agreement, common interests and goals of the group. The dynamic distribution of “memes” in peer networks and local cultures (Csikszentmihalyi 2007) can quickly establish communities of “early adopters” (Rogers 2003) based on the oral spread of reports, on personal contact, and trustworthiness. Here, (common) sense may play a more important role than technology (Fontan et al 2004). As a common indivisible property of a community, a commons, this shared understanding creates a sense of place, a local quality that is difficult to transport and transfer – it is atmospheric (Brenn et al 2012a). These effects, however, have clear spatial dispositions.

3 USIP – The Urban Social Innovation Process

Model

Aiming for an instrument to investigate how social innovation emerges and spreads in the urban realm, a new model will be proposed: “Urban Social Innovation Process” (USIP). A derivative of established innovation models (“Innovation funnel”) and above mentioned arguments, it defines social innovation not from the back-end of the innovation process, i.e. when innovations have successfully arrived in society. Instead it takes account of the specific nature of cities as condensers and multipliers of human interaction, thus becoming the very generators of social inventions and ideas. The model revolves around the condition of “innovation adolescence”, which had been identified before as the critical point in social innovation processes.

In Fig. 2, the marks A, B, and D describe the three general phases of the USIP, whereas marks C and E specify the crucial relationship between innovators and society.

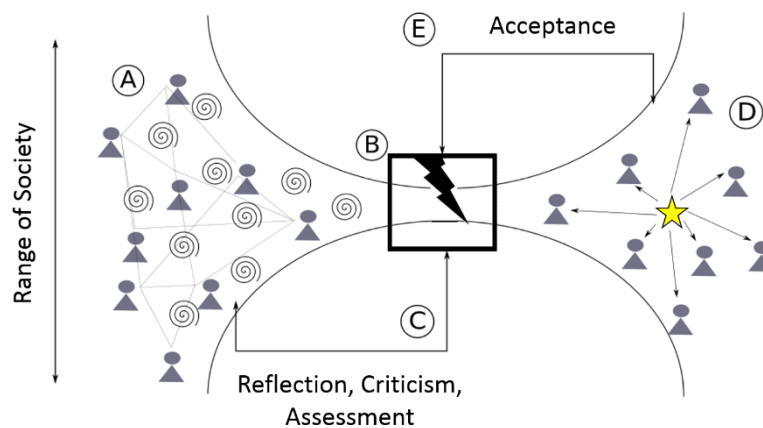

Fig.2 Urban Social Innovation Process (USIP)

(A) Social invention. From actual needs within a community or society, embryonic inventions emerge that reflect cultural, technological, and social disposition. In a way of informal bottom-up creativity, a multitude of ideas appears as a by-product of urban society dealing with problems, needs, and demands. If they have relevance for the community, the primordial inventions become an “issue” of social interaction, awareness, and scrutiny. Through socio-urban processes of mutation (“Chinese Whisper”) and selection (“Hyping”) they may further evolve, or get terminated.

(B) Adolescence. Social innovators pick up inventions with high potential of social or economic acceptance, and develop them further on their own risk and responsibility. Here they enter the critical phase of "Innovation adolescence": in order to mature the concept and its application, certain retreat and detachment from society is necessary, which had been the originator of the invention though.

(C) Social feedback. In the phase of "adolescence", social inventions better survive their "valley of death" before becoming successful if they keep in touch with their social ecosystem. The contact is an essential: Being beneficiaries of society in one way or another (e.g. as scholarship recipient, alimented family member, or accepted crazy neighbour), the "cocooning innovators" are depending at least for a while on the structures which they possibly intend to change.

(D) Social innovation. If a new concept successfully breaks through (i.e. gets adopted and spread throughout the community) it can be considered a successful social innovation. From many inventions for a few (innovators), finally an innovation for many has evolved. The innovation for society has become social itself: this is before all a matter of acceptance.

(E) Social Preparation. Likewise the community plays an essential role as it comes to the acceptance of the innovation "under construction". In order to prepare a soft roll-out for the resulting innovation, diffuse social processes of absorption e.g. "hearsay", "word-of-mouth" are instrumental to spread the innovation through the immediate environment; they activate the essential processes of peer-communication and early-adoption.

In order to clarify the problematic adolescence phase within the whole process, a simple graphic transformation is telling (Fig.3). Assuming that in the case of genuine social innovation (inventions from society develop into innovations for society) the originator of the multiple social inventions is at the same the recipient of the final innovation, the left and right pole of the diagram above (Fig.2) coincide: it is the same people, communities, or societies that are involved on both edges. This sets the central "adolescence"-phase of the USIP drastically aside: the social entrepreneur becomes an outsider, and social innovation is systematically marginalized.

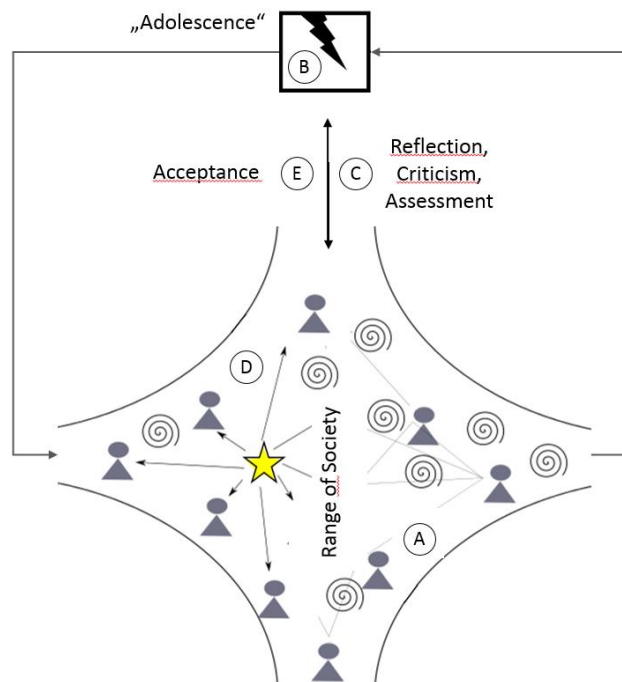

Fig.3 Transformed USIP scheme: Detachment of "Adolescent phase"

Hypotheses

In accordance with above-mentioned key elements of the USIP scheme, a number of hypotheses can be stated that allow empirical testing of the model and of the concept of "Innovation adolescence".

(1) Urban society is a "natural" innovation system. Even without explicit innovation targets, urban societies run iterative mechanisms for the development and diffusion of (social) innovation. Social processes of interaction and invention combine with critical reflection, evaluation and selection. Moreover, there are effective mechanisms for the diffusion and multiplication of innovations. These coupled mechanisms can be identified and descriptive variables be established. Urban factors like impulse density, heterogeneity, or tolerance impact on the inventive capacity ("creative capital") of cities.

(2) Urban society possesses a broad invention basis. Existing models of innovation ignore urban society as one of the richest pools of ideas. Inventions are continuously generated within the whole range of society. Citizens as users of tools, systems, and envi-

ronments are predestined to be the first improvers to these items themselves. Just as inventions can be harvested and collectively refined in internet communities with crowd-sourcing approaches, urban communities too form a reservoir of “crowd” creativity for which suitable platforms shall be devised.

(3) Social innovation needs withdrawal from society. In the case of social innovation, the phase of “Innovation adolescence” demands withdrawal, radicalization, and experiment. The pursuit of social innovation necessitates a-sociality, at least for a period of time. For social entrepreneurs, in order to process social inventions towards accepted innovation, temporary retreat is needed.

(4) Adolescence of innovation demands embeddedness. The retreat of social innovators, paradoxically, should happen within society: subtle connections (“weak ties”) are to be kept to the community. Certain kinds of urban environment provide appropriate free-zones while still being close to ordinary urban society. Invisibility is a key quality for the temporary withdrawal within the community, thus allowing radical experimenting while being “inside”.

(5) Acceptance depends on place of origin. Social innovations are more readily accepted when their basic inventions originated from the same community. Urban societies as critical recipients of social innovations, decide about appropriateness by reflecting about the innovation’s place of origin. That implies that innovations cannot be easily transplanted or transported between different urban contexts. Urban society implements concepts more easily if they are place-responding. Good innovations are likely to occur where they are due – and they are better fit to places where they occurred. Social acceptance needs embeddedness within the overall process.

4 Outlook

The USIP model and its associated hypotheses explains how creative knowledge gets “extracted” from, and applied to urban communities (“crowds”). It sketches the urban environment as a powerful generator of socially applicable ideas, inventions, and innovations. In practical application, the model supports the identification of “natural incubators” which realize participation as a core element not only for social welfare and communal life, but also for the economic development of “knowledge cities”. Thus, the concept hints at a long-term innovation policy– in contrast to existing support practices

which often are too focused and only kick-in in the late stages of the innovation process. Future research shall outline the appropriate processes and places that effectively translate the creativity of urban population into implemented social innovation.

Abstract

Presenting findings from a knowledge management project in a German science-to-engineering research cluster, the paper addresses issues of cluster formation, cooperation, and innovation. In the project, a novel knowledge management approach was developed that stresses activity from within the organization (“Embedded Knowledge”), and combines scientific expertise with strategic-methodical knowhow (“Synthesizing Knowledge”). Integrating measures of knowledge and innovation management and technology transfer, a “Knowledge Architecture Toolbox” was set up and applied. The project not only serves as a case-study for the idea transfer from basic research to engineering, but also presents a prototype for design-oriented knowledge management in large science and technology clusters.

Keywords – Cluster, embedded knowledge, knowledge architecture

Paper type – Practical Paper

1 Background: Cluster Formation

As a reaction to increasing complexity, uncertainty, and competition, the formation of clusters has become a general trend (Bathelt et al, 2004). Large-scale projects, in most cases, lead to large-scale project consortia. In science, technology, and economy alike, organizations tend to transform into extensive alliances in order to increase their competitiveness, to utilize synergies, and to pursue their strategic and operative goals (Gulati, 1999). The formation of clusters is due to an “epigenetic” disposition: the fierce innovation race between institutions, regions, and nations triggered by networked and globalized science and technology. For maintaining public financing, political support, or just a voice in the scientific community, “critical mass” must be built up; organizational bodies are urged to grow, to fuse, and to accumulate momentum (van Hemert et al, 2013). Often

stipulated by economic policy making, the core motivations include administrative synergies, sharing of information and technology, as well as the acceleration of high-level knowledge production (Krätke, 1999).

For the formation, management, and termination of clusters, however, appropriate strategies are rare. This is due to fast changes in science and technology, but also to project partners themselves being already highly differentiated organizations. In effect, the management of cluster cooperation has become an issue of growing importance throughout the past years; the demand for appropriate concepts can be clearly sensed (Landsperger and Spieth, 2011). – A knowledge management project for a German science-to-engineering research cluster provided the opportunity for a case-study and systematic inquiry.

2 The Case

The cluster in case consisted of several hundred scientists, organized in ~ 15 research teams with a total >100 scientists, plus management group. Distributed over different locations but still in geographical proximity within a German city of 500.000 inhabitants and rich science and technology environment, it bundled groups from ~10 public research institutions (university, non-university). In terms of environment, this setting was in ideal accord with conditions necessary for the well-functioning of science networks (Boschma, 2005). In terms of content, the cluster was formed to boost interdisciplinary cross-scale research in engineering and natural sciences, and to establish direct links to industry. As its research outcomes have high relevance in terms of application in high-technology fields, the cluster received massive public funding.

In order to facilitate intra-cluster cooperation and knowledge exchange, a special knowledge management team of 4 to 6 people (“Knowledge Architects”) was established and associated to the central management group for nearly two years (Fig.1). The university-based team itself was of interdisciplinary composition, including natural scientists, computer scientists, architects and designers.

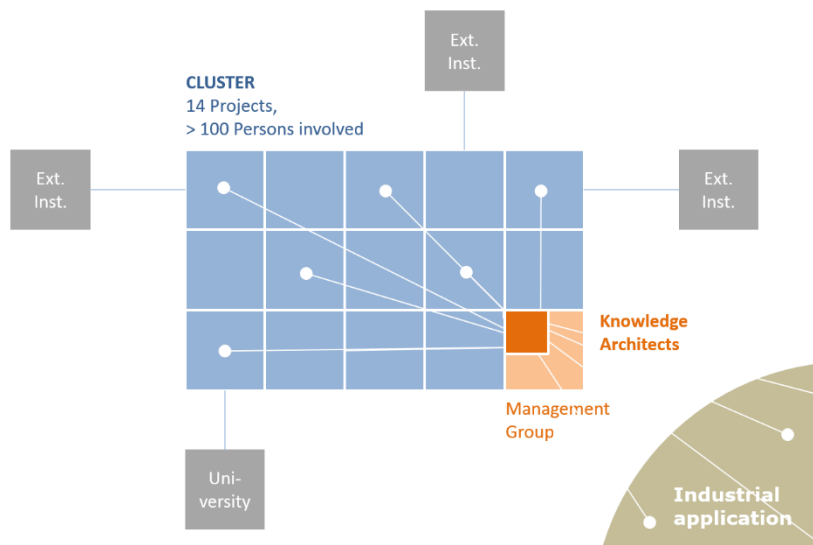

Fig.1 The cluster, management group, and Knowledge Architecture team

The Knowledge Architects could draw from previous experiences in technology management and cluster cooperation projects, ranging from small-scale creativity workshops to joint product development of high-tech consortia on national level. There, agility concepts (Pichler, 2010), Open and user driver innovation (Rass et al 2013; Hippel, 1995; Chesbrough, 2011), ideation and design thinking approaches (Brown and Katz, 2009) had been tested, among others. These practical consultancy experiences provided a basis for long-term meta-research on cluster formation and cluster cooperation, resulting in a number of studies and new concepts. In a previous project, the model of semi-open innovation was developed, featuring a small “impulse-team” that co-develops with a “crowd” of scientists and technologist ideas towards innovative marketable products (Gräning et al, 2013). This model provided the methodical basis for the project presented here.

3 Dynamic Perspective

When commencing work for the science-to-engineering cluster at stake, it had to be clarified how the team’s activity would differ from existing services. A number of public and private agencies existed in the immediate environment, committing themselves to technology transfer, innovation, and science management. The point of distinction became clear upon raising a question that commonly occupies science and technology managers: How deep shall knowledge management immerse into its object of work? In other

words: How much expertise is needed for the scientific content of the consulted projects?
The discussion can be broken down to two opposed arguments:

- **The expert argument: Entering the Ivory Tower.** From an expert perspective, in-depth knowledge is necessary to understand demands, context and culture of the researchers and their projects – especially as it comes to high-technology. In order to communicate with advanced scientists, elaborate scientific knowledge is due. Superficial expertise leads to defective results. This argument supports the tendency to entitle experienced scientists for management duties, i.e. to manage from scientific perspective. This, in turn, brings about narrowing of perspective and focus, as scientific thinking tends to be specific, not strategic; problem- and not project-driven.
- **The manager argument: Highflying bird.** On the other hand, knowledge managers argue that a structural and strategic perspective is needed, a more general view on the multiplicity of activities and projects to be coordinated. Too much detailing distracts from the general direction and the bigger picture. This however, leads to unspecific and abstract concepts which may fall victim to “concretization dilemmas” solutions that looked plausible in a larger prospect (“birds eye view”) turn impossible when touching the ground of reality, i.e. scientific research (Rescher, 1998).

Established forms of knowledge management will either act from within, or from above. The “Ivory tower” can hardly coincide with the “Highflying-Bird” at the same time. A combination of both seems impossible if not a kind of zoom-in/zoom-out method is found that quickly changes perspective from high-above to deep-inside (this is perhaps best known from Google-Maps, which brings new information into scope when zooming in). Addressing this problem, a dynamic perspective was developed by the Knowledge Architects in reference to “classical” architecture as a discipline that creates abstract and highflying concepts on the one hand, but turns concrete and matter-of-fact on the other. Perspective shifting became the core element of the team’s cluster activities.

4 Embedding Knowledge

Perspective 1 takes an inside view; it is based on the idea of embeddedness. The Knowledge Architecture team was established within the cluster with the clear ambition to acquire expertise on the scientific projects. While preparing for interviews and focus-talks, intensive studies were conducted in order to become “communicable” to the experts, and to gain an inside view of their topics. Certainly, exchange on eye-level was not achieved: nobody becomes an expert for 15 highly advanced fields of research within half a years.

Instead, this basic scientific training proved a powerful move on interpersonal and psychological level. Scientists, who tend to be sceptical about management issues impinging on the scientific logic of their projects, clearly notice when efforts are taken towards understanding their issues and concerns. As a matter of trust-building and accommodation, a productive attitude and atmosphere easily appeared which stimulated scientists to simplify their explanations to a degree that they became useful also for knowledge management concepts. The tiny movements on both sides provided for encounter, not unlike political or business negotiations. Both sides moved: the management team to some level of scientific understanding, trying to embed itself to a certain degree in the research projects; the scientist to a level of general abstraction. Thus, small but effective interfaces emerged which originated in turn new projects and developments.

5 Synthesizing Knowledge

Perspective 2 clearly takes a meta- or bird-eye position, due to the overall task of the project. The endeavour could be compared to work in a chemical laboratory. Analysing the core substances of the individual research projects and breaking them down into small compounds of knowledge (“molecules”), subsequent syntheses were attempted eventually. New combinations of knowledge had to be generated and tested with scientists and technologists, ideally to a state of marketability. Once new compounds of knowledge were created, extensive assessment and profiling followed up. Due to the ambitious goal of spanning the whole “production lane” from idea generation to industrial application, three major components had to be combined:

- Knowledge Engineering: In order to stimulate communication and exchange of knowhow between the different research groups, and to recombine their knowledge, in-depth surveys of the on-going projects and structured interviews were carried out, creating the input for a digital data base. For the active recombination of these “molecules”, a matching algorithm was developed.
- Innovation management: In order to develop fresh ideas and research projects, intensive brainstorming was carried out, supported by modelling and visualization techniques. The Basis for these “idea talks” were combinations of existing research results, carried out either digitally by the “matcher”, or by human “wetware”.
- Technology Transfer: In order to identify and promote findings towards industrial application, an expansive market matrix was created to assess the transfer and market potential of the respective findings. For high-potential projects, active promotion with industrial partners was undertaken and a strategy developed for back- and fore-propagating ideas to, as well as from, the market.

6 Results

For putting the above mentioned elements together, a “synthetic” approach was applied which demanded genuine architectural thinking. As the Knowledge Architecture team included members that were indeed educated in architecture and design, a comprehensive toolbox could be developed way beyond conventional management tools and methods. Completely new instruments and methods were invented, or existing tools re-configured, including visualization and diagramming techniques, infographics as well physical models (Fig. 2). The new tools not only discovered existing yet dormant cross-connections between the researchers and their activities, but also effectively supported the generation of new ideas and projects

Fig. 2 Competence radar “Matcher” (left);
Physical and digital concept modelling “Project cosmos” (centre, right)

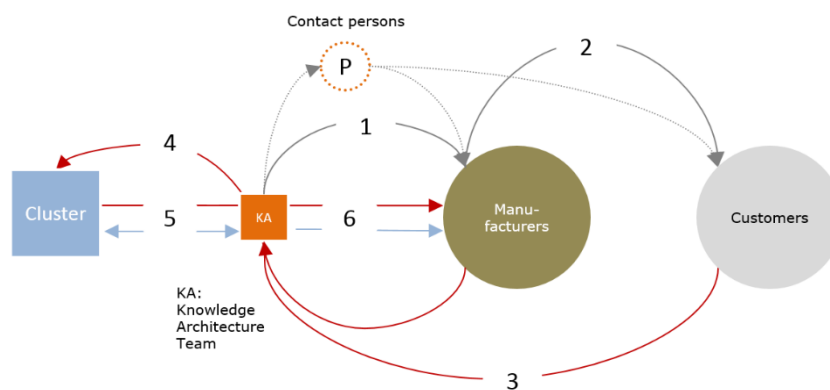

Fig. 3 Marketing strategy: Back- and fore-propagating ideas from / to market

The core result of the project, however, is a formal framework that cross-connects all stages of scientific research and technological application. Key is the careful mapping both of market demands (“properties of products and applications”) as well as of scientific projects (“properties of research items”). The essential ontological link “properties” is the key parameters for the translation of market language into science language, and vice versa. On this basis, a marketing strategy for scientific ideas could be developed and applied for some of the generated projects (Fig.3).

An interesting side-effect of the project was the discovery of new role-models for knowledge managers, for instance as “go-between” for partners inside and outside the cluster. Due to the group’s overview and insight into ongoing research projects in the cluster and related institutions, strategic knowledge was built up that attributed a natural “connector function” to the knowledge architects even beyond the boundaries of the cluster. Metaphorically, the team acted like “bees” in an ecosystem, transporting tiny yet fertile bits of information between various partners and parties. Sometimes the team itself was not aware of this function, or role. The transported “gifts”, however, immensely con-

tributed to the effectiveness of encounters: they easily built up trust, expectation, and commitment among the scientists.

7 Outlook

Foreseeably there will be no unified, or general strategy for knowledge management in science or high-technology clusters. Any large-scale research consortium develops its distinct organizational behaviour which must be carefully investigated in order to be understood and addressed. That implies design-oriented knowledge management: instead of recipe-like, replicable approaches, “fresh” creation of custom tailored strategies becomes a key issue. The prototypical toolbox developed in the project supports the customization of such strategies. By its method of embeddedness, not only the pursuit of cooperation between scientists of different fields is supported, but also institutional strategy-building, policy making, and the development of organizational culture in research clusters.

Abstract

As an extract of an ongoing cooperative project of Wrocław University of Technology and TU Dresden, the paper explores the emergence of innovation and asks whether innovation can be to any extent predicted spatially. Cellular Automata (CA) have been chosen for this study as the spatial modelling tool. The goal is to understand the nature of the spread of innovations in a limited space, and to equip the CA with information needed to calibrate it to actual, real-world processes. The CA spaces are formed by cells with specific characteristics concerning their absorptivity, or attractiveness for innovators. In addition, information is given how the agents behave and act depending on the nature of their innovation.

Purpose – The final goal of the research is to examine the possibilities of forecasting the appearance of innovations with the use of spatial, architectural, and economic data.

Design/methodology/approach – Cellular automata were created and tested. As input, categorised data of selected entities were gathered and organised into a matrix. The CA were calibrated in order to recreate the historical processes described in the antecedent research.

Originality/value – The assumption of the study is that well-calibrated CA can model real-world knowledge diffusion processes with acceptable precision. This methodology allows for credible – numerical and spatial – estimation of the likelihood of the appearance of innovation inside a specified branch of economy and inside a specified area.

Practical implications – As a starting point for extended research, the study wants to establish a scientific basis for knowledge and innovation-based spatial planning, having implications for economic development, urban management, and policy-making.

Keywords – Innovation, Knowledge diffusion, Cellular Automata, Environment

Paper type – Academic Research Paper

1 Introduction

Cities evolve constantly, but only few urban areas manage to develop an innovation culture that accelerates social and economic evolution eminently that substantial advantage in the global competition is gained (Florida 2008, Krätke 2012). Examples for urban areas with immense magnitude of innovation have been New York at the beginning of 20th century, or the Japanese Megapolis after WWII. Here certainly scale mattered (Bettencourt et al 2007), yet the innovation capacity of cities is not only depending on size. Below the megacity scale, the Boston-Cambridge area, the Silicon Valley, or the Basel region in Switzerland-Germany-France may provide prominent contemporary examples.

On that background, knowledge research has commenced to investigate spatial features and the geographical dispersion of ideas and innovations (Rogers 2003, Krätke 2012). From an analytical point of view, a central question is how the emergence and spreading of innovations can be properly measured (Scharnhorst et al 2012). From a perspective of urban planning and development, in turn, the question is whether the emergence and growth of innovations in urban realms can be predicted and conditioned. In order to address this obvious desideratum for planners, local authorities, and investors, the paper presents an ongoing study on the mechanisms of innovation emergence and diffusion in urban environments.

2 Relevance and Background

To understand the mechanisms of knowledge generation and transmission is a key issue in the context of the so-called ‘Knowledge Society’ (de Solla Price 1963). It is similarly important for contemporary economy that is increasingly knowledge-driven due to accelerating innovation cycles, globalization, and information and communication technologies (Marx, Gramm 2002). General insight is needed how ideas, inventions and innovations emerge and spread, be it in smaller collectives (e.g. work teams, learning groups),

or in larger societies (enterprises, schools, cities). In response to this demand, Knowledge Management (KM) and Knowledge Engineering (KE) have emerged as new disciplines with a range of applications, e.g. in science and technology clusters, in R+D facilities as well as in learning institutions (Drucker 1969, Senge 1990).

2.1. Knowledge Dynamics

In current discourses in Knowledge Management, notions like ‘knowledge transfer’, ‘diffusion’, ‘spill over-effects’, and ‘serendipity’ have become key concepts (Rogers 2003). They not only indicate the subtle dynamics behind knowledge work, but also the fact that knowledge is being processed by actors (e.g. knowledge workers, innovators) in spatial resp. environmental settings (Nonaka and Konno 1998, McCallum et al 2009). These may be physical spaces (e.g. buildings, campuses, cities) as well as virtual environments (e.g. networks, online communities, platforms). Case studies and statistical investigations have given empirical evidence for the connection of the above-mentioned knowledge processes with their contextual settings, both on small and larger scale (Boutellier et al. 2012). As one result, the new field of knowledge mapping has come into existence. Its aim, among others, is the dynamic mapping of knowledge processes, i.e. the diffusion, spreading, and transmission of knowledge in space over time (Scharnhorst et al. 2012).

Yet, the majority of current attempts in representing knowledge dynamics in space are limited to static maps and statistical schemes of distribution. Most methods are based on data collected in retrospective, and if models are formulated, they are derived from statistical correlation and probability. Based on the “soft” methodology of social sciences, the models’ power of explanation and practical (purposeful) application is limited – they do not allow a priori investigation or forecast. There are few spatial models of knowledge dynamics which can be rigorously studied and tested by inductive simulation. Arguably, this deficit is due to lacking insight into the micro-processes of knowledge generation and diffusion. It is the key parameter ‘knowledge’ which itself remains obscure and vaguely defined, and thus obstructs research on its evolutionary mechanisms. Most definitions of knowledge are based on indexes e.g. publication rates or patent registrations. They acknowledge the results of knowledge work, but give no account of the generative processes of knowledge itself. This diffuse notion of knowledge may explain the lack of sophisticated models for knowledge dynamics in regards to the environment.

Taking into consideration recent advances in the neurosciences, but also well-established concepts in science studies, cognitive psychology, etc., it is surprising that only few concepts on micro-processes of knowledge have entered the discourse of Knowledge Management and Knowledge Engineering. Among the more elaborate models of knowledge dynamics in regards to environment certain approaches from Japanese researchers (Nonaka and Konno 1998) deserve attention which adopt the concept of implicit (tacit) knowledge (Polyani 1966) to organizational as well as to spatial environment. These concepts are interesting for they acknowledge the nature of knowledge as procedural-dynamic, and also because they underline the importance of implicit knowledge. With the concept of 'Ba' (place) reference is given to environmental factors, as implicit knowledge must be understood as being environmentally conditioned to large extent.

2.2. Knowledge Diffusion

The phenomenon of diffusion can be viewed from two perspectives. One view differentiates expansive diffusion from relocative diffusion, while the other juxtaposes contagious diffusion and hierarchic one (Zipser 1983).

Expansive diffusion only transfers the idea or phenomenon to another point in space. A simple example may be mailing between people, which is clearly able to transmit ideas. *Relocative diffusion*, on the other hand, requires a material carrier of an idea or phenomenon to be physically moved in order to spread. This type of situation applies for instance when a teacher or messenger meets other people and introduces new thoughts or modes of behaviour to the travelled area. Relocative diffusion may also involve machines or other objects, whose implementation in a new place equals the introduction of a new idea there.

Contagious diffusion describes scenarios in which the spread of an idea or phenomenon is continuous in geodetic terms or, in other words, covers an area more or less gradually. This can be imagined by way of weather reports, most notably in times of a change of atmospheric fronts. Finally, *Hierarchic diffusion* stands for a "leaping" idea or phenomenon, i.e. for situations where the spread is punctual. This may be observed with ideas that are carried between particular places in space and/or particular groups of people, e.g. academics, artists, followers of a religion, or generally focused groups with shared interests.

The four types of diffusion most frequently overlap and mix and are not necessarily easy to distinguish. That is especially true for urban conditions, where the multitude of

persons and interests, the differences in world view, and the times of globalisation make the tracing of the spread of ideas much more difficult.

Also, the four stages-concept of innovation spread (Hägerstrand 1953) provides a noteworthy model. The concept distinguishes following sequential phases:

1. Penetration (stage prior to the proper innovation);
2. Diffusion (spread of the innovation; creation of links);
3. Condensation (continued growth of the innovation on the area of diffusion);
4. Saturation (final stage; end of spread of innovation).

Further, the theory roughly matches the four stages with four types of users or participants of innovation: Innovators, Early Majority, Late majority, and Laggards. In Figure 1 the blue line represents the estimated average distribution among the groups (with innovators being treated as highly original and few in numbers, and with a mid-group of early adopters added). The orange line marks the cumulated market share taken by the idea/phenomenon, in other words: its success rate.

Fig. 1 Four types of users or participants of innovation (Hägerstrand 1953)

2.3. Knowledge Diffusion in Urban Environment

An indication that environment influences innovation processes and knowledge work comes from the fact that innovators of one discipline look for different local conditions than innovators of another discipline (Fontan et al. 2004, McCallum et al 2012). This choice is possible only in cities: The various urban environments form a variety backdrop

for innovation and knowledge work (Gridneva and Noennig 2012); they establish a kind of “creative matrix” that functions by mechanisms such as:

- Socio-spatial concentration / dispersion
- Co-operation between various types of innovations res. Innovators;
- Inhibitions of innovation activities;
- Successive generations of innovations.

Eventually, the recognition of the complex interplay of knowledge work processes (ideation, invention, innovation, learning) and environmental conditions (spaces, buildings, cities, regions) has led to the concept of so-called “Knowledge Ecosystems” – which is turning into a new paradigm at the intersection of urban and regional development and innovation management. In this context, the study presented here endeavours in two directions: (1) It works towards a formal description of urban environments on the background of innovation discourses (“Urban Topology”) and (2) it sketches a dynamic model for innovation processes in regards to urban structures, management, and design (“Urban Innovation”).

3 Cellular Automata Simulations

Computational tools may be of substantial help to investigate dynamic processes like innovation and knowledge diffusion within complex systems such as urban environments. For this, several well-established scientific methods suggest themselves and have been tested already e.g. resource-based planning models (Dantzig and Saaty 1973), Multi-Agent-Algorithms (Bettencourt and West 2010, Bettencourt et al. 2007), or simulation via Cellular Automata (Ishida 2005). As the core idea of the study presented here was to model knowledge dynamics in space, it was found that Cellular Automata (CA) might serve this purpose best as they combine spatial representation with dynamic modes of propagation and diffusion. Subsequently, two CA were designed specifically upon processes of knowledge spread (CA 1: “Meme”) resp. attractiveness of place (CA 2: “Affordance”).

3.1. Cellular Automaton 1 “Meme”

For the purpose of creating a CA for the inherent dynamics of knowledge processes, the simplified notion of knowledge as an “event with viral capacity” was chosen, based

on the theory of memes (Dawkins 1976). Memes are understood as a kind of intellectual substance that have capacities of genetic replication and evolutionary development. Inference about how memes emerge, or where they come from, is of no relevance for the concept; their emergence is understood as being highly accidental. The following assumptions are implied:

- Memes transmit and transfer like viral infections: they multiply and modify when being communicated;
- Memes degenerate as the number of transfers and the range of spread increases, they exhaust and lose value, but will never fully expire;
- Memes have varying quality, magnitude, and level of innovation;
- Ideas may emerge at any place at any time, differing by density and frequency (invention probability).

In order to simulate various modes of knowledge spread on this basis, a prototypical CA was designed which allows systematic exploration of knowledge spread within a defined environment. According to the definitions of memes given above, the CA obeys the following rules and features:

- Delimited space of n cells (micro-spaces), defined as experimental “test-bed” for meme growth; each cell being a potential meme-host;
- Random generator introducing “memes” of various quality in random locations and distribution in the CA;
- Parametric interface for adjusting quality level and frequency of meme appearance, thus profiling certain environments (e.g. “Silicon Valley”);
- Graphical code representing high quality memes as black, low quality (or degenerating) memes in various shades of grey.

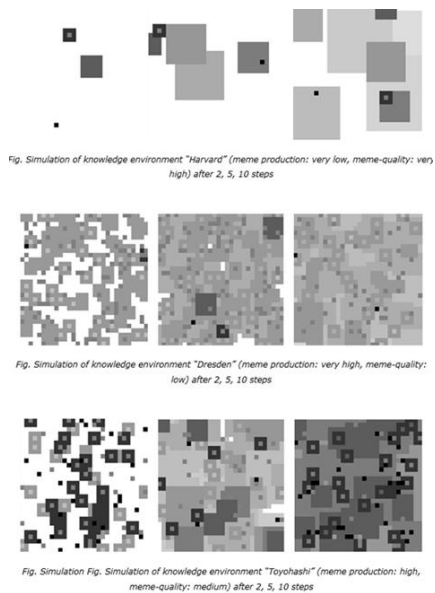

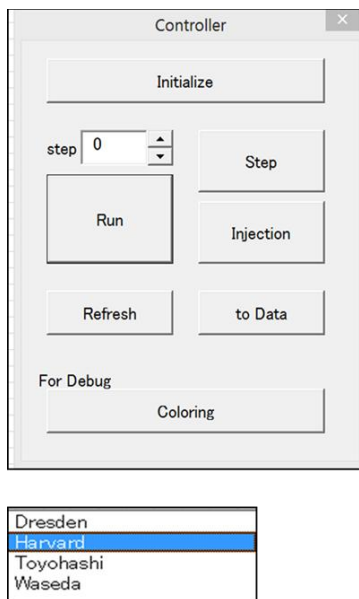

Fig. 2 CA 1: Control Panel for manipulating parameters and various simulation stages

After the basic meme-concept was translated into evolutionary rules, the CA was programmed in Microsoft Excel / Visual Basic (VBA). Test-runs were undertaken and the CA modified; before all alterations regarded the size of the area and the user interface. Finally, the number of cells was limited to 600 in order to maintain reasonable computing speed on ordinary PC. Having a working CA, a set of distinctive profile of fictitious knowledge environments (here called “Harvard”, “Dresden”, “Toyohashi” e.g.) were created (Table 1). For the purpose of generating maximum contrast between the profiles, the following parameters were set:

Table 1: Knowledge Environments.

	Meme Productivity*	Meme Quality**
	(number)	(%)
“Harvard”	1	100
“Dresden”	100	1
“Toyohashi”	50	50

* Indicated by overall number of memes produced by iteration, non-regarding their quality.
 ** Indicated by proportion of low vs high level memes in overall production per iteration

With these “profiles” initial simulations could be conducted, the number of iterations (generations) of memes being limited to max 10, due to minor observable changes in iterations >15.

Fig. 3 Simulation of knowledge environment “Harvard” (meme production: very low, meme-quality: very high) after 2, 5, 10 steps.

Fig. 4 Simulation of knowledge environment “Dresden” (meme production: very high, meme-quality: low) after 2, 5, 10 steps.

Fig. 5 Simulation of knowledge environment “Toyohashi” (meme production: medium, meme-quality: medium) after 2, 5, 10 steps.

The observations can be summarized in a set of preliminary results:

- Already with the few parameters (numbers of cells, frequency of meme appearance, level of meme quality) distinctive representations of knowledge places resp. their qualities can be achieved.
- According to the respective environment, different “pulses” of knowledge generation with different magnitude appeared. This may be related to innovation cycles (Schumpeter 1942).
- With varying speed, a knowledge base is being formed from degenerated memes (graphically represented by grey background shades) which appears after a number of rounds. This can potentially related to fundamental knowledge cultures.
- The resulting graphs indicate major differences of quality in regards to the expansion of light grey / dark grey areas (accumulations of base knowledge vs islands of advanced knowledge).

3.2. Cellular Automaton 2 “Affordance”

Version 1.0 For the second set of investigations, a different strategy was taken, based on parameters of local attraction, preference, or affordance. This time the software Netlogo was chosen, largely due to comfortable programming and the possibility to comfortable addition of modifiers (sliders).

Fig. 6 Model 2, v.1.0. Two sets of two types of cells.

The abstract input area was a square, whose cells were divided in two sets of two features: *centre* (as in “city centre”) and *non-centre*, and *road* and *not-road* (Fig.6). That corresponded with the attractiveness of certain parts of the area for agents: the *centre*

characteristic was preferable to the *non-centre* one, while the *road* feature disabled the agents from settling in such cell, therefore leaving the *not-road* cells as those enabling settlement. In other words, from among all *not-road* cells, the agents were able to settle in cells with either the *centre* or *non-centre* attribute, with the former being more attractive to them than the latter.

Figure 7 presents the starting situation of a simulation. A set of input data can be seen: The number of agents = innovators (one; the small green plane); the number of innovations (zero; cells settled by the innovator); initial energy (representing the founding capital of the agent); cost (of movement from cell to cell; the direction of movement was random); profit from the agent's activity in a cell, and the minimum value of energy "to innovate", i.e. to transform a cell by the agent. This very basic exercise had the agent travel across the area and decide over each cell whether to settle there or not. If the calculation was positive, then the cell was being subjected to the process of innovation and marked white. The other part of Figure 7 includes an example of an advanced stage of the simulation (tick/iteration 81), where the agent has already innovated several cells.

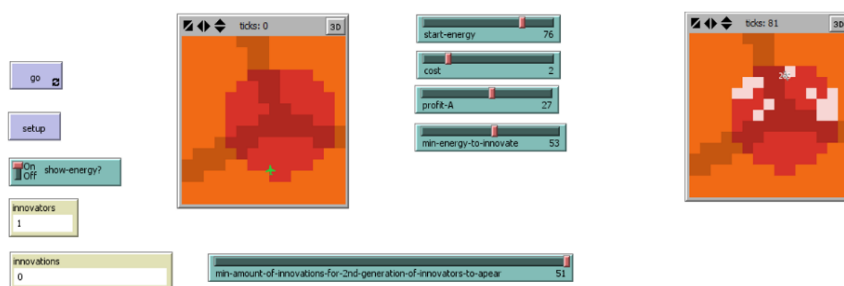

Fig. 7 Model 2, v.1.0. Input data and example of advanced-stage situation.

This small model, associated with the theory of living systems (especially the input-throughput-output process perspective) (Bailey 1994), serves to show an example of decision-making process that is thoroughly dependent of the topology of the area of operation. The agent, in order to act, required initial information concerning the examined area, and made decisions based on these information. This, in turn, allows to create a very rudimentary 'map of attractiveness of the area'. In the perspective of this research project, this is in line with the struggle to uncover the patterns of the emergence of innovations in a given spatial (urban) environment, based on a set of data about that environment.

Version 2.0 With a new version, the model was expanded not only in terms of cell information (features), but also three significant modifications were applied: the creation of new agents was enabled, the advancement of agents was enabled, and the process of aging of innovations was instituted. Similarly to the version described above, the agents were characterised by their initial energy (capital), the travel cost (random direction), cell activity profits, and the innovation energy threshold were provided. However, in this scenario the agent or agents were allowed to decide not only whether they settle or not a cell, but also whether they want to duplicate. Figure 8 displays an example of the command section of the software, in which rules of behaviour of the agents were set. While arriving in a cell, an agent examined its own current energy, the attractiveness of the cell, and juxtaposed it with the provided cost of two available activities: reproduction or innovation. Moreover, the system counted at each iteration the number of cells that reach or exceed a certain level of attractiveness, and if a provided threshold was met, it generated a car symbol – a ‘generation 2’ agent (visualised on Figure 9 as the slider “Minimum amount of innovations for 2nd generation of innovators to appear”). Finally, the ‘innovated’ cells were set to ‘fade away’, i.e. lose its innovated status, in the case they would not be settled by an agent after a certain number of iterations.

The updated version lends itself to the theory of living systems even more in the way that it has more variables and therefore is more complicated. It is possible, among other scenarios, to take the model to the situation where the resources would wear out due to the cheapness of action and the number of agents rise to the point of overcrowding, then it would diminish because of that, and then again rise – just as the systems theory describes the pattern of behaviour of food chains in the animal kingdom.

Fig. 9 Model 2, v.2.0. Input data and examples of advanced-stage situations.

4 Outlook, Future Work

The presented CA certainly are preliminary test-runs results of which shall not be overly generalized due to the limited scope, number of included parameters, and level of abstraction etc. Yet the investigations have established a promising format for future research on knowledge dynamics in space. On this basis, the following items shall be addressed in future work:

Introducing on real-world data: Real-world data (e.g. number and density of actors, patent records, educational level, communication rate, patent expiration) must be translated into CA parameter (number of cells, infection rate / propagation, frequency of memes occurring, background knowledge, memes degeneration etc.).

Acknowledging ground fertilisation: In respect to discourses on “Knowledge Ecosystems”, the role of “ground fertilisation” is crucial. It can be hypothesized that environmental enrichment, or pre-fertilisation with knowledge by way of more or less degenerated memes, impact on knowledge growth and spread. Ground fertilisation must be related to the notion of innovation work’s ‘Background Noise’ (also ‘Cultural noise’ or ‘Environmental noise’) – a description of environment taking into account the respective elements that work in favour of, or against, innovations such as: obstructions and obstacles, rivalling innovations, idea absorptivity, capital potential, multiplicity of actors, etc.

Enabling Memes movement: As a key factor for knowledge spread in a real-world context, the movement, or mobility, of the agents themselves must be regarded in the CA as well. They would not only “infect” their immediate neighbours but scatter the “infection” quickly over larger distances (just as the case is in pandemics distributed by air-traveling, see Fig. 10 left).

Fig. 10 Memes travelling across CA (left) within a multiple CA-knowledge environment (center), forming a dynamic urban ecosystem (right).

Combining different CA into environmental patchworks: No real-world knowledge ecosystem can be restricted to a single-program environment, as represented by the simple CA 1. Combining differently programmed CA into a system of systems will allow more realistic modelling e.g. of urban environments featuring university campuses, residential districts, and technology areas (Fig. 10 center, right)

Combining memes movement & CA patchworks: A final integrative step can be taken when memes do not only transfer, or travel, freely across one CA table but when they transfer between different environments, or patched CAs (Fig. 10 left, center, right). Such model would help simulating the functioning of knowledge ecosystems where success depends on the effective transfer of ideas, talents, memes etc. from one context to another, such as from university environment to industrial application; from expert sphere to public audience; from lab to school etc.

Mapping attractiveness: Acknowledging the spatial-functional structure of a city as environment for innovations, with the CA maps of attractiveness for innovation and innovators can be derived, which may serve as pragmatic planning tools in future. For different scales (city, region, country) and different spatial criteria (real estate value, infrastructural proximity, centrality, university neighbourhood, competition in the area etc.), probability rates for the emergence and spread of innovation can be given then.

Structured Abstract

Purpose – Major challenges of knowledge transfer processes in cross-disciplinary projects result from differing disciplinary terminologies and from work groups which are located at different locations. From a representational viewpoint, visual media such as pictorial images, drawings, or sketches are widely used for cross-disciplinary communication to bridge these gaps in order to build a joint understanding and support a computer mediated collaboration of spatially separated work groups.

Originality/value – Concerning the described settings, the paper discusses the importance and presents practices of representation and structures in Computer-Supported Collaborative Work as common ground in cross-disciplinary processes using examples related to a) the reconstruction and visualisation of “lost” buildings in humanities and b) spatial-based generic configurations inspired by architectural theory and the design of public spaces.

Design/methodology/approach – To cope with these challenges the authors combined both theory-driven and empirical methodological approaches for research and performed three stages of analysis. The first stage was a content analysis for publications to examine current usage and production scenarios of virtual 3D models in cultural heritage, its outcome and purposes. A second stage included four case studies to examine aspects of communication about the reconstructed architecture and their evolution during a project creation process. A third stage investigates aspects of the usage of architecture as media and common ground of cross-disciplinary understanding comparing sociological approaches to virtual and mediated spaces.

Practical implications – The article will provide practical implications on how practices of visual representation and the usage of structures such as architecture as common ground will foster cross-disciplinary processes.

Keywords – Visual representations, knowledge transfer, Computer-Supported Collaborative Work, cross-disciplinary process

Paper type – Academic Research Paper

1 Introduction

Problem – Major challenges of knowledge transfer processes in cross-disciplinary projects result from differing disciplinary terminologies and from work groups which are located at different locations. From a representational viewpoint, visual media such as pictorial images, drawings, or sketches are widely used for cross-disciplinary communication to bridge these gaps in order to build a joint understanding and support a computer mediated collaboration of spatially separated work groups. From a theoretical point of view both phenomena are widely thematised, especially by social sciences and psychology, but also relevant in certain contexts of many applying disciplines, such as cartography, computing, and architecture.

Cross-Disciplinarity

Disciplinarity is closely related to “epistemic cultures” (Cetina, 1999), which contains aspects like a certain methodology and terminology of disciplines. Cross-disciplinarity addresses the phenomenon that individuals with different epistemic backgrounds collaborate in certain projects.

Common Grounds

As one of the most common explanation models for cross-disciplinary understanding, the Common Grounds approach originates in cognitive psychology and explains factors and recommendations for successful communication (Repko, 2007). For a successful knowledge transfer between two individuals their knowledge, beliefs and assumptions must be synchronised (Clark, 1996). Especially for a cross-disciplinary communication, aspects such as varying meanings of the same terms across disciplines or, in an opposite manner, a usage of different terms for the same content is relevant (Bromme, 2000). Closely related to such effects is the fact that the differences are not known in advance, but usually show up only in the course of an interdisciplinary cooperation. While the common grounds theory focusses on communication between individuals, the trading

zones approach focusses on modes of information exchange and collaboration in interdisciplinary working teams (Galison, 1997).

Representation

While common grounds focusses on principles of communication, the aspect of representation addresses the replacement of a represented object by an – e.g. lingual, pictorial, or architectural - representing object. Aspects of representation are closely related to semiotics and model theory. From the point of semiotics an object can be represented by a sign which a recipient could identify as symbolisation for that object (Müller, 2003). Such symbols can represent linguistic and iconic characters, but also, for example, gestures. Character meaning or application contexts are dependent on the conventions and the epistemic culture of the application area and the culture of the user (Schumann and Müller, 2000). On this basis, Bertin developed a specific graphic semiology (Bertin and Jensch, 1974), which subsumes and analyses the various degrees of freedom of a graphic design. Based on the laws of Gestalt theory, a generalised assumption is that only differences and similarities can be perceived between visual signs (Bollmann and Koch, 2001). While semiotics focus on a function and Gestalt of signs, model theory focusses on the relation between an original and a model as its “abstraction” (Mahr, 2004). An established explanation schema provides the general model theory of Stachowiak. This embodies a model of a simplified or abridged image of an original, a “pragmatism” of said component in the sense of a subjective purpose orientation effect (Stachowiak, 1973).

Roles of architecture

Related to the described phenomena, architecture addresses several functions. On the one hand architecture represents concepts, ideas and messages of the builders and manifests and transfers these for the public. In that function architecture can work as common ground to symbolise attributes like power via building height, or wealth via ornamentation and overwhelming craftsmanship, or for more sophisticated concepts like an arrangement of parts of medieval cathedrals which represent the corpus Christi (Horst, 2012).

On the other hand architecture is the object of discussion and is represented by various media and embedded in various contexts. That includes aspects like the representation of

scale (Yaneva, 2005) and spatial dimensions as far as a multi-sensual representation of architecture and its optical, haptic, or aural constitution (Ch'ng, 2009).

Concerning the described settings, the paper discusses the importance and presents practices of representation and structures in Computer-Supported Collaborative Work as common ground in cross-disciplinary processes using examples related to a) the reconstruction and visualisation of “lost” buildings in humanities (Münster and Köhler, 2012) and b) spatial-based generic configurations inspired by architectural theory and the design of public spaces.

2 Methods

Design/methodology/approach –To cope with these challenges the authors combined both theory-driven and empirical methodical approaches for research and performed three stages of analysis. The first stage was a content analysis for publications to examine current usage and production scenarios of virtual 3D models in cultural heritage, its outcome and purposes. The investigation included a sample of 478 journal articles, conference proceedings, and project reports related to 3D modeling of cultural heritage objects and especially a cross-disciplinary virtual reconstruction of no more extant or never realized architecture (Münster et al., Im Druck). An investigation took place via inductive and deductive qualitative content analysis to identify and classify project constellations and related phenomena. While an investigation of reports provide only a retrospective view on communication and exchange during the creation process, a second stage included four case studies exploring reconstruction and visualisation projects of historic architecture over time to examine aspects of communication about the reconstructed architecture and their evolution during a project creation process. Leading paradigm for an evaluation of that stage was a mixed methods approach including a heuristic framework basing on empirical findings in stage one and theories as a base for a grounded theory analysis (Kelle, 2010). While both approaches address architecture as a result of a cooperative reconstruction process, a third stage investigates aspects of the usage of architecture as media and common ground of cross-disciplinary understanding comparing sociological approaches to virtual and mediated spaces. That includes theories from architecture sociology, environmental sciences, and social psychology.

3 Results

As outcomes of these investigations, the article will highlight four aspects. As pointed out in the introduction, communication is highly affected by settings and purposes. Especially in professional contexts a computer mediation and support plays an important role to support both face-to-face and distance communication. Closely related to these aspects of computer mediation are virtual spaces as a computed model of spatiality and related aspects like perception and interaction. Even if visibility is just one of the attributes of architecture, visual media plays a critical role as common ground for communication about architecture. As presented at the beginning of the article, another perspective is to focus on architecture as a common ground of communication.

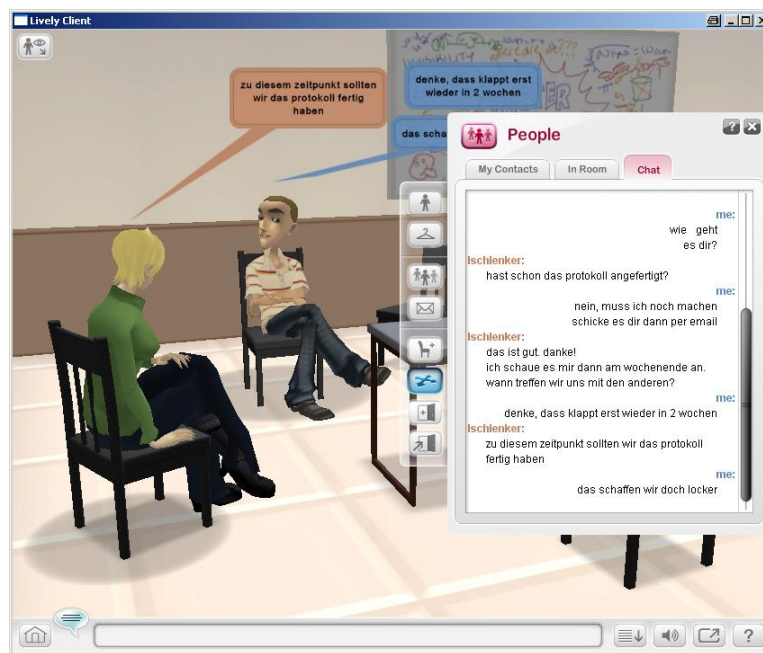

Computer-mediated Communication

As a result, several strategies as well as the media were used for distant communication and cooperation. For such purposes, in a mixture of synchronous and asynchronous strategies, widely established computer-based technologies such as computer-mediated communication (email, teleconferencing, chats etc.) (Köhler, 2013) or environments for Computer-Supported Collaborative Work (CSCW) were employed. A selection of synchronous or asynchronous tools is highly dependent on the urgency of information requests, their complexity and skills, and rank of the communication partner. Computer-based interaction is an exchange of knowledge of people who are not assembled at the same time in one location or room. Measured in terms of the high social contextualisation of face-to-face conversations, computer-mediated interaction is as impersonal as its perception of another person is limited. It therefore leads to problems such as a reduced social presence of the participants and a limitation of a commonly shared knowledge background.

Spatial references of social action

The environment always contains spatial elements with social significance and social elements that they structure spatially themselves (Bahrtdt, 1974). The spatial elements of human environment are socialised at different levels. They can only be understood through its cultural symbolism. Social production of space takes place in the interplay of socio-spatial symbols, formal spatial structures, and social usage patterns. Artifacts and elements of architectural form are by their functional or aesthetic design social symbols

and sign makers. In socio-cultural processes learned and normalised, they must be recognised and interpreted in everyday use of space. The architectural form is a socio-spatial structure supporting social communication symbols. Actors who are socialised correspondingly and are culturally competent can decode rooms in this sense. Foundations of correct interpretation are socio-spatial concepts. The importance of their artefacts, symbols and distances are not innate or automatically transferred from the architectural design; it is a product of a gradual socialisation and learning process. The architectural form refers to a system of acquired expectations and habits like a code (Eco, 1962). They include also specific expectations in terms of spatial situations and contexts with which people are confronted upon entering a room or building. A lecture room evokes other social contexts, features, contents and players, including their behaviour by its architectural design, its cubature, its colours and the nature and arrangement of its elements of equipment, as e.g. a library (Adamus et al., 2013).

Google Lively: A virtual spatial-based environment as a common ground for collaboration processes

Visual Communication (300 w.)

Communication about architecture is highly correlated with a use of visual media, as was determined through an investigation employing case studies of projects which focus on a 3D reconstruction of no longer extant buildings. In all observed projects, visual media such as historic plans and panorama have widely been the most important sources to reconstruct architecture that is no longer extant or has never been built. As a result from such reconstruction projects, mostly visual media such as images, animations, or even interactive visualisations like computer games would be created (Münster, 2013). Besides that, images and visual media would be intensively used to foster communication and quality negotiations, especially when working groups with different disciplinary backgrounds are involved in such projects. While common strategies for quality negotiation in such projects is based on a comparison between source images and images of the created reconstruction, images in communication contexts are especially used in combination with textual or oral explanations. While widely established symbols like arrows are used in all projects, some projects created their own graphical codices or metaphors for communication. Several projects successfully adopted highly standardised conventions from architectural or engineering drawings for interdisciplinary exchange.

Images as sources

Visualisation of reconstruction

Visual quality negotiation comparing images of sources and reconstructions

These empirical findings describe the importance of the role of visual media and are widely supported by research literature. A major potential of visual media is to be found

in the possible visual similarity to the depicted object and the low level of abstraction associated with it. In this context, Tversky speaks of a “naturalness” of iconic objects in terms of an orientation at physical analogies and “spatial metaphors” of human world experience (Tversky, 2002). Through just a low level of abstraction, visual media support decision-making as well as memorisation processes significantly, especially for professionals like architects, art historians, or archaeologists who are responsible for the quality of reconstructions and whose vision is highly trained on the reception and negotiation of visually perceptible phenomena (Goodwin, 1994).

Architectural design as common ground for communication processes (300 w.)

A spatial structure design formulates architectural statements with structural instruments and the making of communicative contexts (Bär, 2008). People use built forms to store and transfer social experiences. It is the reality in real spaces and also in the virtual spaces of online environments. Physical and virtual environments contain spatial elements. They constitute spaces with specific social conditions in this way. Spatial elements in online environments have a similar social meaning as in the real physical environment. This manifests itself in the generation of specific spaces for communication and collaboration. Space production takes place in an interplay of socio-spatial character repertoire, formal spatial structures, and social usage patterns. But the user of online environments cannot perceive their spatial features identically to the real physical environment. Nevertheless, the perception of virtual rooms and spaces takes place before the same socio-cultural background. Their spatial elements and structure are perceived based on existing (social) experiences of space and the associated knowledge. Rooms and spaces in the online communication and collaboration processes cannot be reduced to a container function for the structuring of people involved in online communications, as it often happens in text chats and collaborative learning environments, such as virtual classrooms. The different manifestations of spaces in online communication environments and massively multiuser virtual environments like online worlds cannot be considered in isolation from their social implications. This is especially important for socially-oriented online environments and learning environments that want to support the collaboration of learners. They align their functions, characteristics and rules instead of reaching playful objectives, e.g. in online games, to promote social contacts between their participants. In the context of collaborative learning and knowledge working processes,

they provide a specific reference to socio-spatial typologies and a way of deliberately contextualising rooms in online environments for communication and collaboration needs (Noennig and Schlenker, 2013).

4 Conclusion (200 w.)

The daily contact with the forms and structures of architecture and built space in everyday life creates a strong familiarity with their characters, symbols, and representations. It is a system that means concrete content and structural concepts on the one hand and social markings on the other hand. It provides a supply of well-known (spatial) signs for the construction of shared structures of meaning also far from their home domain. Their use as a bridge in understanding unknown domains in terms of a symbolic order or as a shared metaphor to organise cross-disciplinary processes in terms of a symbolic environment is therefore obvious.

That leads to several implications. Especially in contexts of distant and computer-mediated communication, architecture and built spaces are important to represent and illustrate spatial relations and build analogies for space referred social behaviour processes. Important attributes are that architecture and its visual representation allow a “natural” human world experience and contain a high level of information about design patterns and spatial relations of objects and make them easy perceptible for recipients. On the other hand, architecture and architectural representation lacks the ability to transfer abstract, non-nomothetic information like multiple reconstruction alternatives of no longer extant historical buildings or relational information, i.e. about personal connections in virtual spatial-based environments. While such information could be more properly transferred via media like text or speech, often a combination of visual and textual media would be used in such scenarios. Especially if both media address the same issue, a Dual Coding (Paivio, 2006) takes place which could enhance the quality and sustainability of information transferred between involved persons.

Related to the usage of architecture as common ground, it seems most important that the participants of communication have a joint understanding of inherit metaphors. As a practical implication it would be necessary, on the one hand, to obey different cultural connotations such as disciplinary meanings, especially of non-directly visible aspects. As an example, concepts or symbolisms incorporated in architecture could have different meanings and varying aspects could be of interest for different disciplines. On the other

hand, a visual representation of architecture and spaces in combination with a high level of interactivity encourages participants of virtual collaborative environments to develop certain and sophisticated forms of social interaction within such virtual spaces. One important finding is that in these cases not only a visual representation or modelling of spatial features is relevant, but a space-related interaction gains importance as an object, too. That implicates the idea that an evaluation of such social practices provides impulses for the design of such environments in order to support knowledge transfer processes in a cross-disciplinary collaboration.

At a glance, architecture and built space add important values to foster a wide scope of cross-disciplinary processes and build a common ground for communication. These issues are not only related to a representation of concepts and mental models via architecture, but to a modelling of architecture via visual representations like virtual environments or images, too. Especially in that last context it seems obvious that visual representations, on the one hand, allow a low level of abstraction in comparison to an original and can build a widely understandable common ground to foster cross-disciplinary processes. On the other hand, such media do not just represent an original, but become a stand-alone object (Mahr, 2004) connoted with certain social and cultural practices, requirements, and meanings.

Structured Abstract

Purpose - The importance of eco-innovations for industry has been rising exponentially in recent years. However, even if recent trends show that firms are increasingly committed to eco-innovations, there is little knowledge on why and how companies integrate environmental sustainability into new product development. In this paper we offer a detailed analysis of the drivers of eco-innovation in the wine industry. We account for environmental regulation, demand factors and firm-specific and technology-push factors.

Design/Methodology/Approach - The empirical evidence is based on an original questionnaire survey carried out on Italian wine producers. 334 questionnaires were returned and the response rate was of 16.5% and the response rate was of 16.5%. we distinguished between two different types of environmental innovation: cleaner production (CP) and end-of-pipe technologies (EOP). A set of logit and ordered logit models helped in estimating the effects of environmental regulation, demand factors and firm-specific and technology-push factors on CP and EOP innovations.

Originality/Value- In this paper we attempt to respond to some recent challenges set in the economic literature adding knowledge on why and how companies integrate environmental sustainability into their production. The analysis of a specific industry and product allows to control for cross-industry differences which are common in other empirical works on eco-innovation.

Practical Implications - Our results confirm the importance of regulatory aspects and networking across the supply-chain for eco-innovation. These factors determine to a large extent firms' adoption of an ecological profile. The empirical evidence confirms the appropriateness of the recent developments in the EU agenda with respect to eco-innovation.

Keywords: Wine industry, eco-innovation, environmental innovation, green innovation, innovation drivers

1 Introduction

The importance of eco-innovations for industry has been rising exponentially in recent years. Traditionally, eco-innovation was understood mostly as a solution to minimise or fix negative environmental impacts from production and consumption activities. This interpretation derives from consumers' increasing willingness to reduce the ecological footprint of their consumption choices (Harrison et al., 2005), and from public concern about pollution, supporting increasingly restrictive policies punishing environmentally harmful behaviours (Porter and van der Linde, 1995a). It is increasingly evident today, however, that the key challenges of the 21st century are not only about reducing pollution, but also about controlling the overconsumption of natural resources. There is evidence that substantial resource-efficiency gains in industrial production can be realised relatively easily and cost effectively (EIO, 2011:7). However, lack of strong coordination between different public policies may lead to an incoherent policy-mix with negative effects on the development and diffusion of environmental-friendly technologies (Costantini and Crespi, 2010) and on the geographical distribution of environmental performance (Costantini et al., 2010).

Over the past decades the global wine production has undergone fundamental changes, characterised by the emergence of New World producers. The new shape of competition is pushing towards the application of strict rules and techniques for wine standardisation, processes optimization, certifications and cost reduction in order to increase the international competitiveness. At the same time, concern about the environmental impact of wine production has increased because of changes in consumers' awareness and in producers' mission, supported by government incentives to the adoption of environmental friendly technologies and processes.

According to this, the environmental economics literature emphasises the key role that environmental regulations play in stimulating eco-innovations. The innovation literature, on the other hand, underlines the relevance of other important determinants of eco-innovations, such as technology push and market or demand-pull factors for the explanation of innovation activities (Bernauer et al., 2006; Hemmelskamp, 1999; Kesidou and Demirel, 2012). Eco-innovation in the wine industry includes a wide set of actions and possible investments, which might mitigate the environmental impact of wine production and reduce the use of resources. Although in the common perception wine firms could be considered eco-friendly when compared to firms in other manufacturing industries, such as plastic and oil processing, some basic information on energy use and water use (e.g. there is an average consumption of 25 litres of water per 1 litre of wine) could question that initial prejudice. Supporting this, Demirel and Kesidou (2011) classify the manufacture of food products and beverages as a highly polluting sector.

In line with very recent works on eco-innovation (Horbach et al., 2012) the aim of our paper is to contribute to the existing research on the drivers of eco-innovation focusing on different environmental impact areas. In this paper we offer a comprehensive analysis of the drivers of eco-innovation in the wine industry. We analyse the impact of firms' characteristics and their technological and organizational capabilities. On the basis of a large survey on Italian wine producers carried out in 2013 we investigate the main characteristics of eco-innovations in the wine industry and the key drivers of their adoption. The relevance of these drivers in influencing the probability of introducing eco-innovations is measured with a latent class econometric model. We argue that, even in the case of eco-innovation, technology adoption is a complex task that relies on several factors, where business characteristics and research activity could be at least as relevant as other drivers highlighted in the economic literature such as government environmental regulations, demand factors, market opportunities and resource saving in driving eco-innovation.

In this paper we attempt to respond to some challenges set in the economic literature adding knowledge on why and how companies integrate environmental sustainability into their production. The analysis is based on an original survey in which data are used to determine the impact of the drivers identified by the non-industry-specific literature on a single sector, which results singular for tendency to radical eco-innovative and knowledge intensity. The fine grain analysis of a single sector aims at understanding how different a

single focus could be compared to a broader analysis on the highly diversified industry of a country. In order to verify this aspect we referred to the literature for the identification of the drivers included in the analysis.

2 Theoretical background

2.1 *The background to eco-innovations*

Eco-innovation encompasses all innovations that have a beneficial effect on the environment regardless of whether this effect was the main objective of the innovation (Bernauer et al., 2006). According to the Eco-Innovation Observatory (EIO): “Eco-innovation is innovation that reduces the use of natural resources and decreases the release of harmful substances across the whole life-cycle. The understanding of eco-innovation has broadened from a traditional understanding of innovating to reduce environmental impacts towards innovating to minimise the use of natural resources in the design, production, use, re-use and recycling of products and materials.” (EIO, 2011:VII). According to Frondel et al. (2007) typically, the literature distinguishes between two different types of environmental innovation that mitigate the environmental burden of production: cleaner production (CP) and end-of-pipe technologies (EOP). Cleaner production reduces resource use and/or pollution at the source by using cleaner production methods, whereas end-of-pipe technologies curb pollution emissions by implementing add-on measures. Thus, CP technologies are frequently seen as being superior to EOP technologies for both environmental and economic reasons.

Resource efficiency and eco-innovation have both recently climbed the EU policy agenda. The Europe 2020 strategy includes a dedicated flagship initiative on “Resource Efficient Europe” (EC, 2011), which responds directly to the challenge of resource scarcity. Other flagship EC initiatives, mention explicitly that support to the issue of sustainable supply and management of raw materials in the context of industrial processes among the strategic commitments for action (EC 2010a, 2010b). Eco-innovations could bring relevant savings of material costs and for SMEs the potential to improve material productivity is estimated to be even higher than for large enterprises. Accounting for material flows properly and realising potentials to save costs through increasing material productivity will become one key determinant for European companies in the coming decades, in order to maintain competitiveness on global markets (EIO, 2011).

Despite the interest on eco-innovations in the economic literature and in policy-making is on the rise, research on this field is still limited (De Marchi, 2012). Even if recent trends show that firms are increasingly committed to eco-innovations, there is little knowledge on why and how companies integrate environmental sustainability into new product development (Dangelico and Pujari, 2010). Some recent economic studies attempt to provide a comprehensive analysis of the factors that drive eco-innovation.

Innovation theory stresses the relevance of technology-push and demand-pull factors for the explanation of innovation activities (Hemmelskamp, 1999). Building on this framework, Horbach (2008) and Triguero et al. (2013) classify the determinants of environmental innovation in three groups: technology-push (or supply-side) factors, demand factors and environmental policy. Horbach et al. (2012) use a simple framework for separating four groups of factors that have been found to be the main determinants of eco-innovation in the literature: firm specific factors, technology-push, market (or demand) and regulation.

We classify the drivers of eco-innovation in three groups: environmental regulation, demand factors and firm specific and technology-push factors.

2.1.1 Environmental regulation

The environmental economics literature has underlined the relevance of regulatory aspects in the promotion of eco-innovations. Differences in environmental regulations across countries determine different levels of development in their eco-innovation capabilities (Klaassen et al., 2005; Popp, 2006). As argued in Brunnermeier and Cohen (2003), given the significant regulatory and non-regulatory pressures on firms to abate pollution and the resultant cost burden, it is natural to wonder whether environmental innovation is a response to these pressures or to other market forces such as international competition and industry or economy-wide characteristics. The question of what role environmental regulation can or should play in this regard has become ever more policy-relevant in recent years. According to the seminal papers of Porter and van der Linde (1995a, 1995b), properly structured environmental regulation may not only benefit society but also the business sector by making firms realize otherwise neglected investment opportunities. Environmental regulation could force industry to innovate and thus increase resource efficiency and enhance productivity. Environmental regulation increases firms' turnover and profits by creating markets for environmentally improved products and technologies and compliance costs might be offset by the gains from these

innovations (Porter and van der Linde, 1995b). From this point of view, regulation is not seen as an undesirable cost-increasing factor but as a driver of firms' innovation, leading to a first-mover advantage in markets for eco-innovations (Bernauer et al., 2006) and providing economic opportunities that offset the burdens and costs induced by regulatory compliance (Rennings, 2000). However, this "win-win" hypothesis has been heavily criticized in neoclassical economists, whose supporters argue that regulation might motivate firms to develop eco-innovations, but that these efforts would produce opportunity costs offset only in exceptional cases (Jaffe et al., 1995; Palmer et al., 1995). Moreover, the effectiveness of regulations for firms could potentially differ depending on whether or not they are already ahead of their peers in eco-innovation investments and activities (Kesidou and Demirel, 2012).

A further step in the analysis of the impact of regulation on eco-innovation has been taken in recent years, with the major shift from mandatory environmental regulations toward the use of voluntary modes of regulation (Lyon, 2013). These new approaches encourage environmental improvement but do not compel it. According to L  v  que (1996) they can take the following forms: unilateral commitments by industrial firms; public voluntary schemes, in which participating firms agree to standards that have been developed by public bodies such as environmental agencies; negotiated agreements created out of a dialogue between government authorities and industry. A growing body of research has emerged that is beginning to provide a comprehensive framework for understanding these new voluntary efforts (Lyon, 2003). In general, corporate environmental voluntary initiatives have been attributed to a variety of different motives, including cost-cutting, marketing to "green" consumers willing to pay extra for environmentally-friendly products, and pre-empting government regulation (Lyon and Maxwell, 2001). In some cases voluntary approaches can be adopted more rapidly than alternative policy instruments, like new regulations. However, according to the OECD (2003), their environmental effectiveness is still questionable.

Finally, Frondel et al. (2007) point out that the effects of regulation may differ across different environmental technology fields: Whereas cost savings and environmental management systems (EMS) tends to be more important for the introduction of CP, and regulation being important for the introduction of EOP.

2.1.2 *Demand factors*

It is now acknowledged in the innovation literature that demand factors play a critical role for innovations. However, these factors have generally been overlooked in the case of eco-innovation (Kesidou and Demirel, 2012). A small number of recent empirical studies suggests that they play a significant role for the creation of eco-innovations (Horbach, 2008; Horbach et al., 2012; Wagner, 2007). There is empirical evidence (Darnall, 2006; Horbach, 2008; Kesidou and Demirel, 2012; Wagner, 2007) demonstrating that factors such as the influence of consumers associations and customer requirements for environmentally friendly products affect positively firms' decision to invest in eco-innovation and enhance their environmental management practices (Hart, 1997). Eco-innovations offer to companies implementing environmental concern into their strategies the opportunity to consolidate their competitive advantage (De Marchi, 2012). There is empirical evidence that expectations of increases in the turnover of the firm, is an important determinant of eco-innovations, at least in the case of manufacturing firms (Horbach, 2008). Eco-innovations create new market opportunities for companies, increasing the competitiveness of firms and countries that eco-innovate (Arundel and Kemp, 2009).

However, as suggested by Triguero et al. (2013) a precondition for the positive impact of demand for eco-innovation on firms' performance is that environmentally friendly products need to be seen as such by consumers and there must be a potential improvement of the firm's image and reputation based on environmental products. The exploitation of green image allows firms to gain from the rise in sales or in the price of the products. However, producers will be urged to implement eco-innovations only if consumers are provided with appropriate information on companies' eco-friendliness through eco-labels (Bleda and Valente, 2009; Rennings, 2000). Supporting this, Kammerer (2009) provides evidence that customer benefit plays a key role for environmental product innovations. According to the author, firms that attribute a large potential for customer benefit to an environmental issue are significantly more likely to implement eco-innovations. Perceived customer benefit fosters the implementation of product eco-innovations, their broad application and their level of novelty.

Finally, there is some evidence that demand factors do not influence the intensity of allocated investments (Chen, 2007; Demirel and Kesidou, 2011). In fact, according to Kesidou and Demirel (2012) the societal pressure and demand for environmentally

friendly products and processes may not necessarily lead to increasing investments in eco-innovation, but rather be limited to initiate a minimum investment in eco-innovation that will signal the commitment of the firm to 'green issues' (Bansal and Hunter, 2003; Darnall, 2006). In fact, the authors provide evidence that demand factors, especially corporate social responsibility (CSR) and customer requirements for environmentally friendly products, do not affect the level of investment in eco-innovation.

2.1.3 Firm-specific and technology-push factors

There is limited evidence in the economic literature concerning the role of firms' organisational and structural characteristics as drivers of eco-innovation. As in the case of other innovations, the development of eco-innovations is driven by firms' organisational capabilities (Florida et al., 2001; Kemp et al., 1992; Winn and Roome, 1993). Kesidou and Demirel (2012) highlight the role of EMS in eco-innovation. Although external certification alone does not boost eco-innovation because the organisational implementation of EMS is often rather ostentatious, and often dependent on scale factors (Johnstone and Labonne, 2009), organisational capabilities are not only important in firms' decision to undertake eco-innovation activities, but also in increasing the level of resources allocated to eco-innovation activities. Trigueiro et al. (2013) provide evidence that firms' technological and managerial capabilities positively influence process eco-innovation. Giving much importance to a good access to external information and knowledge, including technology support services, is also correlated with the likelihood of process eco-innovations. Supporting this, Horbach (2008) shows that the improvement of technological capabilities by R&D triggers eco-innovations. However, the arguments raised in innovation theory supporting R&D efforts as key determinants of the firm's ability to access new knowledge and innovate need to be considered with some caution in the case of eco-innovation, especially in the case of SMEs, where alternative components of firms' learning processes as human capital capabilities and quality assume a key role in driving innovation, and in generating absorptive capacity (Muscio, 2007). Supporting this, unlike in the case of other types of innovation, there is recent evidence that R&D intensity is not a significant driver of eco-innovation (De Marchi, 2012; Horbach, 2008).

With regard to external or networking technological capabilities, innovation studies have underlined the crucial role played by the interaction of different organisations in fostering the innovation process (Dodgson and Rothwell, 1994; Von Hippel, 1988). With reference to eco-innovation, De Marchi (2012) provides evidence that R&D activities and

cooperation trigger environmental innovation, even if they do not complement each other. According to Trigueiro et al. (2013) collaboration with universities, research institutes and agencies positively influences the decision to perform product and process eco-innovations by contributing to access to external knowledge. However, Horbach et al. (2012) do not find any significant influence of such factors. This result is in line with Cainelli et al. (2012) who point out that the existence of knowledge transfer mechanisms and firms' involvement in networks contribute to eco-innovation activity.

Finally, there is sparse evidence in the literature about other firm-specific drivers of eco-innovation. Firm's size seems to be a structural characteristic that boosts green innovations to a greater extent than other innovations. Several empirical studies show that, by and large, firm size has a positive influence on environmental innovation (e.g., Cleff and Rennings, 1999; Rehfeld et al., 2006). Cainelli et al. (2012) significant impact of size on eco-innovation. Baylis et al. (1998b) and Clayton et al. (1999) argue that environmental activities are associated to a higher amount of financial and human resources, which is why larger firms have better opportunities and abilities to reduce environmental impacts and eco-innovate. Supportive evidence is found concerning the impact of export orientation on eco-innovation. According to Porter and van der Linde (1995b) world demand is moving rapidly in the direction of valuing low-pollution and energy-efficient products. Thus, they speculate that internationally competitive industries are more likely to innovate in response to environmental regulation than industries that are uncompetitive to begin with. In support of this, Cainelli et al. (2012) find that in the case of Italy export orientation has a significant impact on eco-innovation in internationally competitive industries and Scott (1997) finds that R&D investments in air emission controls by US manufacturing firms increased in response to foreign competition. Therefore, these results are consistent with the notion that foreign demand for greener products spurs environmental innovation. Finally, Cainelli et al. (2012) argue that in general, "foreign effects" on eco-innovation overshadow agglomeration effects. Agglomeration economies and industrial district effects spur the adoption of eco-innovation only in areas that have historically rooted specialization patterns in eco-innovation friendly sectors, such as for the ceramics sector. Supporting this, Florida et al. (2001) and Theyel (2000) find little evidence that geographic factors such as spatial clustering or agglomeration affect the adoption of environmentally conscious manufacturing practices.

3 Empirical analysis

3.1 *Introduction on eco-innovations in the wine industry*

The empirical analysis investigates eco-innovation performance and dynamics, focusing on the identification of firm-level drivers of eco-innovation in the Italian wine industry. Choosing one specific manufacturing sector for studying eco-innovative behaviour provides the opportunity to minimise the potential bias in the introduction of eco-innovations which derives from the co-existence of different set of regulations for the promotion and adoption of eco-innovation across different economic sectors, as suggested in Kesidou and Demirel (2012). Moreover, focusing on one specific country we can overlook any country-level differences in environmental mandatory regulations and focus instead on voluntary aspects.

The focus on the wine industry also has a number of interesting aspects. First of all, the food and beverage sector is the first manufacturing industry in Europe and is particularly significant in economic terms in Italy. After the automobile industry, this industry is on top of the list for radical eco-innovation (EIO, 2011), thus, policy implications could be a leading example for other sectors. Frondel et al. (2008) demonstrate that food companies are particularly willing to introduce EMS with respect to other sectors. Secondly, the wine industry is a highly innovative, export-oriented sector, especially within the food sector, and unlike in other food industries, the absence of a price cap allows unlimited product differentiation and innovation. Thirdly, the wine industry is potentially one of the most representative sectors for the implementation of a win-win strategy, which has been found to be a key driver of eco-innovations (Porter and van der Linde, 2005). Given the wide product differentiation and the growing consumers' concerns for environmental and safety aspects, companies are becoming increasingly committed to develop green competences (Chen, 2007). Finally, the wine industry is characterized by the presence of stringent regulation and the grapevine cultivation has pervasive effects on landscape preservation and countryside tourism. Therefore, investments in eco-innovations could have relevant indirect effects on rural economies and their sustainability.

Italy leads the world market, together with France, for volume of wine production (about 18% of global market). The value of Italian production is estimated at €8.3 bn and consumption at €4.6 bn (Rabobank, 2012). A significant share of wine manufactured in Italy is exported. In 2011 volume and value increased respectively by 9.1% and 12.4%,

with an increase of the average price of wine exported (Rabobank, 2012). A large share of Italian wine companies are family-managed. Family control accounts for 54% of the total net equity. Cooperatives account for a significant part of the total number companies, although their share is gradually decreasing over the years. Foreign investors own some 18% of net equity. 2011 saw a general reduction in level of investments, which were the lowest in the last 6 years, there was a general increase in sales both in Italy (7%) and abroad (about 9%).

The environmental impact of wine production and of the food sector as a whole is an issue that is worth consideration (Demirel and Kesidou, 2011). Italian wine companies must comply with a set of rules,¹ which regulate conditionality in agriculture and national laws,² which discipline waste management and phyto-sanitary use. Companies implementing EMS can choose to certify, as cost saving and diversification tool, through the application of standards with different level of intensity and different actions that can be verified by third party entities. Among the environmental certifications we find the family of ISO 14000³, and the carbon footprint.⁴ Mandatory and voluntary rules for environmental management, however, could be accompanied by a set of other actions and investments that companies implement to increase input efficiency and reduce the production of emissions and waste aimed at improving management practices, with the final aim of optimizing outputs and reducing costs. The environmental impact of wine production could be reduced by adopting a wide set of technical solutions.⁵ Following the conceptual framework introduced by Dangelico and Pujari (2010), we can define green product innovation as a multi-faceted process wherein three key types of environmental focus – material, energy, and pollution – are highlighted based on their major impact on the environment at different stages of the product's physical life cycle. A frequent distinction in eco-innovation literature is between Cleaner Process (CP) and End of Pipe (EOP) technologies, as suggested by Del Rio Gonzalez (2009), and this distinction is also applicable to the wine industry, where we account as CP indicators of eco-innovation:

¹ E.g. the EU Reg. 1698/2005

² E.g. the no. 152/2006 and no. 4/2008, as well as the Ministry Decrees no. 12541/2006, no. 13286/2007 and no. 21/2008.

³ It aims at promoting more effective and efficient environmental management in organizations, and to provide useful and usable tools - ones that are cost effective, system-based, flexible and reflect the best organizations and the best organizational practices available for gathering, interpreting and communicating environmentally relevant information, as well as carbon footprint certifications.

⁴ It measures the total amount of carbon dioxide (CO₂) and methane (CH₄) emissions of a defined activity. The basic concept is that once the emission are known, then strategies can be adopted for its reduction, and their impact can be assessed.

⁵ See www.agro.geoenvi.org

- Improvements in resource efficiency – improvements in productivity of raw materials, optimization and technologies for the reduction of waste;
- Reduction of water consumption – reuse stabilization solution, high-pressure washing, rainwater collection systems, reuse of washing water.
- Reduction of energy consumption – solar and wind energy systems, biomass plants for energy production, underground cellar for reducing air conditioning costs, solar panels system for heating water, electrolytic separation of tartrate;

We account as EOP indicators of eco-innovation:

- Waste management – wireless technology and ozone use for cleaning cloaks, multiple steps sanitation of bottles, recovery of antioxidants from solid wastes, use of recyclable materials and lighter glass bottles;
- Gas emissions – use of solar irradiation for heating, recovery and purification of CO₂, use of cooling systems, use of hybrid machines.

3.2 *Econometric analysis*

In order to estimate the key drivers of eco-innovations we selected a sample of 2000 wineries and set up a questionnaire for a CATI survey addressed at company managers⁶. Wineries were randomly selected and their number has been determined regionally, proportionally to the local number of companies. Moreover, stratification based on company size has been applied in order to have a more representative sample.

In order to gather the information on the companies and analyse the drivers of eco-innovation coherently to the literature, the questionnaire included questions that allowed identifying proxies of regulatory aspects, demand factors, and firm and technology factors including networking and market orientation. The survey has been set up on a web-based platform. A first phone contact has been established in order to ask for companies' availability to participate. We then sent an email with our phone contact details and the link to the questionnaire to those managers that agreed to participate. 334 questionnaires were returned and the response rate was of 16.5%⁷.

⁶ *The universe of Italian companies is of about 380,000 wineries (ISMEA, 2012)*

⁷ *Sampling choices and stratifications have been oriented to the minimization of the selection bias. When comparing to National data on wineries (ISTAT 2011 - Censimento dell'Industria e dei Servizi), the sample represents well all the size classes (expressed in terms of number of employees) with less than 4% deviation, with the exception of wineries with just one employee, which are under represented, and companies with 3 to 9 employees, which are over represented.*

3.2.1 Methodology and Results

Most of the firms are medium-small size with about 20% of graduate employees. The majority of firms are part of a cooperative or a limited company, although more than 30% is a sole proprietorship. Frequently they establish collaborations with other wineries and suppliers, while collaborations with universities and research centres is less frequent. About 20% adheres to organic production discipline while other types of ecological certifications such as ISO 14000 and Carbon Footprint are pursued less frequently. About 20% of companies conduct routinely winemaking experiments in order to improve their products.⁸ The adoption of eco-innovation is less frequent than traditional types of innovation. Product innovation and process innovations concern about 70% of companies, while organizational innovation concerns about 54% of them. While CP concerns about 40% of the sample and EOP about 25%, the simultaneous adoption of both types of eco-innovation (Any Eco Innovation - AEI) concern 22% of the wineries surveyed.

The test of the research hypothesis is based on a set of *logit* regressions and one *ordered logit* regression. The *logit* regressions estimate the correlation between the theoretical drivers on the probability of firms adopting CP and EOP innovations. The ordered *logit* regression evaluates the impact of the same drivers on the cumulative probability of firms to adopt one specific type of eco-innovation (CP or EOP) and AEI. Individual regressions allow understanding the mechanisms enabling a specific type of innovation. CP concerns the improvement the resource/cost efficiency in production process and technologies. Thus, their implementation could follow profit-maximizing reasons, implying high knowledge of technologies and skills of personnel working in the process. EOP concerns waste management and CO₂ reduction. Their implementation could refer more to the environmental profile of the company and imply a tighter networking across the supply-chain. Those regressions are then compared to the regression measuring the determinants of AEI, which is aimed at identifying the factors driving firms' cumulative effort to introduce both CP and EOP innovations.

The generalized model used here is the following:

$$\text{Prob}(Y_i = j) = \sum_{\mu} c_{\mu} + \sum_k \beta_k R_{ik} + \sum_{\tau} \beta_{\tau} D_{i\tau} + \sum_{\gamma} \beta_{\gamma} T_{i\gamma} + \sum_{\delta} \beta_{\delta} G_{i\delta} + \varepsilon_i \quad \text{Eq. 1}$$

⁸ Winemaking experiments are generally considered as good proxies of R&D effort in the wine industry.

Where J represents the variables CP and EOP in the *logit* estimation and is equal to zero when no eco-innovation has been introduced and the value 1 when the company adopted CP or EOP . In the *ordered logit* estimation J is equal to zero when no eco-innovation has been introduced, 1 when the company adopted either CP or EOP and 2 when it adopted AEI. μ equals 1 in the *logit*, 1 and 2 in the *ordered logit*, indicating the cut points. With respect to the independent variables:

R represents the $k = 1, 2, 3$ proxies of Regulatory Factors;

D represents the $\tau = 1, \dots, 4$ proxies of Demand Factors;

T represents the $\gamma = 1, \dots, 11$ proxies of Firm-specific and technology-push factors;

G represents the $\delta = 1, \dots, 4$ Geographical and Economic Control factors.

Table 1 presents information on the variables used in the econometric analysis. Table 2 presents some descriptive statistics.

Source: Authors' elaboration of survey data

Table 3 reports the results of the econometric analysis, which includes the *ordered logit* and the *logit* regressions, with the corresponding marginal effects. The analysis of the marginal effects of the *ordered logit regression* confirm that those factors driving CP and EOP innovation are also relevant when firms' cumulative effort to eco-innovate is considered. The large majority of the estimated coefficients in the ordered logit model are similar in terms of sign and marginal effect to those estimated in the logit models.

Overall, the results of the regressions show that some regulatory aspects have a strong impact on the probability of adoption of eco-innovations, confirming that regulation does not necessarily represent an undesirable cost-increasing factor but can be a driver of firms' innovation (Bernauer et al., 2006), bringing a win-win strategy with positive economic impacts (Porter and van der Linde, 1995b). Voluntary certifications such as the ISO 14000 group, working as process control and impact measurement, increases the awareness about the environmental impact and promotes firms' investments towards eco-innovation. The organic discipline in wine production, on the other hand, refers mainly to grape production and results confirm that it has no impact on eco-innovation activity. Similarly, carbon footprint, being a new and not widespread certification, does not show a significant impact.

Outcomes of the distinct regressions for CP and EOP, following the definition in Del Rio Gonzalez (2009), highlight different elements that could be defined as peculiar of the type of innovation. Voluntary certifications have stronger and more significant impact on EOP innovations. Such result matches the expectation given that the measurement of the impact and the control of the environmental performance of the production are key elements of those certifications. The awareness of the emissions, for example, could drive the company to increase the probability of adoption of EOP technologies. Weaker impact, on the other hand, has been found for R&D effort. In fact, general innovation activity, e.g. product quality improvement could be less related to the final environmental impact of the company. Relevant differences emerge at the level of the type of organization involved in networking activities.

Although demand factors are acknowledged to be crucial in innovation activity as a whole, they have been overlooked in the eco-innovation literature. Our results confirm that their impact on eco-innovative activity is not significant, and confirm the argument raised by Kesidou and Demirel (2012), societal pressure and demand for green products may not necessarily lead to higher investments in eco-innovation, but rather be limited to initiate a minimum commitment on "green issues".

Several firm specific and technology-push factors are found to be positively correlated with eco-innovation activity (Triguero et al. 2013, Horbach et al., 2008). R&D effort measured in terms of on-firm wine experimentations is highly correlated with the probability of eco-innovating. This result confirms what found in the eco-innovation literature (Horbach, 2008) and more generally in the innovation literature. Confirming the

determining role of firms' internal effort, we find that the employment of an internal wine maker is also highly correlated to eco-innovation. Similar results are estimated for both CP and EOP innovations, although CP innovations, being strictly linked to the production process, are more correlated than EOP to internal efforts expressed both in terms of the intensity of experimentation and to the employment of an internal wine maker. The indicator of internal capabilities, expressed in terms of share of graduate employees, is never significant in any of the regressions. In wine companies, in fact, the wine maker and its staff has often the exclusive responsibility of innovation. Moreover, in the case of EOP, none of the variables concerning the capabilities has been found to be significant, indicating that internalization of skills and competences are not relevant to this type of innovation, and that such capabilities are probably more easily found externally.

Wine companies that are more outward-oriented are also more likely to eco-innovate. These results confirm that firms' interaction with external agents supports the development of innovations (Dodgson, 1989; Dosi, 1988a, 1988b). Nevertheless, some differences emerge in the relevance of different external agents in influencing innovation capabilities and in the way the innovation process is performed.

A good access to external information and knowledge via networking, including the access to technology transfer services, as showed in Trigueiro et al. (2013) positively influences eco-innovation. Cooperation with universities and research Centres affects the intensity of eco-innovation estimated with the AEI regression. This result is in line with Cainelli et al. (2012) who point out that the existence of knowledge transfer mechanisms and firms' involvement in networks contribute to eco-innovation activity. However some differences emerge between CP and EOP: in our case, collaboration with universities and research centres resulted significant in the case of CP innovation, and not significant in the case of EOP innovation. This result could be justified having more information on the scope of the cooperation with research institutions, which could be characterised by a stricter focus on CP innovations.

The significant coefficient of the variables "collaboration with suppliers" confirms this finding. Suppliers of technologies and products for wine processing, thus, generate a common knowledge that contribute to wine companies' eco-innovation. We also find a positive correlation between eco-innovation activity and firms' networking with other wineries and consortia. The exchange of knowledge within such a network could generate a leader-follower mechanism that enhance eco-innovation propensity.

Cooperation with other wineries or consortia, as well as relationship with customers is found to be less significant. This set of results indicates a specific profile of wine company investing into cleaner processes: a company that tends not to share competences with direct competitors. CP innovations, most likely, could be perceived as differentiation elements that allow increasing company competitiveness.

Structural characteristics, such as size and corporate organization, do not seem to affect significantly eco-innovations adoption. This result does not confirm the results of Cainelli et al. (2012), in which size impacts the adoption of green investments.

4 Concluding remarks

The importance of eco-innovations for industry has been rising exponentially in recent years. EU and national policies are focusing more on more on environmental aspects of production and sustainability across the supply-chain. In this paper we offered a comprehensive analysis of the drivers of eco-innovation in the Italian wine industry in order to add knowledge on why and how the companies integrate environmental sustainability into their product, processes and organization. The analysis we provide is based on an original survey in which data are used to determine the impact of the drivers identified by the non-industry-specific literature on a single sector, which results singular for tendency to radical eco-innovative. Differently to the empirical literature on the topic, we offer a fine grain analysis on a single sector, in this case wine sector, in order to understand how different a single focus could be compared to a broader analysis on the highly diversified industry of a country, from regulatory to technological aspects. In order to verify this aspect we referred to the literature for the identification of the drivers included in the analysis.

Our results confirm the importance of regulatory aspects. More specifically, given that a single sector follows identical set of mandatory regulations, we found voluntary certification aimed at measuring and keeping track of environmental impact to be highly correlated with eco-innovation investments of wine companies, implying that creating environmental awareness about own production boosts targeted investments. Moreover,

voluntary certification corresponds to entrepreneurial attention to environmental issue, becoming a fundamental proxy of the environment related aspects of the company mission. Secondly, networking across the supply-chain, which could be intended as the perception of a supply-chain dimension, determines an important share of knowledge that drives a more ecological orientation of production choices. In addition, relationships with technology transfer institutions and high knowledge centres such as universities and research centres accelerates the acquisition of cleaner production technologies more than end of pipe systems. Last, R&D attitude is correlated with eco-innovative behaviour in general, confirming what already found in the literature.

Important policy implications derive from the outcomes of the investigation. European orientation of incentivising sustainable entrepreneurship through R&D multiplier effect, obtained by networking and collaborations across the supply-chain and with knowledge intensive institutions, has been found to be in line with our results.

However, in order to provide a stronger evidence of the impacts, as well as a clearer direction of the causality between the drivers and the eco-innovative behaviours, historical information on the companies instead of a cross-sectional snapshot should be used. Further research, moreover, could focus on a in depth qualitative analysis of the correlations found in order furnish a finer grain understanding of the mechanisms behind the correlations presented in the paper.

Can the Knowledge Management discipline help municipalities improve their environmental policies? A multiple case study of zero waste initiatives.

Gianfranco Elia

Università LUM Jean Monnet
S.s. 100 Km 18 - 70010 Casamassima (BA)

Structured Abstract

Purpose – The purpose of this paper is twofold. Understanding if knowledge management can help local governments develop more effective environmental policies and, if so, to provide some guidelines to increase the uptake of knowledge in the policy process. This requires discovering the recurring good or bad knowledge management practices within some zero waste initiatives undertaken by municipalities. The human and material resources available for the local authorities are obviously scarce; therefore, being able to identify some useful elements for the success of an environmental policy can save time and resources, and, above all, can save irreversible damage to the environment (i.e. the use of landfill practices).

Design/methodology/approach – Research strategy is a qualitative case study approach, using a qualitative approach to data collection and analysis. We used existing data from previous research done by Robert Krausz for his own PhD thesis and official documents available on websites dedicated to zero waste initiatives. The rationale for using existing data is the perfect coincidence of the study population and also the unit of analysis. The study population is the complete set of local government zero waste programs which exist, or have ever existed; the unit of analysis is an individual zero waste program taken from this population. Results are analysed using specific theoretical perspectives.

Originality/value – This paper puts forward evidence for the value of the knowledge management discipline in the design and implementation of a zero waste strategy. It is known that the implementation of all municipal policies is laborious, time-consuming and expensive, so it may be useful to know in advance all the determinants of the success of a policy. When we talk about environmental issues, it becomes even more important considering that some environmental problems are irreversible (e.g. the pollution of an aquifer in proximity to a landfill); the failure of an environmental policy could have disastrous consequences.

Practical implications – The outcomes of the application is related to the fact that municipal waste management is one of the key areas of municipal environmental policy and is also the item on which citizens spend most resources. Therefore, for a good environmental policy a wide range of tools needs to be used, including knowledge management discipline, to obtain ever improving results. There are many municipalities who have adopted a zero waste strategy and many of those who have adopted one have benefited from it, considering all possible factors critical to the success of this strategy.

Keywords – – Knowledge management, public sector, knowledge to policy, municipal solid waste, zero waste strategies. (*max 5 words*)

Paper type – Academic Research Paper

1 Introduction

Stephen Tindale (Greenpeace Executive Director), in his foreword to the book Zero Waste, written by Robin Murray, affirms: The issue of waste has become a political hot potato. Central Government wants sustainable waste management but passes on the buck to local authorities. Local authorities decry the lack of funds from central government to enable anything but the cheapest option and reproach householders for failing to participate in reduction and recycling schemes. And the public opposes waste disposal facilities – both incinerators and landfill – with a vehemence they normally reserve for nuclear waste disposal.

The purpose of this paper is twofold. Understanding if knowledge management can help local governments create more effective environmental policies and, if so, to provide some guidelines to increase the uptake of knowledge in the policy process. This requires an understanding of the recurring good or bad knowledge management practices, within some zero waste initiatives undertaken by municipalities.

Human and material resources available for the local authorities are obviously scarce, while the design and subsequent implementation of a program for management of municipal solid waste requires time, expertise, material resources and involves many stakeholders. Being able to identify some useful elements to facilitate a more effective uptake of new knowledge in their work, particularly on environmental policy, can save time and resources, and, above all, can save irreversible damage to the environment (i.e. the use of the landfill practices).

Considering that in December 2013 in Italy 200 municipalities and more than four million inhabitants which represent 7 % of the national population have adopted a zero waste strategy (www.rifiutizerocapannori.it), we can imagine that this work could be useful in many local communities to prevent the waste of time as well as human and natural resources.

This paper puts forward evidence for the value of knowledge management in the design and implementation of a zero waste strategy. If we consider that annually in Europe (27 countries) we produce more than 250 million tons of waste, and more than 60

% of waste produced is still incinerated or sent to landfills, it is easily understandable that many municipalities have yet to implement an effective policy to reduce waste (Report 2013 on solid waste – ISPRA). As a consequence, the present study can be useful in order to increase the chances of implementing a successful environmental policy.

It is known that the implementation of all municipal policies is laborious and expensive, so it may be useful to know in advance all the determinants of the success of a policy. When we talk about environmental issues, it becomes even more important considering that some environmental problems are irreversible (e.g. the pollution of an aquifer in proximity to a landfill); the failure of an environmental policy could have disastrous consequences.

The agenda of the paper is as follows: The next section examines the theoretical background. The third section defines the methodology used in the paper. In the fourth section, the results are reported. The fifth section discusses the results. The last section provides the conclusion of the research.

2 Theoretical background

The theoretical background of this paper is focused on the link between knowledge and policy.

It is useful to start with the broad definitions of knowledge and policy.

Although today knowledge is recognised worldwide as the most valuable resource within all types of organizations and institutions, there is not a standard definition of knowledge nor of knowledge management.

So, what is knowledge?

Justified belief that increases an entity's capacity for effective action (Nonaka, 1994).

Knowledge is information which changes something or somebody – either by becoming grounds for action, or by making an individual (or an institution) capable of different or more effective action (Druker, 1989).

Some definitions of knowledge highlight the role that experience and tacit knowledge play, as well as other definitions, framed in a positivist view, suggested that knowledge primarily functions to 'describe' the world, and justification must involve 'testing' propositions through experiments and direct experience. Criticising this true and justified belief perspective, Quine argues that individual pieces of knowledge cannot be 'justified' or held as true in isolation, but rather a whole belief system is tested. Kuhn, also describes

how paradigms effect our experience and change the outcomes to collective value judgements, pointing to the shared nature of these paradigms. Other definitions emphasise the inseparability of knowledge from action, and suggest that ‘understanding’ is something that comes about from, and demonstrated through, ‘doing’.

Anderson (1975) defines policy as a purposive course of action followed by an actor or set of actors. Nielson (2001) points out that policy encompasses not just discrete decisions, but a set of processes, activities or actions. This paper focuses on public policy, and, in particular, on the municipal level of government. Court, Hoveland and Young (2005) define a policy as something adopted and implemented by government which affects or is visible to the public.

Within the numerous schools of thought focusing on the link between knowledge and policy, there are three paradigms that can help for understanding the link.

Rational. In this model, also described as the linear model, knowledge inspires and guides policy. Knowledge is a neutral input that improves policy, while, according to reason and logic, policy-making works in a problem-solving mode.

Pluralism and opportunism. The second paradigm challenges the ‘rationality’ of the policy process. Policy-making does not necessarily proceed as a linear problem-solving enterprise, but rather involves pragmatic decisions taken in uncertainty; the flow of knowledge into policy is not taken as a given, and is opportunistic and dependent on explicit efforts of various actors. Although this entails a wider view of useful sorts of knowledge, including non-academic producers of knowledge and local populations and civil society, there is still an underlying assumption that the incorporation of knowledge is generally ‘good’. For example, work on innovation systems argues for the importance of both supply and demand of knowledge as well as the need for intermediaries and regulatory framework conditions, but retains an assumption that innovation and the uptake of knowledge will generally be ‘good’, that promoting such innovation will lead to social and primarily economic benefits. Other work which falls under this paradigm are the practice-centred approaches to KM, and sustainability science (Jones, p.11).

Politics and legitimisation. Under this conception, power is infused throughout the knowledge process, from generation to uptake. Rather than being universally instrumental, knowledge will often reflect and sustain existing power structures and imbalances. The policy process is seen as the site of politics, processes of contest, negotiation, marginalisation, etc., with knowledge production and use entwined with

these forces: knowledge can serve to add legitimacy to political action often after the decision, and what counts as ‘legitimate knowledge’ is itself politically determined. Work in this area might focus on how ‘technical’ knowledge is used to gloss over contested and political aspects of situations, for example (Jones, p.11).

What is knowledge management?

Knowledge management is not a new phenomenon per se, but it has only recently emerged as an explicit area of inquiry for managing organizational knowledge (Wiig, 1997).

3 Methodology

Research strategy for this paper is a qualitative case study approach. Methodology used is a qualitative approach to data collection and analysis.

Existing data was used from previous research done by Robert Krausz for his own PhD thesis and official documents available on websites dedicated to zero waste initiatives.

The rationale for using existing data is the perfect coincidence of the study population and also the unit of analysis. The study population for this research can be defined as the complete set of local government zero waste programs which exist, or have ever existed. The unit of analysis is defined as an individual zero waste program taken from this population. Results were analysed using specific theoretical perspectives.

Because the data used in this study was generated by other research, it is important to describe how the data was generated.

One important decision made by Krausz is about the choice of the sample of case studies from the population. Among all the zero waste programs a non-random selection of cases is chosen for this research.

In order to select a sample of 3-5 cases which well represents the diversity of the population, the following criteria are applied to selection: Geographic diversity, diversity of local government features and diversity of position on the timeline. An additional constraint is applied: that all case studies be selected from English-speaking countries (Krausz, p.36-37).

Based upon these criteria and constraints, the following set of four case studies has been chosen, with prominent reasons for selection given for each location:

- 1) Australian Capital Territory (ACT) – Canberra and surrounds, Australia;

- 2) Christchurch, New Zealand;
- 3) Toronto, Ontario, Canada; and,
- 4) San Francisco, California, United States.

These case studies thus comprise a set that meets the diversity criteria in the following ways:

- **Diverse in Geography:** They cover four different countries, on two different continents (Oceania and North America), in both the northern and southern hemispheres.
- **Diverse in Local Government Structure and Intergovernmental Dynamics:** The four cases include three local governments (two cities and one city/county) and one dual city/territory government. In addition, one of the local government cases is also a case where the local initiative has operated simultaneously under a national government zero waste policy.
- **Diverse in Position on the Timeline:** One case (Canberra) abandoned its original zero waste to landfill goal just one year before the target date, and has since renewed the same goal but with no specific deadline. Two cases (Christchurch and Toronto) abandoned their original goals years in advance of their target dates, and replaced them with less ambitious % diversion goals. And, one case (San Francisco) is still before its target date and is continuing along with its original overall goal unchanged (Krausz, p. 37-39).

Each case study was reviewed from the point of view of either good or bad KM practices through the literature review to provide some guidelines and warning to help local governments better understand the link between knowledge and policy.

4 Results

As indicated in the previous section, the results are drawn from research carried out by Krausz's PhD Thesis.

4.1 Australian Capital Territory (ACT) formed by Canberra with its surrounds

The city of Canberra serves a dual role as Australia's capital city, and seat of the Australian Capital Territory (ACT). Canberra is the only city in the ACT, a region with an estimated population of around 347,000 residents (Krausz, p. 58)

Canberra, by the “ACT NoWaste by 2010” initiative launched in 1996, represented the world’s first local government adoption of a zero waste to landfill goal with a finite deadline. As a consequence, Canberra gained instant global notoriety as a sustainability exemplar (Krausz, p.57).

After the campaign was launched, the ACT reported a steady increase in their % diversion from landfill rate, from 42 % in 1996 to 73 % in 2009. However, the resulting decrease in per capita waste to landfill was comparably modest: a reduction of less than one-third by 2006, which has since been followed by a levelling off and even slight increase in this rate. The key statistic which can explain this poor achievement is the overall per capita rate of waste generation, which increased steadily during this time, rising by over one third between 1996 and 2009 (Krausz, p.57).

The warnings of likely failure of the initiative grew increasingly acute as the deadline of 2010 approached, culminating in the abandonment of the zero waste to landfill initiative in 2009. A new ACT Waste Strategy was formally adopted in 2011, which replaced the zero waste to landfill by 2010 goal with a more modest long-term goal of 90 % or greater resource recovery by 2025 – and as of 2012, the ACT is planning to expand its existing landfill site to extend capacity beyond 2015 to at least 2035 (Krausz, p.57).

4.1.1. Good KM practice

A good knowledge management practice was the attempt to generate knowledge for policy. The zero waste to landfill declaration arose based on feedback gathered from a series of community workshops and stakeholder meetings in 1995 and 1996, after which the ACT government articulated the specific goal of “a waste free society by 2010” (Krausz, p.60).

Another attempt to generate knowledge for policy, in particular from the process of implementing a program, was when in 1999, the ACT’s Commissioner for Sustainability and the Environment, Joe Baker, conducted a study of ACT NoWaste by 2010’s progress to date, and released a report in 2000 titled, *Progress towards No Waste by 2010*. Overall, the Commissioner commended ACT NoWaste by 2010 for “some good work done to date”, but stressed that “there is a very challenging task ahead” (Krausz, p.61).

A good KM practice was about knowledge sharing, outlining a three-year plan for the years 2000-2002, which included interim waste reduction targets in advance of 2010, and a mixture of top-of-pipe and end-of-pipe strategies for meeting these targets. Other

commitments listed included increased public awareness and education, including the development of a No Waste Education Centre (Krausz, p.62).

A further good KM practice was the attempt to capture new knowledge about the continuation of the zero waste initiative, by giving a task to external consultants. Later in 2008, a consultant's report titled, *ACT No Waste Strategy and Targets – Review & Assessment of Options*, was released (Krausz, p.65). The consultant's overall assessment echoed the Commissioner's then-recent recommendation to abandon the "No Waste by 2010" initiative (Krausz, p.66).

Another good KM practice was the attempt to generate knowledge before setting a new waste strategy. 2010 saw the release of the *ACT Sustainable Waste Strategy 2010-2025 Draft*. This draft document was issued by the ACT Minister for the Environment, Climate Change and Water, Simon Corbell, and it invited public submissions towards the preparation of a final strategy document for 2010-2025 (Krausz, p.66). Subsequently, in 2011, the *ACT Waste Management Strategy 2011-2025* was released, and this officially replaced the "ACT NoWaste by 2010" initiative as the ACT's overall waste policy (Krausz, p.67).

A further good KM practice was the attempt to generate knowledge for policy before launching a zero waste initiative. The idea of setting the higher aim of zero waste to landfill emerged from community member feedback, during a period of public consultation in 1995-1996, notes ACT NoWaste by 2010 Senior Project Officer at the time, Gerry Gillespie (Krausz, p.69).

4.1.2. Bad KM practice

A bad KM practice was the lack of an appropriate stakeholders' management strategy with regard to the opposition party, the Labour Party, which was unlikely to be supportive. As reported by Krausz, in 2001, Labour Party government elected in the ACT, replacing the Liberal Party government which had been in power since 1995 and had brought in the NoWaste by 2010 initiative.

Indeed, during the period 2004-2008, funding for the initiative was scaled back by the ACT government, and no further progress reports were released after 2004 (Krausz, p.64).

Another bad practice of KM was the over optimism in goal definition given low attention to the previous similar initiative with more realistic goals. As reported by Robert

Krausz ACT NoWaste by 2010 followed similar waste-related legislation that was passed in Australia in the preceding years: in 1992, the Commonwealth of Australia government set a nationwide goal of 50 % diversion from landfill by 2000; and, in 1993, the neighbouring state of New South Wales set its own higher goal of 60 % diversion by the same deadline of 2000 (Planet Ark Environmental Foundation, 2005).

This is supported as stated by Graham Mannall (Operation and Contrats Manager, ACT NoWaste). He points out that the ACT achieved a 75 % diversion rate, which was a first for Australia and among the best outcomes anywhere in the world – yet the NoWaste initiative was still largely viewed as a failure because of its stated goal of zero waste to landfill. He states that setting a finite deadline was a mistake that initiatives elsewhere have avoided (Krausz, p.70).

This is supported also by Zero Waste South Australia’s CEO, Vaughan Levitzke, who explains that their relatively modest stated goals have been very consciously selected, to deliberately aim for reachable targets that generate short-term success, rather than long-term failure, as has been attributed to the ACT’s NoWaste by 2010 programme.

Besides, Mannall wonders if the ACT community would have viewed NoWaste as a success if their stated goal had been 70 % diversion, given that they achieved a 75 %age rate.

4.2 Christchurch (New Zealand)

The City of Christchurch, with approximately 370,000 residents, is New Zealand’s second-most populous city. It is also the most populous city and the economic and cultural centre of the country’s South Island (Krausz, p.83).

In 1998, Christchurch City Council (CCC) became the second local government and first major urban one in New Zealand to declare a zero waste to landfill goal, with a deadline for achieving this set at 2020. The launch of this initiative arose in response to growing public interest in the concept of zero waste, and followed from Canberra’s pioneering launch of the ACT NoWaste by 2010 just two years earlier. Christchurch’s adoption of a zero waste to landfill goal also came at a time when the privately-funded Zero Waste New Zealand Trust (ZWNZT) was offering financial incentives to local councils around the country – and while the CCC campaign operated independently of this programme, it nonetheless represented an important part of the overall zero waste movement that was growing in prominence at this time (Krausz, p.82).

Christchurch's zero waste to landfill by 2020 initiative, however, was remarkably short-lived, with the goal officially dropped three years later in 2001 in favour of a 65 % diversion by 2020 goal. In 2006, the CCC revised the waste reduction goal again, to a target of 320 kg/person/year to landfill by 2020, which would represent a 60 % reduction from the 1994 baseline rate (Krausz, p.82).

Christchurch is a well-articulated case study with regard to its peculiarities:

- that CCC's coincidental, concerted efforts to develop a new regional landfill site, as part of a public/private joint venture, placed them in a conflicted situation whereby the profit motives to landfill inherent in the joint venture business model ultimately and irreconcilably compromised the zero waste to landfill campaign (Krausz, p. 82);
- the Zero Waste New Zealand Trust launched a programme that offered a \$25,000 funding incentive to councils that adopted a formal zero waste to landfill policy with a specific deadline (Krausz, p. 87), although Christchurch's initiative operated independently of this scheme (Krausz, p. 116).
- the pivotal role that a single City Councillor managed to assume, by taking on a virtual monopoly of waste-related committee Chairmanship roles, and subsequently championing both the adoption and soon-after abandonment of the zero waste to landfill initiative (Krausz, p. 82).
- the evolution of the central New Zealand government's national Waste Strategy. Beginning in 2002 with an aspirational goal of zero waste for the country, this policy swung away from and then back towards identifying with 'zero waste', and was ultimately dropped completely in 2010 by the National Party government which replaced the Labour Party government in 2008 (Krausz, p.83).
- the destructive earthquakes of 2010-2011 have only pushed waste reduction further back on the list of CCC's priorities, as the rebuilding process is set to last and dominate the City's overall agenda for several years to come – with zero waste not a particularly evident part of the renewal plan (Krausz, p.83).

4.2.1. Good KM practice

Good practice of KM can be traced in the attempt to generate knowledge, when Christchurch City Council commenced a process to deliver a formal waste management plan to meet the new requirement defined by a 1996 amendment to New Zealand's Local Government Act. In 1998, a draft Waste management Plan was produced by City staff, and the public was invited to submit feedback. This is a way to acquire knowledge before setting policy. Later that year, the Plan was formally approved by the Council (Krausz, p.89).

A further good practice of KM was the attempt to generate and share knowledge when, three years after the March 2001 meeting, the Council voted to notify Christchurch residents of its intention to make the above revisions to the zero waste to landfill goal, with the additional goal of zero organics to landfill by 2010. A subcommittee of three Councillors, including Councillor O'Rourke, was appointed to consider public submissions on the proposed revisions and then report back to the Council with its findings (Krausz, p.95).

Another good KM practice was the attempt to capture and share knowledge within the process by declaring a priority product (a tool that gave the central government unprecedented powers to address the waste problem) which would include consideration of advice from Waste advisory board and public consultation. This tool for preventing waste gave the Minister the authority to declare any product to be a priority product if it was deemed to cause significant environmental harm once it was disposed (Krausz, p.112).

4.2.2. Bad KM practice

One bad practice of KM was having first requested a public submission and then not having considered the objections. O'Rourke acknowledged that the public submissions to the proposed revision included considerable opposition, but he pointed to the various factors that he had outlined in his previous comments and commented that "some members of the public will not understand these factors, but we must take account of them in making our decision" (Krausz, p.98).

Another bad KM practice was the lack of knowledge before setting waste reduction goal of 100 % by the year 2020 or by time the new regional landfill was filled. Evidence can be traced to Councillor O'Rourke's words: "back in 1998 he had

proposed and the Council accepted, the goal of zero waste to landfill, and a target – the year 2020, but added that we had little idea whether this rather idealistic target was feasible, or how would be achieved in practice” (Krausz, p.96).

O’Rourke also summed up the need for revising the goal in this way: The target date of 2020 for zero waste to landfill was optimistic in the extreme. Idealism was fine in the context of our knowledge in 1994, but in the context of experience gained since then, persistence with a zero waste target by 2020 would now simply be dishonest. This does not mean, however, that I or the Council are retreating in any way from the zero waste goal. Indeed, we have determined to increase our efforts, as proposals published in the council’s draft annual plan for increased expenditure on composting and recycling clearly show. But the zero waste goal must be pursued in the context of a waste plan which has credibility. This requires realistic targets rather than pie-in-the-sky idealism.... The zero waste goal therefore remains intact, while the constraints in achieving zero waste are openly and honestly acknowledged (Krausz, p.96).

Another bad KM example is the lack of knowledge sharing when O’Rourke pointed to information from international sources which suggested that a diversion rate in the 30 % to 35 % range was towards the very top of current international best practice. He notably, however, did not cite the example of Canberra, which at this time was reporting a 61% rate of diversion from landfill (Krausz, p.96).

A further bad KM practice was the lack of attention paid to experiential knowledge when the report (presented at the June 2001 by Waste reduction goal Subcommittee) acknowledged that a local grassroots group had conducted a poll in which 57 % of respondents indicated that zero waste by 2020 was achievable. The Subcommittee’s response to this, remarkably, was: “Without a proper understanding of the constraints set out in this report such opinions are of little value. Furthermore 57 % is hardly a large majority in support” (Krausz, p.99).

4.3 Toronto (Canada)

The City of Toronto has a population of 2.7 million, making it the largest city in Canada and the fifth largest in North America. It is an amalgamated city, resulting from the merger of seven municipalities in 1998. In addition to being Canada’s principal financial and corporate centre, it is also a seat of government, being the

capital of Ontario – the country’s largest province by population and second largest by area. Toronto is located in the Great Lakes region of North America, along the northwest shore of Lake Ontario (Krausz, p.140).

In 2001, the City of Toronto launched Task Force 2010, a waste reduction initiative with a zero waste to landfill by 2010 goal. This goal was adopted amid ongoing challenges regarding the location of a new landfill site for the City’s solid waste, in anticipation of the impending closure of the last local site at Keele Valley at the end of 2002 (Krausz, p.139).

Prior to the decision to undertake a zero waste to landfill initiative, the City had actively considered the option of shipping its waste 500 km by rail, to the decommissioned Adams Mine site, in northern Ontario. However, amid extensive opposition from both the Toronto and northern Ontario regions, City Council rejected this option in 2000 (Krausz, p. 139).

Toronto began its zero waste to landfill initiative with a reported residential diversion from landfill rate of 27 % in 2001, and surpassed the Phase I goal of 30% diversion by recording a 32 % rate in 2003. The Phase II target of 60 % diversion by 2006 appeared increasingly out of reach, and in 2005 the deadline for this intermediate target was pushed back to 2008 – and the ultimate zero waste to landfill deadline of 2010 was likewise postponed to 2012 (Krausz, p. 139).

The purchase of the Green Lane site, which offered Toronto up to more than 20 years of further landfill capacity, coincided with a policy shift from the City regarding its waste reduction goals. In 2007, City Council voted to replace the zero waste to landfill initiative with Target 70, a new programme with an overall goal of 70% diversion from landfill by 2010. By 2010, however, even this scaled-back initiative had fallen short, with the City reporting a diversion rate of only 47 % (Krausz, p. 139-140).

The fate of Toronto’s zero waste to landfill initiative appears to be linked closely to the City’s perceived availability of future landfill capacity – starting with the initiative’s launch amid an acute imminent inability to find a new site, and ending with the securing of the Green Lane site which was followed shortly thereafter by the outright abandonment of the zero waste programme (Krausz, p. 140).

4.3.2. Good KM practice

One good KM practice was (in the attempt to capture knowledge), the formation, in January of 2001, of the Waste Diversion Task Force 2010. This group comprised all Toronto City Councillors, and was co-chaired by Mayor Mel Lastman and the Chair of the Works Committee, Councillor Betty Disero (Krausz, p 144).

Another good KM practice was also, in the months that followed the creation of the Waste Diversion Task Force 2010, consultation meetings were held across the city, with councillors and staff seeking input from the general public for the purpose of shaping the final strategy (Krausz, p. 144).

Another good KM practice, with the same purpose to capture knowledge, was made in 2003, the year when the number of truckloads of waste going to Michigan peaked at 142 per day, City Council created the New and Emerging Technologies, Policies and Practices Advisory Group, comprising a mix of Council-appointed expert and non-expert citizens. The overall mandate of this committee included providing guidance on whether or not 100 % diversion from landfill was an achievable objective, and assessing and developing opportunities to apply new technologies aimed at going beyond 60 % diversion and towards zero waste to landfill (Krausz, p. 147).

This advisory group, early in their tenure, expressed concern that the overall timelines for diversion were too short, and suggested that this pointed to a City staff preference for incinerating waste in the long term (Krausz, p. 147). That is to say, that incineration should not be considered a means of diverting waste from landfill, partly because the contract with the landfill operator in Michigan contained a clause which precluded the City from incinerating its waste (Krausz, p. 149).

Good KM practice was also made in February 2006, when Toronto City Council established a new citizen advisory group, the Community Environmental Assessment Team (CEAT), which was charged with guiding the City's environmental assessment process for managing residual waste (Krausz, p. 150).

4.3.3. Bad KM practice

A bad KM practice seems to have been in sharing knowledge about of the scope of the Zero Waste to landfill goal.

Looking at the Waste Diversion Task Force 2010 report of June 2001, it seems that the task force had sufficient knowledge about the enormity of the goal.

The following statement from the report acknowledged the ambitious nature of the goal:

It's a visionary plan — a great city needs to dream great dreams. It's an ambitious plan — a great city must have a big reach (Krausz, p. 144).

In this other statement the Task Force acknowledge the need to focus effort not only at the end of pipe, but also at the top of the pipe:

Changing habits is important. But so is changing minds. We have to encourage the people of Toronto to see leftover household material not as "waste" but as a valuable resource that can be used again and again. Indeed, we shouldn't even be talking about "municipal solid waste (MSW)" but rather "municipal solid resources (MSR)." Public information and education must be a large part of our effort (Krausz, p. 145).

Also the New and Emerging Technologies, Policies and Practices Advisory Group, early in their tenure, expressed concerns that overall timelines for diversion were too short, and suggest that this pointed to a City staff preference for incinerating waste in the long term (Krausz, p. 147).

Another bad KM practice was an excess of information that appear to have been in the words of Heather Marshall (Campaigner, Toronto Environmental Alliance) when she suggests that the city has not offered much education on avoiding waste because they are still trying to get people informed about how to sort their waste for recycling – including the work of translating this information into 26 languages (Krausz, p.158).

A further bad practice was that the Phase III goal of 100 diversion was already outlined in the Task Force's initial media release, *before* the period of public consultation. It is reasonable to argue, therefore, that zero waste to landfill was something that the Mayor and other Councillors had decided to pursue, regardless of public opinion, by 2001. Positive feedback from the public – particularly from environmental activists in the city – simply offered validation of this agenda, and from there City Council was able to sell the concept to its more sceptical waste management staff (Krausz, p.167)

4.4. San Francisco (California)

San Francisco is a consolidated city-county on the northern half of the west coast of the State of California in the USA. There are around 800,000 residents living within the city county jurisdiction, while the San Francisco–Oakland–Fremont Metropolitan Area has a population of around 4.3 million, making it the 2nd-largest urban centre in California, and the 11th-largest in the USA. San Francisco is also a central part of the larger ‘Bay Area’, which includes the eight other counties that surround the San Francisco Bay, and is home to over 7 million residents (Krausz, p. 173).

Following from a State of California law that required cities to divert a minimum of 50 % of waste from landfill by 2000, in 2002 the City and County of San Francisco launched its own further initiative to reach a diversion rate of 75 % by 2010, and a 100 % diversion rate – zero waste to landfill – by a time to be determined once the 50 % diversion rate was confirmed (Krausz, p.171).

San Francisco confirmed it’s surpassing of the State goal of 50 % diversion in 2003, and in that year set a deadline of 2020 for achieving zero waste to landfill. The City thereby gave itself 17 years to reduce the per capita waste to landfill rate from over 800 kg/person/year, down to nothing. Since the 2003 adoption of the goal, the programme has been run from the Zero Waste department of SF Environment, under the authority of the City’s Mayor and Board of Supervisors (BoS), and their appointed Commission on the Environment (CoE) (Krausz, p.171).

In the nine years since 2003, the City has passed a significant number of ordinances which legislate change with respect to waste generation in San Francisco (Krausz, p.171).

Since 2003, the reported % diversion from landfill rate has risen from 63 % to 77 % – and this statistic has been widely promoted by the City as evidence that San Francisco is an exemplar for waste reduction among cities across the USA and around the world. Other statistics, however, suggest that San Francisco’s performance on waste reduction has been less impressive. During the period since 2003, absolute amounts of waste to landfill have dropped from 800 to 500 kg/person/year – which is a positive reduction trend but one that has not matched the increase in the diversion rate. The reason for this is that the overall generation of waste in San Francisco has actually *increased* over this same period, from 1900 to 2200 kg/person/year. So, while

the City has achieved success at managing waste at the end-of-pipe, it has thus far failed to address the fundamental problem of consumption which is driving waste generation at the top-of-pipe (Krausz, p. 171-172).

In the face of these prevailing circumstances, it appears that San Francisco's zero waste to landfill by 2020 initiative is headed for failure (Krausz, p.173).

4.4.1. Good KM practices

A good KM practice was made in the early nineties when waste characterisation studies were done which found that food scraps represented the bulk of the City's waste, so this was targeted to get to 50% diversion. San Francisco was the first city in the state to launch large-scale food composting, beginning with commercial service in 1996 and moving into the residential sector in 1997, with citywide service commencing in 1999 (Krausz, p. 178).

A further good KM practice was made with the passage of the Environmentally Preferable Purchasing for Commodities Ordinance. The legislation gave SF Environment the authority to declare as a Targeted Product Category any "broad category of products routinely purchased by the City which have been identified by the Commission as having undesirable environmental health impacts for which alternative products should be identified and substituted. For each Targeted Product Category, the Department would develop, in consultation with City staff and relevant experts, an *Approved Alternatives List* of products which "will have a lesser impact on human health and the environment compared to other similar products, consistent with the Precautionary Principle (Krausz, p.181).

Good KM practice was also the use of the fee of \$ 0.20 per pack of cigarettes sold in San Francisco to create the Environment Cigarette Litter Abatement Fund which would pay for the administration of the fee, cover the cost of cleaning up cigarette litter, and also provide outreach and education to address the cigarette litter problem (Krausz, p. 183).

4.4.2. Bad KM practices

A bad KM practice appears to have been when the knowledge on the previous Zero Waste initiatives was used to launch the initiative, when the stated motivation for adopting the zero waste goal included that "several jurisdictions have adopted zero

waste as a long term goal, including Santa Cruz and Del Norte Counties in California; Seattle, Washington; Toronto, Canada; Canberra, Australia; New South Wales, Australia and 45% of New Zealand's local governments" (Krausz, p. 179), omitting to say that none of these cases had obtained a successful.

A bad KM practice is a lack of sharing knowledge about of the scope of the Zero Waste to landfill goal.

Indeed, although the Commission of Environment (CoE) resolution No. 002-03-COE included the acknowledgement that the goal was ambitious and will require product manufacturers and consumers to take responsibility to ensure that all discarded materials are diverted from landfill (Krausz, p. 180), does not appear to have been sufficiently communicated to the various stakeholders the burdens resulting therefrom.

Another bad KM practice is about the knowledge capture, within the too exclusive relationship between SF Environment department and Recology, when Bob Besso (Recycling and Waste reduction manager, Recology) explains that the prevailing system is one where SF Environment "essentially tells us what it wants – and we figure out how to make it work." He cites the example of the City's food waste collection programme which started back in 1996: "The City told us what they wanted, we told them what we thought it would cost, they said we could go ahead and charge for it, and so we did it – almost a decade before anybody else" (Krausz, p.195). This kind of relationship ignore the risks of "regulatory capture" (The theory of regulatory capture is associated with Nobel laureate economist George Stigler, one of its main developers).

Another instance of that hazardous relationship is about the choice of the landfill site. According to David Tam, Research and Development Director of the Bay Area grassroots Sustainability, Parks, Recycling and Wildlife Legal Defence Fund, there are better landfill options for the city than Recology's Yuba County site. Tam observes that the Bay Area has 15 existing landfills with only one-third of their capacity used up, and suggests that six of those sites would make more sense for disposing of San Francisco's waste. Meanwhile, David Tucker, Government Affairs Director with existing City landfill contractor Waste Management, argues that the Yuba County landfill proposal contains a host of unknown costs, and points out that the rail transport component – touted as one of the key environmental strong points in

Recology's bid – lacks the necessary infrastructure in place to make it work. Tam concurs on the latter point, describing the rail haul component as “a long shot” (Krausz, p.196).

A further bad KM practice was the lack of exploitation the knowledge generated in the process of implementing of the plastic bag reduction ordinance. As affirmed by Kevin Drew (Residential Zero Waste Coordinator, SF Environment) studies on the impact of the PSB ban have been very costly and time-consuming, so further studies on this have not been done (Krausz, p.199).

5 Discussion

In the previous section for each case we had put in evidence some good and bad KM practice, but there is a result that is important to point out: each zero waste to landfill initiative has either failed, or is on track for failure: Canberra, Christchurch and Toronto all abandoned their initiatives in advance of their target dates. San Francisco is ahead of its target date and is still officially committed to its original zero waste to landfill goal; however, as discussed within case analysis of results there indicates that achieving the goal is highly unlikely under present trends and circumstances (Krausz, p.214).

In this section we will try to analyze the causes of this widespread failure from the standpoint of KM. In particular, we will investigate the link between knowledge and policy in order to identify some guidelines for local governments who have embarked on a zero waste initiative.

5.1. Guideline n. 1: Use different perspectives to understand the role of power in the policy process

A good way for understanding the role of knowledge in policy process is following the Summer and Jones (2006) insight. They argue that there are three interlocking domains of interest based around different types of power relations: actors, institutions and discourses. Of course between these domains there are areas that overlap.

Actors and networks: this appears to be the driving force in policy processes as material political economy, with interest groups competing over the allocation of resources and the formulation of rules and regulations. Knowledge is often seen as subordinate to interests, used tactically or as ‘ammunition’ in adversarial decision-making. Taking a closer look, the effect of actors deploying information and ideas, and

the role that knowledge and ideas play in structuring networks, coalitions and ‘interests’, suggests a more active role for knowledge¹ (Jones, p.5). For example, in the case of San Francisco we have an actor with extraordinary power that has withstood by a wide margin several ballot initiatives to end its monopoly.

Institutions: this attributes an ongoing force in policy-making to the context and institutions that shape the formal and informal ‘rules of the game’ such as constitutional rules and cultural norms. Knowledge and ideas are refracted, altered and translated to fit prevailing institutions, or certain types of knowledge may be excluded entirely. It can also play a role through becoming institutionalized, embedded in bureaucratic procedures, laws, or organizational forms² (Jones, p.5). For example, in each case there emerged the role of the central government in the waste management and its role for addressing 100% of problematic wastes at the top of pipe waste. In the case of Christchurch, for instance Central Government attention to the issue of waste has generally oscillated between a waste management focus from National Party governments, to a waste minimization focus from Labour Party government. In the case of Toronto, for instance, in 2003, the Ontario General Election saw a new Liberal Party government replace the Conservative Party government that had ruled the province since 1995. In June 2004, the Liberal government passed the *Adams Mine Lake Act*, which prohibited the disposal of any waste in the Adams Mine site, and revoked, with financial compensation, all of the permits which had been granted to the private developer by the previous Conservative Party government, between 1998 and 2001. With the ongoing pressures against waste shipments across the USA border, and the Adams Mine landfill proposal now off the table, Toronto was under increased pressure to secure new long-term landfill capacity – or else make good on its goal of zero waste to landfill by 2010 (Krausz, p. 149).

Discourse: this sees knowledge and power as intertwined, with considerable power held in concepts and ideas seen as relevant for policy, and exerted through interactive processes of communication and policy formulation. There are various areas of study within this, for example: the role of cognitive paradigms in limiting the range of policy options considered, and the dynamics of ‘narratives’ in the policy process, simplifying

¹ For more on this see Keeley and Scoones 1999, Knots 2006, Sumner and Jones 2008, Weiss 1977, Heklo 1978, Haas 1992, Kingdon 1984, Nutley 2007, Campbell 2002.

² For more on this see Steinmo et al. 1992, Steinmo 2001, Court 2006, Collier and Collier 1991, Beland 2005, Schmidt and Radaelli 2004, Campbell 2002, Lukes 1973, Sanderson 2004.

complex situations and driving policy¹ (Jones, p.5). In each case there is a story to tell for launching an initiative. In some cases, like Christchurch and Toronto the story is about the landfill crisis; in other cases, like Canberra and San Francisco, the story is about sustainable development.

2* guideline: Take into due account the “sites” of the policy process: when and where knowledge meet policy.

In policy making, a range of different actors are involved; different institutions, evidence and knowledge are used; and decisions are made. In other words, it is important to pay attention to when and where policy is made.

When policy is made: Stages and streams

Under the rational paradigm of the policy process, it is possible to separate policy-making into different stages (Nielson, 2001) and in each stage there is a potential role for knowledge (Pollard and Court, 2005).

As well represented by Jones (p.16-17):

At the agenda-setting stage, knowledge is used to identify new problems or highlight the magnitude of a problem; uptake of knowledge is enhanced if it is crystallised around a policy narrative, and credibility and communication are shown to be important. There has been a lot of work from the third paradigm on agenda-setting. For example, as well as Kingdon’s model, Cobb and Elder (1972) argue that an unequal distribution of influence generally leads to systematic biases in the range of issues considered, sustained by significant pre-political forces. The Christchurch case is paradigmatic, with the pivotal role that a single City Councillor managed to assume, by taking on a virtual monopoly of waste-related committee Chairmanship roles, and subsequently championing both the adoption and soon-after abandonment of the zero waste to landfill initiative (Krausz, p.82).

At the formulation stage knowledge plays a role in structuring various alternative policy options, and in suggesting the causal links between the policy and its outcomes; the quantity and credibility of the evidence is important, and analyses of costs and benefits tend to be required. For example we can look again at Christchurch case when O’Rourke acknowledged that the public submissions to the proposed revision included considerable

¹ For more on this see Foucault 1991, Schmidt and Radaelli 2004, Campbell 2002, Hall 1993, Krznaric 2007, Sutton 1999, Knots 2006, Molle 2008, Lewis et al. 2005, Jasanoff 2005.

opposition, but he pointed to the various factors that he had outlined in his previous comments, and commented that “some members of the public will not understand these factors, but we must take them into account in making our decision” (Krausz, p.98).

At the implementation stage operational knowledge functions to improve the effectiveness of initiatives; it needs to be relevant and generalizable across different contexts, and directly communicated with those implementing policy. In each case we have found that too little attention has been paid to the implementing stage of the policy process.

Evaluation functions to monitor and assess the process and effects of an intervention; objectivity or independence are important for accountability functions.

Kingdon (1984) offers a model of the agenda-setting process building on the ‘garbage can’ model of the policy process, where choices seek problems and solutions seek issues, rather than vice versa. The framework is built around three streams of activity that attempt to move alternatives higher on the agenda: The ‘problem stream’ denotes which issues are recognised as significant social problems; the policy stream involves the ideas about how to solve identified problems; the political stream characterises the political environment with elections, changes in government, changes in public opinion, etc. Policy windows - moments that constitute significant opportunities for influence – occur where there is an opening for new views, often triggered by a major event such as a crisis or international agreement. At this stage there is an opportunity to couple the policy stream with the political or problem stream with the policy stream to produce action (Jones, p.17).

Delvaux and Mangez (2008) argue that knowledge plays a particularly important role in defining problems and fabricating policy ideas, during which ideas must pass a series of ‘tests’, which shape the types of knowledge that must be mobilised.

Where policy is made: Places and spaces

Ranging from more literal notion of the place to more conceptual ones, there are various ways to identify where policy is made. One perspective may be the level at which policy is made, such as local, national and international ones. The actors involved, relevant institutions and prevailing discourse will significantly differ according to each of these (Jones, p.17-18). In each case, we have found that different levels of government had affected the zero waste policy. For instance, it is useful to recall what happened when San Francisco tried to pass legislation to address the use of the plastic shopping bags

(PSBs). When the initial bag fee idea was proposed, there was a lack of political will to approve it, in response to opposing arguments that poor people would suffer as a result. Instead, a voluntary agreement was reached with grocers to reduce PSB consumption by 10% within a year – with the proviso that if this failed the City would revisit the fee option. During that year, grocers and the American Plastics Council went to the State Legislature and managed to get Proposition 2449 passed, which pre-empted local charges such as the proposed bag fee. Dmitriew recalls that City Hall took this as a “really bad-faith move” by industry – counter to the negotiations that had been done before. When the year ended, grocers did not bother to provide the City with data on bag consumption – as the new State law pre-empted asking the industry for this information, on the grounds that it was considered a trade secret (Krausz, p.193).

5.3 Guidelines n. 3: Pay attention at the key sources of knowledge for policy

Research

One of the key sources of knowledge for policy is research and a large part of literature focuses on how to promote the production of research in order to more strongly link it to policy.

This will involve the promotion of policy-oriented research, knowledge produced in order to directly assist decision makers in dealing with the policy problems they face. This is often produced in a consultancy-type mode, with organisations selling their analytical services to policy-makers. One key element of this is the commissioning of scoping reviews to identify the state of research in priority areas, as well as producing and updating systematic reviews of existing knowledge in priority areas (Lavis et al 2006). In general, the involvement of users in all stages of research is advocated in order to ensure its relevance (Jones, p.19).

The main risk in the generation of such knowledge is about the instrumentalism of knowledge. This problem can be addressed the promotion of critical and ‘reflexive’ research and advocacy, or with other tools such bodies are proposed to ‘police’ the boundary between science and policy (Waterston 2005) or to ‘peer review’ policy for intellectual content (Choi et al 2005), or to ensure ‘buffering’ and separation between knowledge producers and users (Jones et al 2009). In each case we had found a lack of link between good research and policy. Each Zero waste to landfill initiative was

launched without previously having promoted a critical and reflexive research and advocacy on zero waste to landfill initiatives.

Process

The knowledge generated in the process of policy implementing can be an invaluable resource (Powell, 2006) as well as research.

As argued by Mosse et al. (1998), this sort of knowledge can inform policy makers about the viability of a generally applicable development model, or give implementing agencies a means of monitoring progress or generating solutions to a specific problem.

There are two significant obstacles to usefully linking this kind of knowledge with policy. Firstly, there are a number of well-documented practical problems. As well as issues such as staff capacity for carrying out monitoring and evaluation, and the time commitments required to carry it out (when project workers may already be under great pressure), there may be issues such as the timing of the results. For example, 'impact' may take years to come about, and, hence, the knowledge could be available too late to inform the particular intervention that caused it to come about (Jones et al 2009).

Second, is that it is difficult to 'spread' the knowledge from its locality – project and process information is frequently based heavily on tacit knowledge, which must be formalised or made explicit in order to be shared, and then people who might need it must be aware of it and have access to it. Processes such as formalising knowledge possessed by workers on the ground are central elements of knowledge management strategies (Devlaux 2008). For example, it would be useful to acquire the knowledge produced in the process of implementation of previous initiatives so as not to repeat avoidable mistakes, but that does not seem to have been done, excepting Canberra that was unprecedented.

Voice, participation and citizen knowledge

In order to properly incorporate citizen or participatory evidence in policy process, Jones and Sumner (2009) affirm that they should enable people to express, enhance, share and analyse their knowledge of life and conditions, to plan and act within policy processes.

A relevant concern about this knowledge is a power imbalance.

Morgan (2008) also argues that citizens experiential knowledge of social issues hold a legitimate and worthwhile perspective, and cannot be lightly dismissed by social scientists. In each case we have attempted to capture this kind of knowledge.

Multiple sources and interdisciplinary

Traditional science and research is not well equipped to deal with such challenges due to being divided into ‘silos’ and disciplines, focusing on specific dimensions instead of holistic understandings of the problems faced (Clark 2007).

Lomas et al (2005) argue that decisions must be based not just on ‘scientific evidence’, knowledge gained through formal research, but also colloquial evidence, which refers to “anything that establishes a fact or gives reason to believe in something”. Important sources of knowledge for guiding policy include: values, political judgement, habits and tradition, and professional experience and expertise.

This is echoed by other authors who emphasise that facing significant uncertainty requires scientific experts to share the field of knowledge production with a variety of actors such as stakeholders, activist groups, think tanks, media professionals or even theologians and philosophers (Funtowicz and Ravetz 1992, Nowotny et al 2003).

Brown (2007) argues that there are five key contributors which bring the knowledge necessary for long-term, constructive decisions: key individuals, the affected community, the relevant specialists, the influential organisations, and a shared holistic focus. Solutions require establishing patterns of connection which replace existing hierarchies. In each, we have found a lack of a interdisciplinary approaches to addressing the waste issue.

5.4 Guidelines n. 4: The processes that mediate between the generation and use of knowledge play a crucial role in the link between knowledge and policy¹.

These processes are really important for a better uptake of knowledge in policy. When communicating and translating ideas and knowledge it is relevant to make messages sticky, short and easy to understand, adapting them to the audiences’ mind-set. In these circumstances. There is a risk of a wrong kind of influence.

For example, the link between generation and use of knowledge requires stimulating interaction and collaboration in order to take on board the contextual nature of knowledge and the complexities of its use.

In this process it is important to take into account social factors such as face-to-face communication and social networks that are good ways to spread messages through peer influence.

¹ For more on this see Nielson 2001, Jones et al 2008, Maxwell 2003.

Sustaining long-term links between knowledge and policy requires intermediary organisations. As well as communicating and translating knowledge, they must also 'mediate' between different actors and types of knowledge, which require trust and credibility.

Another factor to take in account is the importance of the right capacities and incentives for policy actors to use knowledge, as well as political determinants of demand.

6 Conclusions

In this study we achieved two results. The first is that each case consistently fails to achieve its goal; the second is that in each case we have found an overall lack of knowledge management in policy setting and implementation.

The causes of the failure could be, separately or jointly, the definition of an overambitious goal or a poor policy implementation. In any case, having provided evidence of the usefulness of knowledge uptake in the policy process, it is reasonable to argue that the answer to the first research question can be affirmative. About the second research question, we have provided a set of guidelines to improve the uptake of knowledge in the policy process for a more effective policy setting and implementation.

As argued by Funtowicz and Ravetz (1992), facing significant uncertainty requires scientific experts to share the field of knowledge production with a variety of actors such as stakeholders, activist groups, think tanks, media professionals or even theologians and philosophers.

That said, since it is certain that environmental problems involve uncertainty, a policy process that utilises knowledge from many sources, it is desirable to make use of KM techniques.

Relationship between knowledge management and effectiveness of reverse logistics

Radoslav Škapa

Department of Corporate Economics
Masaryk University
Lipová 41 a, 602 00 Brno, Czech Republic

Structured Abstract

Purpose – The paper explores the relationship between three constructs: customer orientation of reverse logistics, knowledge management and effectiveness of reverse logistics. Reverse logistics is generally seen as an instrument for sustainable development due to its ambition to minimize the extent of waste “generated” in supply chains. The role of knowledge management is investigated in this field.

Design/methodology/approach – The explorative research is based on primary data that were collected through personal interviews with representatives of 162 companies operating on the Czech market. The majority of presented findings are based on subjective statements of informants due to the fact that many questions asked for the data that companies don't measure, collect and reprocess. Majority of the questions were constructed as scales; the data were reprocessed by means of uni-, bi-, and multivariate statistical analysis.

Originality/value –The originality of the paper stems from the fact that it tests the relationship among maturity of knowledge management, customer orientation and effectiveness of reverse logistic by means of a structural model. The more elaborated knowledge management is found to be related to the effectiveness of reverse logistics and its customer orientation. The paper also shows that knowledge management is linked with other motives related to reverse logistics.

Practical implications – The empirical study suggests that effort in application of knowledge management might bring also benefits for companies in the field of reverse logistics. Traditionally, it is accepted that knowledge is important in the inspection and sorting activities of reverse logistics, when the material flow (including waste) is analysed and then dispatched for economically efficient reprocessing. The data shows that the importance of knowledge management in the field of reverse logistics might be crucial for tactical and strategic decisions too.

Keywords – reverse logistics, waste management, knowledge management, empirical research

Paper type – Academic Research Paper

1 Introduction

The term of reverse flow in context of logistics refers to material that is transferred from “a place of consumption” to “a place of origin”. This material flow, typically made by returned, used or unsold products and packaging that producers, retailers, and end-users return to their supplier, is referred to as reverse flow (de Brito, 2003). The managerial activities associated with these materials and their reprocessing started to be called reverse logistics (RL) in the mid–1990s (Rubio et al, 2008). The scope of reverse logistics has been broadened since that time. Whereas in the beginning the RL was about re-sale and redistribution of unsold products and product warranties, now it is a broader concept for an overall supply chain optimization, whose aim is to support a closed-loop character of supply chains by affecting activities such as product design, supply chain design, and product and material recovery (Škapa & Klapalová, 2011); as it is apparent from nowadays definitions. For instance, Brito and R. Dekker (2003) claim that “Reverse Logistics concerns activities associated with the handling and management of equipment, products, components, materials or even entire technical systems to be recovered... Recovery can simply be just reselling of a product or it can be accompanied by a series of processes as collection, inspection, separation, and so on, leading to e.g. remanufacturing or recycling”.

RL is currently considered to be one of the key supply chain management competencies (de Brito, 2003), critical factor of competitiveness (Rogers & Tibben-Lembke, 1998), and source of value (Mollenkopf & Closs, 2005). It implies that there is the variety of motives, which leads to companies’ involvement in reverse logistics some of them are voluntary, necessary and compulsory or mandatory. “This division is very important for the right approach of management and employees to RF and usually is reflected in policies, strategies, plans and resource commitment. Companies usually have to cope with all three groups depending on type of industry, character of business and its environment, and consciousness of management” (Klapalová & Škapa, 2012).

The problem with RL is that for the majority of organizations it is not a primary business activity and due to specificities of reverse flow, managerial commitment is often low: An U.S. survey revealed that 39% of companies perceived RL as relatively insignificant and 26% of managers reported the lack of interest in RL (Rogers and Tibben-Lembke, 1999). Later on other studies came to similar conclusions (e.g. Chan and Chan, 2008 or Ravi and Shankar, 2005) with one exception analysing Turkish

environment (Erol et al, 2010) that ranked the commitment as a less typical obstacle for reverse logistics.

As commitment is “one of the most important components for promoting the formation of new knowledge within an organization” (Nonaka, 1994, 17), the consequences for knowledge-intensive reverse logistic are more awkward. Therefore it is a task of senior managers to assign the resources and re-align the rewards, incentives and measures to develop cross-functional capabilities (Klapalová & Škapa, 2012).

Despite the fact that reverse logistics is knowledge-intensive activity, the application of knowledge management in reverse logistics is surprisingly rare (Sarkis, Zhu and Lai, 2011).

2 Research questions

The paper explores the relationships among customer orientation of reverse logistics, its effectiveness (focus of companies on RL-effectiveness), and the knowledge management. More specifically, both the extent of applied principles of knowledge management (i.e. the maturity of knowledge management in companies) and customer orientation is expected to increase effectiveness positively.

The study of Škapa & Klapalová (2012) suggested that the view of managers on reverse logistics is “narrow-focused”: The analysis of performance measurement systems revealed that companies monitored the measures that were related to efficiency of reverse logistics; whereas the effectiveness was monitored in substantially lesser extent. This might be a burden for companies’ effort in gaining more value from reverse flows (and in pursuing sustainable development) (Ravi and Shankar, 2005). As the effectiveness relates to customers and their needs, it is necessary to focus on customers’ orientation in the field of reverse logistics. For that reason the hypothesis is H1a formally introduced as follows.

Hypothesis no. 1a: The customer orientation of reverse logistics is positively linked to RL-effectiveness.

Because the prevalent part of reverse flow comes from the external environment of companies and because of stochastic character of this flow the companies’ reactions need to be very flexible. Therefore managerial competencies must be dynamic enough to react properly to the rapidly evolving environment. This flexibility and dynamism is directly linked to learning and to innovative behaviour. For this reason RL is a knowledge

intensive activity (Klapalová, Škapa, 2012). Thus we can assume the positive impact of knowledge management tools and their applications on performance of reverse logistics. This leads to the hypothesis H1b and H1c:

Hypothesis no. 1b: The maturity of knowledge management applied in the companies is positively linked to RL-effectiveness.

Hypothesis no. 1c: The maturity of knowledge management applied in the companies is positively linked to the customer orientation of reverse logistics.

Figure 1 Suggested model

In the next step, further analysis is conducted with the aim to verify a broader context of this issue: The question is if there is a relationship between the character of motivation for reverse logistics and maturity/advancement of knowledge management system in companies. Thus, the hypothesis is defined as follows:

Hypothesis no. 2: There is a relationship between of types of motivations for reverse logistics and the advancement of knowledge management system.

The above hypotheses were verified by means of statistical testing using a primary data. Whereas the hypothesis 1a and 1b are tested together as one structural model, for testing of the H2 cluster analysis and χ^2 test were employed.

3 Research design

3.1 Data collection

For collecting of data, a questionnaire was designed. Its questions were adopted from works of Rogers and Tibben-Lembke (1998), Klapalová (2007), Wang and Ahmed (undated) and Škapa and Klapalová (2011) and it contained 28 main questions, which were in most cases refined in more detailed sub-questions. Only the questions analyzed in this paper are described here. The majority of presented findings are based on subjective

statements of informants due to the fact that many of our questions asked for the data that companies don't measure, collect and reprocess.

The identification of respondents covers a company name that the respondents represented; his/her job position, number of employees of the respective company and its location and classification of its main business activity. The effectiveness of reverse logistics was measured by two scale questions (the one covering the necessity, the other the usefulness); and an additional question was employed to inquire the impact of reverse logistics on the company profitability. The motivation was covered by 10 items (scale questions), two of which had a form of semi-opened question. Because of quantitative nature of this paper these two questions were left out of further analysis. The motive-items were applied from works of Rogers & Tibben-Lembke, (1998), De Brito; (2003), Škapa and Klapalová (2011).

A battery of 18 scale questions related to multiple issues of knowledge management; three of them measured a perceived maturity of knowledge management system within a particular company.

The analytical part relies on the application of statistical tools such as frequency count, crosstabs, χ^2 , ANOVA, structural equations modeling and cluster analysis. All the calculations were conducted in SPSS v.22 and SPSS AMOS v.21.

The scales ranged from 1 to 7 and were defined positively; higher scores denote strong agreement, high impact or high usefulness or high necessity. The univariate outliers' identification was skipped in case of these scale variables. The data did not fulfill the requirements of normality, which was tested visually and by means of Shapiro-Wilk test W. The problem of items – the negative skewness of data – was corrected by power and square root transformation as suggested by Tabachnick and Fidell (2006). As this transformation led to almost identical the results as calculation on the original data, the transformation was skipped and all the presented numbers come from non-transformed data.

3.2 Research sample

The collection of data was realized by means of personal interviews with representatives of companies operating on Czech market in the beginning of 2014. Due to research funding restrictions the convenience sampling was chosen: the respondents were

selected on principle of direct and indirect contacts of the researchers. This should not cause serious problems as the nature of the research study is explorative one.

The sample amounted for 162 cases, of which 67% belongs to services (according to respective core business activity) and the remaining 32% represents the manufacturing companies. Whereas the service group is quite homogenous (majority of cases operated in hospitality industry), the manufacturing group is mixed of businesses operating in mechanical engineering, chemical, food and construction industry. The detailed view on sample structure (Tab. 1) reveals that the majority of companies consist of small enterprises; it is due to the fact the prevailing services are small companies typically. For the subgroup of manufacturing companies, a typical representative is a medium sized firm.

Tab. 1 Structure of companies in the sample ($N=162$)

Industry	Small	Medium-sized	Large	Total
Manufacturing	32.1%	52.8%	15.1%	100
Services	85.0%	13.1%	1.9%	100
Total	67.5%	26.3%	6.3%	100

4 Results

4.1 The description of variables employed in the models

The analytical part relies on three latent variables – effectiveness of reverse flows, maturity of knowledge management, and motives, which was designed as multidimensional variable. All the three latent variables are constructed as reflective.

The effectiveness was designed as three item variable, as a combination of necessity, usefulness and the extent of profitability of reverse logistics activities (measured in per cent as impact of reverse logistics on overall profitability). However, the last item didn't correlate with the remaining two. The reason was revealed by a result that relates to question of performance measurement (also contained in our questionnaire): the data shows that 69% of companies don't measure the reverse logistics cost, which means that they are unable to indicate a reliable impact on profitability. Based on this reasoning the variable was left out from further analysis and the effectiveness was calculated from the two scales only.

The scores for both items suggest that companies perceive their reverse logistics in rather positive light, as slightly effective (both the median and mean are through the midpoint of the scale – 3.5; see Tab. 2). The left item, the impact in per cent, confirms this – the average value for the whole sample is 3.48% ($SD=15.79$).

The maturity of knowledge management is calculated from three items. The level of knowledge management is probably not optimal, which is suggested by median and mode – one item is even below the midpoint of scale. The customer orientation consists of three items; the remaining items about motivation for reverse logistics are used in connection to Hypothesis no. 2. As it is apparent from basic description of all motivation items (Tab. 2), in the whole sample, the customer related motives (i.e. customer orientation) are ranked higher than remaining motives ($Mdn = 6$ vs. 5 and 4).

4.2 Test of the structural model

In the first phase, the convergence validity is tested by four different measures: The standardized regression weights presented in Tab. 3 are higher than the recommended cut points of 0.7 (or 0.5 at least) (Hair et al, 2010). Cronbach alpha, Construct reliability, and AVE for all variables indicate acceptable convergence validity (Tab. 3), because the values are higher than the recommended cut points of 0.7, 0.7, and 0.5 respectively. Thus, we can accept the latent variables to be valid in terms of convergence.

The measurement model is tested by means of confirmation factor analysis for the three latent variables as depicted on Fig. 2. The fit of the measurement model is estimated by three indicators. The essential indicator of the statistical validity of the model is Chi-square, which should be non-significant for the sample of 162 cases and for 8 observed variables (Hair et al, 2010, p. 672). In this respect the model is less than perfect as $\chi^2(17, 162) = 33.895$, $p = .009$; such numbers might suggest that there is a difference between theoretical and observed covariance matrix. However the Chi-square test itself is not very reliable and therefore additional tests are used CFI and RMSEA. The calculated values of both speak slightly in favour of the model; they provide an argument that the suggested model might be accepted and might fit the empirical data. CFI = .969 (the recommended value is .97 and higher) and RMSEA = .079 (the recommended value is less .08). Of course, the fit is not perfect as both values are at their thresholds.

Tab. 2 Description of scales

Latent variables	Items (scales)	Median	Mean	Std. Deviation	N
Effectiveness of RL	Necessity of RL	5	5.02	1.61	161
	Usefulness of RL	4	4.37	1.59	161
Maturity of knowledge management	KM included in corporate strategy	5	4.76	1.66	157
	KM is planned and integrated with all processes	5	4.35	1.78	160
	Company has a system and rooms for knowledge sharing and mutual learning	3	3.23	1.72	156
Customer orientation	Customers' satisfaction	6	5.90	1.43	162
	Customers' loyalty	6	5.72	1.57	162
	Image	6	5.34	1.46	162
Remaining motives	Cost reduction	5	4.75	1.82	162
	Productivity increase	5	4.55	1.76	161
	Competitors' pressure	4	4.25	1.88	162
	Differentiation from competitors	5	4.75	1.81	162
	Compliance with legislation	4	3.88	1.95	160
	Corporate social responsibility	4	3.58	1.81	156

Note. For all items Range = 6

Tab. 3 Standardized regression weights for the items used in the model

	Estimate		Estimate
Effect1 <--- Effectiveness	.936	Km1 <--- Knowledge_m	.894
Effect2 <--- Effectiveness	.622	Km2 <--- Knowledge_m	.902
Co1 <--- Cust_orient	.901	Km3 <--- Knowledge_m	.598
Co2 <--- Cust_orient	.853		
Co3 <--- Cust_orient	.600		

	Effectiveness	Cust. orient	KM
Cronbach alpha	.736	.821	.751
Construct reliability (CR) Joreskog rho	.767	.835	.796
Average Variance extracted	.631	.634	.590

Figure 2 Measurement model

In the second steps, the structural model is computed (applying maximum likelihood approach) and the same procedures are used for its validity testing: χ^2 , CFI, RMSEA.

The value of Chi-square test $\chi^2(17, 162) = 35.083, p = .006$ suggests that the model is less than perfect and the supplementary indicators Comparative index fit (CIF= .964) and RMSEA = .081 are in harmony with the statement about the measurement model. I.e., these tests don't provide an unwavering support the proposed model in terms of its fit with the observed data. On the other hand, because of the CFI and RMSEA reach the threshold values, the model as a whole can be accepted and it is sensible to analyse the model's elements.

The structural relationships in the model are statistically significant at $p < .000$ except for the relation between Effectiveness and Customer orientation (hypothesis H1a), which is significant at $p < .05$ (Tab. 4). In other words, the H1a, H1b, and H1c hypotheses cannot be rejected; therefore they can be accepted provisionally. The standardized regression coefficients supply another piece of information (see Fig. 3): The highest coefficient was found between Effectiveness and Knowledge management (Beta = 0.40) – H1b. There is also modest relationship between Knowledge management and Customer orientation (Beta = 0.30). The Customer orientation and Effectiveness are linked with a weaker relationship (Beta = 0.20). The model explains 25.6 per cent of the variance in

Effectiveness and 8.7 per cent in Customer orientation; therefore the explanatory power of model can be interpreted as satisfactory.

Tab. 4 Regression Weights

			Estimate	S.E.	C.R.	P	Hypothesis
Effectiveness	<---	Cust_orient	,238	,100	2,384	,017	H1a - supported
Effectiveness	<---	Knowledge_m	,420	,090	4,664	***	H1b - supported

4.3 Results relating to the hypothesis 2

To test the H2 the exploratory analysis using a clustering method is applied in the first step. Its ambition is to identify a small number of companies' segments that would be internally homogenous in terms of the reverse logistics motives. In the next step, the link to the maturity of knowledge management is investigated.

The variables (items) representing the motives for reverse logistics (all listed in Tab. 5) entered the procedure of Hierarchical cluster analysis, so that the coefficients of agglomeration could be calculated. The Ward's methods based Squared Euclidian

distance was chosen for the clustering. This decision was done arbitrary and has reflected advantages and effectiveness of Ward's method as it was proved by Kamakura and Ozer (2000), or Vriens et al (1996). The coefficients of agglomeration together with the dendrogram suggest that an optimal number of clusters for our purpose is three. After that, classification of the companies into three clusters is done in k-means cluster procedure in SPSS. The final groups have varying frequencies: Cluster 1 consists of 15.4% cases; Cluster 2 of 37.2% and Cluster 3 of 47.4%. Only 156 cases are clustered, because 6 companies didn't answer the any of the questions about their motivation.

Tab. 5 Analysis of clusters in relation to motives

	Cl. 1	Cl. 2	Cl. 3	Mean for all	S.D. for all	F	<i>p</i>
Competitors' pressure	2,46	4,14	4,80	4,25	1,88	16,648	.000
Cost reduction	4,54	3,48	5,77	4,75	1,82	37,893	.000
Productivity increase	2,88	4,05	5,43	4,55	1,76	30,298	.000
Customers' satisfaction	3,67	6,03	6,45	5,90	1,43	59,443	.000
Customers' loyalty	3,38	5,86	6,27	5,72	1,57	50,934	.000
Image	3,29	5,24	5,99	5,34	1,46	49,801	.000
Differentiation from competitors	2,29	4,67	5,64	4,75	1,81	51,699	.000
Compliance with legislation	2,92	2,59	5,22	3,88	1,95	57,869	.000
Corporate social responsibility	2,75	2,40	4,78	3,58	1,81	51,770	.000
Motives together	28.17	38.47	50.34	42.51	9.67	195.756	.000

The affiliation to clusters is related to each of the motives: As it is apparent from Tab. 5 the means differs substantially among clusters. This fact is further confirmed by results of ANOVA, as all the tests are statistically significant at $p < .000$. The last line in Tab. 5 shows the index of all motives (calculated as the sum of all nine motives above) and the fact that it differs significantly among clusters. Because the nine motives should represent the most common motives of companies as documented in the literature, the index can be interpreted as an indirect measure of the extent of motivation (or interest) for reverse logistics.

The Knowledge management in Tab. 6 provides information of the maturity of knowledge management in relation to cluster membership. The three items used for estimation of latent variable (Maturity of Knowledge management) were transformed into

the single one, as an arithmetic average. The means of this new variable suggests that there is a statistically significant relationship between cluster-membership and the maturity of knowledge management – $F(2, 149) = 15.588, p < .000$. The post hoc Bonferroni test reveals that the differences are significant between Cluster 1 and Cluster 3 (Mean difference = -1.39, $p < .000$) and Cluster 2 and 3 (Mean difference = -1.04, $p < .000$).

The cluster membership is also linked to effectiveness of reverse logistics as measured by necessity and usefulness items (Tab. 6).

Tab. 6 Analysis of clusters in relation to knowledge management and effectiveness

	Cl. 1	Cl. 2	Cl. 3	Mean for all	S.D. for all	F	p
Knowledge management	3.62	3.98	5.01	4.41	1.40	15.588	.000
Necessity of RL	4.25	4.75	5.37	4.97	1.61	5.591	.005
Usefulness of RL	3.75	4.07	4.70	4.31	1.59	4.531	.012

5 Conclusions

The model about relationship among customer orientation, knowledge management and effectiveness was tested on the empirical data. Despite the fact that the model fit is less than perfect it can be acceptable and it confirmed the expected relationships. The explained variance of 25.6% in terms of effectiveness means that both variables can be interpreted as being the important factors. On the other hand, the link between the knowledge management and customer orientation is weaker. The statistic model calculated the impact in the extent of 8%, which means there are other, more important factors than knowledge management. Anyway, the results suggest that knowledge management affects the effectiveness by an indirect mechanism. It increases the customer orientation/focus of reverse logistics; which in turns positively influence the effectiveness. This can be substantiated by the fact that the effectiveness is not about doing the thing rights, but also doing right things. In context of business decisions, the right things mean the things with respect to customers – that it the customer orientation.

To improve the understanding of this phenomenon, the analysis was supplemented by cluster analysis. Based on the differences in motives for reverse logistics, the companies were divided into three groups. The first one, labelled as Cluster 1 consists of companies

that are less motivated for reverse logistics generally, which is depicted on Fig. 4 by bold line in the radar chart. Out of nine motives, there is one only that plays an important role – Cost reduction (M = 4.54); the others are close or below of scale cutpoints. The companies of Cluster 1 probably don't see the reverse logistics as the means for fulfilling any of their strategic goals. If they invest their energy into reverse logistics, it is with an ambition of reducing their cost only. The scores of perceived effectiveness of reverse logistics, which was measured by scales of necessity and usefulness, speak in favour of such interpretation. What is also evident is that the level of knowledge management system in the companies is less developed.

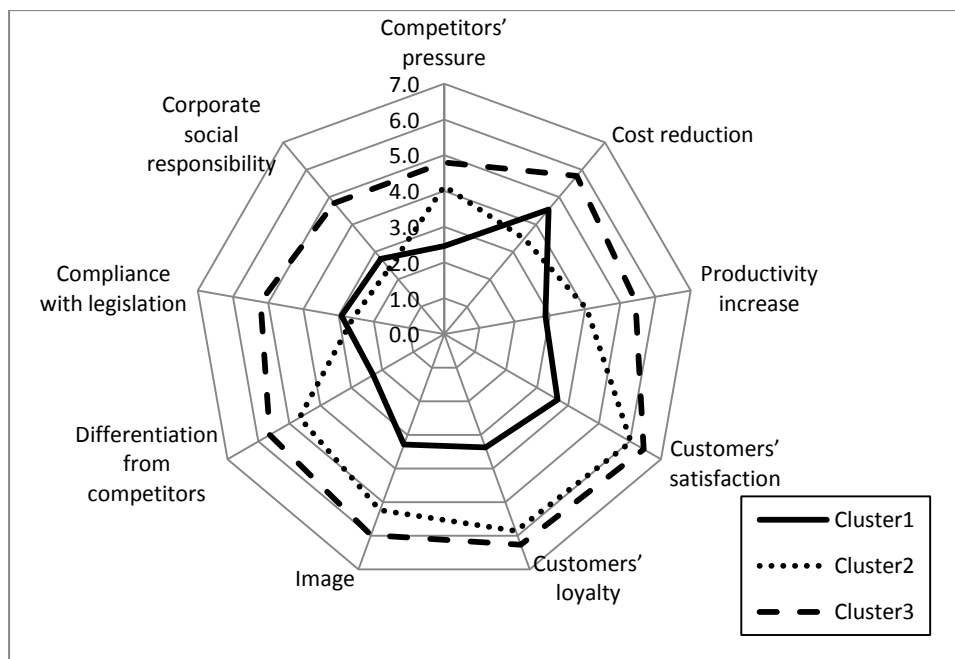

Figure 4 Clusters based on reverse logistics motivation

The Cluster 2 perceives reverse logistics in connection to marketing activities that relates to customers; the motives of internal efficiency are of less importance compared to motives such as customers' satisfaction, customers' loyalty, Image, and differentiation from competitors. We can label this approach as effectiveness oriented. The knowledge management system is more developed here.

The Cluster 3 doesn't focus (on or neglect any of) the motives. So, the approach is rather balanced. The score for knowledge management is the highest in this group. An

important fact is these companies rate the necessity and usefulness of reverse logistics with the highest scores.

These relationships lead to a conclusion that knowledge management is probably an important facilitator of reverse logistics programs. Several studies suggest that in many companies, reverse logistics still remains a unused potential that might bring additional competitive advantage, if managed properly; it means when there is a managerial commitment for this activity and when appropriate resources are assigned.

Thus, based on our study we suggest a proposition that in relation to reverse logistics, knowledge management is beneficial for two reasons: The principles of knowledge management can increase the awareness for reverse logistics among managers as a result of spreading the knowledge about reverse logistics and through better understanding of consequences of reverse flows for different departments (cross-functional understanding of this issue). This better understanding can lead to higher managerial commitment and to an increase of resource for reverse logistic. Both thinks enables to utilize the potential of reverse logistics better.

The second benefit of knowledge management stems from the nature of reverse flows; they are very unpredictable and require higher amount of information support as well as of knowledge for their effective reprocessing. In other words, this second benefit relates more to operative level of management.

Of course, the study has some limitations that diminish the general validity of results. The main limitations are connected to the research strategy – the explorative one: the sample is rather small and no random sampling was applied. Next burden is caused by single informant approach; the complex systems like a company should be describe by more than one person. The last thing is that presented data were collected as a part of a broader research, focusing on more topics. Therefore, the variables and constructs utilized in presented study were measured less precisely than they could have been theoretically; e.g. measurement of knowledge management maturity could have applied any of the theoretical maturity models. Despite of these flaws we believe that the analysis provides such coherent and convincing results that it is sensible to accept the findings.

Structured Abstract

Purpose – The purpose of this article is to create a comprehensive review of existing research in the area of knowledge management of waste management. This study is part of a larger research project, which is aimed on knowledge management of reverse logistics. Waste management can be considered as a related field to reverse logistics, therefore the ways how the knowledge is managed in waste management can be important for reverse logistics as well. As the research regarding knowledge management of reverse logistics is undeveloped, it can be more developed in the field of waste management.

Design/methodology/approach – This study is based on qualitative content analysis which is appropriate for concept generation. The concepts were generated from knowledge management studies in the field of waste management. The sample of studies was created as follows. First, citation index databases (Web of Science, SCOPUS) were searched on keywords (knowledge management and waste management). Second, results of this query were refined according to content of abstracts. After that, refined set of articles was analysed by full text qualitative content analysis method. The analysis revealed categories which were compared with research topics of knowledge management and waste management.

Originality/value – This study is the first literature review of knowledge management of waste management. It enables further research of the topic by introducing a basic framework of concepts (codes) of knowledge management of waste management. The framework can serve as a starting point for future knowledge management research in waste management field. Practitioners can use the results of this study as a general body of knowledge of concepts of knowledge management of waste management.

Practical implications – The outcomes of this study have several implications. First, knowledge management research of waste management is significantly undeveloped. This should imply increase in studying of several topics, such as organizational learning, knowledge sharing and creation, knowledge management of re-use of waste and minimisation of was. Second, this study revealed misinterpretation of some crucial terms regarding knowledge management. Some analysed studies used terms data, information and knowledge interchangeably or did not defined the terms. This fact can lead to misinterpretation of the whole study and creates confusion in the research field.

Keywords – Knowledge management, Qualitative content analysis, Waste management, Review, Categories.

Paper type – Academic Research Paper

1 Introduction

In the knowledge society, importance of knowledge management (KM) is growing, and therefore, the attention of academia and practice should grow as well. Unfortunately, it seems that this is not the reality in the field of reverse logistics (RL) and waste management (WM). Our initial intention was to review studies focused on KM in RL with special attention on knowledge management systems (KMS). Primary keywords search queries ("knowledge management" AND "reverse logistics") revealed very scarce attention of this topic (only 10 search results in SCOPUS and 6 search results in Web of Science). Further refinement of search results regarding KMS was meaningless. Therefore, we tried to extend our search by using identified keywords by Škapa and Klapalová (2011) that are connected with RL in order to make reviews concerning KM in sub-disciplines of RL and related disciplines to RL in order to synthesize findings from this "partial" reviews.

Although *"reverse logistics is different from waste management as the latter mainly refers to collecting and processing waste (products for which there is no new use) efficiently and effectively. Reverse Logistics concentrates on those streams where there is some value to be recovered and the outcome enters a (new) supply chain"* (Brito and Dekker, 2004). Oxford Dictionary defines waste similarly as: *"Unwanted or unusable material, substances, or by-products"*. Therefore, strictly speaking De Brito and Dekker are right and by definition, WM is different from RL. However, the difference between RL and WM in practice is not so clear. Some categories of WM (e.g. solid or electronic waste) can be closely connected with recycling and reuse. Therefore, WM and RL can be considered more as relatives than as strangers. Because the main aim of WM, besides waste evasion, is turning wastes to non-wastes (Pongrácz, 2002), thus finding value in waste in order to utilize it further (see section 2.3).

Because of the absence of a specific review on the topic of KM in WM research field, the main goal of this study is to: explore published research that deals with KM in the

field of WM. This area has not been broadly researched so far, therefore, we decided to apply qualitative design of content analysis.

The paper has standard structure as follows. In section 2, basic concepts of KM regarding this research are discussed. Next, review on important issue of difference between information management and KM was conducted. For the purpose of specifying context to WM, literature review of this research field was done. In section 3, methodology is described. Section 4 presents overview of results that are presented in various tables. In section 5, results and findings of the study are discussed, commented, interpreted and compared with other research. In section 6, conclusions are drawn.

2 Literature Review

2.1 Knowledge Management

Process of defining KM is not straightforward, because no universal definition exists. We present several definitions of KM provided by (Dogan et al., 2011):

- KM is the effective learning processes associated with exploration, exploitation and sharing of human knowledge (tacit and explicit) that use appropriate technology and cultural environment to enhance an organization's intellectual capital and performance (Jashapara, 2004, p. 12).
- KM is the coordination and exploitation of organization's knowledge resources, in order to create benefit and competitive advantage (Drucker, 1999, p. 157 in Dogan et al., 2011).
- KM consists of processes to capture, distribute, and effectively use knowledge (Davenport and Prusak, 2000 in Dogan et al., 2011).

Several activities or processes regarding KM can be retrieved from definitions (list is enriched by processes from (Beljić et al., 2013)):

- exploration (capture, acquiring),
- creating,
- sharing (distributing),
- using (exploiting).

Besides defining KM, distinguishing between terms data, information and knowledge is crucial for understanding KM research. Literature on KM emphasizes that the relation among information, data and knowledge is often misunderstood. Davenport and Prusak

(2000 in Dogan et al. 2011) emphasise that these terms have different meaning and are not interchangeable. Dogan et al. (2011) bring summary of these three terms: data are defined as “*facts or things used as a basis of inference*”; information means “*systematically organised data*”; knowledge is considered as “*actionable information*” (Jashapara, 2004, p 14 -17).

Knowledge has several types. According to Alavi and Leidner (2001) it is essential to understand the concept of knowledge and knowledge taxonomies because distinction among the different types of knowledge might influence theoretical developments. Nonaka and Konno (1998) start with the primary distinction between two basic kinds of knowledge: tacit and explicit knowledge. Tacit knowledge is difficult to communicate, it is not easy to formalize it and share with others. It can include intuitions or subjective insights. Tacit knowledge has also two dimensions – technical and cognitive dimension. Technical dimension represents informal personal skills or it is usually referred as “know-how”. The cognitive dimension of tacit knowledge comprises values, ideals or beliefs that are deeply seated in humans. Explicit knowledge can be expressed in numbers, words and it is possible to share with in the form of manuals or data. Spender (1996) considers distinction between these types of knowledge vital because with different characteristics of knowledge is possible for researches to posit numerous different adaptation mechanisms.

Two different categorization of knowledge can be found. First, declarative (descriptive knowledge, know what) and procedural (knowing how to) knowledge can be distinguished. Second, tacit (cannot be articulated), implicit (can be articulated but has not been yet articulated) and explicit (has been articulated) knowledge can be distinguished. The relation between these two categories is such that tacit knowledge tends to be procedural and explicit (implicit) knowledge tends to be declarative. But all combinations of knowledge types exist. Considering knowledge creation and conversion, SECI model by Nonaka et al. (1996) can be used. It contains four dimensions (processes):

- socialization (tacit to tacit);
- externalization (tacit to explicit);
- combination (explicit to explicit);
- internalization (explicit to tacit).

2.2 Difference between information management and knowledge management

There is ongoing debate in KM research (Bouthillier and Shearer, 2002; Dogan et al., 2011; e.g. Al-Hawamdeh, 2002; Lopes and Morais, 2010) dealing with a problem what exactly KM is and how it differs from information management. This fact has important consequences not only for this study, but for entire research on KM, because when someone treats explicit knowledge as information (e.g. electronic manual from enterprise content management view), it is automatically matter of information management. But explicit knowledge can be also viewed as part of KM, and knowledge management systems can be viewed as a way how to capture tacit knowledge. Consequently, information management must be defined differently than KM. Dogan et al. (2011) simplified several definitions of KM (see fig. I) and information management (see fig. II) to logical models. As conclusion, knowledge (management) is more associated with humans (and their minds) whereas information has technological implications (Dogan et al., 2011). In other words, while the focus in information management is mostly on information and explicit knowledge, KM brings a new dimension, the need to manage tacit knowledge by focusing on people and enhance their capability by improving communication, information transfer and collaboration (Al-Hawamdeh, 2002).

Figure I: Scheme of knowledge management

Source: (Dogan et al., 2011)

Figure II: Scheme of information management

Source: (Dogan et al., 2011)

Information management can be therefore seen as part of KM. But when focus of the research is on information management without KM in mind, only technical perspective (usually of information and explicit knowledge) is researched, and thus it lacks entirely KM perspective. From this reason, only articles focused on KM were analysed, and articles that focused on information management were excluded (see section 3).

2.3 Waste Management

The Council Directive on waste (European Council, 1991) defined WM as: “*Waste management shall mean collection, transport, recovery and disposal of waste, including the supervision of such operations and after-care of disposal sites*”. Pongrácz and Pohjola (2004) bring summary of some waste definitions:

- *Waste shall mean any substance or object in the categories set out in Annex I which the holder discards or is required to discard* (European Council, 1991).
- *Wastes are materials other than radioactive materials intended for disposal, for reasons specified in this Table* (OECD, 1994).
- *Wastes are substances or objects, which are disposed of or are intended to be disposed of or are required to be disposed of by the provisions of national law* (European Council, 1993).

Pongrácz and Pohjola (2004) argue that WM cannot be viewed only as an approach how to dispose waste, but WM should be control of waste-related activities with the aim of protecting the environment and human health, and resources conservation. Waste-related activities include waste-creating processes, waste handling as well as waste utilization. The main aim of WM besides waste evasion is turning wastes to non-wastes (Pongrácz, 2002). This view comes from WM hierarchy, which includes waste minimization, re-use, recycling, incineration and disposal (Kirkpatrick, 1993). From this point of view, WM is much wider concept than standard "institutional" defined WM, and therefore WM is close to RL (as stated in section 1). The definition from Kirkpatrick is used for comparison of codes in analysed literature.

3 Methodology

3.1 Content Analysis

Content analysis is a method which might be used with qualitative or quantitative data and in deductive or inductive way. Qualitative content analysis is one of several methods which might be used to analyse text data and its aim is to classify selected text into categories (Weber, 1990 in Hsieh and Shannon, 2005). Krippendorff (2013, p. 24) defined it as „*a research technique for making replicable and valid inferences from texts to the context of their use*“. Elo and Kyngäs (2008) state that qualitative content analysis

provide broad description of the researched phenomenon and the outcome of the analysis itself might be a conceptual model or map.

Many authors (e.g. Cavana et al., 2001; Hsieh and Shannon, 2005; Elo and Kyngäs, 2008; Easterby-Smith et al., 2012; Krippendorff, 2013) specified certain steps for conducting a content analysis, the most common ones are:

1. formulating the research questions,
2. locating relevant texts,
3. selecting the sample,
4. outlining the coding process,
5. implementing the coding process,
6. developing coding categories,
7. mapping the relationships across,
8. analysing the results of the coding process.

Content analysis can be conducted by using software program (for instance NVivo) or manual coding can be used. While using manual coding, it is crucial to highlight each topic as it occurs and classify it as theme code; by using computer program (in comparison to manual coding) is possible to save some time because it is not needed to physically undertake these activities (Cavana et al., 2001). We have chosen to employ qualitative content analysis for two reasons. First, we wanted to explore the content of the text and evaluate its quality. Second, due to underdeveloped research on this topic, only few papers were published, and thus utilizing manual content analysis seems more suitable than using software tool.

For the purpose of this study, qualitative data and qualitative content analysis were used. Qualitative content analysis is a method which provides interpretation of the content of text data through the coding process whereby, in our case, is achievable to identify topics and themes emerging in the area of KM of WM. We followed the analytical process including eight steps which were mentioned above and this process enabled description and interpretation of the content and also included evaluation of quality of the content. The outcome of the whole analysis is conceptual model which contains researched categories and depicts research in the field (see tables 3, 4).

3.2 Goal

Our main goal is to explore published research that deals with KM specifically in the field of WM. By achieving this goal, we will be able to identify topics that are studied in KM of WM and also identify topics for future research. According to our goal we have specified three research questions:

- Which topics are studied within KM and WM field?
- How are the topics studied?
- Why are the topics studied?

These research questions correspond with four coding categories: WM, KM, methodology (how), purpose (why).

3.3 Sample

To find empirical studies on KM of WM, search in SCOPUS and Web of Science was carried out. We used a search query “knowledge management” AND “waste management”. We designed this query, because we assume that if the study focuses on our topic, the author(s) would include these words in keywords or at least mention it in title or abstract. These searches yielded 74 (SCOPUS), respectively 8 (Web of Science) search results. Results from SCOPUS and Web of Science were overlapping; therefore we had 71 articles for disposal. To assess these articles according to their relevance, following criteria were established:

- type of article,
- source of article,
- time of publishing,
- language,
- abstract content,
- occurrence of word knowledge in full text.

First, the article had to be original research, thus we exclude review and letter article. Through this restriction, we wanted to avoid any possible confusion of review findings. As there was no published review article on this topic, this criteria was not necessary in our case. Second, only scientific articles from conferences and journals were used, trade journals and book series were excluded. Third, we did not apply any time limits, thus all published articles in this area were considered as valid. The search was conducted at the beginning of January 2014; therefore, newly published articles since that time are not part

of the study. Fourth, only English language articles were used (no other language was in results). Fifth, the topic of the study had to be consistent with our goal; therefore the last two criteria were content of the abstract and occurrence of word knowledge in full text. Last criterion was in some cases difficult to assess, therefore in some cases, full text analysis had to be conducted. The final sample of articles that were analysed can be found with its basic characteristics in Table 2.

3.4 Procedure

Before coding procedure, having relevant articles (ensuring validity) according to our goal was necessary to ensure. We applied sequentially criteria mentioned in previous section according to their position in the list, having six stages of refinement. If an article did not meet a criterion during any stage, it was immediately rejected from inclusion, and was not assessed in next stage. During fifth and sixth stage of assessing (and later even during coding), we stumbled upon an issue mentioned in section 2. Some authors probably misinterpreted the meaning of terms data, information, explicit knowledge and tacit knowledge. From this reason, it was not easy to distinguish information management articles (to be excluded from analysis) from KM articles. When full text was available, keyword “knowledge” was searched in full text and context of usage and meaning of this term was examined. Illustration of some possible misinterpretation can be viewed in Table 5.

After sixth stage, 18 articles complied with all criteria. We did not have access to all full texts, thus coding procedure was divided into two separate parts: coding of full texts and coding of abstracts of articles without full texts.

For analysing full texts and abstracts, we applied qualitative design of content analysis. The reason is because we want to evaluate the quality of the text and interpret/describe the content. We did not use any software tool to automate the procedure, because small sample of articles allowed us to manage the procedure faster manually without the necessity to accommodate to software tool.

In order to code this extensive literature and to ensure inter-reliability of coding, both authors independently participated on process of coding and the whole procedure was completed by both authors without disagreement. However, most articles were not coded similarly, but the difference between codes was complementary and not contradictory (e.g. one author had more extensive codes). Occurring dissimilarities were caused mainly

by different background of both authors. The first author has pure management background, while the second author has business informatics background. After merging codes from both authors, refinement of codes was done by one author. In the case of uncertainty, how to merge codes, both authors discussed the issue in order to come to an agreement.

After code merging, one author, which is more skilled in qualitative research, started to build sub-categories from codes. Sub-categories were divided to four domains (topic, WM, KM, methods and purpose of the research). Sub-categories were consulted with and reviewed by the other author.

Next step was to compare KM sub-categories identified by content analysis with types of knowledge and with processes that are part of KM (as described in section 2).

Some abstracts of studies without full text (6 instances) lacked explanation of what kind of methods were applied or what was the purpose of the study. Thus, from these abstracts was not clear how the study was conducted or what was the initial purpose of the study. These parts of text were considered as inconclusive and they were not included in our coding scheme, even though the codes which fit the other category as WM and KM were included.

4 Results

4.1 Sample characteristics

From 18 articles, we were able to obtain 10 full texts for content analysis. The ratio of conference to journal papers is 11:7. The numbers of publication in particular years are displayed in Table 1.

Table I: Number of publication in years

1999	2005	2006	2007	2008	2009	2010	2011	2012	2013
1	2	1	1	1	4	2	3	2	1

The most frequent conference, in which articles were published, is International Conference on Radioactive Waste Management and Environmental Remediation with 5 articles (almost half of all conference papers). Other conferences have only one published

article. Approximately half of conferences are from the WM field, the other half is aimed either on KM or information technologies.

The situation of articles published in journals is different from conferences. There is no journal which published more than one article. Most journals are from environmental issues field, except of one that aims on information and KM. Detailed information about articles can be found in Table 2 in appendix.

4.2 Results of Content Analysis

Our findings from the application of our categorization scheme to research into KM in the field of WM are summarized in Table 3 and 4 in appendix. These tables show topics which have emerged from our coding process. These topics were grouped categorically under established theories among those broader categories. The central categories are concurrent with research question which we have specified (see section 3) and they are:

- WM,
- KM,
- methods,
- purpose.

Within the WM category it is obvious that the radioactive waste management has deserved the most attention from scholars so far (7 instances). However, topics as waste water management and process of WM have received the second largest quantity of interest. Nevertheless, it is important to mention that we have recognized that different researches often conceptualize the same topic differently, which might cause misunderstanding in this area (see section 5). When considering what we have stated in the literature review about WM, there are many topics, e.g. waste utilization, waste-creating processes and incineration, which seem to have attracted less interest so far.

In category of KM, the most attention has been devoted to establish knowledge management system where the highest priority had been dedicated to creation and using of knowledge bases (7 instances). The other researched topics within this sub-category were KM practices and mechanism, knowledge sharing and assessing of KM. Only in one article the attention has been paid to organizational learning.

The vast majority of researchers have applied theoretical approach to research KM in the field of WM (6 instances). Nevertheless, some authors (5 instances) have employed

qualitative approach as case study or qualitative analysis of documents. Quantitative approach has not been broadly utilized (only 1 instance).

According to our coding scheme the main purpose of research in this area is to manage knowledge, which includes activities as structuring KM, supporting whole concept of KM and in one case is the purpose of having flexible and transparent. However, the most common reason is need to manage knowledge which usually has some specific focus. The second important purpose of conducting research in this area is to support decision process with accessible and convenient knowledge and technology tools (KMS).

4.3 Terms misinterpretation

As we suggested in section 2, terms information (management) and knowledge (management) can be misinterpreted. During analysis of full texts, we identified some misinterpreted or interchangeably used terms information and knowledge, and in some cases even data. This caused problems during analysis. Table 5 serves as a list of examples of some misinterpretations.

5 Discussion

Some results of our study suggest that research of KM in WM field is seriously undeveloped. First argument in favour of this fact is number of studies on the topic of this research. Only 18 studies in 15 years make roughly 1 study per year. This is in high contrast with approximately 41.000 studies on KM in SCOPUS and approximately 14.500 studies on KM in Web of Science. Supportive argument can be ration of conference to journal papers which is in favour of conference paper. On conferences, usually first stages of research are presented. Second argument for undeveloped research of KM in WM field is used methodology analysed in content analysis. Most research designs were theoretical or qualitative. This corresponds with the premise that the topic of KM of WM is under researched, because undeveloped research is usually typical by theoretical (conceptual) research designs or qualitative approach.

Different conceptualization of the same topic was identified, which might cause misunderstanding and misinterpretation (see section 3 and 4). Thus, we would encourage researchers to think more carefully about whether they use appropriate terms which adequately reflect underlying theory. This phenomenon occurred both in WM and KM

category. But more severe problems can be caused in the KM context than in WM context, because in WM context, it was more about using synonyms (e.g. radioactive waste and nuclear waste), however in KM context, terms with entire different meaning were used interchangeably (e.g. information and knowledge).

According to identified possible misinterpretations in table 5, some conclusions and questions can be drawn. Is constructing of knowledge-bases matter of KM or information management? Knowledge-base contains structured and unstructured information. This information is used by users of knowledge-base for constructing knowledge. Therefore, from our point of view, knowledge base automatically does not mean that KM is involved, because in terms of constructing and designing knowledge-bases, only information management perspective is concerned. KM is involved, when knowledge-base starts to be used for knowledge creation or conversion. Bigger problems can be caused by interchangeable using of information and knowledge. Although these two terms are connected with each other, their meaning differs deeply (see section 2.1 and 2.1). When terms and concepts are not grounded in theory (or even not defined at all as in some articles), their interpretation and further analysis is complicated or not possible. Therefore, our recommendation for future studies is to always employ in theory defined concepts.

Implications of our findings in coding category of WM come from comparison of sub-categories from content analysis and theory from literature review. First, KM research in the field of WM should focus more on parts of WM hierarchy introduced by Kirkpatrick (1993). The focus of research, in compliance with Pongrácz and Pohjola (2004), should be targeted more on KM of re-use, recycling and waste minimization and not only on disposal.

The fact that only in one article, the attention was paid to organizational learning, which is from our point of view one of the most important category of KM research, implies (as stated above) that development of KM research is not satisfactory. Our analysis revealed that great attention is paid to articles focused on KMS. As this complies with development of information technology and its spread in organisations, these articles were the most problematic articles regarding misinterpretation of terms data, information and knowledge. Their nature and background is usually technological, and they employ more from information management perspective than from KM perspective.

6 Conclusions

The goal of this paper was to explore published research that deals with KM specifically in the field of WM. We have used content analysis to fulfil this goal. The most important finding of this study is the fact that research of KM in the field of WM is seriously undeveloped. The supportive evidence to this statement comes partially from sample characteristics and its size, and from analysed category aimed at employed research methodology.

Another important finding is misinterpretation and low theory grounding of concepts and terms regarding KM. Some authors are using terms information and knowledge interchangeably, possibly without knowing the difference and implications of such misinterpretation. When using other studies, alignment between concepts and terms is important (and it is the very basis of academic nature), otherwise it has no point of using research of others, when it is not clear, what are they writing about.

Acknowledgements

This study was conducted as a part of the research project MUNI/A/0814/2013 supported as Student Projects' Support Grant (Specific Research) by the Masaryk University.

	Decision support (Beljić et al., 2013; Chou et al., 2005; Garrido-Baserba et al., 2012; Jain et al., 2008, Aulinas et al., 2011; Makino et al., 2009a)					
	Sustainability through KMS (Soderberg and Kain, 2006)					
	Performance by organisational learning (Chen and Chang, 2010; Makino et al., 2009a)					

Table V: Possible misinterpretations in articles

Article	Possible misinterpretation
Chen and Chang, 2010	Through a designed or planned system, employee in the organization can acquire valued knowledge , generate and share the information .
Aulinas et al., 2011	In order to systematize the reasoning process, the knowledge in the UWS domain can be described by means of multiple strata each one containing a specific type of knowledge . The reasoning process can then be expressed by the various relationships between these layers, as a process that takes information from these different levels.
	Capturing and managing the huge quantity of data/information that has to be considered is an intrinsic factor that makes environmental systems a sophisticated domain. Organizing this data in a naive way can impact the efficacy of any knowledge-based system. Another intrinsic factor is the variety of data sources , which can result in inconsistent, uncertain or incomplete knowledge bases when different data sources are considered.
Garrido-Baserba et al., 2012	This global approach is based on a hierarchy of decisions that uses the information contained in knowledge bases (KBs) with the aim of automating the generation of suitable WWTP configurations for a specific scenario.
	The second compatibility knowledge base (C-KB) contains information about the different interactions amongst the treatment technologies
Umeki, 2007	Knowledge Management (KM) is a term commonly used in many areas of technology but, in general, focus is on conventional approaches to systematic handling of technical information .

Reverse flows as the source of knowledge for zero waste performance – integration of knowledge, quality, innovation and reverse logistics management

Alena Klapalova

Department of Corporate Economics, Faculty of Economics and
Business Administration, Masaryk University
Lipová 41a, 62800 Brno, Czech Republic

Structured Abstract

Purpose – Reverse flows consist of material, financial, information, knowledge, services and waste flows and should be handled as the resources that have more or less tangible and intangible value. Without the understanding of reverse flows as the valuable resources both efficiency and effectiveness problems arise that have negative impact on sustainable development of business. The primary goal of every enterprise is to minimise the emergence of some of these flows (especially material ones) since significant part of them turn into the waste for disposal. This means that enterprises should follow zero waste strategy. There are several business functions as well as fields of study which role is to help to follow such strategy. Nevertheless the statistics concerning the growing volumes of reverse flows and especially waste (e.g. municipal and industrial waste) show that despite the effect of consumerism there is the potential gap in the needed integration of those functions and fields of study. The purpose of this paper is to gain better understanding of the interrelationships among several business functions which integration supported with appropriate management approach should lead to zero waste performance. Design of the conceptual framework with the knowledge management as the basis for the integration and some empirical evidence of its functionality are presented in this paper.

Design/methodology/approach – Extensive literature review of knowledge management and quality, innovation and reverse logistics management was carried out to design conceptual framework. This framework was tested through the empirical survey of 130 enterprises. Data acquired from the structured questionnaire were analysed with the aim to find out the existence and character of hypothetical relations among the elements of proposed conceptual framework.

Originality/value –The results of the survey represent one of the first attempts to find empirical support for the role of knowledge management as the integrator for quality management, innovation management and reverse logistics. Proposed conceptual framework takes rather broad perspective, considering points of contact among these business functions and the existing theoretical knowledge in order to facilitate zero waste strategy.

Practical implications – The proposed conceptual framework has both theoretical and managerial implication. It contributes to the existing management literature by identifying and highlighting the intersections of those parts of quality, innovation and reverse

logistics management that should be interconnected for accomplishing zero waste and to minimise reverse flows and show the role of knowledge management.

Keywords – Reverse logistics, Knowledge management, Quality management, Innovation management, Zero waste performance.

Paper type – Academic Research Paper

1 Introduction

There are many processes that help to minimise waste or eliminate the formation of waste. From the internal processes value management, product and process design, or more broadly innovation management or quality management, from processes that overlap the borderlines of companies supply chain management and logistics together with reverse logistics and for instance demand management belong to the most important areas (Andersson et al., 2006; Heidrich et al, 2009; Mossman, 2009; Scott, 2009).

Several decades yet the theory devoted to the issue of knowledge management and even much longer history of theory building concerning innovation and waste management has been developed but despite of this fact there is a gap in integration of the interest and existing knowledge among these three fields of study and practice. Knowledge management seems to be strongly ignored and neglected by academicians dealing more or less broadly with waste issues. Waste management is the complex problem solving area and to offer efficient and effective solutions it requires also the knowledge from multidisciplinary, interdisciplinary and transdisciplinary points of view, predominantly from experts on quality and innovation management. Nevertheless theory is almost silent and only fragmented knowledge is available (e.g. Sharma, and Vredenburg, 1998; Lapré et al., 2000; Bowen et al, 2001; Ameri and Dutta, 2005; Söderberg and Kain, 2006; Orsato et al, 2007; Egbu and Renukappa, 2008; Vachon and Klassen, 2008; Genchev et al., 2010; Sarkis, 2012) are available.

There is strong need for research and investigation of best practices, approaches, barriers, triggers focused on knowledge management and its application and progress in managing waste with the inspiration from and for innovation and quality management while especially these fields are very rich – on individual basis – in the sense of disposing with many methods, tools and techniques that can be applied across each other field to solve various problems with waste.

There are several aims which this paper is focused on. The first one is to offer the review of current state of theoretical knowledge about integration of five areas – reverse

logistics and waste, quality, innovation and knowledge management. The second one is to introduce the suggestion of conceptual framework as the base for further investigation of integrated areas. And third is to present some findings of the empirical survey to make an “entry evidence” of conceptual framework functionality. Two research questions were formulated for the empirical survey, namely: 1. Is there some relation and probably also the impact of the existence of quality management system on knowledge, innovation and waste management? And 2. What relations can exist between knowledge, quality, innovation and waste management?

2 Theoretical background and conceptual framework

Waste represents enormous and globally still growing share of reverse flows. There is no agreed definition of reverse flows. From existing literature it can be concluded that as reverse flows flows of products, packaging, waste, materials, raw materials, in process inventory, components but also related flow of information and money that are returned from any forward supply chain link to some point for further disposal may be termed (De Brito, 2003; Quesada Fernández, 2003; Rogers & Tibben Lembke, 1999; Thierry, Salomon, Nunen, & Wassenhove, 1995). According the report of McKinsey (2011) 10 million tons of material in companies every day is designated to be waste and 70% of this volume goes to landfill which is the terminate mode of disposal.

Reverse logistics (or reverse supply chain management) deal with waste as one part of other reverse flows. To clarify the essence of reverse logistics for instance Vogt et al (2006, s. 234) define reverse logistics as:

"Reverse logistics is the management of all the activities involved in goods, demand information, and money flowing in the opposite direction of primary logistics flow. It involves reducing the generation of waste, as well as managing the collection, transport, disposal, and recycling of both hazardous and non-hazardous waste in a way that maximises the long-term profitability of the business."

This definition enables relatively broad understanding of the environment in which reverse logistics operates because it does not exclude internal business processes from the angle of vision. What we mean with this is that waste emerges in many internal processes and must be handled somehow that is mostly provided also by internal logistics. Nevertheless the prevalent view on reverse logistics is connected to the external relations of companies.

Empirical research shows that not all companies are able and capable to manage waste, or the outcomes from processes that are evaluated as waste although a substantial part of it need not to be reckoned as waste (Eurobarometer, 2012). There are of course many reasons explaining such situation. One of them can refer to knowledge management as the central point which have linkage and effect (and mutual effect) with other areas of management.

There is probably no doubt to claim that waste is created from resources that companies have and spend to produce some value. If resources and produced value turn into waste, companies must cope with problems and try to find solution what to do with waste. Nevertheless this is reactive way solving consequences. What is much better is to be proactive and try to detect and eliminate reasons or causes and discover possibilities how to utilise unavoidable waste as opportunity. Otherwise waste can be very costly and works as lost opportunity (Knott, 2009).

If and how waste can be minimise, eliminate or evaluate as an “old-new” resource or new input for the company itself or for some stakeholder and so help to sustain, keep old one or gain a new competitive advantage depends especially on the other group of resources, namely knowledge, capabilities and competencies of managers, owners, employees (e.g. (Barney, 1991, Grant, 1991).

Prahalad and Hamel (1990) call these resources as group learning – in the meaning of connecting and sharing of individual knowledge and competencies across organizations together with perfect coordination among functional activities (Day, 1984, p. 2). Amit and Shoemaker (1993) state that specifically capabilities are developed mostly in the functional areas (as the consequence of specialization and the possibility of layering, deepening and widening of knowledge and skills) but also at the corporate level by the combination of diverse physical, human and technological resources.

But what serves as the starting point is the existence of people with knowledge and capabilities and competencies. For the case of waste management as one example (and the primary example for this paper) it means that if there are such people they are able to perceive waste as resource and they are also able to look for and find solution for its minimisation and elimination in both the internal and external environment. This is the case of so called dynamic capabilities/competencies (Teece et al, 1997) and often the „superior knowledge“ and probably capability and ability) as well that lead to more effective and efficient internal resource utilisation in comparison with the purchase and/or acquisition of external resources (Priem and Butler, 2001)..

Searching for new possibilities and new combinations is connected to innovation behaviour (Hunt and Morgan, 1996). Walker (2004) writes about „innovation capabilities”. This is one tight link between knowledge and innovation management. But innovation capabilities can be jointed to the concept of learning within continuous improvement. According Mukherjee et al (1998, in Linderman et al, 2004) there are two categories of learning in the frame of continuous improvement activities - so called conceptual learning, i.e. „know why“ and operational learning, i.e. „know how“. As Linderman et al state this understanding of learning and knowledge is based on so called technical knowledge what means to comprehend the effects of inputs on outputs. When dealing with waste Linderman et al also cite study of Lapre et al (2000) – verifying results of previous study of MacDuffie (1997), focused on waste minimisation activities in one company and on long-term effect of learning on these activities. According the results of both studies only those projects, which composed „know why“ and „know how“ in lead to positive outcomes in waste minimisation (Linderman et al., 2004). Continuous improvement is concept that belongs to quality management. One other example of quality management and learning linkage is Shewhart or Deming cycle PDC(S)A (Plan, Do, Check, resp. Study, Act), that was called by Deming as learning cycle (Linderman et al, 2004).

There are many other examples of relations between quality management, waste management itself and as the part of reverse logistics, innovation management and knowledge management in the practice of companies. One of quality management purpose is to prevent waste creation also by knowing what customer needs and wants. Customer in the point of view of quality management can be also the internal one – as the receiver of inputs from preceding value creator – internal supplier (Juran et al, eds., 1998). This means that quality management should detect information for product innovation and design and with this stream also the information for process design and innovation. If and how this is provided is also the result of knowledge management. When considering the role of reverse logistics and for instance that one which covers external supply chains, reverse logistics should bring many information and knowledge about why, where, when, how much and what type of waste emerge that again can be turned into some innovation of products and processes. Nonetheless as for instance Wadhwa et al (2006) conclude is that knowledge management in reverse logistics that would lead to innovation is not well understood, well researched and also in many companies not well practiced in average except of some examples from recycling and

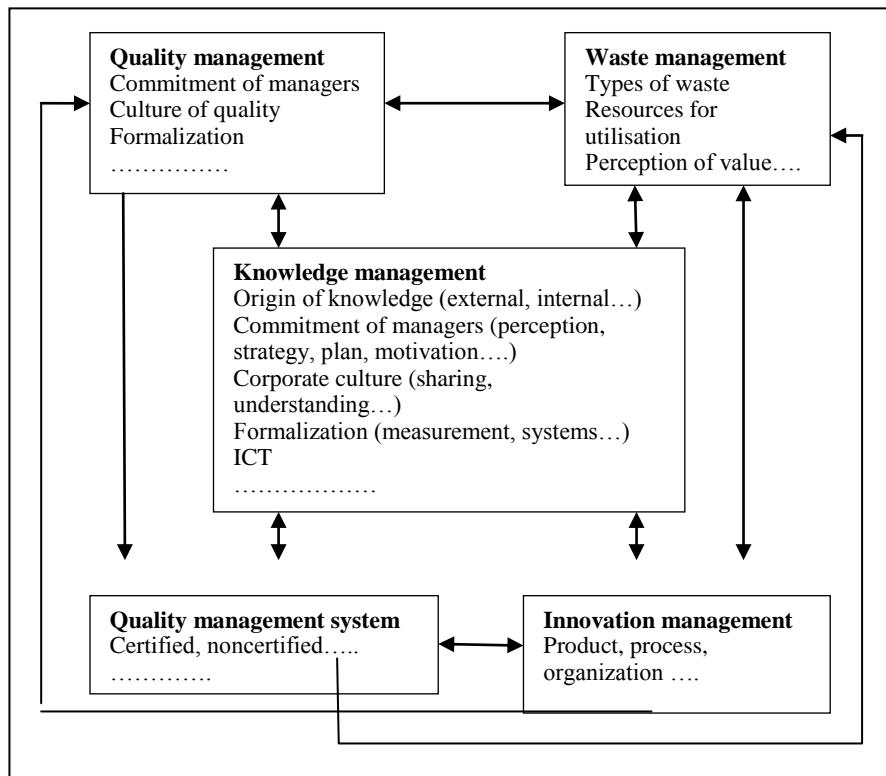

green product and process design (Pohlen and Farris, 1992; Orsato et al, 2007; Henriksen et al., 2012).

Our review also shows that probably the only one existing academic work that deals with the integration of reverse logistics, quality management (Total quality management - TQM) and innovation is the paper of Mihi-Ramírez and Arteago-Ortiz (2007). Some other scarce examples less or more concentrated on the integration of all or at least two or three mentioned areas are for instance: Harms (2011) – supply chain, knowledge management and environmental sustainability, Robinson et al (2006) – knowledge management and environmental sustainability, Schiuma and Carlucci (2012) – knowledge management and product innovation or some other papers of Mihi-Ramirez and his co-authors (2011; 2013) – knowledge management and reverse logistics, resp. green supply chain management.

3 Conceptual framework

The ideas from theoretical review presented in preceding paragraphs enter into the proposed conceptual framework displayed in Figure 1 and outlined further.

Figure 1: Conceptual framework

Conceptual framework is not static; on the contrary it is opened to other relevant concepts, areas of concern, issues of management etc. In its illustrated form presented in this paper it covers those elements that can be regarded as the most typical or the most general for all individual “macroelements”, i. e. basic concepts. Some of the elements and their relations are empirically tested for the purpose of this paper as the outcomes of the first analysis coming from our research.

Conceptual framework indicates also basic relations and directions of relations. Most of the relations are bidirectional, only two of them are unidirectional. Both concern quality management system. The idea behind it lies in the presumptions that quality management determines if and what quality management system will be and the existence of some system influences quality management only negligibly if anyhow. The same is with quality management system and waste management. Nevertheless this is point for further research and study as well as for discussion.

4 Methodology of survey and analysis

Since year 2009 longitudinal empirical research on various aspects of reverse logistics management in the Czech Republic has been realised by author of this paper and her colleagues. Findings from interviews as well as from some answers to some open questions embodied in questionnaires that were employed in the course of research showed that there are several issues in practice of managing reverse flows worth of deeper concern. Among them link between reverse logistics, quality management, innovation and knowledge (although not explicitly referred to management) has revealed as one of solutions for handling with reverse flows of material, packaging, goods and waste. This was the impulse to start to deal with this theme and some points were integrated into the investigation in the year 2012. Nevertheless, the literature review which has been done from this year lead to the need to research the problem into more depth and broaden especially the issue of knowledge management for the research in the year 2013. The main goal was to get started to look into this linkage and try to find expected relations and association of the linkage mentioned by several respondents and interviewers during the previous years of research and to test outlined hypothetical relations indicated in the conceptual framework (presented above).

Data from 162 questionnaires from the same number of companies were analysed for the purpose of this paper. Since there are more aims related to the research and despite broader space given to knowledge management, issues of quality management,

innovation management and waste management are covered much narrower. The logic behind it lies in the exploratory character of survey and in the goals for next years with the focus particularly on more dimensions of all four areas and their linkages.

The level of knowledge management in companies was measured through 16 statements covering various areas of knowledge management. Respondents were asked to evaluate perceived level by choosing one point on 7-points scale from 1- “I do not agree absolutely” to 7 – “I agree absolutely”. Level of reverse logistics management knowledge was measured with one question utilizing 7-points scale as well where 1 stands for the answer “knowledge of reverse logistics is considerably **higher** than knowledge of forward logistics” and 7 stands for the answer “knowledge of reverse logistics is considerably **lower** than knowledge of forward logistics”. Waste management directly and innovation management non-directly were involved in two of these questions and for the issue of waste and innovation management also one other individual order scale question was formulated. This question examines how much of existing waste companies use as the inspiration for their innovation activities with 7-points scale where 1 stands for “no share” and 7 for “100% share”.

For the investigation of quality management area three questions entered from the questionnaire into the analysis. One question is described below in the text as it had to be recoded for the purpose of analysis. Both two other questions are again 7-points order scales. The first one explores real implementation level of Total Quality Management philosophy in the practice of company and the second one real level of implementation of established quality management system in the practice. Point 1 represents answer “not at all” and point 7 answer “fully implemented”.

In this paper no causality was probed just simple bivariate relations. Following broad propositions were formulated to verify assumptions about relations from conceptual framework:

1. Companies with established quality management system are more likely to evaluate their knowledge management higher than companies without quality management system.
2. There will be positive relationship of knowledge management involvement and quality management involvement.
3. There will be a positive relationship of knowledge management involvement and waste and innovation management involvement.

For data analysis several statistical methods were involved. While the assumption of sampling distribution normality was deviated for whole sample as well as for split sample

into separate groups based on results of Kolmogorov- Smirnov (K-S) test (for all scores K-S test were highly significant) nonparametric tests were applied.

To obtain results to first research question and Proposition No 1 (looking for expected differences in answers to knowledge, waste and innovation management issues when companies have and have not established quality management system) Man-Whitney U test was employed. Existence and non-existence of quality management system were used as independent binary variable. This variable was created as the new one after recoding the semi-opened question searching for the type of quality management system, where several types of standardized system were proposed together with the ability to mark the answer “own company system”. If respondents did not choose any of the answers and they also did not mark anything or they marked 1 on the scale from another question which investigates the level of real implementation of established quality management system, these answers got 0 as binary variable. Another binary variable was 1 for companies which have some established system.

Second statistical method applied to obtain answers to the second research question and for Proposition No 2 and 3 was Spearman’s Rank correlation test for non-normally distributed data measuring relationship of two ordinal scales. We used SPSS IBM statistical software (version 22) for data analysis.

5 Empirical findings

5.1 Descriptive statistics

From 162 companies 106, i.e. 56,4%, belong to the service industry (mostly from HORECA sector, i.e. hotels, restaurants and cafés) and 56, i.e. 34,6% to other industries. 106, i. e. 65,4% companies are with the number of employees the small ones (1 – 49 employees), 34, i.e. 21% companies are middle (50 to 249 employees) and 22, i. e. 13,6% are big companies (250 and more employees). In 39 companies (24,1%) there is no existing quality management system, the rest 123 companies (75,9%) have some system (with certification, e.g. ISO 9001, ISO 14001, HACCP or without certification in the form of own system).

Table 1 shows results of Means (together with frequencies and Standard deviations) to the scale questions. Waste as the source of ideas for innovation is employed at the very low rate – 40,1% of companies in ample are not inspired by waste to innovate at all (54,1% of companies without any quality management system and 35,8% of companies

with some quality management system). Level of knowledge how to manage reverse logistics is lower than level of knowledge of forward logistics, but the Mean (4,362) indicates that the situation is not “so bad”. Companies do not implement very much the philosophy of Total Quality Management in their practice as it is evident from the Mean related to this issue (just 3,105 from 7-points scale). Nevertheless if they have any quality management system the level of its real implementation is smoothly better (Mean 4,106) although Standard deviation shows bigger differences in answers.

From all sixteen questions that investigate knowledge management the highest level of answers in average was found in cases when:

- a) companies apply knowledge management to solve problems with errors and waste minimisation endeavour (Mean 4,811);
- b) when needed knowledge is acquired through employees training and qualification improvement (Mean 4,800) and
- c) when knowledge management is incorporated into company strategy (Mean 4,764).

On the contrary the lowest level of knowledge management was detected when:

- a) companies purchase needed knowledge (Mean 3,019);
- b) in the case of evaluation the role of information system as the tool that should help with knowledge and ideas search, acquisition, categorisation and sorting (Mean 3,158); and
- c) when respondents should give the rate of agreement with the utilisation of specific measures for knowledge management quality assessment (Mean 3,166).

Measurement of knowledge is probably of less use within companies as the result for another statement related to this area is also below the average – namely the Mean for the statement “level of knowledge management is monitored, measured and assessed on a regular basis” which is 3,231.

Also the Means for such dimensions of knowledge management as: 1. the individual self-training of every employee (Mean 4,443) and 2. conscious planning of knowledge management within all processes in companies (Mean 4,350), 3. attitude of managers to knowledge management perceived as of strategic important (Mean 4,321), 4. sharing of knowledge and information (Mean 4,323) and 5. Benefits of information technologies for obtaining needed information about the environment (Mean 4,323) are relatively high above the average which implicate the role of managers and employee commitment and understanding of knowledge management as the tool for improvement (see Table 1).

Nevertheless it seems that companies are more focused on their own internal milieu and probably less formalized distribution of information and knowledge within companies. This can be explained by the prevalent size of companies (small) and

character of business (not high tech knowledge) that need neither special structures and system for knowledge management nor specific knowledge which have to be gained from the external experts.

Table 1: Descriptive statistics (frequencies, Means and Standard deviations) for surveyed variables

variable	innovative ideas from waste	level of knowledge of reverse logistics (inverse scale)	real implementation level of TQM	real implementation level of QMS	knowledge acquisition is a part of individual self-training of every employee
N	157	160	162	123	158
Mean	2,344	4,362	3,105	4,106	4,443
SD	1,5554	1,3198	1,8199	2,0115	1,7540
variable	knowledge management is a part of company strategy	knowledge management is consciously and planned integrated into all company processes	needed knowledge is acquired through employees training and qualification improvement	needed knowledge is acquired by purchase	needed knowledge is acquired by sharing with partners
N	157	160	160	160	160
Mean	4,764	4,350	4,800	3,019	3,712
SD	1,6646	1,7811	1,7762	1,5025	1,6306
variable	specific measures are used for knowledge management quality assessment	level of knowledge management is monitored, measured and assessed on a regular basis	in company there are systems and spaces for knowledge exchange among people and for learning from each other	employees often share ideas with other people with common interests although they work in different departments/ areas	our information system helps with knowledge and ideas search, acquisition, categorisation and sorting
N	157	158	159	158	158
Mean	3,166	3,231	3,797	3,874	3,158
SD	1,6166	1,7296	1,9213	1,7122	1,8426
variable	thanks to information and knowledge sharing we often find new ideas that can be utilised for company development	thanks to the information technologies we have access to various information and knowledge related to the environment, e.g. competitor,	managers evaluate knowledge as the strategic resource critical for the company existence	knowledge management is focused on errors and waste minimisation	employees who brings new ideas that lead to reverse flows minimisation are remunerated

		market changes etc.			
N	158	158	159	159	159
Mean	4,323	4,278	4,321	4,811	4,031
SD	1,6978	1,7038	1,7254	1,5718	2,0296

5.2 The impact of quality management system existence on differences in knowledge management dimensions, knowledge of reverse logistics and innovation from waste management

Table 2 reports findings of nonparametric Mann-Whitney tests of differences between companies that have and have not any quality management system and impact of the existence or non-existence on (or relation with) investigated dimensions of knowledge management, knowledge of reverse logistics and level of waste utilisation for innovation. It is obvious that except two variables to have or not to have quality management system manifest substantial statistically significant differences in observed indicators. Existence of such system does not have substantial relation with the level of knowledge of reverse logistics management and knowledge acquisition in the form of individual employees training effort. Statistically significant difference was not found also with the information system as the tool for environment information and knowledge gathering however p value is just slightly above 5% significance level ($p=0,056$). Medians explain differences more illustratively

Table 2: Differences between companies in knowledge and innovation management dependent on existence/nonexistence of quality management system

variable	innovative ideas from waste	level of knowledge of reverse logistics (inverse scale)	knowledge acquisition is a part of individual self-training of every employee	knowledge management is a part of company strategy	knowledge management is consciously and planned integrated into all company processes

5.3 The association of measures within quality management, knowledge management dimensions, knowledge of reverse logistics and innovation from waste management

Spearman Rank Order Correlation test proved at the significance level 0.05 that there is an association between two measure of quality management and measure of waste and innovation management as well as between two measures of quality management and several measures of knowledge management (see Table 3). All presented associations are positive. Stronger positive association were discovered with measure that evaluated the level of TQM implementation in practice of companies in view of the fact that the number of companies that could reply to the second measure of quality management was substantially lower. Correlation coefficients are relatively small (and very small) however this fact can be explained by the number of cases (162, or about 130 and about 32 for individual measure respectively).

Results of the Spearman correlation coefficients indicate the strongest associations (significantly approved by p values) between TQM level of implementation and the level of:

a) use of specific measures for knowledge management quality assessment ($r=0,498$, $p=0,000$);

b) agreement with the statement that information system helps with knowledge and ideas search, acquisition, categorisation and sorting ($r=0,412$, $p=0,000$);

c) agreement with the statement that knowledge management is a part of company strategy ($p=0,383$, $p=0,000$);

d) agreement with the statement that knowledge management is monitored, measured and assessed on a regular basis ($r=0,363$, $p=0,000$);

e) agreement with the statement that knowledge management is consciously and planned integrated into all company processes ($r=0,363$, $p=0,000$);

f) agreement with the statement that in company there are systems and spaces for knowledge exchange among people and for learning from each other ($r=0,360$, $p=0,000$);

g) knowledge management is focused on errors and waste minimisation ($r=0,276$, $p=0,000$).

For all of these measure except one also statistically proved association was found with measure of the level of quality management system real implementation. The only one exception concerns letter d) in the items introduced above what reports little bit controversial situation. One of requirements for any management system (and all certified quality management system) is to monitor measure and evaluate the system. It could be expected that if company provides such activity for one area, it probably would provide it also for another area, especially if both are logically interrelated. On the other side, p value is not significant at 0,05 level ($p=0,056$), but it indicates that there is some relation, just not strong.

Measure of association between waste and innovation management (1 variable) and quality management (TQM) shows also statistically significant result, nevertheless correlation index is very small ($r=0,188$) with p value 0,018. For another quality management measure the association is not statistically proved ($p=0,280$).

No association was found with both measures of quality management and 4 measure of knowledge management as well as 1 measure of reverse logistics knowledge. The 4 measures of knowledge management are connected to the statements: a) knowledge acquisition is a part of individual self-training of every employee, b) needed knowledge is acquired by purchase, c) needed knowledge is acquired by sharing with partners and d)

thanks to the information technologies we have access to various information and knowledge related to the environment, e.g. competitor, market changes etc. The first result can be influenced by the size of companies again. The individual self-training of every employee can be regarded as natural with or without any quality management effort, philosophy “enforcement” or system involvement. This is supported also by Medians for companies that have some quality management system (MD=4,00) and which do not have (MD=5,00) as introduced above. Missing associations in the case of two variables linked to the external acquisition of information and knowledge, regardless of the relative high Means showing relative average utilisation of the way how to obtain needed information and knowledge, can be evidence of absencing mental linkage of managers between their perception of what knowledge management can involve and quality management content. Another explanation can be that quality management may be reckoned as more internal matter of companies without just very low impact of knowledge flow from some external stakeholders.

If analysing just quality management system implementation level (1 variable) even more no-associations were detected (despite the existence when TQM issue is employed) where p value cannot be considered as significant at level 0,05 (the most of all calculations are realized at level 0,05 as stated above) nevertheless as significant at level 0,10. They are linked to the statements: a) innovative ideas from waste, b) employees often share ideas with other people with common interests although they work in different departments/areas and c) thanks to information and knowledge sharing we often find new ideas that can be utilised for company development.

Table 3: Association between quality, knowledge, waste and innovation management measures

Sig.	0,011	0,000	0,001		
r (QMS)	0,156	0,156	0,170		
Sig.	0,085	0,084	0,060		

When splitting the file into one with companies that do not have any quality management system and into the one with companies that have some system also differences in correlation of knowledge management measures were detected. We introduce here just the results with coefficient above 0,600 and one finding with coefficients above 0,500 which seems to be interesting. Strong association was ascertained in the group of companies which do not have any system between variable *“knowledge management is a part of company strategy”* and variable *“knowledge management is consciously and planned integrated into all company processes”* ($r=0,747, p=0,000$) and between the second variable and variable *“thanks to information and knowledge sharing we often find new ideas that can be utilised for company*

development” ($r=0,754$, $p=0,000$). In this group also association between knowledge acquisition from partners and variable “*employees often share ideas with other people with common interests although they work in different departments/areas*” was detected ($r=0,536$, $p=0,000$) and also variable “*thanks to information and knowledge sharing we often find new ideas that can be utilised for company development*” ($r=0,778$, $p=0,000$). This was not the case in the group of companies with existing system of quality management or rather found association of the first pair was relative weak when considering correlation coefficient ($r=0,351$) although p value proves significance ($p=0,000$). No association was found with second pair. What was nearly the same for both groups is the strength of correlation between variable „*knowledge management is a part of company strategy*” and variable “*knowledge management is consciously and planned integrated into all company processes*” ($r=0,692$, $p=0,000$). And finally strong association was discovered between both variables concerned measurement of knowledge management for this group ($r=0,633$, $p=0,000$) but also for the group with no system ($r=0,585$, $p=0,000$).

With all of these associations we have to point out to differences in Medians introduced in Table 2 which give picture better explaining and supporting these results.

4 Summary of findings

Findings support the importance of attitude and commitment of managers to knowledge management which is reflected in the strong positive association to quality, waste and innovation management. Specifically the incorporation of knowledge management into the strategies and plans seems to be very important together with understanding of the effects of knowledge sharing (both spontaneous and formalized) and measurement of knowledge management. Another conclusion stemming from the survey is the perception of value contained in some form in waste as a part of knowledge management effort and also the motivation of employee to share and develop mutual knowledge. Total quality management as the way of continuous learning has stronger association with knowledge and waste management in comparison to the existence of quality management system. But also the existence-non-existence of quality management system examination confirm the positive role of existence and its closer relation with knowledge and innovation management as well as waste management.

5 Limitations of empirical survey

The major limitations of survey lie in the number of responses which cannot support the relevance of the conceptual framework sufficiently. Number of responses does not allow using more sophisticated statistical tools – or in other words – results of statistical analyses (and not only of more sophisticated) cannot be generalized. Another limitation relates to the multipurpose character and design of questionnaire. All four researched issues (knowledge, innovation, waste and reverse logistics management) should be investigated more deeply and not just through very limited range of variables. Structure of sample with the prevalence of small companies and from HORECA sector also reduces the validity of results to be considered as the typical picture of reality and to be accepted as the solid foundation for the framework. Nevertheless they can serve either for the imagination of a picture how reality can be and for comparative studies for the same and/or different industries and sectors.

6 Conclusions and further research opportunities

As it was stated in the previous text the presented conceptual framework can serve as the very general basis for further research. There are many directions that can bring many new knowledge helping to enrich both theory but also the practice. Our empirical survey has brought some evidence about the importance of the existence of quality management system for knowledge, waste and innovation management. But – as introduced in limitations – there is much to investigate also in case of quality management system in the frame of multiple relations to much more diverse knowledge and innovation management issues with or without direct linkage to waste management. The framework itself can be filled in with the area of human resource management in the context of managing waste and managing innovation. Or as another suggestion the role of various stakeholders and knowledge flows for waste an innovation management can be examined.

Intellectual Capital Reporting at Italian Universities

Daniela Sangiorgi, Benedetta Siboni*

Department of Management
University of Bologna

Structured Abstract

Purpose – Intellectual capital (IC) plays a crucial role in the university sector, which could be considered a proper knowledge institution (Ramirez and Gordillo, 2014). In Italy IC report is not mandatory for universities. Nevertheless, several institutions include IC information within their social reports (Ricci *et al.*, 2014). The purpose of the research is twofold. First, it aims to investigate the amount and nature of IC voluntary disclosure in Italian universities' social reports, as well as to examine the influence of the size of universities in IC reporting. Second, it aims to examine the internal perspective of Italian universities' General Directors on IC management and disclosure.

Design/methodology/approach – This study answers to Bezhani's (2010) call for comparative research, by applying the same methodological approach. Content analysis (Krippendorff, 2004) has been used to determine the amount and the nature of IC disclosure in a group of 17 Italian university social reports issued before February 2013. In addition, an on-line questionnaire has been submitted to all university General Directors, in order to investigate the internal perspective of Italian universities on IC disclosure and the opportunity of establishing an IC mandatory report in universities.

Originality/value – To our knowledge, no previous research has been conducted on IC reporting with regard to Italian universities yet. Thus, the current paper contributes to creating new expertise with concern to IC reporting in the university sector. Also, it gives insights into General Directors' views on IC management and disclosure as well as on IC mandatory reporting. Finally, the study fosters international comparative research on IC reporting in universities by providing the Italian picture.

Practical implications – This work encourages Italian universities to enquire on the benefits achieved by IC reporting. Moreover, the paper gives recommendations for additional IC reporting indicators with regard to the university sector, in order to provide a comprehensive assessment of IC assets. Furthermore, the study prompts policy-makers to enquire on the utility of mandatory IC reporting by universities. In doing so, it opens up new horizons, both for future research and policies.

Keywords – Intellectual Capital, University, Social Report, Italy, Content Analysis.

Paper type – Academic Research Paper

1 Introduction and background of the study

Starting from the new century a number of critics of traditional financial reporting have pushed academics and practitioners to propose alternative frameworks for organisation reporting. Such frameworks have been grouped in two main categories (Guthrie *et al.*, 2007): Social, environmental and sustainability frameworks, oriented to give an account of the external impacts of organisational activity from a stakeholder's perspective; and Scorecard and intellectual capital frameworks, oriented to put the measurement of knowledge intensive resources within a strategic context.

In such a context, managerial literature on Intellectual Capital (IC) has experienced a significant growth in the last decade (e.g. Guthrie *et al.*, 2012; Serenko and Bontis, 2013). Nevertheless, there is still a lack of agreement within literature upon the definition of IC (Leiner, 2004; Beattie and Thomson, 2007). However, there has been wide agreement upon the fact that IC can be conceived as the amount of not-tangible internal and external resources available for combining tangible, human and financial resources in order to produce value for stakeholders and obtain a sustainable competitive advantage in organisations (Zambon, 2001; Lev and Zambon, 2003).

Recent studies have traced a three-stage development of IC research (Guthrie *et al.*, 2012; Dumay and Garanina, 2013). The first one ranges from the end of 1980s to the late 1990s. It focused on raising awareness and agreement on the meaning of and the necessity to measure and report on IC. Parallels, guidelines and standards for measuring and managing IC in organisations have been proposed (e.g. Edvinsson, 1997; Stewart, 1997). The second stage, in 2000s, continued to refine guidelines for IC management and reporting in organisations. Furthermore, several studies examined the impact of IC in financial performance and value creation. Also, several classifications of IC were proposed by literature (e.g. Petty and Guthrie, 2000; Marr and Chatzkel, 2004). Finally, the third stage of IC, which is currently emerging, is featured by research critically examining IC in practice (Guthrie *et al.*, 2012).

In addition to the development that IC has experienced in the literature several initiatives have been put in place to support the dissemination of that concept within organisations managing and reporting practices. The initiatives that have gained the widest diffusion (Chiucchi, 2004; Fabbrini and Ricciardi, 2007) and that have been strongly backed and accredited from both the international literature and practice were produced by Governments (DATI, 2000; DMSTI, 2003; FMEL, 2004; METI, 2004; SKE,

2005) and by the European Union (Meritum, 2002; ICU - OEU, 2006; RICARDIS – European Commission, 2006; InCas, 2008).

In particular, a call for a European standard for IC reporting and documenting the value of intangible assets was formulated in 2000 by a group of experts working on a project devoted to the knowledge-based economy and financed by the European Union (Cowan and Van de Paal, 2000).

Sometimes initiatives and literature have used different IC classifications (Canibano *et al.*, 2000). Despite that, “*they are all similar with respect to the way IC is measured and valued*” (Leitner, 2004, p. 131). The most popular classification for IC (Leitner, 2004) has been proposed by Meritum (2002) which distinguishes IC in human, structural and relational capitals, where the human capital represents the knowledge owned by employees, that hence they take with them when leaving the organisation. The concept of structural capital represents the knowledge that remains inside the organisation at the end of the working day, because it is embedded in a system of cultures, organisational routines, procedures, databases, etc. Lastly, relational capital refers to all resources activated in the external relationships that the organisation entertains with customers, suppliers, and research partners.

Drawing on the global importance that managerial literature, the European Union and several Governments have assigned to IC, in the last decade also the university sector has been involved in IC management and reporting practices (Ramirez and Gordillo, 2014). In this way the Austrian Government required a mandatory IC report from all universities starting from 2006 (UG, 2002).

Also, OEU (2006) states that “*IC reporting may become mandatory for universities in the near future probably due to the fact that they are considered critical institutional actors in national innovation systems within the knowledge-based economy*” (p. 229). Moreover, Sánchez and Elena (2006) highlight that “*If a knowledge-based economy is mainly characterised by the production, transmission and dissemination of knowledge, universities are unique in all these processes*” (p. 530). Also, Leitner (2004) observes that “*A university’s most valuable resources are its researchers and students with their relations and organisational routines; their most important output is knowledge*” (p. 129). In the university context “*human capital is the knowledge of the researchers and non-scientific staff of the university. Structural capital comprises the routines and processes within an university, an often neglected infrastructure of theirs. Relational*

capital comprises the relationships and networks of the researchers as well as the entire organisation” (Leitner, 2004, p. 133). In doing so, IC has been considered both the result of an organisation’s research and development activities, and the driver that enables the creation of greater value from those activities (RICARDIS - European Commission, 2006).

In particular, Leitner (2004) highlighted the following benefits that potentially can emerge from the mandatory IC report at the Austrian universities. First, IC report provides information for university management in order to develop suitable strategies and objectives (for instance in relation to whether and how to invest in the training of scientists, with whom to co-operate, which research programs should be emphasised, etc.) and to learn about the university knowledge-production process. Second, IC report increases transparency by providing external stakeholders with information about the development and productive use of IC. Among the other stakeholders, the policy-makers in such a way can get information to rank or benchmark universities and get information about the strengths and weaknesses of the science system in order to formulate the national science and education policy. Furthermore, funding agencies, industrial firms, students, etc. might benefit from IC report in order to get information about the IC which is a good indicator of the university future potential performance. This is also of interest for funding agencies that spend their research grants based on peer-reviewed research proposals. Third, a standardised model for IC report allows both university management and external stakeholders to make comparisons between different disciplines and between entire universities.

By contrast, possible difficulties in elaborating IC report have been identified by Leitner (2004) as follows. First, the necessity to define clear goals and evaluation criteria, which are related to the goals and interest groups, in a specific context where there is no agreed definition about outputs and their evaluation. Second, in the university sector there is an intrinsic difficulty on evaluating outputs since they produce important impacts on society and the territory that are difficult to measure and that can be estimated only over a long period of time. In addition, several universities’ outputs belong to the category of credence goods, which are goods that cannot be evaluated only by users *via* direct experience, but which need a broader evaluation from the academic community (Fia and Sacconi, 2013; Sacconi and Tamborini, 2013). Third, the necessity to define commonly accepted definitions and indicators for comparisons on the international level. Fourth, the

necessity for reviewers and funding agencies to learn how to interpret this new kind of information.

Drawing from such assumptions a number of studies have called for research with reference to IC managing and reporting in the university sector (e.g. Sánchez *et al.*, 2009; Bezhani, 2010; Siboni *et al.*, 2013a).

A research published by Bezhani (2010) enquired about IC disclosure by UK universities. The study found that IC disclosure was at its early stage: there were no specific documents devoted to IC disclosure and within annual reports only a little information was found with reference to IC. Furthermore, the research investigated the vision of the university Directors of Finance regarding the IC reports and the opportunity to require mandatory reporting of IC for UK universities. It was found that the university Directors of Finance were not aware of the Austrian mandatory IC report. Most of them agreed on the benefits related to such kind of reporting for external purposes. Also, several universities agreed upon the internal benefits related to IC report.

In order to answer the calls for research and intending to take place in the third stage of development of the IC (Guthrie *et al.*, 2012), the purpose of the current study is twofold. First, it aims to investigate the amount and nature of voluntary IC reporting in Italian universities in order to assess the importance given by these institutions to IC disclosure, and examines the influence of the size of universities in IC reporting. Second, it aims to give insights into the internal perspective of Italian universities on IC management and disclosure, as well as on the opportunity of establishing IC mandatory report.

The paper is organised as follows: section 2 outlines the principal initiatives for IC management and reporting at universities; section 3 presents the research method; section 4 illustrates the results of the analysis; section 5 provides conclusions and discusses the limitations of the research.

2 Initiatives for Intellectual Capital Management and Reporting at Universities

Drawing from the strong promotion undertaken by the European Union to disseminate IC managing and reporting practices within organisations, four main initiatives devoted to universities have been proposed. These are: University Act (UG, 2002), RICARDIS

(European Commission, 2006), ICU Report (OEU, 2006), and Italian Public Administration Law (D.lgs. 150/2009).

2.1 University Act

Austrian universities are legal entities in public law subjected to supervision and founded by the Federal Government. They are regulated by the University Act (UG, 2002) which refers to the paradigm of performance agreements. The performance agreement is an instrument that defines duties for both the universities and the Federal Government and assigns the global budget to universities for a period of three years (UG, 2002, art. 13). By the 30th of April each university has to produce a performance report that states the achievements of such a contract. The basic budget (i.e. the funding of each university) is negotiated by universities and the Federal Government on the basis of four parameters: needs, demand, performance, and social goals (UG, 2002, art. 13, para. 4). In addition, up to the 20% of total funding over the year is allocated on the basis of a list of performance indicators reported by each university.

Moreover, the University Act requires universities to produce an IC report for the past calendar year. *“While the performance report only deals with the topics addressed within the performance contract, the idea behind IC reports is to give universities the opportunity to report on their full range of activities without restrictions”* (Leitner, 2004, p. 132). The IC report has to be prepared by the University Rectorate and approved by the University Council. The document has then to be sent to the Ministry of Education, Science and Culture and published on the online University Gazette, in order to give it public access.

The IC report presents at minimum the following items in order to illustrate the knowledge-production process within universities (UG, 2002, art. 13, para. 6)¹:

1. the university’s activities, social goals (provided by the Ministry) and objectives and strategies (autonomously defined);
2. an account of IC belonging to the university, broken down into human, structural and relationship capital;
3. the processes implemented for elaborations of the performance agreement, including outputs and impacts set out.

In addition to the IC report referred to the whole university, each university can decide to produce separate IC reports on departmental, institutional or disciplinary levels,

as well as an IC report for other stakeholders that addresses the information needs of students or industrial partners, etc.

At the end of the IC report there is the evaluation of the impacts, which inform about deals with the achievements of the performance process with references to different stakeholders. Impacts are measured by a list of financial and non-financial indicators that are defined by the Ministry according to various academic disciplines (Leitner, 2004).

2.2 RICARDIS

In 2004 the European Union Directorate General for Research and Technological Development set up a group of experts (called RICARDIS) that was charged with elaborating a proposal for measures to stimulate the reporting of IC in research intensive organisations. In particular, the aim of the group of experts was to elaborate recommendations to: (1) guidelines for research intensive SMEs; (2) investors and other private stockholders on how to evaluate IC reports; (3) public policy makers on how to stimulate organisations to report on their IC.

The finding of the work of the group has been included in RICARDIS (European Commission, 2006) that states that IC is “*the result of, and the prerequisite for, successful R&D*” (European Commission, 2006, p. 10). It reviews existing regulations, models, methods and guidelines for reporting on IC, while it does not propose any new method. Furthermore, RICARDIS (European Commission, 2006) lists seven recommendations to stimulate reporting of IC over organisations. One recommendation is devoted to supporting IC report in higher education and research organisations, especially in universities with strong research programmes. That sector has been identified as playing a crucial role in participating in the efforts to develop IC reporting cultures and strategies, acknowledging the importance that it assumes in the period of important transformation led by the Bologna Process² and the emergence of the third mission which emphasises relationships with industry, public authorities and the general public. In such organisations, IC report has been conceived as a document for increasing their competitiveness and attractiveness, as well as assisting their internal management and relations with society.

2.3 ICU Report

In June 2004 the Observatory of the European University (OEU) was set up, within the PRIME Network of Excellence funded by the European Commission, with the aim to create management tools for the governance of research activities, as well as to develop a common framework for comparisons among universities and research institutions. In 2006, the Observatory issued a Strategic Matrix and a related Methodological Guide (OEU, 2006). The Strategic Matrix provides the higher education sector with an analytical and comprehensive framework to choose their strategic position in terms of research activities. The Matrix is organised via five thematic dimensions (funding, human resources, academic output, third mission, governance) and five transversal strategic issues (autonomy, strategic capabilities, attractiveness, differentiation profile, and territorial embedding). Also, it lists 141 indicators conceived to assist the management of universities and research institutions to compare performance over time and with different institutions.

The Methodological Guide (OEU, 2006) shows the results of the application of the Strategic Matrix in several universities, and discusses the handling of data. Moreover, it proposes a guide for the formulation of the IC report in universities and research institutions (namely, ICU Report). The ICU Report is intended to represent a sector level of standardisation, proposing specific sector indicators for universities and research institutions. It aims both to improve the universities' internal management and to disclose information to external stakeholders on the organisation's abilities, resources and commitments linked to the key determinant of its value. The ICU Report proposes to disclose information that universities should already gather, although not systematically or on a regular basis and usually spread over various documents.

The ICU Report (OEU, 2006) consists of the following three sections (by referring to Meritum, 2002 and DMSTI, 2003):

- *Vision of the institution* – that describes the organisations' strategy, objectives and the key intangibles to achieve those objectives;
- *Summary of intangible resources and activities* – which lists intangibles that need to be improved or acquired to fulfil the vision, as well as initiatives in process or planned with these objectives in mind;
- *A system of indicators for the intangible resource and activities* – which lists a set of 43 resource indicators for measuring IC in universities. They were chosen from the

141 indicators listed by the Strategic Matrix. The indicators are classified into the IC taxonomy of human, organisational and relational capital, and then organised under different headings corresponding to the strategic objectives that universities are expected to have.

No activity-related indicators were included in the list. This is because indicators were selected on the basis, on one hand, of comparability and feasibility of the gathering of data in universities and, on the other hand, of the willingness on the part of university authorities to disclose information (hence becoming reluctant to disclose sensitive information on strategic activities). For this reason the ICU Report represents an initial step for defining a common framework for IC report in universities, that needs further development in order to become a proper common framework (OEU, 2006; Sánchez and Elena, 2006).

2.4 Italian Public Administration Law

In 2009 the Italian Ministry of Public Administration issued a law (D.Lgs. 150/2009) inspired by the New Public Management approach (Hood, 1995; Lapsley and Miller, 2004; Pollit and Bouckaert, 2004) intended to prompt the introduction of a managerial culture focused on performance and driven by strategies and objectives by improving transparency, efficiency and effectiveness in public sector organisations. Universities, as a part of the broad public sector, are subjected to that law.

Among the other provisions, such law required state organisations (hence also state universities) to include information on IC both in the planning stage and in the reporting stage. Particularly, the framework suggested by the law states that *“to make the measurement systems even more effectively organizations can adopt a strategic map [...] A strategic map is used to link objectives to indicators, intangible resources to tangible indicators and indicators to targets. It can also be used as a means for communicating the strategy both within the organization, and towards external stakeholders.”* (CIVIT, Resolution no. 89/2010, p. 8). Where *“the use of typical intellectual capital indicators facilitates the understanding, even towards the outside, both of the quality and quantity of available human capital”* (CIVIT, Resolution no. 112/2010, para. 3.4.2., p. 16).

Drawing from this the framework identifies four categories for IC management (CIVIT, Resolution no. 112/2010 – Annex). The first category consists of the information capital, which represents the amount of all information flows and information systems,

shared and formalised knowledge at the disposal of organisations. The second category consists of the organisational capital, which is the result of the combination of culture, leadership, teamwork and alignment. The third category is the relational capital, which is the level of trust enjoyed by an organisation and its staff, and the intensity and quality of their relationships with their stakeholders. The fourth category is the human capital, which represents the sum of knowledge, skills, and talents of the staff of an organisation, at a particular time. However, the framework does not provide a comprehensive list of indicators to measure IC. It just gives a list of 21 examples of indicators for measuring human capital with reference to employee and organisational well-being, and gender (CIVIT, Resolution no. 112/2010 – Annex–Tab no. 2).

4 Research Method

The purpose of the current research is twofold:

- first, it aims to investigate the amount and nature of voluntary IC reporting in Italian universities in order to assess the importance given by these institutions to IC disclosure, and examines the influence of the size of universities in IC reporting;
- second, it aims to examine the internal perspective of Italian universities on IC management and disclosure as well as on the opportunity of establishing IC mandatory reporting.

In Italy research and teaching activities are considered public good and public responsibility (Italian Constitution, article no. 33), and are delivered by state and non-state universities approved by the national Ministry of Education. In the 2012-2013 academic year the university system comprised 96 universities, classified into 67 state and 29 non-state (CINECA, 2013). State universities are public entities funded by the national government for up to about 90% of their total needs. On the contrary, non-state universities are funded by the government for up to about 10% of their total needs, and therefore have a higher autonomy in establishing fees (Del Sordo *et al.*, 2011). Both state and non-state universities have scientific, teaching, organisational, financial and accounting autonomy (Agasisti, 2009).

The study applies the methodological approach used by Bezhani's (2010) research, which combines qualitative and quantitative research methods. In particular, content

analysis (Krippendorff, 2004) has been used to determine the amount and the nature of IC disclosure in a group of Italian university Social Reports (SRs).

Content analysis is “*a technique for gathering data. It involves qualitative and quantitative information into pre-defined polices in order to derive patterns in the presentation and reporting of information*” (Guthrie and Abeysekera, 2006, p. 120). It assumes that the volume of disclosure represents the relative importance of such disclosure (Unerman, 2000).

Consistently with Bezhani (2010) the unit of analysis chosen for analysing IC disclosure in Italian SRs was sentences. The content analysis recorded (1) if the IC indicators of the coding instrument were found in SRs, while (0) was recorded for indicators not found in the documents analysed (Annex 1). In addition for each IC indicator that was found in SRs the typology of information according to Bezhani (2010) classification was recorded. The analysis has been applied by one of the authors, who is an expert in the method; also, a reliability test was undertaken by the other author, also an expert in the method, on a pilot sample of SRs and no major issues of difference were reported, showing that the coding was sufficiently reliable.

We decided to analyse SRs for four reasons. First, because the Italian regulation does not require a specific mandatory document for reporting IC. Second, in conformity to GBS (2008)³ that identifies SRs as the documents devoted to include IC disclosure rather than to elaborate a stand-alone IC report. Third, in accordance to previous studies which have highlighted that SRs in Italy include IC information, both with references to universities (Veltri and Nardo, 2008; Nardo, 2014) and to companies (Cinquini *et al.*, 2012). Fourth, because several studies (Bontis, 2003; Abeysekera and Guthrie, 2005; Dumay and Cai, 2014) suggested to analyse reports other than the annual report, as research undertaken up to date found very few information on IC in the latters.

University SRs in Italy are conceived as tools to report on a university’s mission, values, results, resources, and to compare results against objectives, considering that they have a social mission and are funded with public money (Siboni *et al.*, 2013b). SRs have two main functions (Speziale and Zanigni, 2007; Meneguzzo and Fiorani, 2009): accountability and stakeholder governance. In particular, if we focus on the university as an institution, the social report is a document that concerns the creation of IC. Universities produce both internal outcomes, able to increase the human and organisational/structural capital and external outcomes and impacts, which create

relational capital. If we focus on the stakeholders governance function “*the social report is not only a document that describes the creation of intellectual capital, but also a proper system of governance that leads the strategic relationships among the university and its stakeholders*” (Speziale and Zanigni, 2007, p. 197).

For the purpose of the current analysis, SRs have been found by checking all state and non-state universities’ websites in February 2013. In particular, we found 20 SRs available for on-line download, including 17 documents reporting the comprehensive universities’ activities and 3 documents referred to specific university branches or projects. These latter documents have not been included in the current research because they would provide just a partial representation of university activities and therefore would have undermined the results of the research.

The coding instrument used for the content analysis is the one developed by Bezhani (2010), which derived from the Austrian University Act (Annex 2). It is organised in IC categories (No. 8) and IC indicators (No. 39). In addition, consistently with Bezhani’s (2010) study, we submitted an on-line questionnaire to all university’s General Directors, in order to investigate the internal perspective of Italian universities on IC disclosure and the opportunity of establishing IC mandatory report in universities. That decision also responds to the studies of Nurunnabi *et al.* (2011) and Dumay and Cai (2014) which claim that content analysis should be supplemented with other data sources collected by applying mixed methods (such as survey and interviews) in order to obtain a broad range of insights on IC reporting practice.

As shown in Table 1 the group of 17 SRs analysed represents about the 18% of Italian universities.

Table 1 lists the universities analysed according to five categories:

- Mega Universities, which are the universities with more than 40,000 students enrolled;
- Big Universities, which are the universities with students ranging from 20,000 to 40,000;
- Medium universities, which are universities with students ranging from 10,000 to 20,000;
- Small Universities, which are the universities with fewer than 10,000 students enrolled;

- Other Universities, which includes the SRs belonging to institutions of higher education and non-state universities.

*Named as Sustainability Report

For each social report Table 1 shows in the first column the name of the university, in the second column the reporting year, in the third column the number of pages of SRs analysed, in the fourth, fifth and sixth column data on the size of the universities, measured respectively by three main aspects that are (Siboni *et al.*, 2013b): number of students and teachers, the amount of public funding received – FFO. Lastly, the seventh column indicates the position held by the universities analysed in the Italian Censis University Ranking (2013)⁴.

5 Results of the analysis

The current research examines the amount and nature of voluntary IC disclosure in Italian universities' SRs and investigates and gives insights about the internal perspective of university General Directors about IC management and disclosure. With reference to the former this paragraph illustrates: (1) the incidence of IC categories disclosed; (2) the frequency of IC category disclosed; (3) the typology of IC information disclosed (Discursive Forma, Numeric Form, and Quantified in Euro); (4) a ranking of incidence of IC categories disclosed based on the size of university analysed. The latter shows the results of a survey submitted to all universities.

Table 2 illustrates the incidence of IC categories disclosed by the SRs. The incidence has been calculated based on the total observations from the 17 SRs analysed, out of the total possible observations. The first column lists the IC categories (No.=8). The second column shows the sum of the indicators within the coding instrument (No.=39). The third column illustrates the observations from all the 17 SRs (No.=325). The fourth column gives the amount of potential observations from all the SRs (i.e. 17 SRs x 39 = 663). The last column displays the total index, giving the percentage of IC indicators of the coding instrument reported within the SRs. Out of the total 663, 325 were disclosed - that is 49.02% of the possible IC indicators that could have been reported by the 17 SRs.

Table 2: Incidence of IC categories in SRs

Management Challenges	Number of IC Categories (A)	Observations from all 17 ^s SRs (B)	Total possible observations (17 x A = C)	Total Index (B/C)
A. Human capital	10	80	170	47.06%
B. Structural capital	1	14	17	82.35%
C. Relational capital	8	72	136	52.21%
D. Research	7	48	119	40.34%
E. Education	5	39	85	45.88%
F. Commercialising	4	35	68	51.47%
G. Knowledge transfer to the public	2	20	34	58.82%
H. Services	2	18	34	52.94%
Grand Total	39	325	663	49.02%

As shown in Table 2 all the 8 IC categories were disclosed with an incidence ranging from 40.34% to 82.35%. The largest IC category is Structural Capital (82.35%), followed by Knowledge Transfer to the Public (58.82%), Services (52.94%), Commercialising (51.47%), Relational Capital (52.21%), Human Capital (47.06%), Education (45.88%),

and Research (40.34%). This suggests that the Italian universities' SRs have a focus on IC that ranks on average about 50%. Moreover, surprising is the minor role played by relational capital, that is instead the category that generally gains the main attention within IC disclosure (Dumay and Cai, 2014; Bezhani, 2010).

Table 3 illustrates the frequency of IC indicators reported. In the first column we listed the IC categories. In the second column we presented the sum of IC indicators. In the third and fourth column we listed the total citations reported from all SRs via absolute and percentage value.

Table 3: Frequency of recorded items

Categories	Indictores	Absolute Value (No.=1,824)	%
A. Human capital	A.1 Number of academic staff total	66	3.62%
	A.2 Number of research staff	39	2.14%
	A.3 Number of full-time professors	18	0.99%
	A.4 Teaching assistants	31	1.70%
	A.5 Fluctuation of scientific staff	26	1.43%
	A.6 Fluctuation of scientific staff (not employed)	5	0.27%
	A.7 Growth of scientific staff	31	1.70%
	A.8 Growth of scientific staff (not employed)	6	0.33%
	A.9 Average duration of scientific staff	5	0.27%
	A.10 Expenses for training	7	0.38%
Sub-Total A		234	12.83%
B. Structural capital	B.1 Investments in library and electronic media	60	3.29%
Sub-Total B		60	3.29%
C. Relational capital	C.1 Research grants abroad	6	0.33%
	C.2 International scientists at the university	17	0.93%
	C.3 Number of conferences visited	5	0.27%
	C.4 Number of conferences hosted	50	2.74%
	C.5 Number of employees financed by non-inst. funds	9	0.49%
	C.6 Number of activities in committees etc.	88	4.82%
	C.7 Hit rate EC research programs	250	13.71%
	C.8 New co-operation partners	295	16.17%
Sub-Total C		720	39.47%
D. Research	D.1 Publications (referred)	18	0.99%
	D.2 Publications (proceedings etc.)	1	0.05%
	D.3 Publications total	28	1.54%
	D.4 Number publications with co-authors from the industry	2	0.11%
	D.5 Habilitation	2	0.11%
	D.6 PhDs	62	3.40%
	D.7 Non-institutional funds (contract research etc.)	61	3.34%
Sub-Total D		174	9.54%
E. Education	E.1 Graduations	48	2.63%
	E.2 Average duration of studies	14	0.77%
	E.3 Teacher per student	13	0.71%
	E.4 Drop-out-ratio	10	0.55%

	E.5 PhDs and Master's theses finalised	10	0.55%
Sub-Total E		95	5.21%
F. Commercialising	F.1 Number of spin-offs	75	4.11%
	F.2 Employees created by spin-offs	2	0.11%
	F.3 Income generated from licences	35	1.92%
	F.4 Number of licences granted	69	3.78%
Sub-Total F		181	9.92%
G. Knowledge transfer to the public	G.1 Hits internet site	10	0.55%
	G.2 Lectures (non-scientific)	146	8.00%
Sub-Total G		156	8.55%
H. Services	H.1 Measurement and lab services and expert opinions	190	10.42%
	H.2 Leasing of rooms and equipment	14	0.77%
Sub-Total H		204	11.18%
		1,824	100%

As illustrated in Table 3, on one hand the frequency of IC categories is quite variable and varies from 'C' (39.47%) to 'B' (3.29%). With regards to IC indicators, we have found that all IC indicators on the coding instrument were reported. Nevertheless, generally speaking they obtained a very low frequency of reporting. In fact, only three IC indicators obtained a frequency over 5%. These are: New co-operation partners (16.17%), Hit rate EC research programs (13.71%), Measurement and lab services and expert opinions (10.42%) and Lectures (non-scientific) (8.00%).

Table 4 reports on the typology of information disclosed.

Table 4: Typology of recorded items

Typology	Absolute value	%
1 – Discursive Form	741	40.63%
2 – Numeric Form	651	35.69%
3 – Quantified in €	432	23.68%
Grand Total	1,824	100.00%

Table 4 shows the three-range scale used for content analysis (Discursive Form, Numeric Form, and Quantified in Euro) (first column), via absolute value (second column), and related percentage (third column).

As shown in Table 4, the 1,824 observations ranged from about a minimum of 24% of information quantified in Euro to about a maximum of 40% of information reported in discursive form. This result is consistent with the Bezhani (2010) study that found that most disclosure was in discursive form followed by numeric and quantified in currency. Also, a similar prevalence in discursive information has been found with reference to social report and planning documents in Italian public sector organisations (Mazzara *et*

al., 2010; Siboni *et al.*, 2013a; Farneti and Siboni, 2011). A possible explanation for the lack of financial information could be related to the fact that the Italian universities' funding system is mainly derived from the Ministry of Education, and therefore the universities are able to know how many financial resources are available only after the Ministry's funding allocation law.

Finally, Table 5 shows the analysis of the influence of the size of the universities (defined on the basis of the ranking of the universities shown in Table 1) on the amount of IC disclosure, in order to evaluate a possible relationship between university size and completeness of IC disclosure.

As emerged in Table 5 no relationship between the university sizes and the completeness of IC disclosure has been found. In fact, the total index showing the incidence of IC disclosure ranked from a minimum of 33.33% (referred to a Mega University) to a maximum of 74.36% (referred to a Medium University).

Table 5: University size and amount of IC disclosed

University	Censis University Ranking A.Y. 2011/12	IC Disclosure Total Index
Mega Universities (more than 40,000 students) No. 11		
Università degli Studi di Firenze	4	46.15%
Università degli Studi di ROMA "La Sapienza"	6	33.33%
Università degli Studi di Bari Aldo Moro	9	74.36%
Big Universities (from 20,000 to 40,000 students) No. 15		
Università degli Studi di Pavia	1	48.72%
Università degli Studi di Cagliari	4	35.90%
Università degli Studi di Genova	5	56.41%
Università degli Studi di Salerno	10	41.03%
Medium Universities (from 10,000 to 20,000 students) No. 17		
Università degli Studi di Trieste	2	64.10%
Università degli Studi di Macerata	6	46.15%
Università degli Studi del Salento	10	35.90%
Università degli Studi di Ferrara	12	74.36%
Università "Ca Foscari" Venezia*	13	38.46%
Small Universities (fewer than 10,000 students) No. 11		
Università degli Studi del Sannio di Benevento	6	61.54%
Università degli Studi Insubria Varese-Como	7	64.10%
Università degli Studi del Molise	8	53.85%

Finally, with reference to the second aim of the current research, related to the investigation of internal perspective of Italian universities on IC management and disclosure, in January 2014 an online questionnaire was submitted using Qualtrics Survey Software to all the university Director Generals (Annex 3). Just 15% of universities

answered to the survey by the deadline of 15th March 2014, therefore we have submitted a reminder of the survey fixing a new deadline for 15th May 2014. Thus, with reference to this second part of the paper the collection of data and related analysis is still in progress.

6 Conclusion

The last decade has witnessed an increasing relevance for IC at universities. In this path, a series of initiatives have been issued by the European Union and by several national governments in order to promote IC report at universities. Particularly, the Austrian Government in 2002 issued a law requiring universities and research intuitions to produce IC reports (UG, 2002). That law intends IC reports to be used as both a management tool and a disclosure report for external stakeholders. In such a context the IC report provides information about the university's activities, social goals, objectives and strategies, as well as an account for IC (broken down into human, structural and relationship capital).

In Italy IC report is not mandatory. Nevertheless, case study analysis undertaken by Italian literature (Ricci *et al.*, 2014) found IC disclosure within universities' SRs.

The current work analyses a group of 17 SRs issued by Italian universities in order to investigate the amount and the nature of IC disclosure. That analysis was undertaken in order to answer the call for comparative study made by Bezhani (2010).

With reference to the amount of IC information the current analysis found that Italian universities' SRs present an incidence of disclosure that involves several IC categories, ranking from about 40% to about 80%. Within IC categories disclosed, Structural Capital has gained the most attention, while Research was less mentioned. On the contrary, Bezhani's (2010) study found in general a very low disclosure for IC within UK universities annual reports. Also, Bezhani's (2010) study found that the most cited IC category was Research.

With reference to the typology of IC information disclosed, our study found that most IC information within SRs was discursive, however, with a limited variability among the different typology of information (Discursive Form, Numeric Form, and Quantified in Euro). This result is consistent with the Bezhani (2010) study, which found a similar prevalence of discursive IC information; nevertheless it deviates with reference to the variability of IC information since Bezhani's (2010) study found a wider variability among the different typology of information.

Finally, with regard to the size of universities, our study found that there are no factors relevant to explain differences in reporting IC disclosure. This result is aligned with the one found by Bezhani (2010).

Such results suggest that SRs could be considered a more appropriate document for finding information about IC rather than the annual reports, which have been criticised also by previous studies that have questioned whether that such documents are the more appropriated for including IC information (Bezhani, 2010; Dumay and Cai, 2014).

The conclusions of the current study, however, are affected by two major limitations. First, the group of documents analysed is small and does not represent all Italian universities but just the ones that have issued a voluntary social report. Second, in Italy an agreed guideline for shaping SRs does not exist and therefore each organisation decides on its own the information to include within such documents.

Despite the limitations highlighted above, we believe that this work represents a valuable initial step in assessing IC disclosure from Italian universities.

Notes

¹ Such structure has been designed on the basis of the experience of IC report undertaken by the ARC - Austrian Research Centers (Leitner, 2004).

² It is a process started in Europe in the ninetens in order to increase the quality of the research system and to make universities more comparable, competitive, dynamic, and transparent. This process has resulted in the introduction of a common system of degrees, an increase in the mobility of students, lecturers and researchers, the promotion of high quality teaching, and the creation of a European dimension for higher education. Accordingly, the university sector of all the countries which have joined the Bologna Process have experienced a season of university reforms aimed at increasing the autonomy of universities, introducing new funding formulas, giving a central role to performance measurement and efficiency, leading to the creation of national accreditation agencies and promoting the use of new managerial tools (Sánchez et al., 2007).

³ The GBS is a group composed of some Italian academics, researchers and practitioners on social reporting, which issued in 2008 a guideline for reporting on IC within the social report (GBS, 2008) addressed to profit, nonprofit and public organisations. This guideline assumes that IC must represent a section included within social and sustainability reports, since it shares the same multidisciplinary nature, requiring, as a consequence, similar metrics. Moreover, the guideline states that to measure IC there is no universally valid list of indicators, but it is necessary to measure stocks and modifications of its categories over time. It addressed both, and each organisation has to identify key intangibles in relation to its strategy and context, describe actions and commitments on their improvement, and evaluate their contribution to the achievement of its social vision.

⁴ The Censis University Ranking is an Italian university ranking developed each year by Censis, which is a very popular Italian research institute in social sciences, through the definition of a score based on:

- services (number of meals provided for members, number of posts and contributions accommodation for members residing outside the region);
- grants and contributions (expenditure of universities and institutions of the right to education for students in the total enrolment);
- structures (classroom seats/members; places Libraries/members; places laboratories /subscribers);
- website (score assigned to the websites of the universities on the basis of features and content);
- internationalization (registered foreigners on total enrolment, students who have spent a period of study or training abroad on the total number of members; Foreign students who have spent a period of study at the university of total members; expenditure of universities and institutions, the right to study in favour of the mobility of the total reported net of registered).

⁵ The number of observations is given by the total number of times in which each action and initiative has been cited at least once in all 17 SRs.

Annex 2: Coding Instrument (Bezhani, 2010)

Category (8)		Indicator (39)	
<i>A</i>	<i>Human capital</i>	A1	Number of academic staff total
		A2	Number of research staff
		A3	Number of full-time professors
		A4	Teaching assistants
		A5	Fluctuation of scientific staff
		A6	Fluctuation of scientific staff (not employed)
		A7	Growth of scientific staff
		A8	Growth of scientific staff (not employed)
		A9	Average duration of scientific staff
		A10	Expenses for training
<i>B</i>	<i>Structural capital</i>	B1	Investments in library and electronic media
<i>C</i>	<i>Relational capital</i>	C1	Research grants abroad
		C2	International scientists at the university
		C3	Number of conferences visited
		C4	Number of conferences hosted
		C5	Number of employees financed by non-inst. Funds
		C6	Number of activities in committees etc.
		C7	Hit rate EC research programs
		C8	New co-operation partners
<i>D</i>	<i>Research</i>	D1	Publications (referred)
		D2	Publications (proceedings etc.)
		D3	Publications total
		D4	Number publications with co-authors from the industry
		D5	Habitation
		D6	PhDs
		D7	Non-institutional funds (contract research etc.)
<i>E</i>	<i>Education</i>	E1	Graduations
		E2	Average duration of studies
		E3	Teacher per student
		E4	Drop-out-ratio
		E5	PhDs and Master's theses finalised
<i>F</i>	<i>Commercialising</i>	F1	Number of spin-offs
		F2	Employees created by spin-offs
		F3	Income generated from licences
		F4	Number of licences granted

Annex 3: The Online Questionnaire

Default Question Block

Si ringrazia per aver scelto di partecipare all'indagine, la compilazione del questionario Le richiederà al massimo 5 minuti.

Le informazioni da Lei fornite verranno trattate in modo strettamente confidenziale e i risultati della ricerca saranno divulgati sotto forma aggregata allo scopo di fornire un quadro generale degli atteggiamenti riguardanti le aree oggetto di questa indagine.

Prima Parte

Informazioni generali sull'Istituzione e sul Compilatore

1.1 Si prega di fornire i dettagli relativi all'istituzione e alla posizione lavorativa ricoperta dal Compilatore

Istituzione:	<input type="text"/>
Nome e Cognome del Compilatore:	<input type="text"/>
Settore/Area organizzativa di appartenenza:	<input type="text"/>
Ruolo ricoperto all'interno dell'Istituzione:	<input type="text"/>
Contatti (Indirizzo email o numero di telefono):	<input type="text"/>

Seconda Parte

La gestione del Capitale Intellettuale

2.1 Indicare quali degli elementi di seguito elencati rientrano nel concetto del Capitale Intellettuale (è possibile selezionare più opzioni):

- capitale umano (competenze, titoli di studio e formazione ricevuta, capacità, know-how, esperienza, motivazione, capacità di adattarsi, tolleranza, soddisfazione e lealtà dei dipendenti, ecc.)
- capitale relazionale (Immagine/brand commerciale, fidelizzazione dei clienti, soddisfazione dei clienti, rapporti con i fornitori, capacità negoziale, ecc.)
- capitale strutturale (sistemi di documentazione e mansionari, routine, procedure, banche dati, software, utilizzo generalizzato delle tecnologie informatiche, capacità di apprendimento organizzativo, ecc.)
- tutti gli elementi sopra indicati
- nessuno dei precedenti

2.2 Nella Sua Istituzione è presente una figura organizzativa dedicata alla gestione del Capitale Intellettuale?

- Sì
- No
- Altro, specificare:

2.3 La Sua Istituzione si è dotata di una mappa formale delle componenti del Capitale Intellettuale presenti al suo interno?

- Sì
- No
- Altro, specificare:

2.4 Nella Sua Istituzione, le informazioni sul Capitale Intellettuale sono utilizzate per (è possibile selezionare più opzioni):

- la pianificazione degli obiettivi futuri
- la valutazione delle prestazioni individuali e organizzative
- il confronto delle prestazioni dell'Istituzione rispetto ai concorrenti
- la rendicontazione obbligatoria per legge
- la preposizione di una rendicontazione volontaria
- tutti gli elementi sopra indicati
- nessuno dei precedenti

Terza Parte

La rendicontazione del Capitale Intellettuale

3.1 La Sua Istituzione predispone uno o più documenti autonomi di rendicontazione del Capitale Intellettuale?

- Sì
- No
- No, però dedica una specifica sezione del Bilancio Sociale al Capitale Intellettuale
- Altro, specificare:

3.2 Nella Sua Istituzione è presente una posizione organizzativa dedicata esclusivamente alla rendicontazione del Capitale Intellettuale in tutte le sue componenti?

- Sì
- No
- Altro, specificare:

3.3 Dal 2006 la rendicontazione del Capitale Intellettuale è diventata obbligatoria per le Università austriache. Pensa che anche per le Università italiane dovrebbe essere introdotto un obbligo di questo tipo?

- Sì
- No

Structured Abstract

Purpose - This paper presents the preliminary results of a research aimed at mapping the knowledge interactions between universities and industries in Southern Italy. We focused on a specific type of knowledge interactions, namely “research services”, that are activities that firms give to universities and that are regulated by specific contracts establishing objectives, deliverables and available financial resources. They include both research contracts and consulting activities. Despite the fact that research services, especially in technological departments, cover a significant percentage of the research funding in universities and results of these activities are also useful for the firms, allowing them to solve specific technological problems, scarce attention has been reserved to them by researchers.

Design/methodology/approach – Research services are characterized by high relational involvement of the parties, which strongly collaborate over more limited period of time if compared to other knowledge interaction types. To study this phenomenon, we adopted case studies approach. Two big Italian universities were the focus of our research. Main aim was the analysis and comparison of different recent “research services” activities carried out in the last two years. In the first phase of this explorative research, researchers from engineering department from University of Naples Federico II and from Politecnico of Bari and entrepreneurs that interacted with those researchers were interviewed. In the second phase, a cross-case analysis was developed, aimed at identifying recurring categories of data in all the analyzed case studies, namely variables affecting interactions positively, from the researchers’ and firm’s standpoints; and suggestions to facilitate the diffusion of research service initiatives between universities and firms, as expressed by firms and researchers.

Originality/value – This methodology puts in evidence some interesting elements that can contribute to the success and growth of knowledge interactions between firms and universities.

Practical implications – The outcomes of the analysis provide some managerial implications that can be useful for agencies supporting the innovation diffusion among firms and firms systems, for defining new policies and action plants aimed at making the knowledge interaction faster and more effective and therefore improve the innovation processes within firms.

Keywords – Knowledge interactions, University-industry relations. (*max 5 words*)

Paper type – Academic Research Paper

1 Introduction

In recent years, the “third mission” of the universities, namely the research collaborations between universities and firms, has increasing its importance, thus pushing many governments to introduce new policies aimed at encouraging the development of university-industry collaborations. In parallel, several studies have analyzed “knowledge interactions” between firms and universities. Most of the studies focused on different types of interactions or “channels” (Agrawal, 2001; Schartinger et al., 2002; Perkmann and Walsh 2007); the characteristics that affect the propensity to collaborate with firms, in terms of university departments and researchers’ features (D’Este and Patel, 2007; Schartinger et al., 2002) and in terms of firms’ features based on their ability to utilize externally generated scientific knowledge, such as the one transferred from universities (Agrawal, 2001).

In particular, the literature review on studies on this field has revealed two “open issues”. First, referring to the type of knowledge interaction, most of the works focused on research partnerships, that are “formal collaborative arrangements among organizations with the objective to co-operate on research and development activities” (Perkmann and Walsh, 2007). Less attention has been reserved to the “research services”, namely activities that firms give to universities and that are regulated by specific contracts establishing objectives, deliverables and available financial resources. They include both research contracts and consulting activities. In consulting activities, researchers exploit their existing expertise that is used to solve well-known problems, while in research

contracts, firms commission academic researchers to explore specific, previously unresearched aspects of a problem (Perkmann and Walsh, 2007).

Research services have lower costs respect to other types of knowledge interaction between universities and firms, but are more numerous, especially in technological departments. In Italy, they cover more than 30% of the research funding. Furthermore, they are characterized by high relational involvement of the parties, which strongly collaborate over more limited period of time if compared to other knowledge interaction types. The results of these activities are useful for both the firms, allowing them to solve technological problems, and the researchers, having the opportunity to apply their knowledge to new contexts and cases. Generally, the results of these activities are only submitted to committing firm without evidence on university websites. This explains why “an unknown share of these activities is not reported to department and university administration” (Perkmann and Walsh, 2007). Despite of the importance and diffusion of these types of interactions, the literature review on studies on university - industry interactions reveal that they rarely focus on these types of interaction (Hall et al., 2001).

Second, referring to the knowledge interactions effectiveness, most of the studies focus on the effectiveness on the side of the university, by analyzing the outputs of the research produced, directly or indirectly, by the collaboration, such as the number of scientific publications jointly written with firms; the number of Ph.D. theses jointly developed with firms, etc. To the best of authors' knowledge, no study analyses knowledge interaction effectiveness on the side of the firm (Stevens and Bagby 2001; Fontana et al. 2006; Perkmann and Walsh, 2007).

In this paper, we want to contribute to the growing literature on university-industry linkage by filling these gaps, namely by developing a research on a specific type of knowledge interactions, i.e., research services, and studying this interaction also from the side of firms. With this main aim, we developed an explorative research based on multiple case studies referring to 10 “research services” experiences between two big Italian universities, University of Naples Federico II and Politecnico of Bari, and Small Medium Enterprises (SME) located in the same area.

By conducting a cross case analysis, we find the most frequent categories of data in terms of: i) factors influencing interactions' effectiveness, as perceived by researchers and by firms; and ii) suggestions for improving interaction's effectiveness, from researchers and firms.

The outcomes of the analysis provide some managerial implications that can be useful for agencies supporting the innovation diffusion among firms and firms systems, for defining new policies and action plants aimed at making the knowledge interaction faster and more effective and therefore improve the innovation processes within firms.

2 Knowledge interactions between university and industry

Existing literature states the hypothesis that incremental innovation (and not just the radical one) can be achieved through interaction and collaboration between organizations (Chapman and Corso, 2005), and in particular through the direct interaction between the creators of knowledge and its users (Bessant and Venables, 2008). This is not just limited to large firms (Albors et al., 2005). In addition, it was shown that in the context of strategic management of knowledge, there has been a lack of practical guidelines to assist the management of knowledge transfer (Chilton and Bloodgood, 2008). There is a large body of research on the benefits of a possible collaboration between businesses and universities (Agrawal, 2001; Scharfetter et al., 2002; D'Este and Patel, 2007) but the absence of a more critical literature reflects the relative immaturity area of "knowledge management".

The universities play a crucial role in the society in that they are devoted to the production and transfer of knowledge. In this, they play three major roles within an innovation system (Smith, 1995). First, they engage in a general process of scientific research and thus affect the technological frontier of the industry in the long run. Secondly, the knowledge they produce is directly applicable to industrial production (prototypes, new processes, etc..). Thirdly, the universities provide important inputs to the process of industrial innovation in terms of human capital, both through training of graduates who become industrial researchers, both through the mobility of staff from universities to firms.

The emergent concept of open innovation (networked, interactive innovation) (Chesborough, 2003), however, suggests that the relationship between academia and industry - rather than generic links - play a more important role in the generation of innovations.

The links between university and industry and their impact on innovation processes have been analyzed in various academic communities (Agrawal, 2001; Hall, 2004; McMillan and Hamilton, 2003; Mowery and Nelson, 2004; OECD, 2002; Poyago-

Theotoky et al., 2002). Several studies investigate factors that have supported the growth of the connection between academia and industry, such as the change in the legislative environment (Mowery and Nelson, 2004), the public-private research partnerships (Stiglitz and Wallsten, 1999), and increasing political pressure for universities in order to improve national economic competitiveness (Greenaway and Haynes, 2000). The increasing linkage between university and industry is evidenced by several trends: an increased propensity for patenting by universities (Nelson, 2001), an increase in the proceeds from licensing universities (Thursby et al., 2001), a growing number of university researchers engaged in entrepreneurial projects (Shane, 2005), and the diffusion of technology transfer offices supporting the industrial collaboration and science parks (Siegel et al., 2003).

Recent studies show that a high rate of interactions between universities and industry lead to high economic performance in different countries (see *Executive Opinion Survey*, World Economic Forum, 2012). According to the data provided by the *World Competitiveness Index* (Report 2012), the countries that recorded the highest values of the degree of university-industry collaborations (UK, U.S., Germany and Japan) lead to an important growth of the internal GDP if compared to those countries with the lowest rate in the collaboration degree between universities and industries.

The university-industry collaboration can be enhanced through different modes - formal or informal - as well as the exchange of knowledge can occur through different types of channels (Schartinger et al., 2002). The analysis of these different types of channels is crucial in order to properly investigate the nature of the different types of interactions and the analysis of the factors that, at the regional level, may affect the volume and effectiveness of interactions.

The channels used to transfer knowledge depend on the characteristics of knowledge, such as the degree of codification, tacit or explicit nature and rooted in technological artifacts.

The different types of knowledge interactions represent different strategies to keep up with the two main requirements that affect the processes of industrial innovation: to ensure the efficiency of research (this covers a wide range of skills, reduction of costs and risks, exploitation of synergies, appropriation of the return of research) and gain access to scientific and technical opportunities (high quality researchers, research networks, tools, new knowledge, and so on) (Hicks et al., 1996; Katz and Martin, 1997).

The intensity of the flows of knowledge varies by type of knowledge interaction. Knowledge flows from academia to industry are assumed to be stronger in the case of interactions that are based on frequent face to face contacts. This seems to be particularly suitable for joint research projects, joint publications, mobility of academic researchers, and the creation of new spin-off companies. Furthermore, different types of knowledge interaction are associated with different types of personal relationships. Finally, the types of interaction differ in relation to the direction of the flows of knowledge associated.

A common feature of all the knowledge interactions is that they imply a certain flow of knowledge, whose exact scope, quality and effect is uncertain. This is a typical problem in this particular area of research. The creation of knowledge and its dissemination are intangible assets, which are difficult to measure. They are certainly not measurable in terms of what we normally think of as static variables (Grupp, 1990). Because of the intangible nature of knowledge flows, empirical studies face considerable difficulties in their identification and measurement.

3 The explorative research

The methodological approach adopted in this paper is an explorative research based on multiple case studies.

We chose the case study methodology for following reasons:

- the exploratory issue of our research aimed at explaining the presumed causal links between researchers and entrepreneurs/managers behaviors and success of research services experiences
- the need to understand in depth the phenomenon of knowledge interaction between firms and researchers
- the fact that such understanding encompasses important contextual conditions that are highly pertinent the phenomenon of study in the research (Yin 2009).
- research services, which are the focus of this research, are generally not reported on university departments websites or on reports/documents, thus justifying the study of the cases through interviews.

Data collection and analysis were made on the basis of following steps:

a) preparation of the check list for the interviews, which are aimed at exploring objectives leading the interaction, from firms and researchers' standpoints; factors

influencing interactions' effectiveness as perceived by firms and researchers; suggestions for improving the interaction effectiveness, by firms and researchers.

b) interviews for each selected case, conducted to a researcher or the research group manager and to the entrepreneur or the project manager designed by the firm. The process of interviewing consisted of eliciting the following information:

- Story of the interactions (aim, management and results)
- Perceptions of the two parties on the weakness and strengths of the interactions
- Opinions and suggestions by the two parties on initiatives that could foster the success of interactions between universities and firms

c) cross-case analysis, which was aimed at identifying recurring categories in all the analyzed case studies. In particular, these categories refer to: variables affecting interactions positively, from the researchers' and firm's standpoints; and suggestions to facilitate the diffusion of research service initiatives between universities and firms, as expressed by firms and researchers.

3.1. Sample

The sample analyzed in the study consists of 10 knowledge interaction cases between universities and firms in Italy, 5 cases related to University of Naples Federico II and 5 cases related to Politecnico of Bari.

The cases were selected according to the following criteria:

- *Types of interaction.* We focused on a specific type of interaction, the *research services*. This term refers to "paid-for services performed by university researchers for external clients" (Perkmann and Walsh, 2007). Research services include both research contracts and consulting activities. Contrarily to other types of interaction, which allow some degree of "academic freedom", research or consulting contracts define specific objectives and deliverables. Particularly, in the course of consulting activities researchers exploit their existing expertise for finding solutions to specific problems arisen in firms' technological and organizational contexts, while in the case of contract research firms commission researchers to explore specific and unresearched aspects of technological or organizational problems.
- *Success of interaction.* The sample that we analyzed includes only successful interactions, where the term "successful" refers to experiences ended within the

planned schedule and with full satisfaction of both parties. The choice of considering only successful cases is motivated by the aim of the research devoted to highlight strengths, on both the firm's side and the university's side.

- *Similarity of geographical contexts.* Both the universities that we analyzed are located in the Southern Italy, in Campania the University of Naples Federico II and in Puglia the Politecnico of Bari. They are two geographic contexts having some basic similarities, such as: the limited presence of large and medium firms, if compared to the number in North Italy; the high and increasing unemployment rate characterizing both regions; the presence of high qualified scientific and technical universities; an increasing number of small firms operating in knowledge-based sectors (software, biotech, consulting, etc). In both regions universities have assumed a growing role, both as suppliers of skilled professionals and as knowledge producers in emerging fields.
- *Similarities in the characteristics of departments and researchers.* Previous researches (D'Este and Patel, 2007) highlighted that university department characteristics (such as size, number of researchers, research fields, etc.) and researcher individual characteristics (ages, academic status, etc.) influence researchers disposition to set up networks with potential users of their researches. For this reason, with the aim of comparing the results of the 10 cases, we selected departments that do research in engineering fields and mostly on the industrial engineering field, with an average size of about 55 units of scientific personnel. Furthermore, in selecting research services experiences, we considered the age of researchers (35-40 years old) and their academic status (almost all the researchers interviewed are assistant professors).
- *Similarity in field of science/scientific disciplines.* All the selected case studies refer to research services experiences in the field of industrial engineering (Aerospatial, Mechanical, Managerial) or information.
- *Period.* We selected only experiences carried out and concluded in the last two years.

Table 1 and 2 describe the characteristics of the 10 selected cases of knowledge interaction for Politecnico of Bari and University of Naples Federico II, respectively.

Table 1. Description of selected case studies at Politecnico of Bari

n r	Knowledge Interaction's focus	Dept	Field of science	Firm's industrial sector	Interaction type
1	Maintenance management of productions systems	Industrial Eng.	Eng.	Automotive	Consulting
2	Aluminum alloys for new prototypes realization	Industrial Eng.	Eng.	Automotive – stamp construction, Body in White production	Research contract
3	Innovative technologies	Industrial Eng.	Eng.	Mechanics	Research contract
4	Electric motors for aeronautic use	Industrial Eng./Informatics	Eng.	Aeronautics	Research contract
5	Logistics optimization	Industrial Eng.	Eng.	Sofa production	Consulting

Table 2. Description of selected case studies at University of Naples Federico II

n r	Knowledge Interaction's focus	Dept	Field of science	Firm's industrial sector	Interaction type
1	Energy efficiency	Industrial Eng.	Eng.	Energy	Research contract
2	Building energy balance	Civil Engi.	Eng.	Construction	Consulting
3	Quality of work performance increase	Industrial Eng.	Eng.	Aerospace	Consulting
4	Systems refrigerants replacement	Industrial Eng.	Eng.	Engineering	Research contract
5	Consortium accounting	Industrial Eng.	Eng.	Service	Consulting

4 Results analysis

The results of the interviews with firms' managers and researchers are reported in the Appendix. In particular, as previously explained, for each case we investigated the opinions of firms' managers and researchers focusing on the following three key aspects:

1. Objectives leading the interactions
2. Interactions' strengths as perceived by researchers and managers
3. Suggestions for improving interactions' effectiveness

After the within-case descriptive analysis (see Appendix), a cross-case analysis took place, following the guidelines set out by Eisenhardt (1989), Miles and Huberman (1994), and Patton (2002). The comparison of the ten case studies made it possible to examine similarities and differences across multiple cases, and to identify cross-case patterns also

essential for enhancing the generalizability of conclusions drawn from single cases (Voss et al., 2002).

In order to identify common and frequent categories of data, we focused on two of the three key aspects, which were object of analysis in each case study, namely i) factors influencing interactions' effectiveness, as perceived by researchers and by firms; and ii) suggestions for improving interaction's effectiveness, from researchers and firms. We do not address this analysis for the first aspect, that is the objectives of the knowledge interaction, since the specific type of the knowledge interaction that we considered (i.e., research services) has generally well-defined objectives.

We first realized a coding process of the results of each case. Codes are defined as tags or labels for assigning units of meaning to the descriptive or inferential information compiled during a study (Miles and Huberman, 1994). Concepts that are found to pertain to the same phenomenon are grouped to form categories, which are higher level, more abstract concepts which must be developed in terms of their properties and dimensions.

The results of the cross case analysis are summarized in following tables (Tables 3-6).

First of all, it is interesting to note the similarity of findings in the two geographic groups, confirming the validity of the initial hypothesis about the similarity of the two universities and geographical contexts.

Going into details of the findings, Tables 3 reports the factors influencing interactions' effectiveness, as perceived by firms. As the frequency of answers in each category of data shows, the majority of firms (over 5 out of 10) has declared that variables mostly positively affecting the interaction are the researchers' motivation and commitment, interpreted as respect of time of meetings and deliverables by researchers.

Table 3. Factors influencing interactions' effectiveness, as perceived by firms

Category	Bari	Naples	TOT
The research group supported the identification of the specific technological problems to be addressed	3	3	6
Researchers' effort, commitment and motivation	4	5	9
Objectives and schedule sharing	1	4	5
Objectives, activities, deliverable and time planned with researchers	2	3	5
Coherency of time of activities, between firm and researchers	2	3	5
Researchers respected time of meetings	3	4	7
Researchers respected deliverables	4	4	8

Researchers monitored the work in progress	3	3	6
Researchers developed an adequate communication and reporting system for the firm	2	1	3
Financial budget coherent with effort	1	1	2

Table 4 shows the factors influencing interactions' effectiveness, as perceived by researchers. As data show, the researchers perceive as determinant for the success of the interactions the clear understanding of the technological problem to be addressed by the firm. This is coherent with the type of knowledge interaction that we are analyzing, namely the research services, that are regulated by specific contracts, with well defined issues. In line with the firms' opinion, the researchers perceive also important the commitment of the firm, the possibility of planning objectives, deliverables and schedule together with the firm as well as the ability of firm to facilitate the access to data by researchers.

Table 4. Factors influencing interactions' effectiveness, as perceived by researchers

Category	Bari	Naples	Tot
The firm has a clear understanding of the specific technological problems to be addressed	4	3	7
Commitment of entrepreneur of top management	4	3	7
The firm has designed a project manager with adequate technical skills	3	3	6
Objectives, activities, deliverable and time planned with firms	3	3	6
Coherency of time of activities, between firm and researchers	1	1	2
Availability of data and information	3	3	6
Firms respected time of meetings	3	3	6
Financial budget coherent with effort	2	1	3

Table 5 reports the suggestions for improving interactions' effectiveness, provided by firms. The most frequent category (over 5 out of 10 cases) is the organization of periodic meeting with firms.

Table 5. Firms' suggestions for improving interactions' effectiveness

Category	Bari	Naples	TOT
The department website could facilitate the access to information on technological skills to be used in innovation processes	3	2	5

Use of Social Network to facilitate the diffusion of research results, thus increasing collaborations with industrial world	1		1
Organize periodic meeting with firms to present research projects and ideas	4	4	8
Build a shared set of research themes that are interesting for both parties	3	1	4
Strengthen collaboration with researchers in order to participate to national or European funding	3	2	5

Finally, Table 6 summarizes the findings on the researchers' suggestions for improving interactions' effectiveness.

As the data show, among the most important elements to improve the effectiveness of the interaction with the firm (based on the most frequent category of data), the researchers put the organization of periodic meetings among firms and universities, in line with the opinion of firms. At the same level of importance, the researchers identify also the diffusion of the research findings within the industrial world and the participation to national or European funding with firms.

Table 6. Researchers' suggestions for improving interactions' effectiveness

Category	Bari	Naples	TOT
Improve the communication strategies on the research done within the department	5	3	8
Improve the department's website	3	2	5
Use of Social Network to access to research results achieved by researchers in the department	0		0
Organize periodic meetings among firms and universities in order to present research ideas and projects	4	4	8
Build a shared set of research themes that are interesting for both parties	3	2	5
Strengthen collaboration with firms in order to participate to national or European funding	5	3	8

5 Discussion and implications

Although this is an explorative research that does not allow a generalization of the results that is always acceptable, the findings of this study highlight some interesting elements that could be taken into account in developing university policies aimed at increasing research services activities.

The findings of the cross-case analysis, in fact, suggest that it would be valuable to invest on three important aspects:

- strengthening the contact opportunities between firms and researchers, also by using online forum
- diffusing and divulging research results within the industrial world
- exploit national or European research funding

As for the first element, in all the 10 selected cases, the researcher has been known by reading one publications of his or during conferences and meetings. Very rarely the contact between researcher and firm has been created by the university department website or has been promoted by institutions/offices supporting the technological transfer.

The contact, that, generally speaking, can be *direct* (entrepreneur and research meet each other occasionally during a conference, meeting or working seminar) or indirect (the entrepreneur knows the possibility of revenging help by the researcher in addressing technological problems by reading one of his papers/reports) is therefore mainly occasional. In other words, the university-industry interactions that, according to the findings of our study, culminate in effective collaborations are mainly interactions without any forms of brokerage.

The research findings therefore suggest that it would be useful that policies for SME innovations support and increase the contact opportunities between the two worlds.

This consideration can be used to understand (with all the needed cautions due to the small number of cases analyzed) the failure or insuccess of some of the recent policies for supporting SME innovation and technological transfer from the university to industry. In particular, we refer to those policies that base on the central role of the intermediation or brokerage between the innovation demand expressed by SME and the technological knowledge offer by researchers. This intermediation service is generally carried out by specific agencies or experts.

The leitmotiv therefore should be “multiply the contact occasions between the two parties”, namely define policies supporting and facilitating the contact between parties and making the information flow more complete and effective. Living in a virtual world, this contact could be also created “virtually” through online forum that could allow SME to meet a researchers’ community in order to obtain solutions to several R&D problems (an example is the experience of InnoCentive (www.innocentive.com)).

As for the second element (that is the diffusing and divulging research results within the industrial world), very often entrepreneur “meets” or knows a researcher by reading one of the scientific papers published by the researcher on international journals.

Therefore, a question raises spontaneously: how to facilitate the understanding by entrepreneurs of technological issues that could be interesting for pushing innovation within their firms, considering the two challenges represented by the limited time that entrepreneurs can devote to this activity, and the scarce popularity of scientific papers?

One of the possible proposal to address this open question could be the following:

- classify the scientific journals, where researchers publish their papers, on the basis of technological areas that could be object of interest for specific industrial sectors
- define, along with a sample of entrepreneurs, a set of criteria for selecting paper that could be interesting for them
- Periodic analysis of journals content
- Develop synthetic “abstracts” that highlight aspects that could be relevant for firms (such as product innovation, process innovation, management systems, energy savings, etc.)
- Publish abstract in apposite sections of department websites

All these suggestions could potentially be very useful for the entrepreneur since he/she could gather more information, of better quality and geared towards firms’ needs.

Finally, as for the last aspect of strengthening firm-university collaboration in order to participate to national or European funding, it is provided as suggestion for improving effectiveness by researchers. This confirms that in a panorama of decreasing resources, researchers see the collaborations with firms as a good chance of accessing to new channels for funding research.

Appendix. Results of individual case studies

A) Objectives leading interactions, from firms and researchers' standpoints in cases of Politecnico of Bari

nr	Firms' objectives	Researchers' objectives
1	Advanced techniques for optimizing the maintenance management of productions systems	Apply research method and knowledge of the research group to new contexts Exploit new cases to develop new methods and research projects Develop new research streams and projects jointly with the firm Funding research through new ways Improve the reputation of the research group in the industrial sector
2	Study the super-plastic behavior of some aluminum alloys with the aim of optimizing the Blow Forming process with the realization of new prototypes	Have new contexts and cases to apply scientific knowledge already strengthened and developed
3	Development of innovative technologies	Exploit a real case study to formulate research hypothesis, objectives and methodology Apply scientific knowledge of the research group to new contexts Use real case issues to develop new research projects Improve scientific reputation Create occasions to let the industry know the research group
4	Develop highly efficient electric motors for aeronautic use	Exploit real cases to test research hypothesis and knowledge already developed by the research group Possibility of develop new knowledge by using real issues faced by industries Possibility of starting new research activities Possibility of exploiting new funding channel of research activities Foster product innovation and take out a new patent Improve the scientific image of the research group through the joint work with the industry
5	Develop software for optimizing logistics and solving tridimensional problems of Container Loading and Vehicle Routing	Solve industrial issues through the application of knowledge and skills of the research group, thus creating new occasions to develop new knowledge and research projects

B) Objectives leading interactions, from firms and researchers' standpoints in cases of University of Naples Federico II

nr	Firms' objectives	Researchers' objectives
1	Increasing the energy efficiency of a large existing property	Replication of previous empirical scientific research in new contexts Refinement of previous research experiences through the recalibration of existing models Possibility of increasing scientific knowledge and methodological
2	Define the energy balance of the building, locate the technological redevelopment, to evaluate each project technical and economic opportunities, improving the conditions of comfort and security, reduce management costs	Application of new methods and models to real-life contexts Ability to identify new lines of research funding Ability to develop new theoretical and methodological knowledge increases

3	Better governance changes imposed by the market by increasing the quality of work performance	Increase the level of knowledge modeling Identification of new forms of research funding Realization of application instances to improve the scientific reputation
4	Assessing the possibility of replacing the refrigerants used in air conditioning systems (operating with the refrigerant R22) in order to reduce energy consumption	Development of new networks to access new sources of funding Entificare new channels for research funds Identification of novel contexts of application for the calibration of models and tools for investigation
5	Define a unitary system of accounting for all the companies in the consortium (definition of revenue centers, cost centers, intermediate, cost objects and relations among them)	Search for new forms of financing Relations with major enterprises to increase the reputation of the research group at external organizations and associations Application of models and methods in new application contexts

C) Factors influencing interaction's effectiveness as perceived by researchers and managers in cases of Politecnico of Bari

nr	Firms' opinion	Researchers' opinion
1	Research were highly motivated Do the tasks according to plan consistent t with the research group availability The research group respected the time of meetings The research group realized the deliverables, according to the contents and time planned	Identification of the specific technological issue by the firms Interest by the firm in the research activity The firm identified a project manager with adequate technical skills
2	The research group was helpful in supporting the identification of the problems to be addressed Researchers had a strong commitment to doing the activity The research activities were adequately planned The meeting were respected The deliverable were realized as planned The research group carefully monitored the woks in progress The research group adequately reported the activities done to the firm	The project manger designed by the firm had a clear understanding of the technological problem to be solved The project manager had a strong commitment in the project The firm choose a project manager with adequate professional skills The project objectives, deliverables and timetable have been planned together with the project manager Both the firm and the research group planned coherently research activities to be done The firm allowed researcher to access data and information needed The firm respected the time of the project and meeting The financial resources to do research activities were adequate
3	Competence of the research group in identifying and formulating the scientific problem High commitment by researchers The activities planning (time and content) was shared by the firm and researchers Meetings were planned adequately Researchers respected deliverables The researchers monitored and reported the activities during their execution	Clarity of the technological problem to be solved by the firm Commitment by the firm Competency and skills of the project manager selected by the firm objectives and activities were planned jointly by parties Easiness of gathering data and information The firm respected the schedule of meetings
4	Researchers supported the firm in identifying the scientific problem The researchers showed great effort in doing the research activity The time and objective were defined together The research group collaborated in planning objectives, activities and time The researchers respect the deliverables The researcher constantly monitored the activities done	The firm formulated the rproblem to be addressed Top management commitment Skills of the project manager Objectives were jointly defined Availability of information The firm participated to the scheduled meetings Budget proportional to the effort required

	The financial budget was coherent with the effort required	
5	<p>Researchers supported the firm in defining adequately the problem object of study</p> <p>Researcher were strongly involved in the process</p> <p>Researchers defined objectives and time</p> <p>Researchers supported the firm in planning the activities</p> <p>Researchers respect the deliverables</p> <p>Researchers monitored adequately the works ion progress</p>	<p>The firm well knew the problems</p> <p>Interest and commitment by the top management in research activities</p> <p>Activities planned together with researchers</p> <p>Data available</p> <p>Active participation to meetings</p>

D) Factors influencing interaction's effectiveness as perceived by researchers and managers in cases of University of Naples Federico II

nr	Firms' opinion	Researchers' opinion
1	<p>The research group has joined our firm in the project at every stage</p> <p>Researchers were very involved in the project</p> <p>There has always been alignment in respect of time of the project, both in the planning phase that at run</p> <p>The project has been kept under control by researchers in respect of timing and results</p>	<p>The company has shown interest to collaborate actively</p> <p>The company has partners who have made collaboration easy and efficient</p> <p>The company carefully to respect the time of project</p>
2	<p>Competence and dedication of the research group</p> <p>Ability to maintain parity between the objectives of the project on the implementation phase of the same</p> <p>The research group has always respected the times and project deliverables</p> <p>Timely and proper conduct of the project</p> <p>Efficient use of communication tools</p>	<p>Competence and dedication of the research group</p> <p>Ability to 'maintain parity between the Objectives of the project on the implementation phase of the same</p> <p>The Research Group Has always respected the times and project deliverables</p> <p>Timely and proper conduct of the project</p> <p>Efficient use of communication tools</p>
3	<p>Precise organization of the activities to be carried out</p> <p>Ability of the research team to support the company in the development of each phase of the project</p> <p>Compliance by the research group of the design requirements</p> <p>Good ability of the research team to observe the state of progress of the project</p> <p>Good planning of the necessary financial resources to carry out the project</p>	<p>The company has clearly identified the technological problem to be addressed</p> <p>The top management has always shown the present and attentive to the development of the project</p> <p>The company has selected a project manager able to communicate promptly with the research group</p>
4	<p>The research group has supported at every stage of the business</p> <p>The research group has complied with the times so as to project</p> <p>The research group has supported the company in defining the objectives of the project</p> <p>Researchers met all the deadlines</p> <p>The researchers monitored and used a proper system of communication on activity</p>	<p>The company has always had a clear objective of the collaboration</p> <p>The company respected the development of the project on time and within the costs constraints</p> <p>The company has always shown great willingness to provide any information necessary</p> <p>The company has always been present at all meetings and meetings for the development of the project</p>

5	<p>Research group has joined the firm in identifying the technological problem</p> <p>The research team has played with dedication all project activities</p> <p>Research group has always shared time and objectives of the collaboration with professionalism</p>	<p>The company has stated from the outset and clearly the problem of object technology collaboration</p> <p>The commitment from the top management has always been alive</p> <p>The company has made available a trained and competent human capital</p>

E) Suggestions for improving interaction's effectiveness, by firms and researchers, in cases of Politecnico of Bari

nr	Firms' suggestions	Researchers' suggestions
1	<p>Organize meeting between firms and researchers</p> <p>Identify research themes that are interesting for both universities and firms</p> <p>Exploit national and European funding to collaborate with universities</p>	<p>Improve the strategies of research communications by the department</p> <p>Improve the department's website</p> <p>Organize periodic meetings with the industry</p> <p>Develop a list of research streams that are interesting for both parties</p> <p>Participate to projects financed by national and European funding</p>
2	<p>Share a set of research activities with the firms</p> <p>Exploit public funding to support the research</p>	<p>The department should invest on the communication of research done by research group</p> <p>Improve the website to divulgate the research done within the department</p> <p>Collaborate with firms to define new research project financed with public funding</p>
3	<p>Access to technological knowledge through universities' websites</p> <p>Match the scientific interests of universities and firms</p> <p>Strengthen collaboration with universities</p>	<p>Improve the communication of the research by the department</p> <p>Organize periodical meetings between universities and firms</p> <p>Exploit public funding to develop research projects</p>
4	<p>Facilitate the access to information on the research done by the department through the website</p> <p>Search new ways of funding research projects</p>	<p>The department should facilitate the access to information on the research</p> <p>Enrich the website</p> <p>Organize periodic meetings with firms</p> <p>Define a set of common interests between universities and firms</p> <p>Develop research projects with firms</p>
5	<p>Improve the website of the university</p> <p>Meetings with universities as a way of exchanging research ideas and projects</p> <p>Collaborate with firms</p>	<p>Divulgate the research activities done within the department</p> <p>Organize meetings with firms to share research projects</p> <p>Listen to the needs of firms and consequently develop research projects to be financed by national and European funding</p>

F) Suggestions for improving interaction's effectiveness, by firms and researchers, in cases of University of Naples Federico II

nr	Firms' suggestions	Researchers' suggestions
1	<p>Use departmental websites to access information on the specific skills of researchers</p> <p>Using communication tools to disseminate and communicate such social interactions</p>	<p>Using the most effective means of communication on the part of departments</p> <p>Increase the degree of interaction between research and industry in order to intercept the largest sources of funding</p>

2	Using the most effective tools of communication on the part of departments Increase the degree of interaction between research and industry in order to intercept the largest sources of funding	Increase visibility by departments outside of its powers Largest organization of events in which researchers and entrepreneurs can meet
3	Organization of meetings between companies and researchers Creating catalogs of technological expertise of researchers Development of partnerships for participation in invitations to national and European funding	The department should use the best tools of communication with the outside Should be organized regular meetings in which entrepreneurs and researchers can initiate collaborations
4	Organization of meetings between researchers and entrepreneurs Development and dissemination of a repertoire of skills and research topics of common interest between researchers and companies	Improving the website of the university / department Increase opportunities where they meet researchers and entrepreneurs
5	Improve communication on the part of departments Step up meetings with researchers	The department should make the most effective strategies of communication with the outside Increased participation in bids for funding in partnership with business

Urban living labs: learning environments for collective behavioural change¹

Structured Abstract

Purpose – Urban Living Labs (ULLs) are emerging as user driven, open innovation environments characterized by a strong emphasis on knowledge creation. In ULLs innovation arises by the activation of collective awareness and individual learning processes, which ultimately lead to large-scale behavioural change. How this takes place is often the result of complex and concurrent dynamics of several distinct elements of the socio-spatial system that we see embedded in a city or neighbourhood.

This paper aims at exploring the link between knowledge production and behavioural change, using concept of “triple loop learning” (Tosey et al., 2012) as theoretical lens.

Design/methodology/approach – How triple loop learning occurs in ULLs is the fundamental question of our research. There must contexts transformed into proper learning environments, where people reflect together while individually engaging on the co-design of solutions that are then collectively implemented and assessed.

In order to explore the LLs potential for urban innovation, the authors adopt the SECI model (Nonaka and Takeuchi, 1995) to map “triple loop learning” and link learning cycles to behavioural changes referring to the results of the Periphèria project funded under the CIP (ICT-PSP) program.

Originality/value – Innovation systems have been, and still are, widely studied and analysed in the perspective of sustainability. Similarly, it is widely shared that cities, and in general urban systems, are the most promising environments to respond to the global challenge of sustainability by appropriately developed solutions. Despite the above, little attention has been paid to the links between innovation and durable behavioural change in urban communities. The paper aims at filling in this gap by highlighting the importance of shared experiments, typical of ULLs, in driving (triple-loop) learning processes able to make innovation sustainable, from the individual up to the collective scale.

Practical implications – The paper aims at strengthening the value of ULLs and social innovation in support of public service improvement and/or radical change in groups and societies. The resulting methodological framework can be easily translated by public administrators in the perspective of public services innovation. ULLs, in fact, are demonstrating to be highly productive environments, dense in opportunities for collective

¹ This article builds on some results of the EU-funded project Periphèria (CIP ICT PSP Programme - Grant Agreement No. 271015). The usual disclaimer applies to the funding institutions.

learning: here learning is not limited to the most active citizens but also involves local government representatives, who can continuously check their own way to interpret public roles by testing new opportunities for sustainable development together with the citizens, thus becoming direct agents of innovation.

Keywords – Urban Living Labs, Social Innovation, Public Service, Collective Learning, Behavioural Change.

1 Introduction: the cognitive value of Urban Living Lab environments

Urban Living Labs (henceforth: ULLs) are rapidly emerging as user driven, open innovation environments. The essence of the living lab approach (Eriksson et al., 2005) is to integrate users in the development and testing of new products and services in their daily lives. By so doing, users become active parties in the solution development process, providing relevant feedback on prototypes in real-life-like working conditions (Ståhlbröst and Holst, 2013). In a ULL, users are typically city residents and other community stakeholders; the issues of varying nature and complexity tackled by the new prototypes are normally related to public service delivery or local development policies (Juujärvi and Pesso, 2013); and the citizens actively engage in the co-design of solutions together with civil servants and policy makers (Concilio and Rizzo, 2012).

Therefore, a ULL can be defined as a creative community of people (Mulder, 2012) producing innovation at urban level with the support of a number of methods and tools (Friedrich et al., 2013) helping to co-create value out of the experience of interaction (Pallot, 2009) between the citizen/customer and the public/private service provider (Prahalad and Ramaswamy, 2004). How this takes place is often the result of complex and concurrent dynamics of several distinct elements of the socio-spatial system that we see embedded in a city or neighbourhood. Therefore, innovation in such environments has a prominent socio-spatial nature, which is more likely to take on a distinct pattern than individual or social creativity (i.e. the structured or unstructured idea generation pathway of a single actor or social group).

In this paper, we would like to emphasize the connection between the communitarian interactions that make up a ULL, the generation of new knowledge as dependent on (or influenced by) these experimental interactions, and the co-creation of sustainable value for and by the participant actors.

To this end, we adopt the “triple-loop learning” concept (Tosey et al., 2012), seen as a level of awareness and knowledge that is beyond, and probably superior, to Argyris and

Schön's (1978) single- and double-loop learning conceptualisations. We will specifically argue that, while individually engaging on the co-design of new and innovative solutions (for instance, a new public service or the improvement of an existing one), people reflect together and integrate individual with collective experiences, making the communitarian dimension become as relevant and valuable as the individual one. Additionally to that, when turning to experimental implementation and assessment of prototype solutions in a ULL context, we speculate that people become subject to transformational shifts in what they see as the most desirable ways of community living, which induces transitory or permanent changes in their individual and collective behaviour.

Willing to provide evidence in support of the above statements, which we summarize as highlighting "the cognitive value of ULL environments", we organise the remainder of the discussion as follows:

- In Section 2, we explore the relationship between knowledge creation and the innovation processes holding a specific character of "situatedness" (Gero, 1998). We do so by mapping the ULL design, discovery and implementation activities onto the four processes making up the SECI model as originally proposed by Nonaka and Takeuchi (see Takeuchi and Nonaka, 1986; Nonaka, 1991; Nonaka and Takeuchi, 1995). SECI are the initials of Socialization, Externalization, Combination and Internalization, which constitute the successive stages of an iterative learning path, moving from tacit to explicit knowledge and vice versa, and involving individual as well as groups of people within an organisation.
- In Section 3, we use the triple-loop learning concept to describe how the dynamics of reflection and discussion, rather than the mere information used or provided as part of the co-design activity within a ULL, foster the creation of relational capital at micro scale, which triggers behavioural change in a similar way to that described by Döös and Wilhelmson (2011), i.e. as the consequence of a shared distribution of experimental tasks.
- In Section 4, we collect evidence from the Periphèria project, a 30-month Pilot B action funded by the European Commission under the CIP ICT PSP Programme (November 2010 - May 2013), which aimed at deploying convergent Future Internet platforms and services for the promotion of sustainable lifestyles within and across emergent networks of "smart" peripheral cities in Europe. Periphèria used the Living Lab approach shifting technology research and development out

of the closed laboratories and into the real world to demonstrate that, when citizens are involved in public service co-design activities (typical of ULLs), behavioural changes can occur in the direction of sustainability.

- Section 5 draws some conclusions and implications for future work, particularly concerning the scalability analysis of the socio-digital innovations developed in the ULL environments.

2 Mapping service co-design onto the SECI model

According to Marc Pallot (2009), a Living Lab is a user-centred open innovation ecosystem integrating concurrent research and innovation processes within a business-citizens-government partnership. From a procedural point of view, it can involve four main activities, in a cyclically recurrent or increasingly mature fashion, namely Co-creation, Exploration, Experimentation and Evaluation. According to the P2P Foundation (2011), the concept of Co-design is directly related to, or is a specific instance of, Co-creation. In particular, by Co-design it is usually made reference to collective creativity being applied across the whole span of a product, service or technology development process.

In our own view, Co-design can be looked at as a spiral process made up of Design, Implementation and Discovery activities (the latter often resulting from the assessment of consequences of received feedbacks), like the following diagram exhibits. While Design or Implementation per se typically lead to service ideation or artefact making, Co-design as a whole implies something more, namely the generation of new knowledge (Manhães et al., 2010). Thus, we might characterize Co-design as a particular form of knowledge creation (Evenson and Dubberly, 2011).

Figure 1 – Co-design in Urban Living Labs

In ULLs, where Co-design is key to innovation, this production of new knowledge is a collective activity (Concilio and Celino, 2012). In addition, knowledge production is more practice based than theory driven there (Juujärvi and Pessa, 2013).

Potentials for learning dynamics have hardly been noted by extant literature on technology or policy driven Living labs (Bergvall-Kareborn and Stahlbrost, 2009; Svensson et al., 2010), while they are more familiar to relational economic geography scholars (Sunley, 2008) as well as marketing practitioners (Prahalad and Ramaswamy, 2004). The link between knowledge production and learning is not obvious and needs to be explored operationally. To this end, we adopt the well-known SECI model proposed by Nonaka and Takeuchi as a framework for describing co-design activities in a learning perspective.

According to these authors, ongoing knowledge creation is the source of continuous innovation and continuous innovation is the source of sustained competitive advantage. The dynamics according to which knowledge is created and an organisation can learn over time, move from tacit knowledge to explicit knowledge and vice versa according to four main processes¹:

- Socialization (tacit to tacit) “is the process of converting new tacit knowledge through shared experiences in day-to-day social interaction”;
- Externalization (tacit to explicit) is a process whereby “tacit knowledge is articulated into explicit knowledge...so that it can be shared by others to become the basis of new knowledge”;
- Combination (explicit to explicit) is a process whereby “explicit knowledge is collected from inside or outside the organization and then combined, edited, or processed to form more complex and systematic explicit knowledge... The new explicit knowledge is then disseminated among the members of the organization”;
- Internalization (explicit to tacit) is a process whereby “explicit knowledge created and shared throughout an organization is then converted into tacit knowledge by individuals... This stage can be understood as praxis, where knowledge is applied and used in practical situations and becomes the base for new routines.”

¹ *Quotations are from Nonaka and Takeuchi (1995)*

SECI are exactly the initials of these four processes, which particularly occur within a shared context that the authors call “Ba” and that “enables a dialectic process among the actors” of a given organisation. The latter can be regarded as “an organic configuration of various Ba, where people interact with each other and the environment, based on the knowledge they have and the meaning they create”.

Now we think that the Co-design concept can be mapped onto the SECI model as per the following scheme (see Figure 2). In particular, Design and Implementation activities are respectively overlapping the Socialization - Externalization and the Combination – Internalization sequences. For instance, in ULLs, quite often the Design phase starts with a Socialisation process, or the individual realisation of the shared context (or “Ba”) that defines the socio-spatial system of reference for the Living Lab experimentation. In turn, the Implementation phase usually starts with a Combination process, focused on the results of the small experiments carried out towards the end of the Design, which become early initiatives of Implementation. As far as Discovery is concerned, differently from Design and Implementation, this is represented as transversal to the four SECI processes. However, in the practice of Co-design, Discovery is often revealed during the processes of Combination and Internalization.

This mapping exercise of Co-design onto the SECI model has been experimentally tested during the Periphèria project, within six urban pilots, as explained in section 4 below.

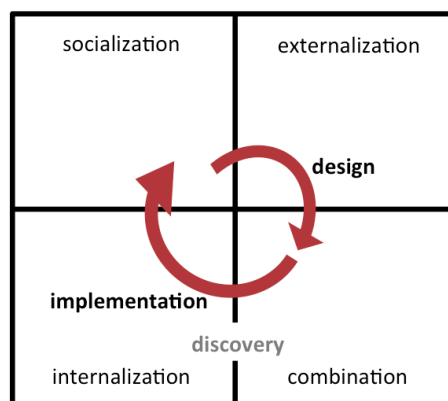

Figure 2 – Co-design mapped onto the SECI model

Successive iterations of Co-design form a spiral, with each loop amplifying the knowledge created to a higher level of penetration and accommodation within the

individual, group, organisational and communitarian dimensions. This complies with both the SECI model and the interpretative framework proposed by Evenson and Dubberly in 2011.

3 From the learning experience to actual behavioural change

While the previous section has argued that the collective experimentations taking place in ULLs are knowledge productive, and ignite learning processes at individual and collective level, it remains unclear whether and to which extent the generation of this new knowledge creates sustainable value for the participant actors and the entire community.

Our interpretation, based on the evidence collected within the Periphèria city pilots (Concilio and Celino, 2012; Concilio and Rizzo, 2012), is that whenever new solution prototypes for urban problems are co-created with a strong contribution by the citizens, a virtuous learning mechanism is activated, in accordance to which the same people who reflect and discuss together on possible initiatives having a social nature and value for the community (city or neighbourhood), then adapt their current and future behaviour, in a transitory or permanent way, making the scope and purpose of their previous engagement inform and shape future attitude towards the public “thing”.

Such learning mechanism is particularly evident in ULLs, where:

- Co-design of new urban services and policies is done with and by the people, not merely for the people;
- Concrete (real-life) trials of service and policy innovations are planned and executed;
- Experience sharing and exchange prevails over mere information (feedback) delivery from trial users to developers;
- Citizens feel “owners” of the socio-technical solutions co-created, together with technology providers and policy makers;
- Behavioural changes (may) follow right from this experience of “appropriation”.

We see clear points of convergence between our vision and the most popularly used of Argyris and Schon’s theories, double-loop learning (Argyris and Schön, 1978; Argyris, 1993). This emphasises that reflecting upon the effects of someone’s action may result in important changes in behaviour as a consequence of recognising eventually unfavourable

or beneficial implications of that individual action. In the ULL case, the involvement of citizens and stakeholders in the co-design of solutions to acknowledged issues of varying nature and complexity, related to public service or local development, brings to a broader level of reflection and discussion on the consequences of collective, as well as individual, behaviour. This affects the “mental model” that people exhibit towards community and society, in such a way that fosters the creation of relational capital at micro scale.

The importance of relational capital has hardly been noted by extant literature on technology or policy driven living labs (see e.g. Bergvall-Kareborn and Stahlbrost, 2009; Svensson et al., 2010), while is more familiar to economic geography scholars (Sunley, 2008) as well as marketing practitioners (Prahalad and Ramaswamy, 2004). We see this as part of civic awareness, or the realisation that a shared context (or “Ba”) exists, which is notably the first process where the Design phase starts from according to the discussion done in the previous section.

Additionally, the initial level of civic awareness is reinforced in ULL actors when turning to (real-life) experimental implementation and assessment of prototype solutions. Here, we speculate that from the concrete appreciation (or Discovery) of the viability of future living scenarios as enabled by the innovations being trialled, people become more effectively and permanently influenced than after a generic or abstract discussion of possible solutions to improve community life. This can trigger behavioural change in a similar way to that described by Döös and Wilhelmson (2011), i.e. as the consequence of a shared distribution of experimental tasks.

We depict the dynamics so far described as per the following Figure:

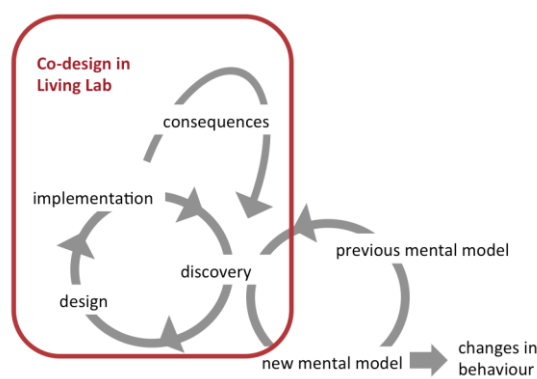

Figure 3 – Living Lab co-design and triple loop learning

It should be quite clear that the scope of the mental model's and behavioural changes expected is far broader than what is implied by a reflection on the effects of individual or collective action. It is a “brand new world” which is being figured out, thus shifting the focus from the micro scale changes brought about by ULL Co-design to the meso and macro scale transformation of neighbourhoods, cities or larger ecosystems.

That is why we propose to evolve from single or double-loop learning to “triple-loop learning” as an interpretative framework. The latter is a most elusive concept (Tosey et al., 2012), regarded as a level of awareness and knowledge that is beyond, and probably superior, to Argyris and Schon's theories. However, this level is rarely attained (Yuthas et al., 2004) as it involves the fundamental questioning of the meanings and assumptions so far attached to the external “world”, ultimately leading individuals and organisations to question the basis of all knowledge. For instance, triple-loop learning is said to occur when “one starts to reconsider underlying values and beliefs, world views, if assumptions within a world view do not hold any more” (Pahl-Wostl, 2009). Accordingly, triple-loop learning is related to transformational shifts in what individuals, groups and societies see as desirable ways of living and may be characterised as shifts in regime.

Now if a Co-design approach can be maintained throughout the shift from the micro scale to the larger environments, where user driven, open innovations are experimented, we posit that a triple-loop learning can be achieved, so eventually making behavioural changes become systemic. This because of collaboration among Living Lab actors, which intensifies the collective learning experience through the creation of “ad hoc” feedback mechanisms during (real-life) Implementation.

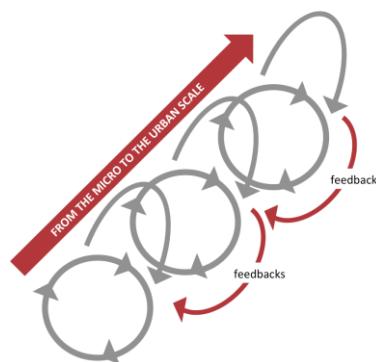

Figure 4 – Concatenation of learning cycles at different community scales

In particular, the above picture shows how the generation of feedbacks from different, scaling up stages of Co-design can consolidate the transformational changes induced by the learning effects of Implementation and Discovery.

This concatenation of learning cycles, as it is well known, does not happen frequently. However, the evidence collected in Periphèria, which is described in the next section, leaves the possibility open that in ULLs the (almost) compulsory need to scale innovation results up to the broader community level can more easily ignite long chains of feedback having higher probability to activate triple loop learning and therefore behavioural change in the communities involved.

4 Some evidence from the Periphèria project

The co-design work carried out within Periphèria project dealt with the six pilots of Athens (EL), Bremen (DE), Genoa and Milan (IT), Malmoe (SE), and Palmela (PT). In the remainder of this section, we take the case of the city of Milan as illustrative and exemplary of the results achieved.

Work has been carried out along three phases, each bridging Design to Implementation: 1) Observing the current situation; 2) Modelling the current situation; 3) Envisioning a better situation; 4) Instantiating the vision. Each phase can be mapped on the four processes of the SECI model, in coherence with Figure 2, as stated below.

STEP 1: Observing the current situation is a form of Socialization. Insight-gathering methods or problem-finding methods, such as ethnography, often rely on acquiring tacit knowledge through inhabiting a specific context and interacting with others in that context. As Nonaka writes¹, “The key to acquiring tacit knowledge is experience. Without some form of shared experience, it is extremely difficult for one person to project her- or himself into another individual’s thinking process”.

STEP 2: Modelling the current situation is a form of Externalization, better if this is carried out by individuals producing artefacts (documents, presentations, graphics, ...). Sharing someone’s experience and insights with others, for example, by writing a piece of ethnographic research, requires abstraction and generalization. As Nonaka writes, “Externalization... is the quintessential knowledge-creation process in that tacit knowledge becomes explicit, taking the shapes of metaphors, analogies, concepts,

¹ *Quotations are from Nonaka (1991)*

hypotheses, or models”. And he adds: “To make a hidden concept or mechanism explicit out of accumulated tacit knowledge, abduction, or retroduction is effective rather than induction or deduction”.

STEP 3: Modelling a better situation is a form of Combination. A designer looks at aspects of what is and imagines combining them with other things that he or she has experienced or imagined. Nonaka writes that Combination “synthesizes knowledge from many different sources in one context. The combination mode of knowledge conversion can also include the ‘breakdown’ of concepts. Breaking down a concept...also creates systemic, explicit knowledge”.

STEP 4: Instantiating a vision is a form of Internalization. Prototyping requires working out many details and determining many relationships, creating a new level of knowledge of the model on which the prototype was based. As Nonaka writes, “Explicit knowledge, such as product concepts or manufacturing procedures, has to be actualized through action, practice, and reflection so that it can become knowledge of one’s own”.

In the following table, the outputs and outcomes of the Milan pilot are mapped onto the four processes along three consecutive phases (cycles) of experimentation.

Table 1 - Mapping Milan Co-design cycles onto the SECI model

	Milan 1st cycle	Milan 2nd cycle	Milan 3rd cycle
Socialization	Exploring the way one of the most important square (Leonardo da Vinci) in the Campus is used and transformed has been the goal of this phase. Many participants have collected data, information, stories and even video, images as well as capturing some situations of the square (during holiday time for example when it is not lecture time and very few students are using this space). Many participants have invented ways for snapshotting specific conditions of the square and for reporting their idea of the square. In this phase some interviews have been carried out in order to widen the points of view of the square users and also to prepare some citizens groups to interact with the academics involved in the initiative. Some participants also started creating analytical syntheses out of their data and information so developing some interpretations out of their observations.	Many citizens and organizations have started thinking to and imagining what to do of/in the square. Some of them have started looking other experiences, inside or outside Milan, in order to get idea of what experiment to implement in order to test transformation of this area. Collecting ideas to be shared with others have been the main activities of this phase that also clustered new actors: new members joined the small academic team that was responsible of the activation of the whole process. Some started interviewing special urban groups like skaters or city writers to imagine new possibilities for using and transforming the space (therefore also enlarging the number of people becoming familiar with the process. Many experiences have been collected and somehow reframed, in order to be proposed and tested in the square.	The problems experienced while implementing the initiatives in Leonardo da Vinci square have been shared among the many involved actors. They have discussed on communication, people engagement, and the needs for the space to be part of the communicative strategy. *** A reflection on the results of the prototyping phase in in Leonardo da Vinci square started in the environments of both the Neighbourhood Council and the Milan Municipality. Some key actors started to reflect on the civic relevance of the experiments and on the great results achieved (citizens as active promoters of the space use and transformation) and to envision how and where else in the city to replicate the same process.

Externalization	<p>Many meetings (called coordination meetings) have been carried out to produce one synthetic view of the square conditions. All the participants have reported their impressions and collected evidences and supported their arguments using, in some cases, some of their reporting products. Personal reports but also reporting others' opinions have been the ways to create a "transfer" environment and to start aligning the vision on the square. In this phase the main discussion focuses have been on general problems, individual narratives, and interpretational mapping of the square situation within the campus context but also considering the square in the wider urban framework. This phase produced a rich document, detailing the square conditions in terms of opportunities and resources that have been also presented to the neighbourhood council and to some officers of the Milan municipality and also discussed with the same group of citizens who collaborated in the previous phase.</p>	<p>The ideas have been all presented, discussed and even adjusted to be all consistent and complementary, in terms of time and financial resources availability. Many meetings have been carried out which have also included the new involved actors. For this phase it has been very useful the presence of newcomers because it required the whole story to be repeated every time so making the externalization deeper and deeper. All the proposals have been also discussed with the Neighbourhood Council so assigning to the experimentation of the square transformation a bigger institutional value. The differences among the collected ideas and also the number of proponents suggested the idea that many actors were engaged in a re-appropriation initiative: the idea of "we can make that public space become the space of ours" started to be discussed also due to the fact that many suggested initiatives had a clear self-made nature.</p>	<p>How to make the link between public space and people deeper? This question brought to the idea to develop an ICT device that could better integrate the space dynamics with the people. Some of the people started to use existing apps in order to better strengthen the link between people and the activities carried out in the square. Foursquare, Layar have been tested as sort of space-based social networks; also others started to look for ideas of ICT solutions to be implemented and shared those ideas with the others.</p> <p style="text-align: center;">***</p> <p>Starting from the results of the Leonardo da Vinci square, some actors started to verify the opportunities for such a replication, which was also discussed during some meetings with the academic team being active in the Leonardo da Vinci square.</p>
Combination	<p>Some scenario design workshops have been carried out to rethink the role of the square in the campus and in the whole city of Milan. The attendees of the workshops have not been the same along all the workshops so requiring many reporting activities to guarantee a shared scenario as main output of this phase. Each participant, coming with different ideas of the future condition of the square (from the ways it can be used to deep physical transformations), argued strongly his/her vision and the construction of the scenario for the square has worked out as a bricolaging/alignment process more than a choice of one solution among many. The square have been thought as an experimental urban lab where new practices for urban transformation can be envisioned, tested and eventually transformed into praxis. This scenario found the enthusiastic favour of the neighbourhood council that arrived at making a formal decision to transform the square from a parking area into a pedestrian one.</p>	<p>Slowly the idea to create a coherent whole out of all the proposed initiatives started to be discussed and enriched. The RiconquistaMi framework has been developed to include all possible initiatives that could be practically and easily implemented and/or activated (sport, music, theatre, paintings, games and parties, ...). A very simple webpage (http://smartplanpolimi.wordpress.com/page/2/) has been created that could support the communication of such initiatives and also represent the virtual narrative of the square experimentation story. The Combination phase of this cycle is also made clear by one formal decision made by the Milan Municipality that formally assigned to a no-profit organization the responsibility to develop and implement a 2 months program of sport activities in the square. RiconquistaMi is framed as an experiment itself: a sort of experimentation of how the city can activate and cluster the many forces that are active in the city and transform them into a driver for public space transformation.</p>	<p>Many ideas of possible ICT tools have been shared and discussed till the idea for a new App came to people mind who involved an ICT private actor to start a long design activity: the app Stick Around has been designed that allows people to create and announce events that appear in the space as augmented reality objects.</p> <p style="text-align: center;">***</p> <p>Recently three additional areas of Milan have been identified by the municipality as available to urban experimentation. The authors have no clear knowledge of the way this decision have been made but in some declarations made by the local government it is clear that the initiative of Leonardo da Vinci square is being replicated and scaled up [see http://milano.repubblica.it/cronaca/2014/04/27/news/meno_auto_pi_pedoni_e_metropolitana_a_cielo_aperto_piazzale_loreto_cambia_vita-84587837/]</p>

Internalization	<p>The use of the square is transformed. The no car zone changed the physical asset of the space and made it be perceived differently by the citizens who started using it differently: from using it only during the week to consider it a public space available 24 hours everyday; from simply walking where earlier the cars were parked to playing there; from playing there to participate there in events organized by others; from being just participants to become organizers of events. A number of opportunities are envisaged at this stage and this gave birth to the second SECI cycle.</p>	<p>Initiatives started to be implemented in the square. Many initiatives have been implemented: some had a top-down nature, some others have been more insurgent and bottom-up. This explains why in this phase prototyping has two different levels of significance. The first one is referred to the level of each single experiment: each represents a prototyping of what the square can be and become but also of the way the square can be transformed and re-appropriated by people. The second one is referred to the prototyping of the way the municipality can manage processes in an experimental perspective. These two levels of prototyping activated two new different branches of the process: one devoted to support operational space transformation (the conception and development of Stick Around) and the other one devoted to replicate the same initiatives in other areas of the city (the reacquisition to public life of many other open spaces of Milan with the same experimental driven transformation).</p>	<p>Still to happen.</p>
-----------------	--	---	-------------------------

The Milan pilot of Periphèria was related to the development of smart services inside the urban environments of the University campus(es); the Table particularly reports about the Co-design activities that took place in relation to the desired renovation of a public square (Piazza Leonardo da Vinci) where the Politecnico di Milano buildings are located.

The three experimental phases also represent consecutive learning loops that have produced feedbacks towards involved actors. In practice, the experiment included many overlapping initiatives that took place in the square and involved a significant number of people (about 400 overall, though not constantly throughout the whole process). These initiatives also had very different nature (university lectures, sport activities, theatre and music events, collective or individual parties, street art initiatives, ...) and involved four different kinds of actor, specifically citizens, academics, municipal administrators, and local voluntary associations, each involved with specific and precise “tasks” interacting with the square renovation and being announced and performed with a diffused awareness of their experimental and exemplary nature. Each experiment produced its own feedback (or set thereof) towards each of the actor categories. Some examples can help the understanding of such feedbacks.

A first example is related to the sport activities. One experiment (“MiMuovo”) within the RiconquistaMi initiative, planned to move some gym activities from the indoor spaces of sport associations to the square; although being the beneficiaries of such an attempt, the sport associations themselves imagined that very few people would have joined the event due to the need of privacy during physical exercise. Instead, the high participation of citizens and the growing number of subscribers showed that people in fact do like open spaces for their gym activities. This result pushed the sport associations to propose more new activities and events under the MiMuovo umbrella. This example shows a feedback created during the second cycle mainly towards the sport associations.

A second example is related to the students’ usage of the square. The Piazza Leonardo da Vinci is widely used by students who consider this urban space a sort of extension of the university space, initially being their private parking place. During the experiments carried out within the “RiconquistaMi” initiative, students have been involved in many different activities, either as protagonists of a temporary transformation of the square (architecture school) or as engaged spectators of theatre or music events. Many of these activities have created conflicts with the Municipal decision to close the square to private cars; nevertheless they could help a completely different use of the square be experienced, that has made participants the real protagonists of experimented urban transformation, bringing them somehow to re-consider their initial position.

Many other feedbacks can be identified throughout these pilot initiatives, which have affected the beliefs and values of many of the actors involved in the ULL. Behavioural changes can also be identified in relation to them, which are all characterized by the fact of being related to a common urban practice, i.e. the use and management of public spaces in the area of the Leonardo Da Vinci campus.

In short, the experimental nature of the whole process transformed specific practices into action fields whereby behaviour changes are revealed. In a general sense it is possible to identify some “trends” in those changes, like a shift in citizen’s view from respecting to transforming the use of public spaces, or one in the public administrator’s vision from an initial scepticism to a later confidence and approval, as testified by the decision of the Municipality to replicate the same “participative approach” to square renovation in other neighbourhoods of the city of Milan. See in the following Table 2 the main identifiable changes that can be associated with the typologies of actors involved.

Table 2. Main behaviour changes and related practices

Actors	Specific practices	Behaviours	
		<i>before</i>	<i>After</i>
Citizens	Use of public spaces	Respectful	Transformative
Academics	Public space design	Bottom-up	Collaborative
Local associations	Use of public spaces	Responsive	Suggestive
Public administrators	Public space management	Delegating	Participative

These behavioural changes are clearly results of a Co-design approach, which has been largely evolutionary in terms of the underlying relational structure (being open to new actors and stakeholders) and also characterized by its constantly being experimental and not repetitive in its manifestations. The idea that the transformation of the area would be the result of a long, participatory and differentiated experimentation on the “urban” dimension (Experimenting the Urban was the early slogan of the whole initiative) has never been abandoned by the Municipal decision makers and academics involved in the pilot. Making this experiment open to anybody, by directly engaging planners and urban designers together with neighbourhood representatives, citizens and local associations, has turned the Leonardo Da Vinci square into a collective learning environment, where practice generates tools for new behavioural tests.

5 Conclusions and Future Work

The idea to relate learning to behaviour is not new (Argyris and Schön, 1978; Ajzen and Fishbein, 1980; Ajzen, 1991; Kim and Hunter, 1993; Witte and Davis, 1996; and many others). The literature on knowledge management and organisational learning has provided various definitions and conceptualisations of social learning. Now there seems to be consensus that learning in complex collective environments requires communication and interaction of different actors in a participatory setting. This is believed to result into a set of collective outcomes, such as the generation of new knowledge as well as the development of relational links (Muro and Jeffrey, 2008) which in turn gives rise to the conditions for the definition of a collective action to which future individual behaviours will be more aligned (Björgvinsson et al. 2010).

The analyses carried out in this paper, and the evidence collected from the Periphèria pilot in Milan, confirm the potential of ULLs for sustainable value creation in civic

communities. This value creation builds on the Co-design activities, carried out for the development of new prototype solutions, in response to previously identified and agreed public service or policy problems. Such activities can be regarded as knowledge creation processes, fostering the generation of relational capital at the micro scale of urban environments, which in turn shapes innovation processes with a character of situatedness, although relating to different environments, somehow less structured and formalized than a city or urban ecosystem. The very generation of valuable relational capital, outside of standardized schemas and protocols, is a situated innovation product by itself.

In this respect, our paper confirms what was analytically demonstrated by Capello and Faggian in 2005, i.e. that ULLs contribute significantly to the production of local knowledge in relation to the development of relational capital. The character of this capital is threefold: it is experimental driven (Periphèria 2013), it gives rise to an evolving and dynamic governance (Concilio et al., 2013), and is situated, or exists in a specific (urban) environment and there it frames a user driven, open innovation process.

Additionally, double-, and triple- loop learning theories imply that the ULL induced processes of reflection and questioning, rather than simple use or provision of information as part of those processes, strengthened by the real-life experimentation of the innovations being co-created with the users, may induce changes in individual and collective mental models, transforming the feedbacks and results of the trials into sources of behavioural change and community scale learning.

Such learning does not occur, however, within the boundaries of a well-identified group or organization; it is rather the consequence of a distribution of experimental tasks among involved actors that shapes the collective, shared, action space (called “shared action arena” by Döös and Wilhelmson, 2011).

The chaining of learning cycles at upper scales than the “micro” in urban contexts can possibly reinforce the above patterns and be responsible of further behavioural (systemic) changes. This seemingly confirms the hypothesis made by Misiko (2009) that longer-term collective experiments develop a strong underlying relational dimension, which is critical for the sharing and scaling up of produced innovation, thus affecting and aligning people’s behaviours towards a collective whole.

Further research and action is required, however, both to document the behavioural impact of ULL knowledge creation dynamics and the conditions under which the value of

innovation can scale up from the micro trials to the meso and macro of neighbourhoods and cities as complex ecosystems.

Referring to these two aspects, empirical studies should possibly take advantage of the “triple loop learning” concept as a suitable theoretical guidance.

Structured Abstract

Purpose – The aim of this paper is to analyse corporate universities as advanced models of knowledge management in a local development perspective. To achieve this purpose the paper investigates the expansion of this phenomenon in Western Europe and emphasizes the role of corporate social responsibility in influencing the diffusion of corporate universities in this region.

Design/methodology/approach – The paper analyses the relationship between the firm and the external environment through corporate universities in the perspective of a sustainable and knowledge-based local development. Notably, we refer to the so-called “stakeholder” corporate university, which is a model that entails an active role of the corporate university in the fulfilment of fiduciary duties imposed by corporate social responsibility. Then, we summarize the main features of European corporate universities based on a review of the existing literature. Finally, we present the main results of a survey on Italian corporate universities.

Originality/value –Our paper puts in evidence the existence of a model of corporate universities in Western Europe that is partly different from the one practiced in the United States. European companies do not only consider the corporate university as a tool for developing and integrating a number of internal organisational processes, but also for keeping a close relationship with all relevant stakeholders and connecting their activity to corporate social responsibility practices. Accordingly, in the European perspective, corporate universities can also be viewed as original educational agencies within local systems of production. Data on Italian corporate universities confirm this suggestion.

Practical implications – Practical implications are twofold. First, corporate universities are required to interact with external educational agencies, notably traditional universities. This perspective would be particularly suitable in local systems of production where the

direct relationship between educational agencies and corporate universities may feed university-industry cooperation. Second, a corporate university oriented to corporate social responsibility would favour the relationship with the relevant local community and support the role of institutions in shaping regional economic change. This evolution may address the increased density of economic and business interactions through the extension of learning processes outside firm's boundaries.

Keywords – knowledge, local development, corporate universities, corporate social responsibility.

Paper type – Academic Research Paper

1 Introduction

The knowledge economy does not homogenise communities and disregard local distinctiveness. On the contrary, it rewards the production and the diffusion of knowledge based on idiosyncratic interactions among economic agents allowing them to take advantage from the opportunities offered by global markets. In this framework, local systems of production are an essential reservoir of tacit knowledge and a source of positive spillovers. Local systems may thus become a "knowledge multiplier" that preserves the collective and contextual know-how generated by the exchange of different types of knowledge, and defines an institutional framework that addresses and regulates the dissemination of knowledge inside and outside the system.

Some typical properties of knowledge are accentuated in this environment. Knowledge is often embedded in employees, it has features of public good, and it can be hardly brought in the market (Cantner et al., 2011). Accordingly, local systems encourage the removal of institutional and economic barriers to the spread of knowledge flows through cooperative arrangements, smart communities, and industrial clusters. In addition, they support the creation of social and territorial capital through the cooperation between public and private entities.

In this model, the firm needs to build up a knowledge management system that pays attention to the different dimensions of knowledge-creation processes in the relevant local context in order to stay sustainably competitive. The exploration and the exploitation of different types of knowledge need to look for places, not necessarily physical, for triggering a virtuous cycle of production, accumulation and exchange of intangible assets in the relevant local system. Therefore, the interaction between firms and the educational agencies stimulates change and innovation in the system as a whole.

As a partially autonomous entity aimed at managing learning processes in a strategic perspective, corporate universities¹ (COUs) can be seen as structures potentially suitable for catalysing knowledge and entering into relationships with local knowledge systems, and eventually supporting the parent company in the pursuit of sustainable competitive advantages. The role played by the COU would thus become significant not only for the parent company itself, but also for the relevant local system. On the one hand, universities and other educational agencies have a stake in the competitiveness of firms located in the territory. On the other hand, businesses have an interest in promoting knowledge creation in the local labour market. The COU may well represent a tool to promote and develop learning in order to preserve the competitiveness of the local systems in the global markets.

Our purpose is to associate this interpretation of the role of the COU with the specific characteristics of this phenomenon in the European context. In Western Europe a strand of theoretical and empirical literature has viewed the COU as an "open" entity that facilitates knowledge diffusion outside the parent company and supports corporate social responsibility (CSR) practices. European companies do not only consider the corporate university as a tool for developing and integrating organisational processes, but also for keeping a close relationship with all relevant stakeholders and connecting their activity to CSR practices. Notably, the COU could take the form of a "stakeholder university" following a partial external path with respect to the parent company. From this position its role in the local systems of knowledge could become highly relevant.

The paper is structured as follows. Section two reviews the literature on local knowledge systems in a regional perspective. Section three defines the COU in a CSR perspective. Section four introduces a model of local knowledge systems that includes the COU. Section five presents the result of a review of the literature on corporate universities in Western Europe. Section six presents the results of a survey on Italian corporate universities. Section seven discusses and concludes.

¹ *Corporate universities are associated with a broad range of organizational forms and knowledge management systems, "ranging from renamed training departments to institutionalized carriers/drivers of strategic knowledge innovation within and between organizations" (Rademakers, 2005, p. 133). In section three we specifically define these entities by reviewing the relevant literature.*

2 Local knowledge systems

Local development increasingly depends on long term intangible interactions between firms and the relevant territorial context. Among the entities that catalyze these interactions we find "human capital factories", mainly represented by traditional universities and other educational agencies. All together they constitute the external organization of knowledge. These agencies are not only conceived as mere educational entities, but they are also regarded as one of the "engines" of an innovation-based development process (Gibbons, 2000; Kenney and Patton, 2006). They are deemed to reduce skill mismatches in local labour markets, to create new knowledge in the form of patents, licenses and spin-offs, to activate partnerships for both research and recruitment, and to provide vocational training programs (Zucker and Darby, 1996). Such a role underlies the hypothesis of a direct relationship between human capital development activity and economic growth, which origins from those models that introduced human capital in the aggregate production function, assuming knowledge as endogenously determined (Lucas, 1988; Barro, 1991, Mankiw, Romer and Weil, 1992). Moreover, in the knowledge economy we do not refer only to knowledge embodied in workforce's skills, but we also include workers' participation to communities of knowledge. This entails an increasing importance of relational competences. Therefore, local knowledge systems enhance economic development even by promoting entrepreneurship, values, and new paradigms of social interaction.

In this framework, educational agencies, especially universities, can be regarded as knowledge producers that foster creation and transmission of new ideas. At local level, however, they may play different roles and activate different paths. Some universities tend to orient themselves to the market, following the model of the "entrepreneurial university" (Etzkowitz, 2003). Other ones can be defined as either "knowledge providers", their activity being focused on general and managerial skills, or innovation incubators. A similar pattern can be referred to the model of the "engaged university", which is able to adapt itself to educational requirements and knowledge characteristics of the region, thereby acquiring a role in the construction of intangible networks and in the promotion of social and territorial capital (Benneworth and Hospers, 2007).

Local governments, in turn, are usually responsible for the provision of vocational training programs tailored on the demand of skills expressed by local firms, and for the provision of subsidies and incentives for firms that directly train newly hired workers

(Batt and Osterman, 1993). Local labour markets and local systems of production can thus become "cognitive multiplier": by reproducing knowledge, they preserve those contextual skills generated by collective learning and promote the exchange of different types of knowledge, defining an institutional framework that facilitates and regulates knowledge dissemination in the system (Bramanti and Salone, 2009).

Such a "local knowledge system" allows the removal of economic and institutional barriers to the diffusion of knowledge between different actors. Assuming that territorial specificities are an essential factor for the development of this system, the adoption of consistent policies by local governments is crucial. Both legal and social norms, together with organizational forms and routines, contribute to determine economic and social interactions and to build those intangible infrastructure assets that channels intra-systemic knowledge flows (Cappellin, 2010).

In this scheme, firms interact with the local system in their processes of acquisition, identification, development, usage, and repository of knowledge. The evolution of the demand of skills and qualifications expressed by local labour markets is an essential element for an effective knowledge-creation process. A dynamic demand activates the interaction between firms and the external organization of knowledge, triggering the recombination of heterogeneous learning processes and stimulating change and innovation (Cappellin, 2010). Three are the main objectives of knowledge management in this respect:

- (i) to acquire knowledge from the outside, through the selection of properly trained workers;
- (ii) to preserve and retrieve knowledge that is already available. This objective is usually achieved through the participation of employees to vocational training courses offered by external agencies, possibly carried out in cooperation with the firm;
- (iii) to generate new knowledge in cooperation with universities and research centres, either targeting existing research activities, or by promoting new research projects.

All types of knowledge are involved in this process. However, it is their combination to serve as a basis for an effective interaction between the different actors. In order to create the conditions for this combination, each local system should find "ad-hoc" places, not necessarily physical, where such a virtuous cycle of production, accumulation and exchange of knowledge can occur. In these places firms acquire knowledge from the system to cope with potential mismatch in the relevant labour markets. The institutional

actors, on their side, are interested in promoting inter-organizational knowledge transfer through the creation and strengthening of complex networks. In this perspective work-based learning is one of the pillars of the so-called "learning triangle" (Ducatel, 1998), whose other corners are represented by the educational system and by the individual and organizational experience. All these pillars must integrate with each other in order to exert their effects in terms of competitiveness of both firm and local system as a whole.

3 Defining the COU in a CSR perspective

In this framework the COU is a thought-provoking phenomenon. It entails both exploration and exploitation of knowledge-creating processes in accordance with the aim of generating and protecting sustainable competitive advantages for parent companies. Knowledge must be transformed and adapted to both endogenous and exogenous change through an "ad hoc" organizational learning process. In turn, knowledge must be oriented towards the development and the implementation of firm's strategy, eventually looking for new opportunities to gain sustainable competitive advantage outside the standing business model. Looking at strategic development as a continuous learning process, the COU can be seen as a strategic tool able to address the requirements to fulfil individual and organizational learning needs, to ensure employees engagement, and to enter into long-term relationship with external educational agencies.

A widely accepted definition of COU is still missing in the literature. The early definition describes the COU as an "educational institution providing training courses created by an organization whose mission has nothing to do with education" (Eurich, 1985 p. 23). According to this view, as it has been later refined, the COU is an "educational entity existing outside the academia..[enabling] businesses, both for profit and not-for-profit, to maintain and expand the expertise of their workforces and, as a result, to secure their position in the marketplace" (Gould, 2005, 510), which is "designed to assist its parent organization in achieving its mission by conducting activities designed to cultivate individual and organizational learning, knowledge, and wisdom" (Allen, 2002, p. 14). Meanwhile, more business-oriented approaches come out, focusing on the relationship of the COU with business strategies. According to them, COU "grows when a company tries to relate their strategies for training and human resource development with the overall business strategy, through the coordination, integration and development of human capital within organization" (Henley Management College, 2005, p. 8), and is

configured as a “strategically useful tool to ensure that an organization achieves its mission” (Moore, 2002, p. 32) and “strategic umbrella of business for educating not only employees, but also secondary customers and suppliers” (Meister, 1998, p. 29). However, despite this variety, the COU is almost unanimously conceived as an entity that favours the renewal, the implementation and/or the optimization of business strategy (Rademakers, 2014), mainly handling the impact of innovation and change on human capital, in particular on systemic and relational skills (Campbell and Dealtry, 2003). Strategic role and reaction to change are therefore the cornerstones of the COU, which represents an advanced solution placed at the upper end of an ideal monotonic growing function of the level of complexity and strategic coherence of work-based learning (Figure 1). In addition, a typical role of modern COUs is to promote a shared corporate culture and provide new learning opportunities, thus eventually sustaining employees’ intrinsic motivation (Blass, 2005) and reducing turnover.

Not surprisingly, the scope of a COU is usually broad. It concerns "all activities that cultivate learning, knowledge and communication of those who, whether or not inside the company, can contribute directly to business success" (Moore 2002). In addition to training programs, the COU can be involved, in whole or in part, in talent recruitment, change management, career paths, geographical mobility, job rotation, mentoring, coaching, partnerships with traditional universities and other educational agencies. In particular, in a knowledge-based firm, recruitment is a channel for acquire competences and trigger the development new capabilities (Song et al., 2003). The COU may thus act as a "knowledge engine" whose strategic role in the era of cognitive capitalism avoids any decision of outsourcing learning practices. Other possible activities are represented by on-the-job training (such as mentoring and coaching), research and development (R&D), vendors selection process, knowledge diffusion outside the corporate (library, working papers, etc.). The common feature is the link between these activities and the factors strategically driving the knowledge within the organization. No COU however is actually involved in all these possible activities (Allen 2010).

The COU can also be differentiated according to the audience of potential “students”. COU activities are not necessarily devoted only to employees, but they may also include external stakeholders, such as independent agents, young graduates, suppliers, and local community members. In this respect, the COU has been seen as “the natural alternative to employee education at work and after college” (El-Tannir, 2002, p. 77), being a

supporting entity in recruiting talents with long run retention perspective. Eventually the COU can exceed corporate boundaries to provide educational services, receive external accreditation for its activities, and eventually act as a proper university issuing legally recognized diplomas. However, its rationale is usually different from the one of traditional universities (Walton, 2005). More frequently, the relationship with traditional universities acts in terms of complementarity, with the COU viewed as a connecting entity between tertiary education curricula and the business domain (Wang et al., 2010). Such complementarity is consistent with a “knowledge-based” firm aiming at expanding its internal learning towards different activities and different types of human capital, awarding a strategic role to education through a greater coordination between contents, investments and performance (Ryan, 2009). In accordance with this framework, the COU would act as a learning facilitator, orientating the individuals and the organization towards an attitude of continuous training, shared values and a climate of openness.

However, the existing models of COUs may substantially differ one to each other according to the relevant theoretical framework and the actual operating context (industry, region, internal structure). Moreover, the heterogeneity of the phenomenon has been exacerbated by the wide spectrum of organizations that have created their own COU: multinationals, SME, non-profit organizations, state-owned organizations. For the same reason we observe some misuse of the COU label. The existence of different labels (Corporate University, Corporate College, Academy, Institute, School, Foundation) is not helpful in this respect, as they often do not correspond to different models.

In this heterogeneous context our focus is on CSR-oriented COU. The relationship with business strategy and the focus on education and training has generated a peculiar approach that views the COU as an actor implementing CSR practices of the parent company. This approach relies on the suggestion that both COU and CSR are related to learning processes and knowledge management. Indeed, CSR has been specifically seen as a set of rules aimed at "increasing the quality of life of the workforce and their families as well as the local community and society as a whole" (The World Business Council for Social Development, 2000). CSR typically leverages on factors such as trust, values and corporate culture for committing both the firm and its stakeholders to engage in learning processes. Not surprisingly CSR has been considered as a suitable institutional tool for closing the gap between private and social value of training investments (Pedrini, 2013).

In the theoretical literature on COUs, CSR-oriented COUs can be referred to the

models of “network COU” (Allen, 2007) and “stakeholder COU” (Allen, 2009; Margherita and Secundo, 2009). In particular, the “stakeholder” COU is defined as a “learning archetype which promotes and develops innovative learning and capability-building processes among globally distributed and integrated networks of employees, customers, suppliers, partners, as well as of academics, professionals, independent learners, and other institutions” (Margherita and Secundo, 2009, p. 199). Accordingly, it can play an active role in the fulfilment of fiduciary duties imposed by CSR, eventually supporting the enforcement of this self-regulatory tool (Renaud-Coulon, 2008). In this way, the COU can be committed to responsibility towards local communities and contribute to build increasingly specialized networks, and, more generally, to share knowledge in the economic system in accordance with the institutional framework. These COUs thus help to ensure not only that parent companies are considered as a good place to work from their knowledge workers, but also that the COU seeks to become an effective learning places for the outside community. The external “students”, in turn, could consider the COU as a place where they can acquire a comprehensive set of skills and eventually to become “better citizens”.

4 The COU in the local knowledge system.

In local systems of production, the changing role of educational agencies affects the relationship between firms and the relevant local knowledge system. On the one hand, universities and training institutions have a stake in the competitiveness of local firms. On the other hand, firms are interested in human capital development in the local labour market.

In this framework, the COU can participate to the process of knowledge transmission in both directions. First, the COU can adapt the incoming knowledge to the production processes while supporting knowledge standardization and codification. In this view, the ability to play that role depends on the capability of the COU to absorb knowledge from outside and make it available for the parent company. Second, the COU can support business schools, vocational training centres, and traditional universities in the creation of intangible networks that channel the knowledge flow between the actors of the system. Accordingly, the COU would attract knowledge inflows from outside the organization, and recombine them before channelling into the parent company. Knowledge outflows, instead, would result from the cooperation between the COU, external educational

agencies and local governments. This cooperation would be implemented through training activities, applied research, local initiatives, conferences and workshops.

Hence, the COU can act as a collector of cultures, skills, technology, and innovation stemming from the local community to the company. In some cases, they may also feed the system in the opposite direction, supporting educational agencies (business schools, vocational training centres, traditional universities) and participating to a network of intangible infrastructures focused on learning and knowledge creation. In this perspective, the COU could contribute to a "triple helix" scheme (Etzkowitz and Leydesdorff, 2000), supporting an evolutionary path of higher education institutions oriented to economic and social development of the local system. The COU would thus represent an "ad hoc" interface for the interactions between educational agencies (and, more generally, the external organization of knowledge) and the parent company (Figure 1).

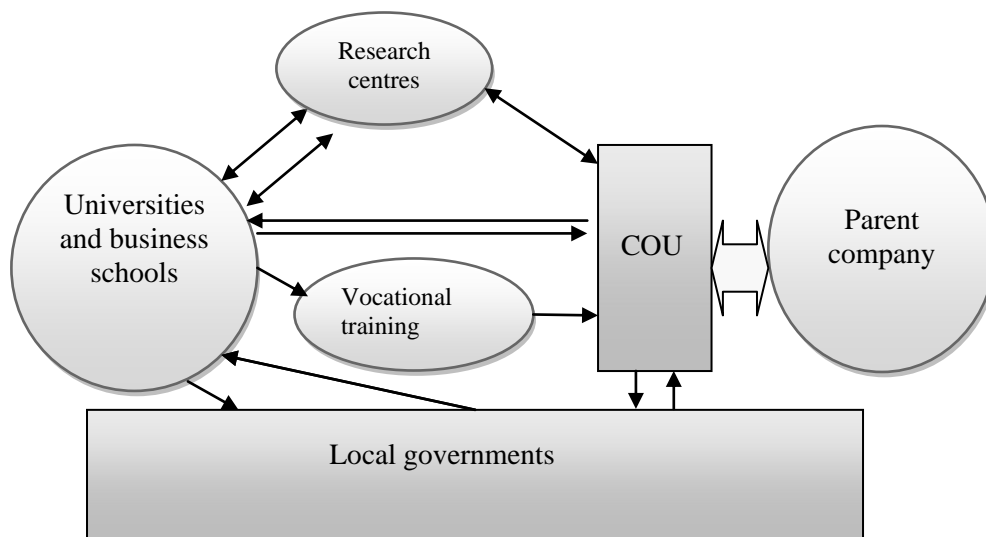

Figure 1 – The COU in the local knowledge system

In this way, educational agencies would be supported by the COU in transferring research outcomes from university to the firms, and in activating local development processes based on tacit knowledge and geographical proximity. In a broader vision, the COU could also be seen as the result of a "reverse spin-off" process. We generally use the term "spin off" when a new business originates from other existing organizations. In particular, university spin-off has been valued as an important tool for the dissemination

and exploitation of knowledge coming from the scientific community. The same process, however, can run in the opposite direction. Assuming an organization that is engaged in a heterogeneous bundle of learning processes, we can imagine the creation of new educational agencies. In this perspective, the COU is an autonomous unit committed to knowledge management which is also oriented to get value from the interactions with the external agencies, and from the provision of training programs outside the parent company.

This role would be emphasized if the COU is involved in the implementation of CSR practices. Several reasons may underlie the choice of adopting socially responsible behaviour. In any case, a CSR-oriented COU could generate value either via positive externalities generated by the knowledge-creation process or through the extension of the recipients of work-based learning activities (Renaud-Coulon, 2008; Allen, 2009). In both ways, the COU would create shared knowledge in the relevant economic system in accordance with local institutions and grounding on the principle of reciprocity. In this respect, communities of practice may represent a suitable method for favouring reciprocal behaviour. These social networks, in fact, can be regarded as points of contact between workers and local context inspired by the principles of cooperation among peers.

The actual role of the CSR-oriented COU in the local system, however, will also depend on exogenous factors: the industry of the parent company, the size of the company itself, its ownership structure, the degree of formal and substantial autonomy guaranteed to the COU, the magnitude of the actual skill mismatch in the local labour markets, the bundle of required skills by both the firm and the local labour market.

5 The COU phenomenon in Western Europe

COUs actually born in the United States where the phenomenon has been experiencing a systematic development as a specific tool for knowledge accumulation and dissemination within the firm since the early 80's. At that time, after the seminal experiences of General Motors (1927), Northrop Aviation (during the second world war), General Electric (1956) and McDonald (1961), other major industrial groups with a vocation of leadership in their industry (Boeing, Walt Disney Corporation, Motorola) set up their own COU. In the following two decades a worldwide spread of COUs occurred. In 1988 400 structures similar to a COU were counted; in early 2000s this number increased to approximately 1,600 only in North America (Bober and Bartlett, 2004). Then

they become nearly 4,000 in 2010 (Abel and Li, 2012), 900 of which refer to the largest companies worldwide, meaning that the phenomenon currently embraces also midsized firms (Maglione e Passiante, 2009; Rademakers, 2014). In parallel, the traditional view of COUs as a sort of re-labelling of traditional training departments was overcome by a new model centred on strategic orientation of organizational human capital (Holland and Pyman, 2006).

In the US, COUs originated as proprietary vocational schools in areas characterized by the presence of major companies. In a classic “make or buy” decision, a limited number of major firms decided to “make” a qualified workforce for their production process. In a second period, COUs introduced managerial competences, becoming more similar to internal business schools. Finally in the last decade a minority of the COUs has shown the attitude to become for-profit degree-granting higher educational entities (Thomson, 2000; Morey, 2004). In this way COUs deals with the need of parent companies to recruit talents and provide them with the required skills, while at the same time capturing the growing demand for career oriented post-secondary and post-tertiary education by external students (Morey, 2004). More generally, the relationship between COUs and traditional universities takes the form of an alliance or a partnership aimed at complementing in-house training with university education and at adding credibility to COU activities (Ryan, 2009).

This evolutionary path has been partially different in Europe. Besides the delayed development that the phenomenon had in our continent, European COUs have been characterized by a high fragmented institutional framework. Therefore, firms in each country have cultivated the concept according to the relevant institutional context. (Dealtry, 2006). To support this intuition we have reviewed most recent surveys referred to Western European countries, while performing a survey in the internet sites of major European companies (Table 1).

Table 1 Number of COUs in the main European countries

Country	Number of COUs	Main industries
UK	24	Banking and insurance
France	39	Banking and insurance
Germany	51	automotive, utilities
Netherlands	17	Banking and insurance, energy
Spain	18	Banking and insurance
Italy	39	Banking and insurance
Scandinavian countries	14	TLC
Switzerland	8	Banking and insurance

Portugal, Ireland, Belgium	3	Energy
Total	213	Banking and insurance

Source: our elaboration from literature survey and internet sites

Existing studies suggest that COUs in Europe represent a peculiar application of the relationship between firms and knowledge, aimed not only at tightening the link between learning processes and business strategies in order to reconfigure existing knowledge assets, but also at facilitating the effective integration with the relevant local knowledge system in order to absorb new knowledge from outside. This feeling is confirmed by the fact that COU are rarely seen as autonomous agents of endogenous change, nor they are directly involved in proper research activities.

In particular, the possible role of the COU in promoting CSR seems to have been positively welcomed in Europe. Case studies show that major European firms willing to provide meaning and relevance to CSR can orientate organizational learning towards an outside-in approach. These COUs, however, support CSR practices in different ways. In terms of methodology a CSR-oriented COU may implement learning open platforms and shape CSR strategy of the parent company (Rademakers, 2014). With regard to contents this type of COU may represent an instrument for embodying CSR-related strategies into leadership development programs (Meyer and Van der Pool, 2014). Moreover, specific sectors are specifically involved in CSR-related activities. This is the case, for instance, of utilities industry. In this sector European COUs look at external stakeholders and enhance cultural integration within the parent company (Antonelli et al., 2013). Moreover, some of them are given an explicit role in the promotion of environmental sustainability applying wider corporate projects promoted by the parent company.

Overall, European COUs are characterized by a substantial degree of openness and show a peculiar propensity to support their parent company in accomplishing fiduciary duties imposed by the CSR. This objective can be actually achieved through either the partial internalization of positive externalities generated by the production of knowledge or by the widening of the recipients of work-based learning activities (Renaud-Coulon, 2008; Allen, 2009). As a consequence, a substantial part of European COUs provide incentive to workers' intrinsic motivation and promote the transferability of human capital outside the company by delivering a wide range of content and offering personalized training paths.

6 Italian COUs and CSR. Results of a dedicated survey.

In analysing Italian COUs we refer to our recent survey on Italian COUs (Cappiello and Pedrini, 2013) that contain specific questions on the relationships between the COUs and external stakeholders and on the existence of CSR-oriented activities.

According to this survey, the framework of Italian COUs is highly dynamic. Although in Italy COUs are not a novelty in itself, most of these entities have been established in recent years and their configuration is still in progress. Their most popular mission is to create shared values in order to support employees' integration and stimulate their participation in learning activities. In this way Italian COUs also provide incentives for employees' retention. Moreover, the majority of Italian COUs recognizes change as a factor of complexity that requires a systematic collection of knowledge and experience in order to develop proper learning paths in different contexts. Only in a limited number of cases, however, COUs focus on the creation of new knowledge, thus acting as "engines of innovation". Nevertheless, most of the COUs claim that they foster creativeness, innovation and change. Similarly, the majority of COUs consider themselves as a tool for addressing the acceleration and the transformation of skills needs resulting from both exogenous and endogenous change.

Concerning the interaction with educational agencies, it is perceived as part of the mission by a minority of COUs. Once established, however, most of them look for complementarities between general and specific training through their relationship with external agencies, mainly represented by traditional universities. In addition, they seek to update the existing skills and foster multi-disciplinary learning processes by offering opportunities for the exchange of knowledge and experience with the external environment (Table 2). However, like most of their European homologues, Italian COUs do not perceive themselves as competitors of traditional universities. On the contrary, most of them enter into a cooperative relationship with the relevant local context and they can be seen as potential incubators of ideas within the organization.

Table 2– Relationship of the COU with external stakeholders

Subject of the relationships with traditional universities	Percentage
Common lectures	60%
Partnership	80%
Stage agreements	70%

Participation to students' and graduates' events (e.g. Career Day)	70%
Joint degree programs	10%

Finally, although CSR-oriented activities are not as much popular as activities related to corporate culture and organizational change, the majority of Italian COUs also play a role in supporting CSR practices (Table 3). For this family of COUs the channel to promote CSR practices is represented by all those activities that are likely to enhance the competitiveness of the parent company while simultaneously advancing the economic and social conditions of the communities in which it operates. In this way the COU creates shared values, which in turn are tightly related to CSR practices. In particular, like in the European framework, CSR-oriented role is acknowledged by COUs belonging to the utilities industry.

Table 3 - Role of the COU in the firm

Role of the COU	Percentage
Knowledge preservation and diffusion	80%
Corporate culture diffusion and talent integration	90%
Support in addressing technological and organizational change	85%
Knowledge creation and innovation	80%
Support in CSR practices	55%

7 Conclusions

In the knowledge economy firms are requested to upgrade talents and leverage human capital towards innovation and structural change, while promoting an effective mutual integration with educational agencies and research centres in order to enduringly support business strategies. In many situations, however, neither the Triple Helix model nor university spin-offs are adequately encompassed by the practice of educational agencies or by the support of local governments to partnership initiatives. Accordingly, local development increasingly depends from other forms of long-term interactions among the relevant actors (firms, workers, government levels, educational agencies, third sector), whose role is a discriminating driver of sustainable competitive advantages .

Within this framework, the COU can be seen as a catalyst for work-based learning, potentially addressing innovation, learning and knowledge transfer in a strategic

perspective, thus playing a peculiar role in the knowledge local system where the parent company operates. On the one side, it can bridge the gap between required and attained skills of workers entering the firm. This gap is higher in presence of a cyclical component of human capital demand which the education system is unable to cope with. On the other side, it can address the need to provide different skills so as to balance the needs to share knowledge, experience and identity with the needs to specialize competences and capabilities. Interconnected and interdependent markets require the activation of complex knowledge management processes able to anticipate change and stimulate the creation of a shared organizational culture.

The review of the scarce empirical literature on European COUs shows that a part of them can be seen as "open" structures, thus complying with the CSR-oriented model. This type of COUs can potentially act as a critical junction in the processes of knowledge transmission and intersection of cultures, technology and innovation. Notably, European COUs differ from US homologues for the existence of a substantial number of CSR-oriented COUs. In particular, the integration between COUs and CSR in our continent is usually aimed at mutually supporting the creation of a shared corporate identity and the promotion of differentiated skill portfolios. For their nature, these peculiar types of COUs can contribute to the promotion of the so-called "local competitive goods". This propensity is partially confirmed by an original survey on Italian COUs. A substantial part of Italian COUs has an explicit role in promoting CSR practices, and in creating interconnected and interdependent situations with the relevant external knowledge system.

In Europe, therefore, the relationships between CSR-oriented COUs and the other components of local knowledge systems can represent an efficient mechanism for the transmission of knowledge and the sharing of a sustainable management model in the local system of production. This perspective would be particularly attractive in those local systems of production where the educational agencies and COUs jointly feed university-industry cooperation. In addition, the relationship between the COU and local governments could support the role of institutions in shaping regional economic change by creating collective identities and developing specialized networks, relying on accepted rules and on a reciprocal basis. Through COUs different actors could look for new aggregation processes centred on human capital, eventually achieving competitive advantages that are sustainable for both firms and local communities.

Structured Abstract

Purpose: This article aims at discussing the problems faced by Higher Education institutions (HEI) in rising economies (South Africa is provided as an example here). Such institutions usually have to cope with ever increasing number of prospective graduates. Like most countries around the world South Africa is also confronted with massification of Higher Education (HE). Moreover local conditions affect the potential strategies for development. Nonetheless there are not enough studies devoted to how such strategies can be successfully applied in rising economies such as South Africa. This study fills this gap in knowledge.

Design/methodology/approach: The preferable research approach identified for this research is theoretical approach with comprehensive literature review. This approach is necessary in order to establish what the trends around the world are with respect to massification of education since the late 80s. Additionally in the case of South Africa it is necessary to consider the situation before and after the demise of apartheid in 1994. This will be done in order to model a solution which could lead to a win-win situation. In the end this could lead to a formulation of a model to be applied in practice.

Originality/value: This methodology puts in evidence the uniqueness of the rising economy (based on South African experience) approach to massification of HE. In the case of rising economies a unique solution has to be found to the problems such as accessing HE and low graduation rates. It stands to reason that by allowing students in HE, failure to graduate within the prescribed period it is to the detriment of all stakeholders. The solution proposed here conforms to a pragmatic approach to a knowledge economy rather than financial or social approach which tend to highlight only one perspective of a multi-facet problem.

Practical implications: The practical implications of this study derive from the fact that the knowledge-based strategies for sustainable education in rising economies will be discussed. These strategies are of vital interest to HE practitioners, government planners as well as prospective students. Moreover this study will provide the outcomes of the

application in HEI in South Africa as a case study. The crucial problem is that if such institutions are to become self-sustained, the gap between accessing HE and graduation rates must be closed. If many students access HE and few graduate the institution in the end will not survive.

Keywords – Accessing Higher Education, Rising Economies, educational sustainability, graduation rates, Knowledge-based strategies

1 Introduction

Higher education (HE) in the world, be it in a first world or a third world country, has been under scrutiny for the past three decades or so as the citizens of the various countries have been demanding more sharing of the wealth of a particular country. Globalisation, increasing gap between those that ‘have’ and the ‘have not’, unrealistic expectations of citizens, increasing costs (and primary, secondary and tertiary education are placed high in annual increases) and many other factors, have forced institutions to be more efficient and effective. With respect to Higher Education institutions (HEI) Hayton and Paczuska (2002, 11) once said HE is a *risky* business while many others (Dennis 1998; Archer, Leathwood and Hitchings 2002) emphasised how *expensive* it is.

The two words in italics describe two important aspects of HE, used together and alone. *Expensive*, in simple terms the (financial) input (running of the institution) brings low returns (low (output) graduation rates). *Risky*, because the institution admits a student who stands about a 50% chance dropping out in the first 6 months and a (average) 75% never graduating, but also for the student who might believe (s)he can graduate but might never do so. The effectiveness and efficiency are hampered by the schism between massification, the right of an individual to HE and the pragmatic side that not only economics dictate but also the status could diminish if standards are not kept.

There is no doubt that in the mind of any academic in knowledge management (KM) that, from all types of business, the one that can always be problematic in applying new KM findings is a university. There is at least one reason for it: They are supposed to be the generators of new knowledge, one of their main function, and to be the first to apply such knowledge by testing-retesting before they export it to the market place. How can they suddenly become users of all types of knowledge? However when higher learning institutions begin to be less distinct from each other the competition for attracting high calibre students in the end will determine their prosperity or demise.

This paper aimed at developing a model that could balance the two opposing views about HE whether it is a “right or privilege” if sustainability is to be achieved.

2 Accessing HE: A right or a privilege? A pragmatic approach

The word “access” to education could be viewed in a number of contexts: Gain entrance to a programme that the minimum criteria are not met (Andrews 2003, 54); for

Tight (1989) it means allowing someone to improve an old qualification or get a more relevant qualification. But it could also mean gaining access to formal education at a level appropriate to the individual (Evans 1985, 134). This is very close to South African situation where all individuals that possess a matric certificate can have access to HE.

Whether access is followed by massification or vice versa in the end is a matter of following pragmatism, charged by emotions due to the apartheid past. Research done around the world conforms in a number of findings. a) Student success rates in South African Higher Education institutions (HEI) are unacceptable. b) Higher Education South Africa (HESA) reports that 35% of first-years drop out after their first year (Sapa 2008). c) Breier and Mabizela (2007: 281) found that only 15% of students who enrol, complete their degree in the designated time; d) 30% drop out after the first year and a further 20% drop-out after their second or third year. Around the world the world these figures do not differ significantly (Bohart, Meyet and Visser, 2009; Tait, Van Eeden and Tait, 2002). Highly selective institutions are excluded although a 10% drop in graduation rates can have detrimental effects even if a 90% graduation rate is achieved.

From a pragmatic point of view economics play a central role in any emerging economy and apart from that they are even above other needs which tend to be short term solutions. For example the dilemma that exists between creating jobs and feeding people and deforestation or preservation of forests. All dilemmas associated with economics are directly related to sustainability.

The concept sustainability has in the past most often been broken out into three constituent domains: environmental (ecological), economic and social (cultural and political) sustainability; these are the known circles of sustainability. "The sustainability paradigm rejects the contention that casualties in the environmental and social realms are inevitable and acceptable consequences of economic development. " Sustainability can be considered to be a "paradigm for thinking about a future in which environmental, societal, and economic considerations are balanced in the pursuit of development and improved quality of life" (McKeown, 2002: 7).

In the case of HE the balance is pursued between the right and privilege of the individual. The simplest scenario is the following: Should one have the right, if scientific evidence shows that the probability of graduating, especially in the prescribed time, is almost 0%? Every stakeholder loses. Luck of funds by a capable individual to access HE makes access a privilege for the rich, the elite (as in the past) but also for the institution else it cannot sustain itself if the individual was not capable; and of course the country could be deprived of a new leader.

Sustainability of HE is also depending not only on quantity (higher graduation rates) but also on the quality of the product, the graduate. Research has shown that quantity can have a negative effect on quality of education, especially if the standards are dropped. If the institution accepts low calibre students that leads to low status institution. To move back to high status more often than not, is impossibility (Macrae and Maguire 2002, 24).

One of the main functions of HEI is to provide knowledge-related services (e.g.: transmit knowledge, process and synthesise knowledge as well as create knowledge or manage knowledge). These services are yet another contributing factor to sustainability.

3 KM and HE

Knowledge is considered as the most valuable asset in an organisation and probably will remain the in the years to come (Razi, Karim and Mohamed). The knowledge contains useful and meaningful information which later involves selection, filtering and assimilation processes performed by human cognition (Noordin, Othman and Zakaria, 2011).

The service oriented HEI have now come to realise the importance of KM as a result there are a number of studies in KM in the HE sector (Razi, Karim and Mohamed, 2011). The successful 21st-century organisations – schools, universities, small businesses or corporate giants – will be those that make the best use of their information and knowledge and use them to create sustained additional value for their stakeholders. At the same time, the concept of lifelong learning means that the learner is no longer regarded as the eighteen-year-old fresh from school, but now includes those entering and re-entering the university. The university is no longer confined within its own buildings; courses are delivered in outreach colleges, in the workplace and online. With these profound changes have come new words associated with learning: distributed, flexible and blended. The university is no longer the traditional bastion of knowledge, defined by its disciplinary boundaries or its physical campus, colleges and buildings (Buckley 2009, p. 80).

According to Buckley (2009), for universities to meet the demands of the global community

- the creation and dissemination of knowledge should be seen as instrumental activities rather than as ends in themselves;
- organisations set up solely for the purposes of knowledge creation and dissemination must have at the core of their brief the ambition to demonstrate the utility of the knowledge they produce and assist in the diffusion and application of that knowledge; and
- in order to implement the above effectively, such organisations must see themselves as part of that interactive chain of relations that constitute the global society rather than as the centre of a given national science system.

As knowledge is evolving and exploding throughout the time, a strategic method is required in order to manage the knowledge effectively and efficiently (Noordin, Othman and Zakaria, 2011).

4 KM strategies and systems

KM systems have become an important means of organisational development and survival. The rapid evolution of information technology has led to a revolution in industrial organisation, wherein competitive advantages are generated through the application of ITs to KM systems (Lee, Tsai and Amjadi; 2012, p. 30). Some organisations rely on conventional codification strategies, focusing on the use of IT to codify and store knowledge.

KM strategies can be primarily categorized based on two key dimensions: KM focus and KM source. On the KM focus dimension, strategies can be categorized as explicit and tacit knowledge based strategy. On the KM source dimension, KM strategies can be classified as internal and external knowledge based strategy. KM strategies outline KM practices required for managing knowledge effectively. The success of universities depends critically on the collection, analysis and seamless exchange of information or knowledge within and across the above organisational boundaries (Akhavan, Owlia, Jafari and Zare, 2011:1592).

Since the business of universities is about knowledge, they must be able to use technology in the management of that knowledge. Organisations today require employees who can quickly contribute novel solutions, communicate and cooperate effectively, independently seek out and evaluate information and readily share their knowledge in a manner that is intelligible and readily usable by co-workers. To execute successfully KM, top management and leadership should formalise KM practices in universities and connecting KM with economical benefit and innovation, allocating resources and the other variable factors. University staff performance in KM field can be evaluated, improved, standardised, developed and been efficient by performance management (Akhavan, Owlia, Jafari and Zare, 2011:1592).

The awareness in the last decade that knowledge and intellectual capital account for a significant unaccountable wealth companies spend significant amounts of money to capture them. However the systems they use could be ineffective, inefficient and do not create value. A knowledge based management (KBM) strategies and systems have to be applied.

5 A KM based system for sustainability of HE.

KM based systems can be used to a great extent for sustainability of HE. As it was revealed in the first section of this paper achieving sustainability in HE in a rising economy such as South Africa is not always an easy feat. There are a number of factors

that need to be taken into account. Some of these factors come from the environment of an organizational institution (e.g. government, society, and economics) and some come from the internal mechanisms (e.g. internal policy, funding and organizational structure). If graduation rates are one of the factors for sustainability (quantity) and if the type of graduate (quality) is another together with research outputs then one way to ensure sustainability is to ensure that graduates possess certain key competencies (Wiek, Withycombe and Redman, 2011).

According to Wiek et al (2011:203) key competencies are critical for graduating students to possess. They identified certain general key competencies regarding sustainability in HE. According to the authors' view modern economy, society and world generate a range of complex problems such as desertification, poverty, war. Sustainable development is believed to be one of the possible responses to these problems. Therefore the sustainability field has gained significant institutional attention over the past few years (number of new academic journals, conferences, symposia and educational advancements from general to HE). Authors propose to employ *competencies* as a references scheme for evaluation of student learning and teaching effectiveness. Competency in this view is a "functionally linked complex of knowledge, skills and attitudes that enable successful task performance and problem solving" (2011:204). What is important in this definition is that competencies in their core are intrinsically linked to knowledge and skills. Therefore it is possible to link them with the wider academic domain – that is knowledge management.

Wiek et al (2011) note that the current research converges towards comprehensive key competencies such as sustainability research, problem-solving and sustainable education. According to the authors in order to relate education to sustainability it is necessary to incorporate five key competencies: system-thinking competence, anticipatory competence, strategic competence, normative competence and interpersonal competence (2011:205). Remington-Doucette et al. (2013) investigate the sustainability in HE and try to assess it. The authors try to "translate" the abstract competencies identified by Wiek et al. (2011) into a functional university curriculum. They note that this is critical for the effectiveness, credibility and long-term viability of the curriculum.

KM based system for sustainably in HE should take into account the competencies identified before. In the case of the rising economies such as South Africa it should additionally consider the constraints posed by the Economy, Society and current political

situation. Adhikari (2010) focuses on the KM in academic institutions. Author provides two basic definitions of KM and notes that they have in common a structured approach to knowledge assets. Based on that he states that any structured activity, which “improves an organization’s capacity to acquire, share and use knowledge in the ways that improves its survival and success” (2010:97) should be part of KM systems. In this view it is possible to see common interest between KM strategy and sustainability strategy, which is long-term existence and success. Therefore all KM activities and systems should be closely tied to organizational objectives, of which one of the most important ones should be sustainability. The next section will focus on achieving sustainability in the case of open and distance learning (ODL) in HEI in a rising economy.

6 Sustaining an ODL (open and distance learning) HEI in a rising economy.

ODL is an important feature of HE in rising economies as compared to developed countries. It is due to the fact that in some cases transport infrastructure may be not as well developed. Therefore ODL is a natural choice of meeting the needs of the population, without huge expenditure on the infrastructure. ODL in this view may be perceived as a factor enabling sustainable HE and reaching population, which otherwise would be deprived of even the basic educational opportunities.

But ODL has extra challenges than a face to face HEI. Nowadays technology is a key factor which was identified by Adhikari (2010) and possibly many others. These key factors are vital to the organizational capability to exploit knowledge. Among these key factors are: technology and organizational structures. These two factors have also to be considered for achieving sustainable ODL. . Rowland and Rubbert (2001) note that the information needs and practice of part-time and distance learning as well as mature students in a lifelong learning environment are rapidly transformed by the use of ICT in HE (2001, p. 758). They also realize that the information needs of part-time and distance learners are different from the “standard” students and may be not fully recognized by Universities and programme tutors.

Additionally distance-learning units may often cater for only some of the programmes that are offered in a given HEI. A successful strategy in the case of ODL should take this into account as well. One of the potential solutions to these problems is provision (by the

institution) of highly specialized distance-learning units. . Rowland and Rubbert (2001) also note that “some of the demands students made will be easier to implement than others” (2001, p. 760). Therefore in order to achieve sustainability in ODL it is necessary to prioritize the potential solutions. Moreover it is necessary to perform cost-benefit calculations in order to decide on the usefulness of specific facilities, courses and services. Additionally a given course, service or offering can only be successfully implemented if existing marketing and promotion strategies can be adjusted to guarantee the long-term future of this given new service or offering. In other words it is necessary to “guarantee” the market for it in order to achieve its sustainability and profitability to the HEI.

At this point authors would like to consider whether a framework for an ODL institution, which implements sustainable development, could be developed. Of course it is possible to see great benefits, which could be achieved by proposing such a framework. As it was discussed previously such framework should take into account the prioritization of the students’ needs and matching them with the budgetary constraints as well as organizational policy. Additionally factors from the environment should be considered too. Figure 1 presents a very early approach to such a framework.

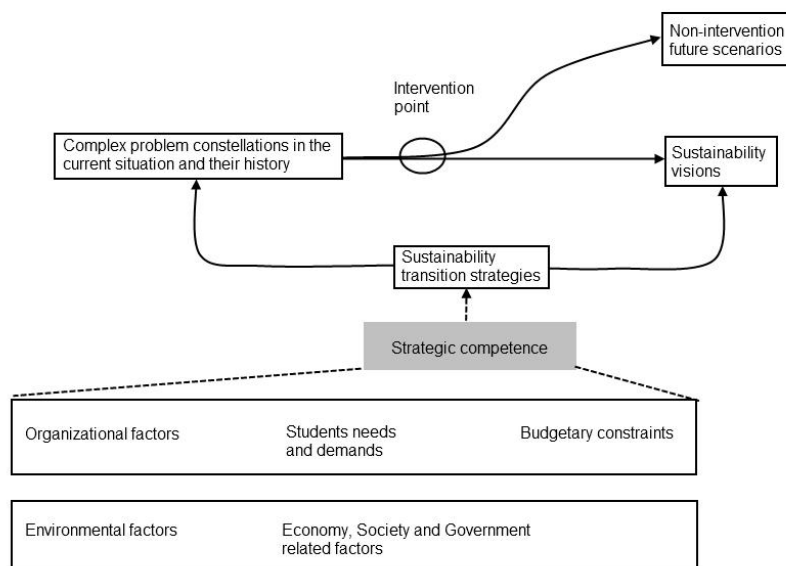

Figure 1. Achieving sustainability in HE (based on: Wiek et al., 2011:206)

As it can be seen on figure 1 the most important key competence in the case of decision makers and solution designers should be strategic competence. This competence should allow formulating sustainability transitions strategies for HE. In other words sustainability in HE can be achieved by a way of shift in paradigms and reformulating given institution's strategies in such a way that they take into account sustainability. Such sustainability transition strategies should encompass ODL as one of the potential solutions to the students' needs and demands on one hand and budgetary constraints on the other hand. Apart from that environmental factors also play a significant role. All this should lead to sustainability visions. These visions in turn help achieve sustainability by providing all stakeholders (not only decision makers) with concrete guidelines. These guidelines may be different for each HEI depending on the factors involved.

7 Conclusion

HEI (also those implementing ODL) are faced nowadays with more challenges than ever before especially massification, competition to attract high calibre students and subsidy cuts by governments. Increase in graduation rates and producing quality graduates are indisputably two factors that will guarantee their existence and of course aiming for being leaders in research and development in the future. However each of these has its own challenges especially for ODL institutions and even more in South Africa, what the authors call 'a hybrid country' that lies between the first and the third world. It is hoped that the suggested model, if properly applied could ensure the sustainability of an ODL institution in the 21st century.

Structured Abstract

Purpose –Advanced web technology offers possibilities for blending two complementary sources of knowledge, academic and entrepreneurial, within a single web-based framework. The main goal of our project is to establish an open educational resources (OER) platform and network for fostering technology enhanced learning (TEL) within HE institutions and enterprises in the Western Balkans. Another objective is to provide training for members of universities and enterprises for production of OER materials. The third objective is to produce materials in various languages, in video, audio and textual format, supported by electronic terminological resources, services, and functionalities for searching and browsing.

Design/methodology/approach – The TEL platform consists of tools and resources: learning, language and implementation resources. Among the tools some are available open source and commercial tools, some are in-house tools developed by the University of Belgrade Human Language Technology Group. Learning resources are both academic: course planning materials, video lectures, thematic content, and entrepreneurial: case studies, best practice examples, expert presentations and software demonstrations. Language resources supporting the multilinguality of the platform, terminology and its search and browse functions are lexical and textual resources and grammars. Implementation resources consists of best practice design principles and licensing tools to promote OER.

Originality/value – Designing usable, effective and interactive TEL environments is a demanding task, which requires creativity and a significant amount of expertise. Especially when knowledge is elicited from two essentially different environments, the academia and the enterprises. The need for multilinguality of OER is a consequence of the novel holistic approach that takes into account all the languages a learner may use. Hence the language support system within our TEL platform, which provides for OER in different languages and allows learners in a specific domain to get acquainted with domain terminology both in their mother tongue and in other languages.

Practical implications –The proposed TEL platform opens a new dimension in OER by blending two major sources of knowledge: the academia and the enterprise. It thus contributes to the important task of preparing university students for their future jobs, but also enables them to improve their academic knowledge after graduating, by offering them a live-long learning opportunity. Finally, it supports mastering of educational

materials and expert terminology in different languages, in contrast to more traditional approaches that look at one language at a time.

Paper type – Academic Research Paper

1 Introduction

The knowledge of professionals with higher education can roughly be divided in two parts: academic knowledge they gain as university students and entrepreneurial knowledge they acquire as practitioners. Although it is safe to say that academic and entrepreneurial knowledge are complementary and intertwine in various ways, the sources of these two types of knowledge and the knowledge acquisition process are in general separated, as higher education offering academic knowledge precedes the solving of practical problems within enterprises that generates expert knowledge. Although higher education institutions (HEI) endeavor towards keeping academic curricula up-to-date with novel entrepreneurial knowledge, this has become a critical issue, especially in engineering disciplines. Technological development generates entrepreneurial knowledge at an ever growing pace, whereas changes in academic curricula require procedures that are time-consuming and considerably slower. But academic knowledge also evolves on its own accord, and the knowledge of a graduate student becomes partly outdated over the time.

Although the acquisition of the two types of knowledge is separated, the need for blending of academic and entrepreneurial knowledge has been recognized (Etzkowitz, 2004). Namely, students are exposed to practical knowledge during their studies, however usually to a modest extent, through student practice and internship in enterprises. On the other hand, once they graduate, and become employees, they are more and more often encouraged to enhance their academic knowledge within the life-long learning paradigm (Longworth, 2013). Nevertheless, blending of knowledge and establishing a continuity of knowledge acquisition still represents a challenge that needs new approaches and tools to be developed.

Technology-enhanced learning (TEL) relies on information technology (IT) to offer support in improving the quality of learning and its outcomes. Designing effective TEL environments in an efficient and affordable way is a demanding task, which requires

creativity and a significant amount of expertise (Goodyear & Retalis, 2010). Within IT, web technology is now widely used in TEL, especially since the Semantic Web or Web 3.0 has been developed (Daconta, Obrst, & Smith, 2003). A variety of web-related educational innovations are now available, enabling further advances in the sharing of educational ideas, materials, and knowledge. Social networking, blogs, wikis, cognitive tutors, virtual learning communities, and especially web-based learning management systems (LMS) are being more and more used in TEL (Rhoads, Berdan & Toven-Lindsey, 2013).

Within TEL, the idea of making university courses publicly available on the web as open courseware (OCW) has emerged, leading to development and implementation of massive open online courses (MOOC), which, in addition to traditional course resources such as videos, readings, and problem sets, also offers interactive user forums aimed at building a community for professors, teaching assistants and students. OCW is embedded within the even wider open educational resources (OER) initiative, where materials are offered openly and freely to educators, students, and self-learners to use and reuse for teaching, learning, and research (Bissell, 2009). The materials are released under an open source license which permits their use, reuse and redistribution with limited or no restrictions.

In this paper we describe an approach to making available both entrepreneurial knowledge to students on a wider basis and novel academic knowledge to graduate employees in enterprises, within a TEL platform founded on OER principles. This web-based platform will enable higher education institutions to publish different academic learning resources in the form of video and lectures, printed course materials and the like, and enterprises to use similar forms to offer expert knowledge, such as case studies or presentations of software implementation in practice.

The platform is being developed within a project funded by the European Executive Agency Education, Audiovisual and Culture (EACEA) in Brussels. Its primary target are universities and enterprises of the Western Balkans (WB), and accordingly educational materials will be published in WB languages, which belong to "small" but closely related languages, but also in "big" languages such as English and Russian. Given the envisaged variety of languages within the platform, a language support system will be embedded to support multilinguality, but also terminology issues and query handling.

The TEL platform will also serve as a model for developing similar platforms as nodes within a TEL network encompassing a larger number of universities and enterprises. The network will feature a common portal for indexing and facilitating access to the various OER within the nodes.

Section 2 of this paper outlines the main goals to be achieved by the proposed approach, whereas the main features of the platform are given in Section 3. Section 4 is dedicated to its language support system, followed by conclusions in Section 5.

2 Objectives to be accomplished

The main goal of our approach is to enable knowledge transfer between academia and enterprises by making OER materials from both sources freely available on the web, and thus foster enhanced learning within higher education institutions and life-long learning within enterprises. Students will be offered an insight into expert knowledge gained through practice within enterprises, whereas employees involved in life-long learning will have access to state of the art high quality academic courses and thus continue with their professional development in a way more suitable to their professional activities than that of the traditional life-long learning programs. By blending these two types of knowledge within one technological framework, the TEL platform developed within this project, our approach additionally contributes to improvement and enhancement of relations between the academia and the enterprises and integration of creative research potential with industry and academic institutions.

The second objective within our project is to develop and implement guidelines and procedures for quality assurance of OER in WB according to best practice offered by the EU, and provide training by qualified OER trainers for both HEI and enterprise staff involved in production of OER materials.

As its third objective the project will produce course materials in several different languages, in various forms such as videos, audio streams and written material. The materials will be supported by electronic terminological resources, as well as services, and search and browse functionalities. Given the composition of the project partners the platform will be initially populated by materials from the domains of ICT, geoinformatics, mining and environmental protection.

Our TEL platform will thus provide educational support for a variety of users at different levels, offering an educational continuum. It will even support the initial phase

of higher education, namely preparation of university admission exams, which precedes enhanced academic education, workplace education and life-long learning. In brief, better quality and accessibility of education through TEL will thus be achieved, enabling OER learners from both universities and enterprises to study the educational materials at their own pace. Our approach also contributes to the development of virtual mobility, as it will enable students to follow a course at another university from their home campus and thus prepare themselves better for continuing their studies elsewhere. It will also increase transparency by offering an insight in the academic content various HEI are offering, which helps students make their choice of the university that best suits their needs. Besides enhancing cooperation between academia and enterprises in general, our TEL platform can be used as a valuable tool for facilitating and enhancing cooperation between different universities, on issues such as development of joint courses, or mutual recognition of diplomas.

Finally, as our TEL platform is conceived as a WB-targeted OCW-based project some of its goals coincide with those of the Open consortium Europe. Namely, as the interest of European universities in OER and OCW rapidly grew, a consortium of HEI led by the Delft University of Technology has been formed. Besides Delft University the main partners within Open consortium Europe are Universidad Politécnica Madrid, Universitat de Barcelona, Katholieke Universiteit Leuven and Université de Lyon, as well as the OpenCourseWare Consortium (OCWC), Creative Commons (CC) and European Association of distance Teaching Universities (EADTU). The universities that initiated the consortium were subsequently joined by more than fifty European partners from Austria, Belgium, Cyprus, Denmark, France, The Netherlands, Poland, United Kingdom and Spain, where the movement is especially popular with almost 40 universities offering free online courses. Partner universities within the consortium are currently offering more than 14,000 courses online.¹

Ultimately, our approach helps OER learners from both universities and industry to fill in the gaps in their knowledge by acquiring new knowledge and become familiar with new technology.

3 Conceptual design of the TEL platform

An overview of the conceptual design of our TEL platform is depicted in Fig. 1. The platform consists of four groups of components, namely:

- *Tools* - composed of FMG CMS, an in-house Content Management System (CMS) developed by the University of Belgrade, Faculty of Mining and Geology (FMG), the Learning management system encompassing several specific content and learning management software tools, and Development tools, software to support the development, use, reuse and delivery of learning content;
- *Learning resources* - both academic, in the form of course planning materials, video lectures, thematic content and the like, supported by evaluation tools, and entrepreneurial, such as case studies, best practice examples, expert presentations and software demonstrations;
- *Language resources* – lexical and textual resources and grammars to support the multilinguality of the platform, terminology and its search and browse functions;
- *Implementation resources* - best practice design principles and licensing tools to promote open publishing of materials.

The content management system FMG CMS was initially developed within FMG as a custom course management system to support blended learning, which started gaining popularity at FMG in the last decade. Namely, where teachers at FMG expressed their interest in integrating IT with traditional face-to-face class activities in their teaching, an in-house tool was developed to provide online publishing of educational materials, organization of tests and e-communication with students. Later on, blended approach at FMG was further enhanced by introducing Moodle (Modular Object-Oriented Dynamic Learning Environment), a free software e-learning platform, conceived by Martin Dougiamas, who is still the lead developer of the Moodle.Org community. Moodle helps educators to create online courses and fosters interaction within the teacher-student community, especially collaborative content development. As of April 2014 there were around 69,000 registered Moodle sites offering 7.8 million courses by 1.2 million teachers to 73.8 million users in 235 countries.²

² <https://moodle.org/stats/>

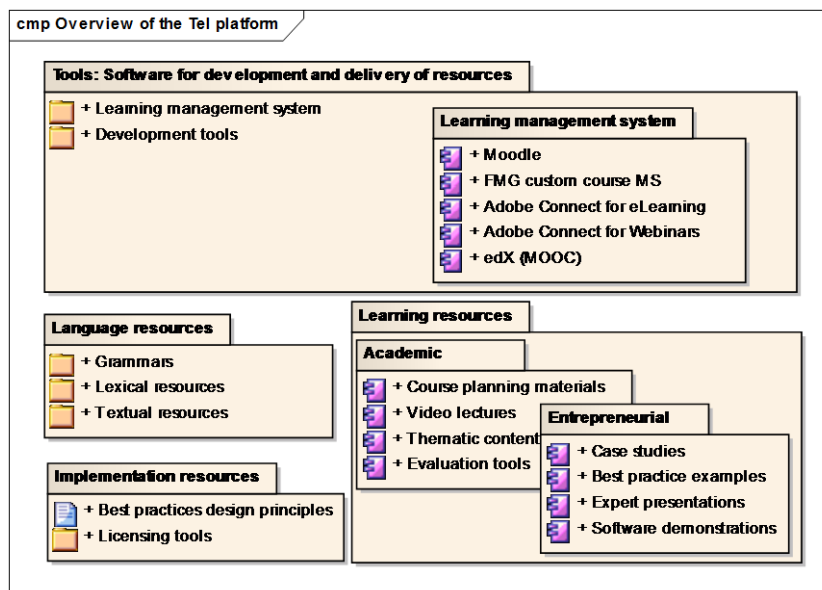

Figure 1: Conceptual map of TEL platform

Besides the FMG custom course management system and Moodle, the Learning management system includes other powerful tools such as Adobe Connect for eLearning, Adobe Connect for webinars, and EdX, a massive open online course (MOOC) platform.

Adobe Connect is a platform that supports e-learning, webinars, and organization of web meetings. Its Adobe Connect for eLearning component is a comprehensive solution enabling mobile learning that is accessible from anywhere, at any time, by means of virtually any PC or mobile device. It features state of the art content authoring tools, as well as tools for measuring real-time engagement in virtual classes and tracking individual student progress. Another component envisaged in our TEL platform, Adobe Connect for Webinars, offers templates for creation of landing pages, speaker information, registration pages, login pages and emails. These templates and content can be customized using several components, such as images, tables, charts, and carousels. It also provides engagement monitoring in real time via an engagement dashboard.³

The EdX platform, recently (2012) conceived by MIT and Harvard University is aimed at supporting massive open online university courses. The platform has been developed as open-source software, akin to Moodle, and is available to other HEI under

³ <http://www.adobe.com/rs/products/adobeconnect.html>

edX Terms of Service.⁴ An important feature of edX is its interactive online learning software offering production of series of short videos, each followed by an exercise where students can immediately check their understanding of the concepts introduced by the videos. The platform also offers creation of online textbooks, as well as discussion forums for student-teacher interaction. Finally, edX provides for online laboratories, as for example in its first MOOC, a course on circuits and electronics, where students were able to built virtual circuits in an online lab (Breslow et al., 2013).

All the aforementioned tools will be integrated within the TEL platform's LMS to provide a synergy of functionalities for efficient realization of the proposed approach. A backend control panel within the platform will enable teachers in the academic environment to track the progress of students while using the learning resources, and thus have an insight into how they are mastering specific concepts, especially those featuring entrepreneurial learning content. This insight could further be used to filter out especially motivated students, and engage them in "peer to peer knowledge sharing", namely in helping students who have problems in understanding some concepts. Motivated students could also be encouraged to become teacher assistants (TA) and publish their own educational materials on the platform.

As for the entrepreneurial environment, the TEL platform's backend control panel provides similar opportunities for tracking the progress of graduate students who started to work in companies and are now involved in life-long learning. The same way university teachers in the academic environment monitor their students, supervisors within the enterprise can monitor how their employees are keeping pace with new knowledge within the learning content offered by academic institutions.

As for development tools, several commercial tools will be used, such as Visual Studio .NET, Adobe Dreamweaver and ArcGIS as well as LeXimir, a multipurpose tool for lexical resources management and query expansion developed at FMG (Stanković et al., 2011).

Besides specific tools, the TEL platform has corresponding resources, which have already been briefly described at the beginning of this section. An important place among the resources is occupied by language resources, which will be described in more detail in the following section.

⁴ <https://www.edx.org/edx-terms-service/>

Besides the TEL platform, our approach envisages the development of an infrastructure for implementation of a TEL network, involving a larger number of universities and enterprises within the WB, and thus giving broader access to OER. The network will consist of nodes at universities and enterprises, featuring their own TEL platforms similar to the platform described in this section, and a common portal for indexing OER and other supporting TEL content throughout the network. Audio, video and written text materials from all partner institution nodes will be indexed and annotated with metadata, thus providing enhanced searching capabilities. Namely, when a critical amount of learning resources is reached, it is very important that they are well described and tagged in a standard way in machine readable form. This approach has many advantages:

- Results returned by search engines are more relevant and better described;
- Those interested in course materials (both educators and learners) can find and compare learning materials that best suit their current needs;
- Developers of educational resources and platforms for development of educational resources can create applications and resources in a well described standard format, thus enhancing the value of the educational materials and their visibility for all potential users (educators, learners, educational and public institutions).

OER metadata management in our TEL platform will follow the guidelines set by international standards and initiatives such as ISO/IEC 19788 Metadata for learning resources depicted in Fig. 2. This standard is intended to provide compatibility with existing ISO Dublin Core (DC) Learning Object Metadata (LOM) standards and to support global requirements for adaptability both from the multilingual and cultural perspective. It has two main goals:

- Provide standard metadata elements and their attributes in order to facilitate the identification and specification of metadata elements when describing a learning resource;
- Offer support for learners, educators as well as specialized software in searching, discovering, retrieving, evaluating, and using learning resources.

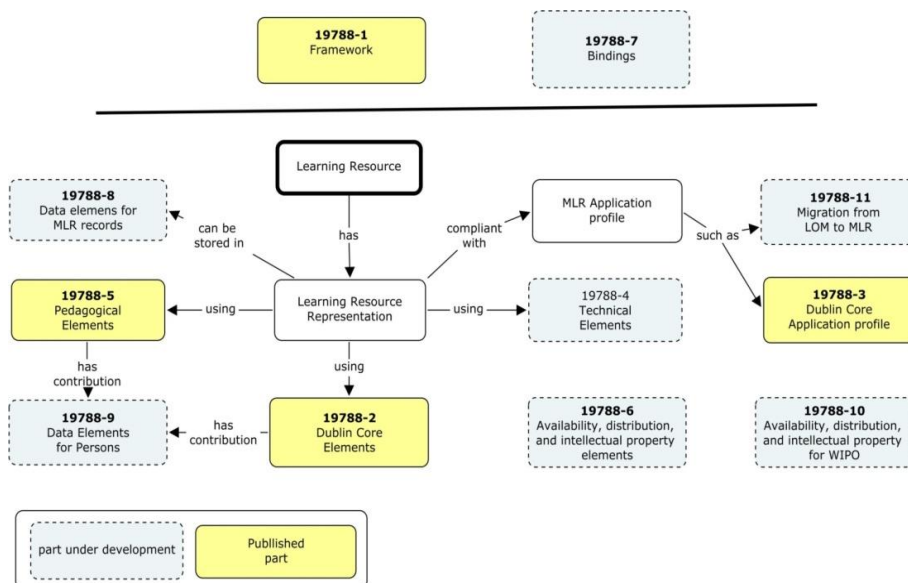

Figure 2: ISO/IEC 19788 Metadata for learning resources

Parts 1, 2, 3 and 5 of the ISO/IEC 19788 standard, marked in yellow are released as international standards, while the seven remaining parts, marked in light blue, are still under development.⁵

4 The language support system

The need for multilinguality of OER is a combined effect of globalization and European integration, favoring a holistic approach that takes into account all the languages a learner may use, as opposed to the more traditional approach looking at one language at a time (Cenoz & Gorter, 2011). Hence, our approach envisages that learning materials within the TEL platform can be in various languages, thus providing an efficient answer to one of the major criticisms of OER being biased towards the so called "big" languages. In order to resolve successfully the issues related to multilinguality, especially terminological issues, but also in order to improve the search and browse functions within the TEL platform, special attention is given to its language support system (LSS). The main goal of LSS is to sustain expert terminology in a multilingual environment and enhance multilingual communication between academic institutions and enterprises.

⁵ http://www.iso.org/iso/iso_catalogue/catalogue_tc/catalogue_detail.htm?csnumber=50772

The language support system, whose structure is outlined in Figure 3, is based on electronic language resources, namely, lexical resources, textual resources and grammars. Bilingual dictionaries in electronic form are one of the simplest multilingual lexical resources. However, for their full functionality in languages with complex morphology, such as Serbian, they need to be coupled with morphological dictionaries. Morphological dictionaries of Serbian simple words and compounds in the so-called LADL format (Krstev et al., 2010) are thus also part of the lexical resources used by LSS. Besides Serbian, such resources exist for many other languages, including English and Russian, which are also envisaged as OER languages within our TEL platform. Another important lexical resource offering support for multilingual terminology is the Serbian wordnet. In brief, a wordnet consists of sets of synonymous words representing specific concepts, called synsets, with a semantic network formed on basis of semantic relations between them. Akin to standard dictionaries, each synset word, or literal, is composed of a literal string and a sense tag, representing the sense of the literal string specific to that particular concept. The multilinguality potential of wordnets stems from the interlingual index (ILI), which establishes relations between synsets representing the same concept in different languages (Krstev et al., 2004).

Finally, among lexical resources within LSS are terminological resources such as GeolISS term and RudOnto (Stanković et al., 2012). GeolISS is a thesaurus of geological terms with entries in Serbian and English, developed at FMG within the GeolISS project.⁶ Thesauruses are complex terminological resources, usually related to a specific domain, with as semantic structure formed by semantic relations between terms, and thus in some of their features resembling wordnets. RudOnto is another complex terminological resource, also developed at FMG with the goal to gradually develop into the reference Serbian resource in e-format for mining terminology. Currently RudOnto comprises of concepts in Serbian, their English equivalents, and a small number of equivalents in other languages.

⁶ <http://geoliss.mprpp.gov.rs/term/>

Figure 3: The TEL language support system

The TEL language support system also handles various textual resources. Some of them are directly related to LMS tools, such as Adobe connect and Moodle resources. In addition to that, textual resources feature aligned texts and corpora. Aligned texts are pairs of texts in different languages, mainly an original and its translation, aligned on some structural level, most often the sentence. Aligned texts in LSS are in the standard, Translation Memory eXchange (TMX) format, which is XML-compliant. Corpora are large and structured sets of texts, both monolingual and multilingual, the latter often composed of aligned texts. Finally the web itself represents a textual resource that LSS makes use of.

Specific features of Serbian grammar need corresponding language resources in the form of grammars. Grammars within LSS are implemented by the so called finite state automata, finite state transducers and compound inflection rules (Krstev, 2008).

The language support system handles various types of requests issued by the tools from the learning management system, usually in the form of a query. The requests are handled by a WSDL (Web Services Description Language) described Language Web

Service, basically composed of a web application and a web service. When handling a query, the Language Web Service uses a component of the multipurpose tool LeXimir, namely the function library LeXimir_Core. A query originating from the LMS is accepted by the web application, which forwards it to the web service. The web service then invokes LeXimir_Core, which processes the query using the available resources. During this processing the system can perform a morphological expansion of the query to improve recall, which is especially important for morphologically rich languages such as Serbian. In order to support the multilinguality of the TEL platform, LSS can also expand the query in one language to another language, e.g. a query in Serbian to English or Russian, and vice-versa.

With all the aforementioned features LSS takes a prominent place within the concept implemented by the TEL platform, offering invaluable support for better understanding and handling of the multilingual OER content.

5 Conclusions

The TEL platform described represents a step forward in OER by blending two major sources of knowledge: academic and the entrepreneurial. Its aim is to provide a leaning continuum, from enrichment of university students' knowledge with entrepreneurial knowledge that might prove useful in their future jobs, to keeping their academic knowledge up-to-date once they have graduated, by offering them a live-long learning opportunity as employees.

There are, however, several critical issues, which might impede the implementation of the envisaged concept. The first one is how to motivate qualified academic and/or entrepreneurial staff to produce high quality OER content in continuity. A similar problem might arise on the learners' side, as students might lack interest or willingness to invest some additional effort in learning and knowledge sharing. Finally, authorship issues might be also an impediment due to lack of adequate legislation regulating the practices and principles of publishing and using OER content, especially in the WB region.

As for the technical issues, successful development of the TEL platform requires coordination of activities among partners with possibly different levels of IT skills. Implementation of the OER network, on the other hand, needs successful organization of public procurement and acquisition of appropriate equipment. As for smooth operation of

both the platform and the network, the hardware and software infrastructure and communication links must function flawlessly.

In brief, there is a lot of work to be done before the TEL platform enters full exploitation to the benefit of university students in their preparation for the labor market, and those who have graduated, in their lifelong learning endeavor.

Structured Abstract

Purpose – Being Mexico a Latin-American country located in North America, strengthens the fact of not being considered as part of the group of countries limited to the core Latin-American characteristics, but also without the characteristics of our developed neighbor countries of the North, Canada and USA. This vagueness also characterizes the inequality gap in the 32 states of Mexico, where the northern states present a high index of development and quality life, and the south region is highly marginalized, though with abundant natural resources (i.e., water and land for agriculture) (CCYTET, 2005). In 2004, the Inclusive Commission for Development was established, which main goal is setting the grounds for development in the South-Southeast Region of Mexico. It has been ten years now, where the actions of this Commission are retaken, and the new governor of the state of Tabasco invites the rest of the states to develop a comprehensive development plan for Mexico (CONAGO, 2013).

Design/methodology/approach – Given the characteristics of this research, we will use a qualitative approach. Our data collection methods will be interviews and focus groups. Because, this is an exploratory research, the design of the model will be based on the experiences and insights of the main actors involved. We will first identify the states that conform the South-Southeast Region. Secondly, we will establish communication channels with the main higher education institutions of this particular region. Every institution will name a key actor, preferably a local expert in management and planning in higher education, and an action plan will be designed to transform the region into a Knowledge Region (Carrillo F. , 2005). In these meetings, a task-force group will be pointed out to elaborate a local analysis of each state and the capacity-building of the institutions. This analysis will consider the cultural, social, economic, environmental factors, and the key actors that are involved in the design and development of policies that effectively integrate sustainability issues in strategy, processes and growth trajectories for the South-Southeast region of Mexico in order to become a Knowledge Region (ITESM, 2003). The key aspects that the Development Commission established were development

and economic growth, regional competitiveness, inclusion and social cohesion, development and environmental sustainability, urban and rural development, and social infrastructure

Originality/value – It has been proved that developing countries have changed their economic status when they orient their actions into knowledge, creating true Knowledge Region, and cities devoted to develop any services or products of the region, and actually becoming world innovation nodes of local expertise of the specific region. In Mexico there is only ten experiences of Knowledge Cities and only one is fully developed; because of the individual characteristics of the places, establishing a region instead of a city will be more beneficial for the states that are embedded in that region, achieving a comprehensive development and better quality life (World Bank, 2012).

Practical implications – Every state of the Region has Public Universities that have progressed in their academic development and parallel have worked together by entailment or academic exchanges. Through a committee composed by these higher academic institutions, these universities coordinate the actions to elaborate the comprehensive development plan for the South-Southeast Region of Mexico.

Keywords –South-Southeast Region of Mexico, Region of Knowledge, Higher educational institutions, Planning and Entailment.

Paper type – Academic Research Paper

1 Introduction

Being Mexico a Latin-American country located in North America, strengthens the fact of not being considered as part of the group of countries limited to the core Latin-American characteristics, but also without the characteristics of our developed neighbor countries of the North, Canada and USA. This vagueness also characterizes the inequality gap in the 32 states of Mexico, where the northern states present a high index of development and quality life, and the south region is highly marginalized, though with abundant natural resources (i.e., water and land for agriculture) (CCYTET, 2005). In 2004, the Inclusive Commission for Development was established, which main goal is setting the grounds for development in the South-Southeast Region of Mexico. It has been ten years now, where the actions of this Commission are retaken, and the new governor of the state of Tabasco invites the rest of the states to develop a comprehensive development plan for Mexico (CONAGO, 2013).

2014 planning processes have changed substantially in the 50 responding to long-term planning in the 60s and 70s used participatory planning in the 80 integrate the planning

processes and quality Corrientes 90 and 2000 strategic planning and prospective is what rules the roost , (Zenon Fuentes , 2000). Knowledge today is highly significant globally as Capital Intellectual, People and Value Added organizations, building models of knowledge regions are models of regional development and planning approach.

2 . Approaches to Planning

Planning is an act that has always existed, but not before it was called so, according to the developments of administrative theories and production creates his nomination; but how to do it has always been different, so that the various planning approaches appear.

The emergence of a new need not imply the cancellation of the above needs primitive forms of planning cohabit with the most advanced in the present (Fuentes Zenon, 2000)

The literature of planning basically consists of various schools of thought or approach is the best option (Bryson & Delbecq, 1979)

Each approach is announced as the final and complete solution that replaces other (Ansoff, Declerck, & Hays, 1990)

The use of wrong planning approach leads the following repercussions (Fuentes Zenon, 2000):

- Planning effort that began with great enthusiasm and then completely misplaced and diluted
- Comprehensive survey volumes of information
- Poor organization of activities
- Serious doubts that did make it what it is what is done
- Numerous unfinished projects
- Targets lacking relevance and realism
- Defective solutions
- Plans that do not pass the paper

An analysis of the different planning approaches reveal that although not homogeneous are not different when comparing it with some other match their purposes but mainly because in general, based on the same source: the Comprehensive Plan directed to effect change through a process to gain consent that includes the following steps:

1. The situation analysis to define problems

2. Formulating plan objectives
3. Identifying options for change
4. The analysis of the advantages and disadvantages of each option to define the most suitable
5. Developing the preferred alternative for implantation

Each author determines the depth of each planning approach some give more relevance to the internal diagnosis, others external to the analysis and some future , adopt a more idealistic stance while others focus their attention on integration of programs and budgets and action meet others consider issues like complexity , risk participation , forms of control and good conflict management (Fuentes Zenon, 2000)

The planning process is conditioned by

1. The nature of the subject
2. Characteristics of the object and
3. The subject-object relationship

In relation to the subject, who or who are involved in planning and behavior:

- ✓ If a single decision maker, then the planning has a highly technical nature
- ✓ Group processes, planning seeks the participation and consensus
- ✓ Groups power planning is seen as a mixture of analysis, negotiation and conflict
- ✓ Social sectors planning is part of a political process

In relation to the subject, about what you want to act? , Stored in what conditions , and what is expected , and what real possibilities for change exist? , What are its consequences?

If the object is relatively simple methods can apply well programmed and build detailed solutions

If the object is highly complex alone, it is possible to obtain a surface fragmented knowledge leading methods apply more generally

Considering the subject-object relationship, is to know the object in its dynamics has to do with the way in which the subject sees the object and change, which to a great extent depends on the thinking subject.

- Fix and enhance system operation
- Strengthen the competitiveness of the organization

- Take advantage of opportunities or future threats sports
- Dealing and give concreteness to the desired direction for the organization

3. Knowledge region

The concept of knowledge society, emerged in the sixties of the twentieth century (Machlup, 1962), is located within an economic perspective initially, and is one in which the sectors that use intensively knowledge are the main contributors the growth of the economy (Rohrbach, 2007) Cities or regions of knowledge, from a more complex perspective of development (Méndez, Michelini, & Romeiro, 2006), they are identified as those able to generate, implement and enforce various forms of knowledge to improve economic competitiveness, welfare population, environmental sustainability, greater citizen participation in public affairs and more effective governance of the territory. In this regard, some international organizations such as the European Commission (2000), World Bank (1999), the United Nations (2001) and OECD (1996) adopt this type of approach in its strategic directions related to global development. (Romeiro & Méndez, 2008)

The growing importance attached to knowledge-based development (Carrillo, 2005) (Komninos, 2002), helps to reinforce the traditional role of the city: that of being the center where there is a higher density of knowledge resources (Knight, 1995). And if, over the last decades, social capital and knowledge infrastructure were being considered key for development parts, the novelty associated with urban development based on knowledge is passed a socio-economic analysis of components and strategies of knowledge management, towards a system analysis of urban values based on the creation, exchange and application of knowledge (Carrillo, 2005). This means moving from an object of study focusing on "islands" where development and innovation processes occur more intensely (as in science and technology parks or digital islands) to a systemic analysis of urban strategies and system associated with knowledge management social values (Romeiro & Méndez, 2008).

The model of the city or region of knowledge, is a model of regional development planning, this model has a number of variables:

1. Human Development
2. Effective and transparent government

3. Development planning based on knowledge
4. Environmental Commitment
5. Intellectual Capital
6. Knowledge Networks
7. Quality Education
8. Business Competitiveness
9. Urban infrastructure and information and communication technologies
10. Innovation and technological development (Baena Paz, 2013)

"An enhancer of design options for cities derives from understanding the urban centers as value systems: human communities configured around an array of value that brings and holds together. The development of cities do not have to be restricted to better accommodate the current population to the legacy infrastructure, it can be oriented to the design of the urban experience: the whole family, social, employment, personal experiences, among others, which make it preferable have residence in a city. The potential for urban development are increasingly confined to the construction of civil works and increasingly open to the design and creation of environments and circumstances that enable meaningful and productive experiences " (Carrillo, 2005)

Thus, in the field of planning and urban development, the association between knowledge and territorial competitiveness currently leads to a proliferation of cities that call themselves as knowledge cities. But these are often associated, to city-regions or large agglomerations,

4. Methodology

"The qualitative method or traditional method, aims to deepen specific cases and not to generalize. Their concern is not primarily measured; but qualify and describe the social phenomenon from determining features, as they are perceived by the very elements that are in the situation studied, it seeks to understand a social situation as a whole, considering its properties and dynamics " (Bernal, 2006).

With this should be considered that scientific activity in the social sciences not only faces the difficulties and complexities which in itself represents , but also when it comes

to choosing appropriate methods and techniques to address , interpret and explain social reality (Tables, 2001).

With the above and according to the research questions posed and the research objective , the States of Mexico that make up the South- east Region and establish communication with the main Institutions of Higher Education in each State of the Region were identified to through meetings with persons designated by each institution , which must be skilled in planning for higher education , ation plan is designed to turn the region into a region of knowledge. This type of experience is considered because it is assumed, which is in the Institutions of Higher Education the right place to make the Model of Regional Development Planning . In these small meetings of States and diagnostic capabilities of the institutions shall be determined and a team dedicated to designing the model , taking the characteristics of the State of Knowledge and considering the cultural, social , economic and environmental factors are formed and strategic actors in the development of policies that effectively integrate sustainability issues in strategy , processes and growth trajectories for the region south-southeast of Mexico Region is one of knowledge. The points mark the Commission for the Integral Development of the Southern Region - South East are : Economic development and regional competitiveness , social inclusion and cohesion development, environmental sustainability of development , Urban Development , Rural Development and Infrastructure. All cualse reflected in a matrix to determine the similarities and thereby develop the model.

Research Questions

1. Who are the subjects in the process of planning the development model of South-east of Mexico Region?
2. Which would be the object to be modified and their new IDs?
3. How would the subject-object relationship in the development of the Model Development of South- East Region of Mexico?

General Purpose

Prepare the Planning Model for the Development of the South-east of Mexico region based on the construction of a Knowledge Region.

5. Development

After 10 years, in August 2013, the Commission for the Integral Development of the South-East Region of the National Conference of Governors (Conago), headed by the governor of Tabasco and attended by the governors of the 9 States reinstated Region South -Southeast of Mexico

It covers nine states with a combined population of 31 million 752 thousand 532 inhabitants, representing 28.2 percent of the national population, 346 thousand municipalities, which account for over 50 percent of the country's municipalities. In addition, concentrated 68 percent of the indigenous population. There is a direct relationship between indigenous people and poverty, which is part of the challenge to face, as the population dispersion results in a high cost in the provision of basic services. States that comprise:

1. Veracruz
2. Puebla
3. Guerrero
4. Oaxaca
5. Chiapas
6. Tabasco
7. Yucatán
8. Campeche
9. Quintana Roo

At this meeting schedules and concrete actions to promote regional comprehensive development were defined. With a focus on working together, it was agreed to develop a proposal for a project around arisen dialogue and consensus. Highlighting the importance of maximizing the competitive advantages offered by the closeness of the nation with the countries of Central America to integrate a wider market and a stronger multinational region, establishing a commitment to build the shortest path heading welfare peoples and a more prosperous region , promoting public policies that meet the requirements of the region, operating a program of work from 2013 to 2015 , in addition to establishing the schedule of activities and program of concrete actions as the South- east shares historical challenges such as poverty, backwardness and marginalization , but also grandeur and wealth of cultures and biodiversity , develop strategies to strengthen the development and empowerment of Mexico (Libertad en Chiapas, 2013).

We cannot have two México. We cannot have in Mexico is progressing north and Mexico to the south- southeast that is lagging behind.

The axes of development of South- east of Mexico Region are:

- Economic development and regional competitiveness
- Inclusion and social cohesion,
- Environmental sustainability,
- Urban development
- Rural development
- Infrastructure.

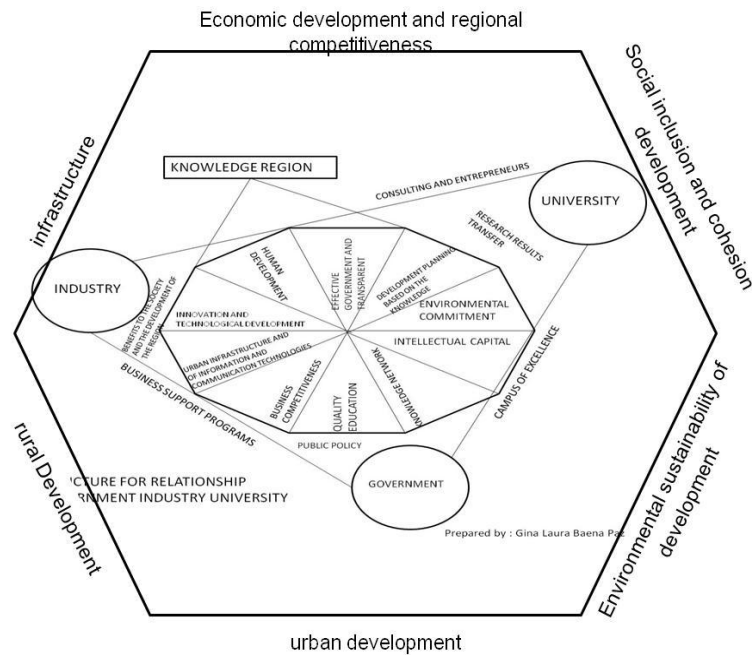

6 Proposal

From the above Matrix Matches are hellebores, to develop the model:

Development priorities of the Region South-southeast of Mexico Knowledge Region	Economic development and regional competitiveness	Social inclusion and cohesion development	Environmental sustainability of development	urban development	rural Development	infrastructure
human development	X					
Effective and transparent government		X				
Development planning based on knowledge			X			
environmental Commitment			X			
intellectual capital	X					
Knowledge Networks	X					

quality education				X	X	
business competitiveness	X					
Urban and information technologies and communication infrastructure						X
innovation and technological development	X					

Then the proposed model is presented Integrator to develop the Model Plan for South-east of Mexico Region under the focus of Planning Cities and Regions of Knowledge

The Triple Helix model in which the University , Enterprise and Government interact through interface relations involving the ten characteristics of the Regions of Knowledge through business support programs , campuses of excellence , consulting entrepreneurs and established public policies , the benefits to society and to the development of the region and the transfer of research results . This in turn is the basis of the guidelines for the development of South- South Region of Mexico.

7 Conclusions

At the present time the disciplinary theories are intertwined and interdisciplinary is present in solving problems, planning takes place in administrative processes and theories

Projects retaking this interdisciplinary trends and taking it to its importance OCCUPY development and by the development of science and technology .

That is why the case presented tends to see the use of knowledge resources in planning approach Regional Development part of Mexico.

This being a purely academic research, will proceed to conduct the interviews and gathering information to determine the operability of the model proposed

Role of University as a Sustainable Organization in Knowledge Management and Challenges for Stakeholders

Iordache-Platis Magdalena

Department of Economic and Administrative Sciences
University of Bucharest
36-46 Mihail Kogalniceanu, 5 district, Bucharest

Structured Abstract

Purpose – The purpose of this paper is to emphasize the efforts universities have done during the latest years towards convergence in terms of quality, as well as to reveal the new challenges that they have to face in the contemporary context. Universities have developed continuously according to different internal and external factors integrating into their strategic orientation the role of the university stakeholders. This paper will focus on higher education curricula, in terms of the efforts to increase employability of the students and will highlight the cooperation between university management and different stakeholders in the process of the knowledge management.

Design/methodology/approach – We propose an approach that takes into consideration several research methods: descriptive analysis based on both literature review and on case studies including examples of good practices; comparative analysis; research based on a questionnaire. Students will reveal their perceptions towards the latest movements in the university curricula, market and environment. They will express how they see partnerships between universities and industries, how they feel about the university efforts to help them better integrate on the labour market, what do they feel about the modern technologies involved in the teaching and learning process etc.

Originality/value – This methodology puts in evidence the new challenges in front of the university management, in the context of the 21 st century requirements. The originality of this paper consists of a new theoretical approach of the university concept, in terms of a sustainable organization, which means a new definition for sustainable university in the 21 st century, plus the concept of customer relationship management for universities in terms of student relationship management. At the same time, the value of the paper is also a practical one, reflecting a direct connection between organizations and universities.

Practical implications – The outcomes of the application consist of several practical implications for universities, students and companies. University management will be able to better understand their role in the knowledge management and to pay much more attention towards important changes and strategic movements. Students will be able to support university change in a more active way, for their own benefit. Companies will be able to reconsider the relationship with universities in terms of mutual advantage.

Keywords – sustainable organization, knowledge management, stakeholders, employability.

Paper type – Academic Research Paper

1 Introduction: The Higher Education Market Context

Individuals and organizations are living in a global context where competition is an important external factor to be always considered. Higher education institutions or universities face the same challenges. Understanding the context is only the first step in dealing with difficult situations. Therefore, universities develop strategically according to their capacity and behave in many aspects like economic agents. The logical essence of the university management is the following flow: context – action – results. These three issues will be explained in the text.

During the latest decades, university management have evolved towards the integration of several management approaches, such as strategic management and quality management into the management of the specific components that are generated from the institutional mission – education, research and society development. In 2009 ENQA - European Association for Quality Assurance in Higher Education provided the *Standards and Guidelines for Quality Assurance in the European Higher Education Area* which has generated an important movement towards convergence at a European level in terms of quality assurance. Ranhvargers (2013), considers that some of the main trends about the higher education market, in terms of international visibility that is reflected by rankings can be summarized into the following ones: a special interest on elite universities, a lower importance of the arts, humanities and social sciences, less understanding of the methodologies, increasing international interest about rankings, criticisms from the providers themselves.

Usually, an economic market for good and services is characterized by few elements: demand, supply, price and competition. For the higher education market, the four components can be expressed in the following terms.

First component of the higher education market is the *demand* for studies. It is expressed by the number of candidates that apply for the study programmes. Many researches have been done in order to understand the potential candidates' interest and motivation to apply for a programme or another.

Second component of the higher education market – the *supply* takes into consideration the effective offer of the study programmes that is marketed in order to attract students. Universities organise or/and participate to educational national or international fair in order to present their studies to potential future students.

Third component of the higher education market is the *price*. As a marketing mix variable, price is important from the availability point of view. Tuition plus accommodation plus living represent an important subject to be discussed at a family context. In parallel, universities provide different price incentives, such as scholarships or grants in order to less discriminate the young generation.

Fourth component of the higher education market is the *competition*. At present, universities are subject to different networks and consortiums, entities from which they benefit a lot. This means that sometimes, competition changes into partnerships or agreements. Main advantages of participating to networking and consortiums are: people learn from each other experience, good and less good practices are shared, mobility and internationalization are encouraged.

None of these four components can be understood in the absence of a general integrated *strategy*. The institutional preoccupation towards an efficient and integrative strategy is easily to be noticed in the case of prestigious universities, such as:

- Victoria University, Melbourne, Australia. In its *Strategic Plan* for the period 2012-2016 the responsible for the university management mentioned the importance of understanding the competitive environment and that they look for excellence, engagement and accessibility;
- Cambridge University, London, UK. In its *Learning and Teaching Strategy* for 2012-2015, part of the action plan – update on progress in October 2013 it is mentioned related to the student support the need to develop the students' skills and employability;

Therefore, in the contemporary global context, the higher education market can be characterized by the aspects shown in the figure no. 1.

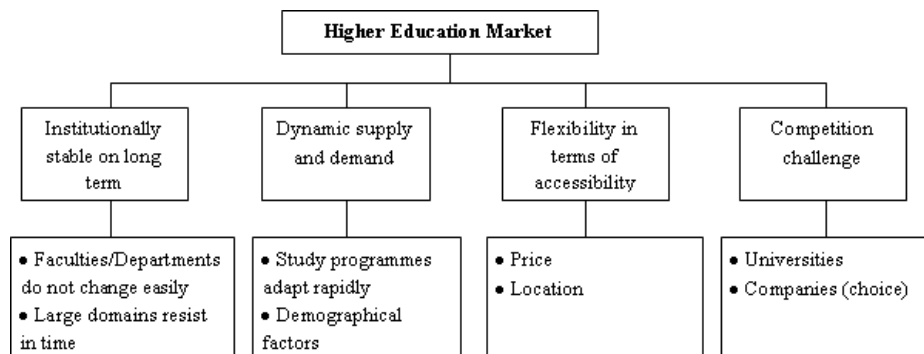

Fig. no. 1. Features of the Higher Education Market.

Source: author

Universities are not small or medium enterprises to be easily established when an initiative comes up. They are public or private institutions with more or less history and on long term they can be seen as stable institutions. What is dynamic is the demand and supply in terms of study programmes; demographical factors affect directly the demand and the institutional strategy determines the supply. In other words, the way the demand and supply adjusts to each other is the university response to the labour market requirements. At the same time, universities are flexible or should be from the accessibility point of view. This means that the price should be so established as to be affordable and the location should be considered flexible when the teaching method is based on blended or e-learning. Competition is a challenge for the universities. Through the exchange of good practices, they become aware of what other institutions did and can become better off.

In addition, in the contemporary context, the higher education market can be characterized by the following aspects:

- higher education is not only provided by local universities. Internationalization has offered a larger opportunity to choose for the students and this is continuously increasing. Local higher education institutions have increased their cooperation agreements and have established joint and double degrees in order to capitalize their strengths and to increase their added value;
- at a large scale, education is also provided by small training companies which generate certificates accepted by the labour market. These are professional

focused programmes of few days, sometimes more flexible in addressing to specific clients of education;

- relationship with the business environment has diversified its concrete actions and has become an important asset in terms of interest from the students and graduates.

Therefore, in order to understand the role of the universities in knowledge management and the challenges for the stakeholders, universities will be described as sustainable organizations and the relationship between universities and stakeholders will be understood from the perspective of a new approach, the student relationship management, as well as the importance of redesigning the curricula in order to increase employability.

2 Universities as Sustainable Organizations

Sustainability is not a new concept. It has revealed the importance to develop in terms of responsibility and environmental protection. Therefore, sustainable organizations have been studied in many perspectives. At the Charter Quality Institute, sustainable organizations are considered a challenge able to be achieved through leadership, understanding and commitment. Pleffer (2010) considers that the main issue to be discussed about sustainable organization is the *human factor*, more precisely - health status at the work force, work hours and work family conflict, work stress and the effects of the job design. Nitu (2011) describes sustainable organizations in terms of strategies and strategic planning and identifies the most important factors for an organization to become sustainable: quality and effectiveness of the strategic decisions.

Taking into consideration the understanding of the sustainable organization, universities are obviously part of these. Features of the universities as sustainable organizations are reflected into the figure no 2.

Fig. no. 2. Sustainable Universities

Source: author

Leadership is what contribute to a better university management, since it involves commitment, professionalism, initiative, professional skills among others. This implies both institutional leadership and individual leadership. The leader university is a reference point for the others, a model to be studied, and an innovator in different actions. In fact, extraordinary leaders are those who are able to continuously generate result as Zenger and Folkman (2007) said.

Strategic management in universities is an important way of institutional development since it contributes to the increasing of the internal capacity to adapt to the educational and labour market. Strategic management means that university has a vision, understands its mission, identifies its main objectives as well as the strategic alternatives, identifies its competitive advantage, correlates the actions to the resources and specifies an adequate timing for these.

Quality management is also part of the university culture. It contributes to the organizational change in terms of the *Plan – Do – Check – Act* cycle. These steps are to be followed systematically when activities are needed to be improved (Have, S. et all, 2008).

It is a direct connection between the sustainability and the organizational success. A sustainable organization achieves success on a long term. Therefore, a sustainable university is an institution that achieves success on a long term. At this stage, two questions arise:

1. Which are the characteristics of a sustainable university?
2. How can the success be measured?

The most relevant features of a sustainable university can be revealed in the table no 1.

Table no. 1. Features of the Sustainable Universities

Crt. No.	Characteristics	Description
1	Creative university	University is able to find solutions.
2	Innovative university	University is generating new activities/programs.
3	Entrepreneurial university	University behaves like an entrepreneur.
4	Learning organization	University has an organizational capacity of learning.
5	Adaptive university	University supports the organizational change.
6	Resource management	University spend rationally the resources.
7	Organizational culture	Strategy oriented towards quality.
8	Efficiency	Partnerships and networks.
9	Research	Strategy oriented towards excellence in research.
10	Social development	Multiple actions.

In order to measure the success, several groups of indicators have been created. Some are institutionally developed, some are nationally ones and some are internationally used, as seen in the figure no. 3.

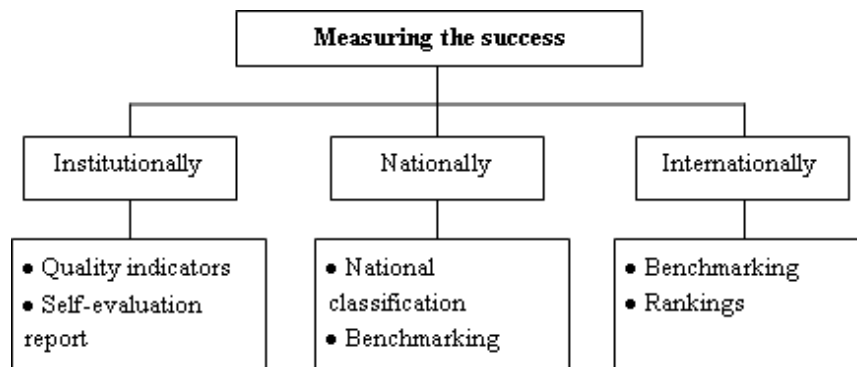

Fig. no. 3. Universities success

Source: author

In order to appreciate the success of a higher education institution, it is important to understand who the beneficiaries of the educational services are. In the quality management context, there are mentioned the *two groups of the university customers* - the students and the companies, as potential employers of the graduates. In addition, one indicator of the university success is the employability. This is going to be explained in terms of the university strategies.

3 University – Stakeholders Relationship

3.1 Student Relationship Management

In the marketing approach, Customer Relationship Marketing is a new type of marketing based on the idea that the relationship with the client has to be developed according to the following flow: contacting the client – convincing the client – informing the client – service to the client – post consuming. (Zollondz, H., D., 2007).

The main features of the *Student Relationship Management* can be expressed according to the following aspects:

- University develops a permanent relationship with the students, they interact continuously; students are integrated into the decisional bodies.
- *Student relationship management* is part of the strategy, where students are considered partners of dialogue.
- the logical flow of the effects are quality in education and research – students' satisfaction – students' involvement – university success.

3.2 Curriculum Design and Employability

In order to better analyse the university role as sustainable organizations in knowledge management, the intergenerational transfer of knowledge has to be accepted. During teaching and learning processes, as well as during the implementation of the projects when students are involved, professors transfer knowledge to students. This is not new. It has always been like this. What has been demonstrated during the latest years in terms of the quality management in universities is the need of evaluation of this transfer. In other words, different assessment have been created and implemented in order to improve the knowledge transfer - self-evaluation of the professors, feed-back from the students, evaluation from the head of the department and so on. At an institutional level, the self-assessment is a requirement for study programmes accreditations.

Many changes have been done during the latest years in order to increase the employability, as a clear indicator for the university success. The most frequent measures adopted by universities in order to help the students to better integrate on the labour market include:

- practical placements integrated in the curriculum and extra curriculum practical stages

- internships offered by companies
- visits organized in companies
- trainers invited from companies to teach practical issues
- debates and dialogues with company representatives in order to explain successful models for students
- different events – such as Career Days, Life Transition Programme, Job Fair
- career counselling.

In most of the cases, the activities involve the career service or centre that exist and function in most of the universities. As institutional bodies, they face difficulties in terms of resources (human or financial).

Two small *researches* were conducted in order get a broader perception on the importance of the university changes related to employability. In this area, no matter how many actions are taken, how many activities are organized, there is always need for more.

First research on what best universities do in terms of employability was conducted at the University of Bucharest in April 2014. Students from a master program were invited as part of the debate dedicated to *University Visibility and Strategies* to study the websites of the first 10 universities included in the Shanghai rank. Here is what they revealed for the first 3 universities:

Harvard University – several articles or results of different short researches on employability, such as if the employable skills are coachable or not; a special link to the employment information, in terms of discovering the possibilities for career. In addition, for their own new employees, the university has created a New Employee Guide in order to accept him or her faster in the community. In other words, university pays a lot of attention towards the awareness and informative role of their actions.

Stanford University – information is differentiated according to the public it is addressed to, such as undergraduate and graduate Alumni, parents, students, international donors. For instance, in case of the parents' information, they are invited to become donors or volunteers. In other words, university look for building a relationship on a long term.

UC Berkley – the Career Center is very developed. Information refers to events or workshops, counselling, career exploration, internships, jobs. What is relevant for this university is the huge activity of the centre, clear structured, for the students. They are the important stakeholders.

The second research was conducted at the same University and was based on a simple questionnaire addressed to students from the Faculty of Business and Administration. The students from an undergraduate study programme and from a graduate programme were asked the same question. Between the two groups of the respondents is a direct connection – many of the students from the undergraduate level continue their studies and become students at the master programme – the undergraduate programme is called *Business Administration* and the graduate one is *Business Administration for Small and Medium Enterprises*. The objective of this research was to reveal the differences between the way of thinking and acting between undergraduate and graduate students to see how they feel about the university efforts related to the students and graduates insertion on the labour market. There were given 120 questionnaires for the undergraduate level and 80 ones for the graduate students. The valid numbers of the answers received from the two groups were 118 and 70.

The questions that are relevant for this study are the following ones:

- How the students define employability?
- If the students have participated during their studies to events dedicated to employability?
- How the students feel about the university effort to organize extra-curriculum events dedicated to university-industry cooperation?

While only 42% of the respondents from the undergraduate level defined correctly employability according to their knowledge, at the master programme, students proved that almost all of them (97%) have a clear idea of what it means.

At the same time, students at undergraduate level are not so interested to participate to events dedicated to employability – only 29% of the respondents participated to programmes. At the graduate level, many of them (85%) have been involved in different training session, which proves not only that they become more mature, but more interested and committed.

In terms of the university efforts, all of the respondents mentioned that they want many more such events, even if they did not participate during their studies at previous ones. At the response moment, they have a better perception of the need of such programmes. To be mentioned that the undergraduate students were selected from the last year of study.

3.3 Strategies and challenges

In different countries, national ranking systems have tried to identify groups of universities either research intensive, or education intensive. Specific national rules made national classifications as compulsory and connect the public financing process to the position in the ranking.

At the same time, international rankings such as Shanghai ranking or Quacquarelly Symonds developed specific methodologies to make universities more visible according to specific indicators.

A brief history of changes which were reflected sooner or later in university policies is shown in the table no.2.

Table no.2. Summary of latest changes in universities.

No Crt.	Document/Action	Time	Purpose
1.	Bologna Process	1999	To create in a decade a European Higher Education Area (EHEA)
2.	Budapest-Vienna Declaration	2010	To recommit to the EHEA objectives
3.	Prague Declaration	2009	To generate a message to political leaders in order to stimulate investments in universities
4.	Promoting quality culture in higher education institutions (PQC)	2012-2013	Project of EUA (www.eua.be)
5.	Empowering universities to fulfill their responsibility for quality assurance (EUREQA)	2012	Project of EUA (www.eua.be)
6.	European Quality Assurance Forum (EQAR)	Annual event, since 2006	To bring together the key stakeholders in the field
7.	World Class Universities Conference, 5 th Edition	2013	Challenges to building www.shanghairanking.com

All these changes included directly or indirectly the concept of quality in university. At present, some of the latest messages in terms of quality in universities can be concentrated in the following ideas:

- Quality has to do with all the processes and activities within a university.
- Quality is easily connected to the position in an academic ranking.

- Quality is not something to be achieved since it is a permanent feature; it has to do with the process of continuously improvement.
- Quality cannot be measured in all its elements.
- The perception of the quality is different for different subjects.
- Quality culture is part of the academic and administrative staff behavior.

At a global context, the issue of quality is more important than ever. The explanation for its importance recognition consists of the following:

- All universities are or want to become preoccupied of internationalization. Student and academic exchange double and joint degrees are a concrete proof of convergence in terms of quality.
- Quality in education, as well as quality in any of other activities generate effects on long term for individuals (either students of professors and researchers), and universities. Therefore, qualitative programs become adaptable and flexible which means sustainability.

Part of the quality management process in universities, many changes have been taken place at institutional level, in terms of university – industry cooperation. The importance of the university – industry cooperation has increased. The general issues revealed from the debates on employability and university involvement described the following aspects:

- ✓ universities must develop programs in order to increase the students' and graduates' insertion on the labour market
- ✓ students are not sufficient tracked when they decide to get a job
- ✓ professional practice is not well integrated in the curriculum
- ✓ internship programs are encouraged

Cooperation between university and industry is seen differently by the stakeholders involved. *Students* - they become better prepared for life; they gain practical skills and develop transversal competences; they can easier find a job. *Companies* - they have new contracts in activities which can be better developed; they have access to less costly recruit young people; they can get ideas for future programs through the involvement of the creative students in projects. *Universities* - they become more applied; they fulfil

much better their mission, mainly having three components: research, education, social development programs; they become more visible and with sustainable programs.

Universities need to understand where the global economy is going to, so that they can adapt and react.

Main steps:

- self-evaluation process – to understand what universities do, how they do and how they know if what they do works
- promote internal actions and external ones connected to real environment
 - Internal
 - Training programs for transversal competences
 - Events like career day
 - External
 - Programs of start-up businesses
 - Competitions organized by multinational companies
- learn from bad practices and good practices at international and national level

7 Conclusions

Students are important actors in the process of change. They pay attention to simple things like attractiveness of teaching and building a relationship with professor. Apparently, students have no idea of what educational process means, but in fact they have a different perception than standards and indicators show. None of the students connect the concept of quality to student/professor ratio or to square meters of the classroom. Young generation pays attention to quality as a result of doing things well and this means that university management should promote equilibrium between the two mechanisms of quality improvement: as external and as internal feature.

Employability issues are part of the quality management process. Universities have done many things in this area. What should they still focus on is to better differentiate the events according to the students motivation and interest. While at the undergraduate level, the efforts should concentrate to event dedicated on how to increase the awareness among the students about the importance of being connected to the labor market, at the graduate level, the events should be based on experiences, internships and jobs offer.

In conclusion, universities are stable organizations as successful ones. Part of the success can be the efforts made in terms of employability. This is an important criteria for self - assessment and evaluation systems, as part of the quality management in universities, as well as part of the ranking indicators. In order to increase the employability, universities develop and implement specific strategies. Part of this strategy is the curriculum design and the extra-curriculum activities.

Structured Abstract

Purpose: In today's world knowledge workers are immersed in a great number of diverse networks. Very often access and exposure to such networks is an indication of how well a given knowledge worker will perform in his or her organization. So far most of the research focused on the formal organizational mechanisms (formal knowledge networks). This is however not enough as noticed by some researchers. There is also a grave need to examine the role played by informal mechanisms. Additionally it is necessary to investigate how the formal and informal knowledge networks operate and interplay between each other.

Design/Methodology/Approach: The research approach is an empirical study. Qualitative approach was used with convenient sampling. Data gathering method was in a form of a questionnaire, with follow up individual interviews. The empirical study was conducted among 70 final year students, who were split into 13 groups with 5/6 members in each group. Students were given an objective to carry out a mine design exercise to the level of a pre-feasibility (PFS) study based on the mineral deposit block model supplied to them.

Originality/Value: The originality and value of this research is as follows - displaying the impact of establishing a formal knowledge network (CoP) on both formal and informal knowledge sharing as well as knowledge integration. Additionally this research reports on the results of an empirical study conducted in South African mining industry and education sector. This can bring another original value as there is in general lack of studies in this area.

Practical implications: This study investigated how the introduction of a Community of Practice (CoP), which is a formal knowledge network, affected the existing informal knowledge networks among the students of the 4th year BSc mining engineering students at one University in South Africa. Moreover it measured the performance of the students that were members of the CoP and those that decided not to (“formally”) participate in them. Additionally it provides an insight into the opportunities of integrating knowledge from formal and informal knowledge networks. The results provided will be interesting for CoP practitioners as well as knowledge networks researchers.

Keywords - Knowledge management, knowledge network, Communities of Practice, knowledge sharing, human resources management

1. Introduction

Communities of Practice (CoPs) have existed for a long time and can be found in schools, universities, research institutes (Nistor, Baltas, & Schustek, 2012) and business organisations. However, the specific guidance to form CoPs in higher educational institutions (HEIs) does not exist. CoPs are one of the most recognised knowledge sharing tools, making it a very highly valued tool of knowledge management. Knowledge sharing in turn enhances effectiveness (Gupta and Govindarajan, 2000) because, unlike other organisational assets, knowledge tends to increase when used or shared: “ideas breed new ideas and shared knowledge stays with the giver while it enriches the receiver” (Davenport and Prusak, 1998, pp. 16-17). One of the most important characteristics of CoPs, which appeals to knowledge managers, is their ability to traverse geographical, organisational and cultural barriers. Lave and Wenger (1991) described it as an activity system that brings together individuals with common values, interests, and varied experiences to share among them.

Gannon-Leary and Fontainha (2007) highlight that the technological developments which gave rise to improved communication and participant interactivity, academic staff and learners (students) in higher education have been functioning in virtual Communities of Practice (VCoPs). These online environments allow participants to communicate synchronously or asynchronously (Baran, 2006). According to Bolger (cited by Gormley 2012) VCoPs can facilitate employee development and learning while preserving crucial organisational knowledge. Nistor et al. (2012) notes that although VCoPs’ usage improves academic participation and learning success, full participation in VCoPs does not occur that often.

Research on the environments of online CoPs has significantly increased (Baran, 2006). There is a wide range of open research questions, which need to be addressed. One of these questions is how to establish CoPs and keep it alive over a longer period of time. It is a difficult task. Gannon-Leary and Fontainha (2007) support further research on CoPs and virtual learning communities across European Union countries. Similarly Petersen (2007) cited by Gannon-Leary and Fontainha (2007) proposed that the concepts of learning in CoPs need to be further developed.

This research project's goal is to investigate how Communities of Practice (CoP) may be used in higher education amongst students to share knowledge. The empirical part of this research took place at the School of Mining Engineering at University of the Witwatersrand. An initial survey questionnaire was distributed amongst various groups within the School of Mining Engineering in January/February 2013 to gauge how students share knowledge and if they are aware of the concept of Communities of Practice. These survey questionnaires were distributed amongst students from the First Year, Fourth Year, Post Graduate and Certificate classes. Researchers observed that the introduction of a CoP (formal knowledge network) greatly increased knowledge sharing among students. Students shared knowledge using both CoP as well as informal knowledge networks that were already established. One of these networks used a mobile app for the purposes of knowledge sharing. Therefore the main research problems of this piece of research focus on the introduction of CoP in the HE institution and the synergy between formal knowledge networks and informal knowledge networks. Most of the research (e.g. Nonaka & Takeuchi, 1995) focused so far on investigating the formal organizational mechanisms (formal knowledge networks) in order to gain insight into how the knowledge is generated, dissipated and absorbed. Some researchers (e.g. Awazu, 2004) noticed that this is not enough and that there is also a grave need to evaluate the role of informal mechanisms (Desouza, 2003a). Additionally it is necessary to examine how the formal and informal knowledge networks operate and interplay between each other.

2. Description of the Research Project

The School of Mining Engineering, where the study was conducted, is recognised as one of the top mining engineering schools and departments throughout the world. Mining engineers play a key role in the planning, exploitation and excavation of mineral resources. The 4 year BSc mining engineering program is the schools flagship program and includes individual and group project work. The final project is a mine design project completed during the final months of the students' undergraduate year (University of Witwatersrand, 2013). The next section will introduce the mining design project and describe the case study.

For the purposes of the study 70 final year students were split into 13 groups with 5/6 members in each group. According to the brief given to the students at the commencement of the project, they had to carry out a mine design exercise to the level of a pre-feasibility (PFS) study based on the mineral deposit block model supplied to them. They were to utilise the knowledge gained over their previous coursework as well as experience gained during vacation work to complete the project. They had to then make a substantiated recommendation regarding the viability of mining the mineral deposit. The financial aspects of the project was thus critical as well as the technical aspects. For 2013, the final mine design project was Lily Gold Mine, close to Barberton in the eastern part of South Africa.

The 4th year Final Mine Design students who were working on the Financial Valuation Chapter of the Mine Design were invited to participate in a Community of Practice (CoP). A CoP is a group formed voluntarily with its purpose to benefit the members by exchanging thoughts and ideas. Thus the 13 groups into which the students were placed for the mine design could not be considered a CoP as they were forced to work together. The association across these 13 groups for the students working on the Financial Valuation Chapter could be considered a CoP because it was their choice to join the group or not. According to the data there were 13 students invited, 9 chose to join the CoP and the other 4 chose to work outside the CoP.

For 2013, the final mine design project was Lily Gold Mine, close to Barberton in the eastern part of South Africa (see Figures 1 and 2).

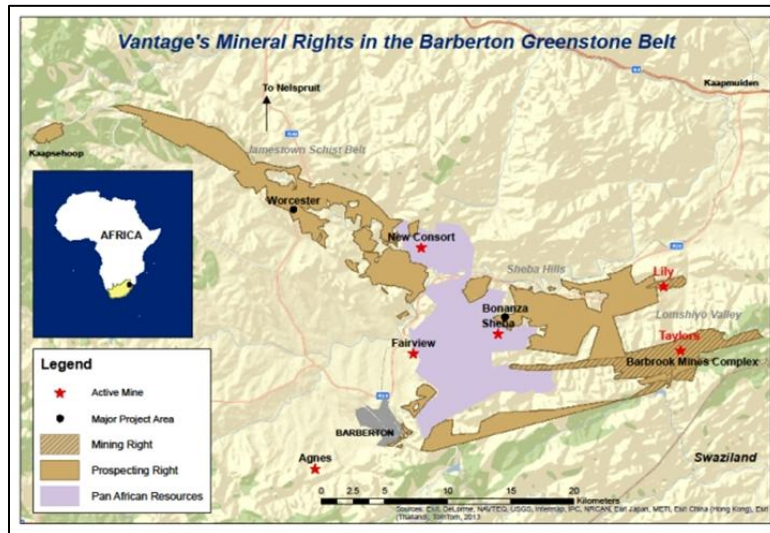

Figure 1. Location of Lily Gold Mine (Vantage Goldfields, 2013)

Figure 2. Entrance to the Lily Gold Mine (Photo by author, 2013).

2.1 Description of the Lily Gold Mine

The Lily Mine began as an open pit operation in 2000. The open pit closed down in 2008 and had produced more than 100,000 ounces of gold. The ore body extends for at least 2,000 m along strike and has been drilled to a depth of approximately 700m (Figure 3). The Mineral Resources are currently estimated to be 2.017 million ounces (22.23 Mt

@ 2.82 g/t) and the Ore Reserves are 0.49 million ounces (4.76 Mt @ 3.18 g/t) (Vantage Goldfields, 2013). The mine has continued as an underground operation and the students were able to visit the current mine and observe the mining method employed (Figures 4 and 5).

Figure 3. Lily Gold Mine Geological Model (Mawson, 2013)

Figure 4 and 5. Students on underground visit at Lily Gold Mine (Photos by author, 2013).

2.2 Mine Design Report

The students were instructed to start their designs at the stage where the mine started their underground operation and that the plant has a maximum capacity for 37 000 tons per month. The students were given the geological model as generated prior to the mine developing the underground portion based on the sampling in the pit as well as the surface diamond drill prospect holes.

For the purposes of their coursework students had to determine the construction/establishment times and costs as well as operating costs for the life-of-mine. They had to determine appropriate levels and methods of beneficiation and apply the correct royalty and income tax rates. They then had to do a full cost-benefit assessment of the project, including a discounted cash-flow analysis (DCF) and calculate the internal rate of return (IRR). Based on these, they had to make appropriate recommendations.

The total marks for the Mine Design Final Project was 350 marks. 300 marks were allocated for the report and 50 for the presentation of the mine design. All the academic staff within the School of Mining Engineering are part of the marking process and responsible for their own areas of expertise. There were 22 specific areas that were marked.

Part of the marking, which was subject to this piece of research, was allocated 20 marks of the total. This mark allocation was split into the following sub-categories:

- Problem Statement and Background Information (2 Marks)
- Cost of Capital, Capital Cost, Working Cost and Revenue (4 Marks)
- Optimisation (4 Marks)
- Conclusions and Recommendations (10 Marks)

One of the evaluation methods of the students' progress was cross checking the figures presented against those presented in other chapters notable Chapter 6 - Technical evaluation (grade-tonnage curves; resource & reserve statements) and Chapter 10 - Production scheduling to ensure that the figures in the geological block model as well as the mine plan were consistent with the cash flow schedule presented.

The concept of Optimisation received special focus and resulted in a large range of interpretations of the mining plan to obtain the highest financial return. In marking the projects, an order of magnitude difference was noted between the group with the lowest Net Present Value and the highest Net Present Value, primarily due to differences in Capital Costs, Mining Volume and Scheduling.

3. Community of Practice Project

According to Etienne Wenger, Communities of Practice (CoP) are groups of people who share a concern or a passion for something they do and learn how to do it better as they interact regularly (Wagner, 2010). The Final Year Mining engineering students all share similar professional backgrounds and experience and all have completed the courses related to Financial Valuation. The groups which the students were assigned to; were not considered a CoP for this study as the students within the groups were each working on different chapters and thus not exchanging ideas specific to the chapter in question. They had to work together with the intention of completing the entire Mine Design by the due date and to the required standard.

3.1 Project Groups

The 4th year Final Mine Design students who were working on the assignment were invited to participate in a Community of Practice (CoP). A letter was sent to each of the students by the lecturer outlining what a CoP was and what benefit they could derive by participating in a CoP. The students who chose to participate were invited to a meeting on the 4th October 2013 where the group was formed and a discussion was held about the aims of the CoP.

Students from 9 of the 13 groups chose to form a CoP. The other 4 students chose to work independently. The students chose to meet formally on a weekly basis to exchange ideas and information as well as establish an informal group on WhatsApp Messenger (a mobile application) to discuss specific ideas. WhatsApp Messenger is a cross-platform mobile messaging app. It allows groups to be established where a single message is sent to all group members. It is more cost effective than sending sms messages. WhatsApp Messenger is available for iPhone, BlackBerry, Android, Windows Phone and Nokia and being cross-platform, the phones can message each other. WhatsApp has recently been purchased by Facebook. (WhatsApp, 2014). All the members of the CoP had cell phones capable of utilising WhatsApp Messenger. At this point it is possible to consider WhatsApp Messenger as a technology-based enabler of an informal knowledge network. The choice of this platform was not influenced by the researchers. Quite opposite it was suggested by the students and it was their choice. Students also committed to complete a

questionnaire at the end of the project for the author to help determine their experiences from working in the CoP.

The students who joined the CoP met every Friday for the period that they were working on the Mine Design project. These meeting were facilitated by the researcher who led the discussion and guided the exchange of ideas between the members. Although the attendance was not compulsory there was virtually 100% attendance by the members.

A group was established on 5th October 2013 and ran until the project was completed in November 2013. Messages included setting up the times and place for the formal meetings, ideas around what should be discussed at these meetings as well as specific questions that students wished to discuss.

4. Findings

4.1 Results of the marking of the assignment

One of the most obvious ways to investigate the effect of knowledge sharing in both formal and informal networks was in a form of the academic results. The marks for the groups for the assignment were used as a measure of the effectiveness of the CoP process. The marking was done not knowing if the student had participated in the CoP or not. Table 1 presents the results of the marking.

Table 1. Marking of the students' assignment

Group	CoP	Mark /20	In CoP	Out CoP
1	x	13	13	
2	x	15	15	
3	x	14	14	
4		11		11
5		16		16
6	x	16	16	
7	x	10	10	
8	x	11	11	
9		14		14
10	x	18	18	
11	x	12	12	
12		17		17
13	x	17	17	
Average		14.2	14.0	14.5
SD		2.5	2.6	2.3

At the first sight it could be surprising to notice that the results for the students who were part of the CoP differed only slightly from those outside of CoP (Average of 14.0 with standard deviation of 2.6 as compared to average of 14.5 with standard deviation of 2.3). The total average for the marks was 14.2 with a standard deviation of 2.5. Researchers investigated the issue further. Next section will provide information regarding survey questionnaires.

4.2 Findings from the survey questionnaires

Five of the nine students who chose to be part of the CoP completed the survey questionnaire. This questionnaire was handed out to the students after their final project presentations. Some of the respondents were group facilitators. Section A (questions 1-4) of the survey questionnaire was collecting information on the students' age, gender, year of study and race, while section B was collecting questions related to CoP functioning (with question 10 aimed at the facilitators) Full questionnaire is provided in Appendix I. Table 2 provides the summary of the respondents' answers.

Table 2. Respondents' answers.

Q No.	Respondent 1	Respondent 2	Respondent 3	Respondent4	Respondent 5
1	Male	Male	Male	Male	Male
2	22 years	22 years	24 years	22 years	23 years
3	Fourth Year	Fourth Year	Fourth Year	Fourth Year	Fourth Year
4	Black race	Black	Black	Black	Black
5	"Neutral" to all questions	5.2 "Neutral", 5.6 "Strongly Agree", rest "Agree"	5.2 "Neutral", 5.5 "Strongly Agree", rest "Agree"	5.1, 5.3 and 5.6 "Strongly Agree", 5.2 "Disagree", 5.4 and 5.5 "Agree"	5.1 "Agree", 5.2 "Neutral", rest "Strongly Agree"
6	"Neutral" to all questions	"Neutral" to all questions	6.3 "Neutral", rest "Agree"	6.1 and 6.4 "Agree"; 6.2, 6.5 and 6.6 "Strongly Agree"; 6.3 "Strongly Disagree"	6.3 "Disagree", 6.5 and 6.6 "Strongly Agree", rest "Agree"
7	First 4 questions "Agree" and rest "Neutral"	7.4 "Neutral", rest "Agree"	7.6 "Neutral", rest "Agree"	7.1 "Neutral", 7.2 and 7.3 "Agree", rest "Strongly Agree"	7.2 and 7.6 "Agree", rest "Neutral"
8	About 7 hours in total spent on CoP	5 hours	roughly 5 hours	12 hours	Overall 24 hours
9	9.1, 9.3 and 9.4 "Neutral", rest "Agree"	9.1 and 9.6 "Agree", rest "Neutral"	9.3 "Neutral", 9.5 and 9.6 "Strongly Agree", rest "Agree"	9.3 "Agree", rest "Strongly Agree"	9.1, 9.2 and 9.3 "Strongly Agree", rest "Agree"
10	No response	No response	10.1, 10.2 and 10.5 "Agree"; 10.3, 10.4 and 10.6 "Neutral", 10.13-10.16 "Disagree", rest no answer	10.1, 10.4, 10.9 - 10.11 "Agree"; 10.2, 10.3, 10.12-10.14 "Neutral"; 10.5 and 10.6 "Disagree"; 10.7 "Strongly Disagree"; 10.8 "Strongly Agree"; rest no answer	10.2, 10.10, 10.11 and 10.15 "Strongly Agree"; 10.7, 10.8, 10.13, 10.14 and 10.16 "Neutral", rest "Agree"

It is possible to observe that most of the respondents gave similar answers for each section. Regarding section five - one student was neutral on all the points of this section but the other four students generally agreed or strongly agreed with all of these points. One student disagreed with the aspect of following their own activities regardless of the prescribed ones.

In the case of section 6 most students agreed or strongly agreed with all of these aspects, except one student who was neutral for all of these. Two students disagreed (one strongly) about the intention to change their role during the CoP phases. Section 7 was one of the sections where all the students were neutral, agreed or strongly agreed to all of these questions.

Section 8 of the survey questionnaire was asking the students how many hours they spent working within the CoP group. Two students answered 5 hours, one 7 hours, one 12 hours and one 24 hours. There appears to be different interpretations of what time spent was referring to with some students interpreting it as the time they spent within the group scenario (roughly 5 hours) and the total time spent working on the assignment i.e. the report (12-24 hours). Regarding section 9 all the students answered this section with neutral, agree or strongly agree responses. Section 10 of the survey questionnaire was supposed to be completed by the facilitator of the CoP.

Three students chose to fill in this section although researchers are unsure of the three which one was the facilitator, or if they considered the author to be the facilitator. There was no definite facilitator defined for this project and thus the responses to these questions are very varied. This is an indication that this section of the questionnaire and methodology needs to be worked upon.

To sum up most of the responses were in favour of introducing CoP as a tool for knowledge exchange and as a help with the assignment.

4.3 Knowledge sharing between formal (CoP) and informal knowledge networks

At the end researchers investigated how formal (CoP) and informal knowledge networks affected students' performance. Based on the students' respondents it is possible to state that the students outside the CoP were communicating constantly with the students within the CoP. It is based on the fact that many of the ideas discussed within the formal CoP sessions were noted in the assignments delivered by the students that were not participants of CoP.

It could be observed that students were constantly exchanging ideas and forming a formal CoP may provide them with a convenient venue to discuss their ideas and problems. Apart from that very often students may opt to form information knowledge networks (or already are part of such networks) as they may feel more comfortable with them.

5. Conclusions

As it was presented in the previous section it is possible to state that there are numerous benefits of introducing CoPs into academia. They are a catalyst for knowledge sharing, exchange of ideas and problem solving. Those students who were in the CoP group and chose to fill out the questionnaire were generally positive about the CoP process and felt it was beneficial to them successfully completing the assignment. Of course there is a grave need to conduct this (or similar) research with different schools, departments and institutions in order to achieve reliability of the results.

Another conclusion that can be drawn from this research is that students very often use informal knowledge networks for similar purposes to e.g. CoPs. Introduction of CoP should take into account this fact that nowadays students use numerous technological services (e.g. WhatsApp, Skype, Facebook or Twitter) to facilitate knowledge sharing. Formal knowledge networks (supervised by the lecture or member of academia) should not compete with those, but rather utilize synergy. This can be achieved by for example encouraging students to share and discuss what was the debated during CoP meeting with those that did not participate. This could be beneficial for all parties involved.

Appendix I

- 5.1 The activities were appropriate for my learning tasks
- 5.2 I followed my own activities regardless of prescribed ones
- 5.3 Activities stimulated brainstorming sessions
- 5.4 I understood my CoP activities
- 5.5 Activities helped in discussing developments of the tasks or project
- 5.6 Activities were meaningful across CoP phases
- 6.1 Roles were suitable for allocated time frame
- 6.2 Responsibilities were clear for my chosen role
- 6.3 I intended to change my role during CoP phases
- 6.4 My role contributed to positive group outputs
- 6.5 Roles were appropriate for our learning tasks
- 6.6 My role inspired others in problem solving actions
- 7.1 Volume of work was manageable
- 7.2 Knowledge covered was appropriate
- 7.3 Overall standard of accomplishment was acceptable
- 7.4 Level of difficulty was endurable
- 7.5 Detail requirements were fulfilled
- 7.6 Required outcomes were achieved
- 9.1 I received enough instructions from my team coordinator
- 9.2 Other CoP members appreciated my ideas and participation
- 9.3 I was proficient in technology to participate in this CoP
- 9.4 I contributed constructively in CoP discussions
- 9.5 I enjoyed sharing my knowledge with others
- 9.6 The social media helped us to effectively share knowledge and experiences
- 10.1. I communicated the primary CoP purpose and specific needs to the CoP group members
- 10.2. The short term goals were set in my CoP group
- 10.3. The CoP charter was developed in my CoP group
- 10.4. Norms for behavior were established
- 10.5. I provided orientation to members
- 10.6. I evaluated member and group activities
- 10.7. I determined the member profile
- 10.8. I facilitated a brainstorming session for CoP benefits, name and branding
- 10.9. I discussed tasks and activities within the CoP
- 10.10. I maintained regular contacts with the CoP group members
- 10.11. I provided support for member roles and responsibilities
- 10.12. I established clear and measureable objectives for each activity
- 10.13. I arranged mentoring/coaching
- 10.14. I clarified rewards and recognition
- 10.15. There was evidence of performance management in my CoP group
- 10.16. I submitted CoP reports regularly to the project leader

Montreal as a Creative City: What Attraction Factors for Artistic and Knowledge Workers?
