favorable business environment in which SMEs can devise effective governance frameworks that will boost their sustainable growth. Therefore, there is an urgent need for Albanian companies to assess good CG standards and promote CG reforms in order to improve future perform and attract foreign direct investment. Despite the efforts made in Albania in this regard, with significant changes to company law in 2008, in-depth investigations of CG practices at the firm level are largely lacking. This study seeks to fill this gap by means of a Delphi-based questionnaire survey. The aim is thus to understand the evolutionary patterns of CG practices in Albania, based on the perceptions of a panel of Albanian Joint Stock Company (JSC) CEOs. Methodologically, the Delphi technique has been shown to be particularly suited to situations where there is a lack of relevant information. As this is the case of CG in Albania, we believe there is considerable scope for the exploration of this methodological approach in this particular context. We know of no prior work using the Delphi technique to analyze the evolutionary patterns and provide development prospects for CG practices in this particular context. In this sense, this study contributes to current research by offering empirical results related to the application of the Delphi technique and forecasting CG practices evolutionary trends in the Albanian context.

The remainder of the paper is set out as follows. The next section presents a review of the literature review and highlights the benefits of CG. Section three presents a brief methodological background of the Delphi technique and justifies its application in the context of the present study. Section four presents the results of our study, and the final section concludes the paper.

2. Sustainable benefits of corporate governance

According to the OECD (2004: 11), CG can be defined as “*a set of relationships between a company’s management, its board, its shareholders and other stakeholders. Corporate Governance also provides the structure through which the objectives of the company are set, and the means of attaining those objectives and monitoring performance are determined [...]*”. This definition is consistent with the one presented by the Cadbury Committee (1992: 14), according to whom “*Corporate Governance is the system by which companies are directed and controlled. Boards of directors are responsible for the governance of their companies [...]. Thus shareholders’ role in governance is to appoint*

the directors and the auditors and to satisfy themselves that an appropriate governance structure is in place. The responsibilities of the board include setting the company's strategic aims, providing the leadership to put them into effect, supervising the management of the business and reporting to shareholders on their stewardship. The board's actions are subject to laws, regulation and the shareholders in general meeting [...]". Research suggests that there are a wide range of advantages arising from the implementation of CG mechanisms in firm strategies. These benefits can be classified into *monetary* (i.e. direct financial effects) and *non-monetary* (which do not directly lead to cash flows but can still be measured in monetary terms) (Weber, 2008); and have been variously empirically demonstrated.

CG variables can affect firm performance and firm performance can, in turn, affect CG (Denis, 2001; Hutchinson and Gul, 2004; Minnick and Noga, 2010; Wintoki *et al.*, 2012). It has been shown, for instance, that there is an iterative relationship between CG and firm performance, such that CG variables can positively affect firm performance, but this in turn also affects the quality of CG. Hutchinson and Gul (2004) demonstrate that CG variables related to monitoring and incentives, such as higher levels of non-executive directors on the board, management share ownership and managerial remuneration, weaken the negative relationship between a firm's investment opportunities and its performance. According to Bhagat and Bolton (2008), the incentive effects of board stock ownership are positively related to both future operating performance and to the probability of disciplinary management turnover in poorly performing firms. Furthermore, improvements in operating performance are greater among firms that have higher average total and active institutional ownership, as well as concentrated ownership (Demiralp *et al.*, 2011). Active family control is associated with higher profitability (compared to non-family firms), whereas passive family control does not affect profitability even in different legal regimes (see also Maury, 2006); and there is an inverted "U-shaped" relation between bank performance and board size, and between the proportions of non-executive directors and performance (Andres and Vallelado, 2008).

Other evidence is also reported in the literature: board size is positively associated with firm value and firm financial performance (Chen, 2011); and there is a positive relationship between post-issue changes in institutional ownership characteristics and long-term stock price performance. Furthermore, firms experience higher productivity growth when operating in markets with intense competition and under control of a strong

ultimate owner (Januszewski *et al.*, 2002); there is a negative correlation between firm value and stockholder dispersion as well as between firm value and the presence and total ownership stake of stockholders (Konijn *et al.*, 2011); and there is a positive relationship between CEO compensation and firm performance as measured by return on equity (Sigler, 2011).

According to Black (2001), firms can greatly improve their share values and, thus, reduce the cost of raising equity capital, through a determined effort to improve their CG practices. The author also suggests the potential value of minimum quality regulation, which can reduce the scope for adverse selection and, thus, enhance all firms' market values. Supporting this line of research, Gompers *et al.* (2003) find that firms with stronger shareholder rights have higher share values and higher stock returns. Ashbaugh-Skaife *et al.* (2006) focused on the value of CG from bondholders' perspective as an important determinant of credit ratings, and argue that a firm that possesses desirable governance characteristics from the bondholder's viewpoint approximately doubles its likelihood of receiving an investment-grade credit rating. Tian and Twite (2011) found that internal CG – more efficient boards and greater CEO stock-based compensation – have a positive impact on the firm's total factor productivity, especially in less competitive product markets or less active takeover markets. Furthermore, it has been variously argued that Corporate Social Responsibility (CSR) mechanisms, as an important component of conceptual value added, can shape the mission and vision of companies beyond shareholder value maximization (Gyves and O'Higgins, 2008), and impact on values by reaffirming the need to have codes of conduct and ethical standards in place (Solomon, 2007; Van Dijken, 2007; Rezaee, 2009). It has been shown that firms that spend on CSR have greater firm value (Ammann *et al.*, 2011).

These findings are not without consequences, even in emerging and developing market. Indeed, Omran (2009) argues that ownership concentration and ownership identity, in particular foreign investors, appear to have a positive impact on firm performance, while employee ownership concentration has a negative one. It has been proposed that the greater proportion of outside directors and the change in board composition following privatization in developing markets have a positive effect on firm performance. Giroud and Mueller (2011) found that firms in non-competitive industries benefit more from good governance than do firms in competitive industries; and that firms with weak governance have lower labor productivity, higher input costs, make more

value-destroying acquisitions, and are more likely to be targeted by activist hedge funds, which suggests that investors take actions to mitigate such inefficiency. In addition, better-governed firms exhibit significantly greater stock price increases and higher rates of physical capital accumulation following equity market liberalization (Bae and Goyal, 2010). Establishing an effective and efficient legal configuration is central to understanding that firms with better shareholder protection raise more funds from potential shareholders than others (Bruno and Claessens, 2010). Indeed, the level of firm-level governance is strongly related to country-level measures of investor protection: firms with large needs for outside financing have more incentives to adopt better governance practices so as to lower their cost of capital (Klapper and Love, 2004).

Despite the cost associated with the implementation of CG policies, CSR mechanisms should be seen as a fundamental opportunity and/or a tool in developing and redefining winning strategies and overcome the turbulence of the competitive environment (Fernández and Souto, 2009; Giannarakis and Theotokas, 2011).

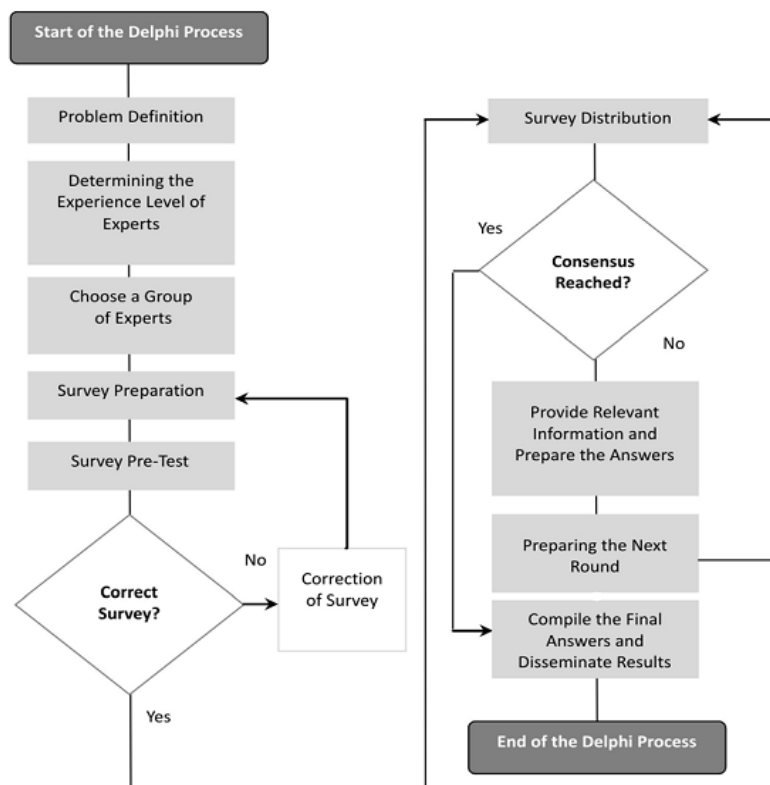

CG should therefore be an ever evolving and proactive concept; and it can be expected to be influenced by differences in the national context (Matten and Moon, 2008), stakeholder requirements, customer and emerging business needs and the constant changes in the business environment (Jones *et al.*, 2009).

3. Methodology framework

In 1950s, the RAND Corporation developed the Delphi technique to investigate USA Air force problems by using the expert judgments on a specific issue. As stated by Ferreira and Monteiro Barata (2011: 246), the technique is “*a well-established sequence of successive individual questions supplemented with information and advice, which permits correcting the first stages of the process. [...] it is a tool, which, under certain parameters, enables consensus. [...] and is based on the rational principle that ‘n’ human minds are better than one when confronting the lack of precise knowledge about a certain subject*”. In essence, the Delphi approach begins with the development of a survey, to be completed individually by experts on a specific topic. It then continues through a repeated sequence of successive individual questions (by interview or questionnaire) (Dalkey and Helmer, 1963; Ferreira and Monteiro Barata, 2011), with the aim of obtaining “*the most*

reliable consensus of opinion of a group of experts” (Dalkey and Helmer, 1963: 458).

The operational structure of the Delphi technique is given in Figure 1.

Source: Ferreira *et al.* (2013).

Figure 1. Operational structure of the Delphi technique.

The Delphi technique is thus based on three basic principles: (1) *anonymity*; (2) *controlled feedback* of the information and knowledge contributions; and (3) *statistical treatment of the group responses*. The method is mainly used when the problem under discussion cannot be resolved by precise analytical techniques, due to a lack of relevant data information about the problem, as is the case of CG practices in Albania.

As with any method, the Delphi technique has strengths and weaknesses. The literature highlights a considerable number of advantages: (1) the technique is simple to

use because its application, design and scrutiny do not require advanced mathematical skills (Yousuf, 2007); (2) the confidentiality of the technique allows many communication barriers to be overcome (Yousuf, 2007); (3) information can be obtained from a large group of experts that are geographically widely dispersed (Yousuf, 2007); (4) physical presence is not required, and direct confrontation between the experts is avoided (Dalkey and Helmer, 1963; Ferreira *et al.*, 2013); (5) anonymity helps participants freely express their ideas and convictions without being under pressure (*e.g.* from the organizational hierarchy or dominant individuals or groups) (Dalkey, 1972; Ferreira *et al.*, 2013; Worrell *et al.*, 2013); (6) the analysis through statistical tools allow for a valid and fair analysis and summarization of the collected data (Dalkey, 1972); and (7) it allows different topics to be discussed (Ferreira *et al.*, 2013).

Despite these advantages, the Delphi technique also has its limitations or challenges. For instance, it may be difficult to motivate the panel members to participate in the Delphi, and keep participating throughout its various rounds. Indeed, the existence of several rounds means that respondents may drop out of the process, either because the survey is always the same or because it becomes perceived as too time-consuming (Ferreira *et al.*, 2013; Worrell *et al.*, 2013). Furthermore, the scope of the technique's application may be limited by the availability of experts on the topic (Ferreira *et al.*, 2013); and the fact that the method does not require participants' physical presence can lead questions to be misunderstood (Ferreira *et al.*, 2013). Indeed, the implementation of the Delphi method is highly dependent on the response rates in each round, and the control of irresponsible feedback can be difficult, especially if panelists are interested in manipulation (Goluchowicz and Blind, 2011). Despite these potential weaknesses, several studies demonstrate the power of the Delphi technique in increasing our knowledge of previously poorly understood topics. The results of our study are presented in the next section.

4. Results analysis

Considering the research purpose outlined for this empirical investigation, the initial Delphi panel was composed of 80 CEOs representing different types of JSCs, from banking, insurance and other financial services; both private and state-owned. These were located mainly in the largest cities in Albania (*i.e.* Tirana, Durrës, Fier, Vlorë, Shkodra,

Tropoja, Elbasan, Gjirokastër, Lushnje and Saranda). After the first round, the number of panel members decreased to 53 and, and after the second round, only 37 panelists provided their responses to the survey. It should be noted, however, that “*there is no ideal number of experts for the application of the Delphi technique*” (Ferreira and Monteiro Barata, 2011: 246), and that the reduction in the number of panel members is anticipated by the methodology. The responses from the 37 panel members in the final round provide the basis of our analysis.

4.1. Sample characterization

The characterization the panel of experts (*i.e.* the 37 respondents of the 2nd round) is provided in *Table 2*, which shows that most respondents were *male* (70.3%) and between 43-47 years old (40.6%). Most of the panel members held a *higher academic degree* (67.6%), predominantly in *economics or management* (67.6%).

Table 1. Characterization of the respondents [second round].

		Delphi Panel	
		N	%
Gender	Female	11	29.7
	Male	26	70.3
	Total	37	100.0
Year of Birth	1952-1956	3	8.1
	1957-1960	3	8.1
	1961-1965	8	21.6
	1966-1970	15	40.6
	1971-1976	8	21.6
	Total	37	100.0
Qualifications	4-Year diploma	12	32.4
	MSc, MBA	20	54.1
	Ph.D.	5	13.5
	Other	0	0.00
	Total	37	100.0
Area	Economics/Management	25	67.6
	Engineering	8	21.6
	Other	4	10.8
	Total	37	100.0

Table 2 shows that the most representative firm owners in the sample possessed more than 2/3 of the company shares, while minority shareholders held only 2% or less of the company shares, indicating specific agency problems related with the direct involvement of owners in many important decisions and daily monitoring of the company.

Table 2. Number of shareholders per owning shares [n=37].

Owning shares	%
More than 2/3	39.8
From 1/4 to 1/2	34.9
From 2% to 10%	19.3
2% or less	6.0
Total	100.0

The data obtained according to the structure of the questionnaire are presented in the next subsection.

4.2. *Development prospects*

In order to obtain a generalized view of the future trends of CG in Albania, we tried to collect the respondents' opinions on the direction in which CG practices are moving, and the current level of knowledge and willingness to apply contemporary international standards of CG best practices. According to Table 3, and based on most panelists' responses, there is a tendency for an increase in CG "culture". Almost 46% of the respondents considered CG as *one of the top three future priorities* (45.9%); and 21.6% said it was a *top or top ten priority*. Only 10.8% considered it was *important but not a management priority*.

Table 3. The CG rating in the company's list of priorities [n=37].

Benefits	%
It's the top priority	21.6
It's one of the top three priorities	45.9
It's among our top ten priorities	21.7
It's important but not a management priority	10.8
Other	0.0
Total	100.0

The next question asked the panelists to rank, by order of importance (*1 = first most important, 3 = third most important*), the three main goals they considered most important for CG practices to achieve in the future. According to *Table 4*, the majority of the responses focused on *improving the company's market position* (67 points), followed by *increasing annual turnover* (45 points), and ranked in third place, *increasing the outcome* (38 points). The advantages deemed least important were *protection of shareholders' rights* (4 points) and *coordination improvements between shareholders and administration* (1 point). It should be noted that attracting investment, especially foreign investment, accumulated only 18 points, which suggests a low level of knowledge of the potential long-term benefits of the CG best practices.

Table 4. The CG rating in the company's list of priorities [n=37].

Benefits	Points
Improved market position	67
Increased annual turnover (company's economic activity)	45
Increased of the outcome	38
Attract investment	18
Improved decision-making	14
Improvement of the company's reputation	14
Increased efficiency in the operations of the company	14
Lower cost of capital	9
Increase the transparency of the activities	4
Protection of the shareholders' rights	2
Improving coordination between shareholders and administration	1
Total	226

The next question related to experts' perceptions of the three main barriers to CG improvement (*1 = main impact, 3 = third main impact*). The final ranking was the following: first, *insufficient legislation* (42 points); second, *costs of implementing and communicating CG policies* (41 points); and third, *lack of information or knowledge and lack of qualified specialists* (40 points respectively) (*Table 5*). Interestingly, *lack of financial understanding on the part of senior executives and the board* was not perceived to be a significant barrier, indicating that the board is perceived to have a good level of knowledge about the company's strategic issues.

Table 5. The barriers faced by the company for governance improvement [n=37].

Barriers	Points
Lack of qualified specialists	42
Cost of implementing and communicating corporate governance policies	41
Lack of information / knowledge	40
Insufficient legislation	40
Lack of business understanding on the part of external auditors	23
Information on governance issues of the company harms competition	21
Lack of business understanding on the part of the board	11
Lack of financial understanding on the part of senior executives	3
Total	221

According to the panelists, and as shown in *Table 6*, training and consultancy are needed in order to improve governance (83.3%), a point with which few (16.2%) failed to agree.

Table 6. Need for training and consultancy for improving governance [n=37].

Benefits	%
Yes	83.8
No	16.2
Total	100.0

For the next question, we were seeking to understand panelists' opinions about what CG tasks can be the most effective in providing high-quality CG practices in Albania. Panelists were asked to rank, by order of importance (*1 = first most important, 6 = sixth most important*), the CG mechanisms that are likely to most affect the effectiveness of CG in Albania. *Table 7* presents the aggregated scores.

Table 7. Most effective tasks for better CG practices in Albania [n=37].

Mechanisms	Points
To make internal corporate mechanisms work better	166
Enhancing the standards of accounting, audit and disclosure	151
Conducting and publicizing corporate governance ratings	140
Prohibiting or tightly controlling some types of related-party transactions	114
To select the most effective external mechanisms	108
Reducing ownership concentration	95
Total	774

According to *Table 7*, the final ranking was: (1) *making the internal corporate mechanisms work better* (166 points); (2) *enhancing the standards of accounting, audit*

and disclosure (151 points); (3) conducting and publicizing CG ratings (140 points); (4) prohibiting or tightly controlling some types of related-party transactions (114 points); (5) selecting the most effective external mechanisms (108 points); and (6) reducing ownership concentration (95 points). The reduction of the ownership was given the lowest importance, which suggests, consistent with Çipi *et al.* (2014), a strong need for concentration of ownership in developing countries such as Albania. “Concentrated owners”, who cannot rely on other institutions and arrangements designed to monitor management, have both the power and incentives to do this themselves. The level of ownership concentration in Albania is strongly associated with the development of the financial market; and agency problems in such countries develop different features due to the direct involvement of shareholders in many important decisions and in the daily monitoring of the company.

Using a Likert scale from 1 to 5 (*1 = not important, 5 = decisive importance*), Table 8 shows the respondents’ evaluation of the future tasks of the board in order to improve the performance of outside directors.

Table 8. Important tasks for better performance of outside directors [n=37].

Measures	Mean	Median	Standard Deviation	Coefficient of Variation
Better attendance at the board meetings	4.04	4.00	0.956	0.237
Better awareness of fiduciary duties to all shareholders	4.17	4.00	0.878	0.211
Better knowledge of the business of the firm	4.69	5.00	0.577	0.123
Better preparation for and more active participation in board discussion	4.42	5.00	0.770	0.174

Based on Table 8, and according to the respondents, *better knowledge of the business of the firm* and *better preparation for and more active participation in board discussion* have a considerable impact, with median scores of 5 (critical importance). The remaining items (*i.e. better attendance at the board meetings* and *better awareness of fiduciary duties to all shareholders*) assumed good level of importance.

Through the next question, we attempted to obtain the panelists’ opinions regarding the readiness of Albanian companies for listing on the stock exchange. Table 9 provides a general overview of the results.

Table 9. If it is the time for the Albanian JSC to be listed on the stock exchange [n=37].

Responses	%
Yes	56.8
No	43.2
Total	100.0

Although most respondents (56.8%) affirm that Albanian companies are ready to be listed, a relevant number (43.2%) think that it is not yet the moment for them to initiate this process. The main reasons for this disapproval are presented in *Table 10*.

Table10. Obstacles to the listing process in Albania.

Influential actors	Points
Lack of information and knowledge	31
Lack of “tradition”	28
The lack of efficiency of the market regulatory institutions	27
Failure on the introduction of the standards in general	25
Insufficient legislation	18
The low need for capital	6
Total	135

According to *Table 10*, and by order of importance (*1 = first most important, 7 = seventh most important*), the obstacles to the listing process are *lack of information and knowledge* (31 points), followed by the *lack of “tradition”* (28 points), *the lack of efficiency of the market regulatory institutions* (27 points), *failure on the introduction of the standards in general* (25 points), *insufficient legislation* (18 points), and *the low need for capital* (6 points).

These results suggest a cause-and-effect relationship between the development of CG at the firm level and Albanian capital markets. If Albanian companies believe that the time has come for them to be listed in the stock exchange trade they must be aware of and prepared to make significant improvements to the CG mechanisms they use. Furthermore, there is a need to implement more “good” CG practices and to increase the CEOs’ level of knowledge about their real benefits.

5. Conclusions and policy implication

CG has become an issue of interest to an increasing number of companies and governments. Good governance is in some ways related to the implementation and

promotion of commonly accepted CG values such as: *equality* (fair and equal treatment of all company stakeholders by the management in the process of operating the firm); *transparency* (periodic disclosure of financial and non-financial information to the public and shareholders); *accountability* (the board's obligation to monitor management and be accountable to the company's shareholders); and *good citizenship* (complying with the expectations of, and developing a good relationship with, the community in which the company operates). This assumption seems to be true not only for firms that operate in developed or emerging countries but also for firms that operate in ex-centralized economies such as Albania. For Albania, it is a paramount issue to find a CG model that is adapted to its institutional and cultural landscape. Despite the attempts made by the government and companies to implement good standards of CG, there is still need for improvement. Thus, in this study we aimed to analyze, based on a Delphi investigation, the evolutionary patterns of CG practices in Albania, and to suggest development prospects for them based on the perceptions of CEOs of Albanian JSCs.

Taking a holistic view on the trends towards CG practices towards which Albanian JSCs are moving, our findings offer some optimistic notes. Albanian JSCs are improving their level of knowledge of (and willingness to apply) internationally accepted CG standards. A "more or less friendly environment" regarding reforms or activities required to improve CG is gradually emerging in Albania. These general conclusions are supported by the evidence: (1) Albanian JSCs appear to be increasing their self-commitment to the application of the best standards of CG practices. Executives rated CG as one of their top three future priorities. Because the implementation of CG practices can improve a firm's market position, increase annual turnover and increase firm outcomes, executives are recognizing the real need for training and consultancy in order to improve governance issues. Furthermore, most of them affirm the need for planning and training funds for supervisory boards and administration on governance issues; (2) there is a predisposition for the implementation of international financial reporting standards. This finding may relate to legal requirements (2008 company law) and it is a consolidated practice at financial JSC which are brands of foreign firms; (3) there is an increasing tendency for a "CG culture". This is illustrated by the growing knowledge on CG issues, for instance. However, the perceived need to foster this culture seems limited to the current concepts that CEOs have, which associate governance improvements in the company's reputation or, business operations, and less with investment attraction; (4) JSCs are recognizing the

need for more knowledge and information about CG concepts. They think it is necessary to attract qualified specialists in the field; (5) Albanian CEOs believe that company legislation is not a significant obstacle to a good level of governance, but some obstacles remain, such as the lack of specialists in the field and the low level of awareness and understanding of the real importance of good CG practices; (6) the panel of experts reacted in a relatively positive manner to the potential opportunity for a listing process in an organized capital market. This trend is most significant within the financial group (mainly banks and insurance companies), which are the first candidates for listing. As entities operating in financial markets and subject to regulatory requirements, they are suitable candidates for a successful listing process; and (7) the panel was quite critical to a functioning organized capital market. They identified these barriers as being lack of information and knowledge, lack of tradition and the low level of efficiency of regulatory institutions, and the failure to introduce standards in general.

Given these results, we recommend further effort on the part of market regulatory institutions and administrative structures for the efficient implementation of this market by providing incentives for the listing process. Furthermore, the on-going CG reform efforts should be continued to encourage the Albanian companies to pay more attention to “content” rather than “form” (*e.g.* enhancing the effectiveness of boards by selecting better qualified and truly independent directors, assuring adequate and timely information to board members). More specifically, priority should be given to making internal CG mechanisms work better and enhancing the standards of information disclosure, accounting, and auditing. Critically important for these tasks are the roles of supervisory and financial agencies, professional associations and independent board directors. There is a need for CG reforms in terms of better awareness on the real and unique agency problems faced by Albanian JSCs (which are related to the concentration of ownership and the underdeveloped financial market). Further, the introduction of good laws is not a guarantee for the implementation of CG best practices. As such there should perhaps be enforcement mechanisms to ensure that companies truly comply with best practices. It is worth noting that the first and only non-mandatory code of CG was introduced recently in December 2011. A broad perspective should be adopted with regard to future CG reforms in Albania based on the stakeholder approach, which helps the development of sustainable economy. A better awareness of the real long-run benefits of CG best practices will help Albanian JSCs to attract important powerful foreign

investors. Furthermore, the need for Albania to be part of the European Union can be a good incentive for the adoption and improvement of practices, in order to be competitive in global trade.

There are several potentially fruitful research opportunities with respect to CG in Albanian firms. In particular, a deeper understanding of specific cultural features, and the level of institutional development in the country, will allow researchers to identify the model of CG that best suits the Albanian context. Such deeper understanding can also help researchers find the weaknesses of the Albanian CG model and help Albanian firms to identify the real benefits of CG and make strategic use of them to grow and thereby to affect the country's sustainable development.

Structured Abstract

Purpose – Our paper deals with the design of dynamic model of national healthcare system of the Czech Republic composing from the qualitative and quantitative part. We use the tools of system dynamics because of its holistic approach that helps unlike the simple math and static analyses to take into account the complexity of the health system. This approach can help to verify the design of new health policy and thus achieve effective problem-solving and improving the overall health system.

Design/methodology/approach – Presented problem represents a macro level strategy planning task. To preserve its clarity and applicability, understandable tools and procedures must be adopted in all related analysis and design stages. Our basic methodology consists of four generic stages, including (i) problem formulation, (ii) conceptual specifications, (iii) computational modelling and (iv) experimentation.

Originality/value – We see the innovativeness of presented research in assumption that strategic concentration on quality in healthcare sector can solve the majority of its current bottlenecks. According to our interpretation, qualitative aspects include primarily the non-clinical activities, such as management, marketing, external relations or staff development. Knowing the historical data, we can estimate future total costs, generated by the existing system and define alternative, sustainable, quality based policies. Viable alternative policies must preserve the major existing characteristics and introduce new processes, leading to the reduction of costs within five years long time horizon.

Practical implications – The proposed model can be very useful especially for current and future policy makers as a tool for decision making. They can create better decisions based on the knowledge of a wide variety of factors influencing the system and achieve the public health objectives more effectively. Thanks to its complexity, transparent representation of the different relationships and their interactivity, this model is suitable for strategic planning, group decision making, learning and sharing knowledge. With such strategic and long term decision we can assure the sustainable development of healthcare system especially better control of health expenditure.

Keywords – simulation, healthcare system, national health policy, public health, system dynamics.

Paper type – Academic Research Paper

1 Introduction

As it is seen worldwide healthcare is one of main issues in many countries. For example these problems are related to funding (sustainability), quality and accessibility of health care and efficiency of invested resources (Tchouaket et al., 2012). This theme takes on importance mainly due to the nature and perception of healthcare. Financial significance is captured in the annual statistics which shows national expenditures on health care and their share in GDP.

Demand for health services is derived from the demand for health (Grossman, 1972). These aspects together with the psychological component put pressure on the demand for accessible and affordable quality health care. Such conditions are becoming a powerful political tool in two ways. First, allow politicians to get support in the election, and secondly, they create barriers for implementation of major changes to the healthcare system (eg. direct payments, out-of-pocket, fee for service). The aim of this paper is not to predict the future of our system but to recognize its complexity and to examine different strategies of national health policy.

2 Purpose

As already mentioned, health care is significantly associated with politics. This disables natural development of the system. Policy makers very often present healthcare as a system but their approach is much different. They do not reflect the nature of system with all of its relations and elements, their interaction. Therefore using a simple analysis to develop a functioning system is not adequate. These simple analyses are typical to consider very little variables and ignore the impact of accumulations as results of interaction between all the elements, time delay, resource limits and other managerial issues.

However, the current trend is that the ruling party cannot conceptually use the challenges and solve the problems that are associated with this given the long term horizon. Often it is decided separately regardless of each elements or subsystems of the whole health care system. This approach it is strictly administrative and bureaucratic

(Shortell, 2006). This is the basis to implicitly set up the variables of the system, which covers reimbursement mechanisms (which does not reflect the market price, real quality, etc.), structure of delivered health services, and distribution of providers, etc.

Our aim is to present a model based on system dynamics because of its holistic approach. It is necessary to take into account that strategic modelling is not intended for future prediction but to help us (and policy makers) to realise the complexity of health system (Millstein, 2010). The use of strategic modelling for the understanding of complex systems confirms Sterman (2006). The final model helps with critical thinking and can help to verify the design of new health policy and thus achieve effective problem-solving and improving the overall health system. To obtain this we have to develop a casual diagram based on policy oriented simulations.

3 Dynamic modeling and its relevance in *Czech healthcare system*

3.1 *The Czech healthcare system*

The Czech healthcare system has its roots in the base of Bismarck approach to financing healthcare. This system is based on compulsory public health insurance. The insurance is paid by employees and employer and state. The employees give out 4, 5 % of their gross wage and employers contribute by 9 % of employees' gross wage. The state is the payer for states' insured (e.g. students, pensioners, maternal leave). In 2014 there were 7 insurance companies, with the major position of General Health Insurance Company, which has 60 % of the market.

Healthcare sector takes a substantial part of national economy in developed countries worldwide. There is no different situation in the Czech Republic. In comparison with other countries, Czech healthcare systems contributes by 7, 5 % GDP, which is less than European average (based on OECD data average expenditure is 9 % of GDP). Even though healthcare expenditures are rising there is a relatively stable level in the quality care provided. This trend is unsustainable in the long run. The cause may be hidden in the management and the planning process of health system.

Table 1- Health expenditure in the Czech Republic

Czech Republic statistics	2006	2007	2008	2009	2010	2011
Total expenditure on health, % GDP	6,7	6,5	6,8	8,0	7,4	7,5
Total expenditure on health, /capita, US\$ PPS	1 555	1 658	1 765	2 039	1 884	1 966

The current strategy is reactive and focused primarily on the quantity. Policy makers use to deal with public health problems simple analysis and solve the problems in isolation despite the fact that many of them are related with a high level of complexity.

3.2 Main elements of healthcare system model

In order to model healthcare system it is necessary to define the basic elements and their relationship typical for concrete country. Our model is based on the substance of the six basic objectives of a quality health care system. These have been defined by the Institute of Medicine, Washington, USA (Saxton, 2009; Shortell 2006) and reflect assumptions of necessity of safety, timely, effective, equitable, efficient and patient-oriented healthcare system.

In our approach (due to simplification) we combine these six goals to three main elements – quality, access, costs. Health policy tools are represented by assurance of resources, reimbursement mechanisms, organization, regulation and persuasion (Hsiao, 2007).

These five tools of health policy are based on previous research (Roberts, 2004). Available resources or *financing (1)* are characterised by the process of obtaining resources in the healthcare system. Ultimately, this directly affects the patient, because the tools are set as direct payments, insurance, out-of-pocket payment, etc. *Organization (2)* refers to creation and adaptation of organization of healthcare market (competition, ownership, centralization). *Payment (3)* in the Czech environment is especially represented by reimbursement mechanism.

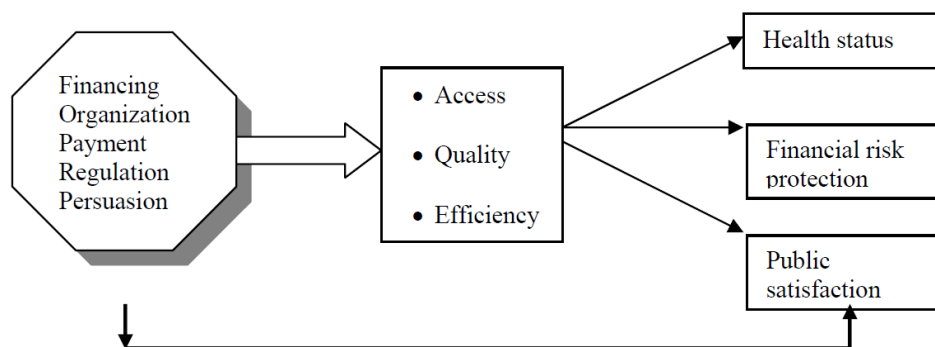

Figure 1: Health policy tools and objectives

This is administratively agreed set up which influences economic development and possible functioning of healthcare providers. But generally this instrument is focused on the distribution of resources (methods and amount).

The tool of *regulation* (4) is used to set boundaries and rules for the operation of providers, organizations and individuals within the healthcare market. Last but not least is the tool of *persuasion* (5). This is concerned on influencing the population. This primarily involves the prevention and pressure to change behaviour that would lead to improve health status of the population.

Tab 2 serves as an example of possible interventions and resulting effects. It is selected due to actually situation in Czech healthcare system. Many countries are considering responding to the above-mentioned aspects through reforms. However, to enable us to contemplate changes we need to understand the individual elements of the system, their roles and relationships and interactions between them.

Table 2 - Examples of health policy intervention and its effect

Tool	Intervention	Effects
Financing	Out-of-pocket payment	positive effect - an increase in income in the health system, regulation unnecessary care negative effect - the social impact
Organization	Change of ownership of healthcare organizations	positive effect - managerial ownership and responsibility resulting in effective functioning negative effect - difficult political implementation

Payment	Motivation in primary care	positive effect - increasing emphasis on prevention (better health status) - negative effect - growth of financial resources needs
Regulation	Definition of health care standards	positive effect - clear rules for reimbursement negative effect - the definition above standard care resulting in increase of financial burden
Persuasion	Increase of information	positive effect - avoiding health risk behavior negative effect - the cost of information campaign

Possible solution may be dynamic modeling of the system or its parts, which is based on systems thinking (Milstein, B. et al., 2008). Dynamic models allow verifying the functionality and impact of the proposed changes before they are implemented in practice.

4 Quality based interventions

Due to the fact that in the initial analysis, it was found that the aspect of quality is a promising way to improve the system, while reducing cost in the long term (Voracek et al., 2014) this paper will focus on quality based interventions. In the Czech healthcare sector it is very difficult to measure or to choose a healthcare provider in accordance with quality aspects or results of its care provided.

It is not very common to find any available rankings which would provide information about quality status of healthcare provider. Czech legislative partly highlights the need of internal evaluation of the quality in health care; however, these tools may not correlate with objective quality achieved. Some of the healthcare providers tend to certificate their services and thus obtain various certificates. It is important to mention that quality is not the only aspect essential for healthcare providers but it is the most perceived by the patient.

4.1 Coordination of care

State of the art health system put a great emphasis on improvement of health care services coordination (especially on continuity of care). In another words continuity of care in primary sector with ambulance specialists followed with aftercare will improve the overall efficiency of the health care system (Tjerbo and Kjekshus., 2005). It is assumed

that integration of care will increase cost-efficiency and the outcome of the treatment in long term (Wan et al., 2001).

Coordination of care is a relatively complex process that requires formal support. To make the change to a system-wide basis can be quite challenging. In this case, it is possible to start with a gradual integration as for example special patient groups, cancer patients, elderly or psychiatric patients (Romøren et al., 2010). The example of this tool can serve a disease management programme (vertical chronic disease management). The results from Germany show a better care process as well as improved clinical outcomes (Schlette et al. 2009).

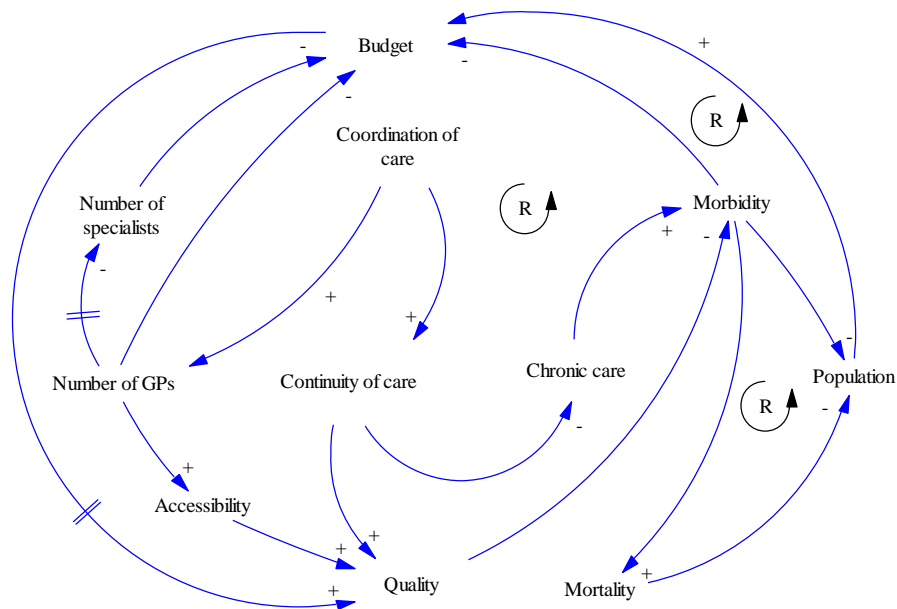

Figure 2: Causal loop diagram of coordinated care

4.2 Causal loop diagram

From the example above, we have created a diagram of causal relationships (Figure 2). The assumption of coordinated care is that the system would need higher number of primary care providers (number if GPs). These would have the gate-keeper function. Such a set up would result into to lower usage secondary care (specialist) a

therefore lower number of these doctors. The secondary aspect of this would be the lower cost on the segment of specialists (decrease of budget drawing).

We suppose that coordination of care would result in initial raise of cost due to increase of reimbursement rates which would serve as a motivational factor for GPs. This step would simultaneously lead to rising of health care quality through continuity of care and accessibility assurance. Better quality would result in better health status (in terms of lower morbidity). Increased coordination of care would result in better continuity of health care provided which would have direct impact on lower level of delivered chronic care.

As it seems in the diagram changes on the budget side have an impact on the quality of care but we have to take into account the delay of this effect. Quality has an impact on population through the changes in mortality/morbidity. The positive effect of lower morbidity would lead to lower mortality and therefore to more healthy and wealthy population. Due to our system setup this will cause increase of contributions to budget.

5 Methodology

Complex problems can be hardly understood and coordinated with traditional tools. Surrounding dynamic environment requires high quality planning, fast responses on frequent changes as well as sophisticated development of resources. Consequently, dynamic simulators form a promising class of tools, capable to enhance possibilities of traditional planning and controlling methods, adopted from mathematics, statistics or economics. This is namely because the computational simulations can expose emergent behavioral features, identify counterintuitive patterns or simplify and visualize multidimensional nonlinear relations. Realistic transformation of real world problems into a software form also allows safe and cheap training or experimentation.

Although any type of simulation cannot replace the final statement of humans, innovative tools definitely can improve efficiency and quality of their decisions - either as a user-friendly artificial micro-worlds, flexible rapid prototyping tools or falsifiers of improper mental models. Practically applicable simulators must be:

- Holistic and systemic, i.e. working with completely defined and properly bounded problems,
- Knowledge-based, i.e. including visible artefacts of organizational and individual knowledge,

- Heterogeneous, i.e. represented as a set of the particularly convenient computational paradigms,
- User-centered, i.e. preserving users' friendliness, usability and applicability,
- Scalable and expressive, i.e. easy to extend and combine particular solutions to more complex, truth-preserving structures.

From the methodological point of view, simulators also act as validators of dynamic hypotheses, i.e. either confirm or reject initial considerations regarding the temporal behavior of multivariate systems (Serman, 2000). Our hypothesis states that additional investments to the quality of healthcare must (later) break its currently growing financial demandingness and turn falling satisfaction of domain stakeholders.

Instead, sustainable level of expenditure will be reached, altogether with reasonable satisfaction and health status of population. The contextual research questions are how long, how much and where to allocate these finances. Another challenge is to find a reasonable balance between the portion of efficient re parameterization of existing system and ratio of its necessary restructuring.

There are also numerous implementation matters, incorporating, e.g., transparent selection and quantification of qualitative attributes, straightforward identification of model leverage points or formulation of convenient utility functions. To validate our research hypothesis and grasp the overall complexity of this problem, we realized system dynamics prototype of national healthcare system in accordance with traditional research methodology (Mitroff and Kilmann, 1978) in the following four phases:

Problem formulation (1), resulting to a structured, verbal description of processed problem. It must provide enough information concerning internal structure, attributes and functionality, as well as apposite specification of surrounding environment. As the major technique in this stage, we used Analytic hierarchy process (AHP), described in (Saaty, 1980). This is a widely used tool for Multicriteria decision making problems (MCDM), which can be considered as static variants of dynamic planning tasks. Beyond the desired problem formulation itself, AHP outputs can provide also approximate stationary solutions, convenient for consecutive validation. Typical MCDM problems have the following four stages with selectively interconnected adjacent levels:

- Alternatives, represented with set of selected attributes, characterizing quantitatively and qualitatively interesting configurations of modeled system.

Concrete values of these state variables and parameters fully determine dynamic behavior of modelled interconnected sectors of population, healthcare policy, insurance companies and healthcare providers. For example, an alternative can structure and enumerate healthcare utility, business models of insurers or selected performance drivers of healthcare providers.

- Criteria, i.e. quantities, based on which the output impacts of single alternatives are evaluated, like costs, quality of life or health status of population.
- Expert opinions areas, combining and summarizing outcomes of particular criteria, for example to a form of individual, organizational, qualitative and quantitative aspects.
- Final objective, i.e. resultant policy function, evaluating experts' contributions.

We found this prototyping based way of knowledge elicitation efficient, especially because of its goal oriented nature and quantitative support of creative thinking.

Conceptual modeling stage (2) transforms previously collected results and elicited knowledge to a set of diagrams, convenient for further computational processing. Although the system dynamics implementations start traditionally with mind mapping, terminology standardization and system diagramming, due to the adopted AHP startup, it was possible to omit these techniques and concentrate directly on dynamic features, represented with hierarchy of Causal loop diagrams.

Computationally (3), our problem is modeled with System dynamics (SD) language, based on paradigm of multiple stocks of resources – state variables interconnected with parametrically adjustable flows (Sterman, 2000; Warren, 2007). Such notation is very intuitive, because stocks can be filled and drained both with quantitative and qualitative variables. For example, flow of patients is processed with services, derived from managed flow of medical staff. Mutual interaction between patients and doctors contributes to the level of public health stock and consumes money from financial reservoir. Consequently, shortage of diagnostic tools, doctors' knowledge or improper insurance plans, act as bottlenecks, cumulating patients inside the system and decrease the levels of their individual satisfaction and quality of life stocks. Global dynamics is composed from sequential nature of modeled phenomena and topological complexity of their relations,

forming complex, delayed loops. As it is impossible to obtain analytic solution of such systems, in parallel with interactive graphical structural design, set of corresponding difference equations is created and solved numerically during the execution of simulation. Block structure of our simulator in SD like notation is in figure 3.

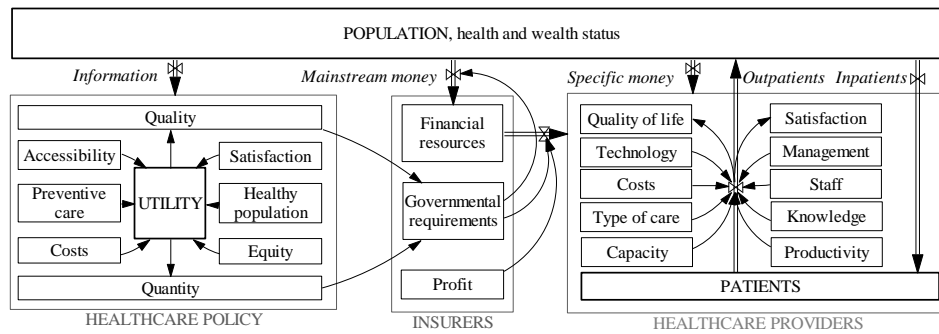

Figure 3: Simplified structure of presented problem

From the behavioral point of view, we can notice there that the population is characterized with its basic health and wealth metrics, such as morbidity (measure of diseased or unhealthy part of population), mortality (measure of dying part of population) and gross domestic product. These rates roughly determine basic inflows of money and patients to the system. Quality vs. quantity balancing policy, derived from public needs and preferences, considers and evaluates numerous wellbeing aspects from their financial demandingness point of view. Resultant governmental strategy represents a mandatory statute for health insurance collecting companies.

The healthcare providers' category is the most complex part of our model. It joins all practical stages, i.e. general practitioners, hospitals and post-acute care facilities, guaranteeing different types, speeds and acuteness of treatment. Both patients and medical staff are represented as aging chains with specific transfer conditions. Complex throughput of patients inside a facility is given by the level and structure of locally developed qualitative and quantitative features.

Left column in this box roughly represents the quantity, the right one is more concerned with quality. The level of patients' stock or the rate of their outflow is affected by any of the depicted categories. As a side effect beyond the retrieved health, outpatients returning back to population are also provided with long lasting, complex intangible

outcomes, called quality of life and overall satisfaction with health care. It is evident that these secondary features considerably affect any kind of their future interactions with this system. Moreover, satisfied discharged patients do not consume any healthcare resources and actively contribute to governmental budget.

6 Results and discussion

Overall dynamic behavior of presented prototype of quality driven national healthcare policy system is shown in Figure 4. Policy level of SD model was calibrated with public data of Czech Republic. The healthcare providers' part was implemented as array of structurally similar, but parametrically differentiated hospitals, interconnected with arrays of general practitioners and subsequent care providing facilities. All concrete parameters were derived from data, provided by selected local hospitals, municipal healthcare departments and the General Health Insurance Company.

The majority of core and advanced processes in this sector is financed directly from the mainstream money, coming either from governmental budget or from other regular private or public contributors. Although the utilization of such cash flow must obey numerous regulations, there is also space for profit generating activities of single insurers. We believe that the desired fundamental changes can be realized only by means of additional finances, dedicated entirely to systematic and sustainable inclusion of quality.

Their estimated amount over time is shown in figure 4a. According to basic scenario, amount of extra funding can be in certain periods of restructuring even higher than standard yearly healthcare expenditure. Focused finances develop infrastructure of providers, educate their staff and establish better managerial practices. Consequently, hospitals become more productive due to increased efficiency. Institutionalized managerial frameworks like Lean, Six Sigma, Total Quality Management or Theory of Constraints (Dahlgard and Dahlgard Park, 2006; Gareth and George, 2010) can minimize waste, standardize internal processes, make flows smoother, support teamwork, establish organizational learning, shift traditional management towards knowledge utilization, drop workload and enhance motivation.

According to basic parameterization, our model outperforms the original one after nine years. From then on, it requires non increasing expenditure and generates better health status of population, expressed in terms of life expectancy (figure 4c). Interesting is initially increasing amount of patients, served by the new system. One explanation is that

the quality driven care must naturally address more people than the original system. It is also probable that quality standards disallow discharges of not fully treated patients. Although the qualitative extension is expensive, total expenditure start to fall already in the fifth year of its operation.

a) Health expenditure

b) Number of patients

c) Life expectancy

Figure 4: Sample simulated courses of selected characteristics of suggested changes in national healthcare system (solid lines) and their comparison with simply interpolated outputs of its past behavior (dashed line).

System efficiency is visible from the comparison of curves on graphs a) and b) in figure 4. Although the new system serves growing amount of patients till the year seven, its overall costs drop already from the year five.

7 Conclusions

We proposed and through a computational prototype also validated idea of strategic orientation of national healthcare system on quality. This research hypothesis is based on assumption that high quality processes cannot lead to faulty outputs. Many studies confirmed that such assumption works well in general services or IT industry, where customers get their value only at the end of particular core process. Similar principles are applied also in electronics, where exhaustive testing of every single complex element is impossible. These neighbouring achievements suggest the reuse of applicable methodological features also in healthcare, because there are many similarities.

Perception of health services is subjective and can be affected in many stages of treatment. Quality, perceived by patients is very fragile phenomenon and its recovery is generally long-time and demanding procedure. Consequently, systematic and sustainable inclusion of quality to everyday healthcare practice can minimize these risks and make the concept of quality more deterministic.

Preliminary simulated results show that decomposition of national healthcare system into qualitative and quantitative part, followed by sophisticated development of the latter is a promising way how to improve this sector. As the proposed simple prototype behaves in accordance with available historical data and experts' opinions, we plan to refine the existing diagrams and study detailed behavioural features.

Structured Abstract

Purpose – Hospitals are the central institutions in our public health system and are an important economic factor. The required collaboration of a large number of different occupational groups necessitates efficient knowledge management. In the workplace, knowledge transfer occurs in all directions and involves the risk of not ideally making use of expert knowledge, process-related knowledge and know-how. The aim of the study was to analyse and depict the general framework of knowledge management in the health care sector. The study's main purpose is to raise awareness of the current situation in order to ensure an efficient transfer of knowledge.

Design/methodology/approach – Both a comprehensive survey of up-to-date literature and qualitative research methodology were utilised in this study. The qualitative research data consisted of ten in-depth interviews with graduates of the health and patient care sector in Austria. The interviews were evaluated with the qualitative content analysis method according to Mayring (2000).

Originality/value – The results of the interviews revealed that the respondents had a differing approach to the concept of knowledge in general. The situation in the health care sector as well as the importance of efficient knowledge transfer was given varying degrees of significance by the respondents. A unification of the approach towards knowledge management and transfer is needed.

Practical implications – It was found that adequate evidence-based knowledge management requires sensible and sensitive handling of health care staff in respect to individual, general and organisational knowledge. If these requirements are met, staff contentment will increase and patient care will improve.

Keywords – Knowledge Management, Hospital, Nursing, Psychiatric Nursing

Paper type – Academic Research Paper

1 Introduction

Hospitals as such are the central institutions in our public health system and have developed into an important economic factor over time. A hospital is an organization with a broad basis of knowledge, and structured in a way that creates many opportunities and challenges for knowledge management. Various professional groups work together to offer a variety of services on the basis of their competences, abilities, and knowledge (Glouberman and Mintzberg, 2001a, 2001b). Since the medical and paramedical professions are strongly oriented on best-practice and evidence based adaptations of procedures and treatments, there is a constant change inherent to the delivery of services and the services themselves. Moreover, constant cost-pressures and reorganizations require attention. This together creates dynamic conditions within the hospital as an organizational system, for the work groups, and for each individual.

For Haasis (2007), the employee's knowledge is one of the company's fundamental resources for the optimization of processes and is mainly created through combination in certain situations where acting (in a potentially new way) is required. The required collaboration of a large number of different occupational groups necessitates efficient knowledge management. However, in the workplace knowledge transfer occurs in all directions and involves the risk of not ideally making use of expert knowledge, process-related knowledge and know-how.

While the literature on knowledge management in the hospital is multifaceted and reaching from solely theoretical works to very specific empirical studies, general knowledge management contexts in nursing so far were not in the main focus. A systematic, well-functioning knowledge management in this profession, however, is highly relevant for ensuring patients are treated in the best way possible. In the context of nursing, this is especially relevant in the quality discourse, as this goes hand in hand with the question of how to bridge the theory-practice-gap. Many models were developed (Katenkamp, 2003), and Nishikawa and Kazuko (2007) even pose the question whether nurses are knowledge workers.

The objective of this paper is to portray the general condition of knowledge management in the health care sector of hospitals, and which ones prosper knowledge transfer between and within occupational groups leading to collective, organizational knowledge. According to Drucker (1994), taking care of providing accessible knowledge resources is fundamental for making flexibility, adaptability and innovation possible. The

main focus will be put on the nursing profession's perspective. The crucial question is how knowledge transfer can be improved, how new scientific developments can be reflected on, shared, and incorporated into daily practice. As the context in which nurses work is very varied and hard to generalize, we chose to focus on one background only. For this paper, we studied psychiatric nurses working in a hospital in Austria. With qualitative interviews, key opinions of ten experienced psychiatric nurses regarding these issues are examined in detail to create an entry point for creating a sustainable knowledge management system.

2 Background

Knowledge sharing can be regarded as an extra-role behaviour that is only shown when the conditions are favourable, i.e. in cases where the individual feels this behaviour would also benefit themselves. However, due to the complex conditions in hospitals outlined above, this situation cannot be taken as an automatic given. Knowledge sharing is more likely to be a matter of organizational politics. The latter is defined as „shared perceptions about the strategic or tactical use of power and influence (both formal and informal), networks, relationships, and knowledge (under conditions of uncertainty, ambiguity, or competing interests) in the service of decision-making, resource allocation and the achievement of individual, team and organizational goals“ (Albrecht and Landells, 2012, p. 5).

According to Glouberman and Mintzberg (2001a, 2001b), a hospital consists of four “worlds” or cultures: cure (physicians), care (nurses), control (management), and community (trustees). All these worlds employ other principles and sometimes have diverging goals, but have to be aligned in the service for the patient. However, due to the amount of ambiguity created, some potential for organizational politics can be expected. Therefore, knowledge management or knowledge protection will not only play a role between, but also within professional groups or worlds in the hospital. The focus in this paper is on the nursing profession, “care”, as Glouberman and Mintzberg (2001a, 2001b) put it.

Knowledge of employees in hospitals is often implicit (see Polanyi, 1966), experience based. It can be categorized as process, patient, service, and organization related knowledge. Process related knowledge refers to organizational processes and clinical paths, patient related knowledge is all data known about the patient. Service related

knowledge comprises all professional knowledge relevant for providing medical or paramedical services to the patient (it consists of theoretical plus experience based knowledge). Organizational knowledge refers to clinical practices, guidelines, etc. required for keeping up the hospitals' operation. (Bohnet - Joschko and Bretschneider, 2006).

Knowledge in nursing, according to Carper (1978), can be differentiated into four types or aspects, which are all equally important: empirical knowledge, intuition, personal knowledge, and ethics.

- (1) Empirical knowledge is based on systematically, rule-based collected, analyzed and interpreted scientific data. Data can be derived from measurements, sensations, interviews, reports, etc. The aim of this knowledge is to describe, explain and predict incidents relevant for nursing. Therefore, it is imperative that the analytical procedure is intersubjectively transparent.
- (2) Intuition is an implicit knowledge based on experience and empathy, a feeling which action would be right in a given situation. Externalisation is only possible in a retrospective way, for example by interviewing experienced nursing and analyzing their reports on specific occasions.
- (3) Personal knowledge also is considered to be implicit and is based on reflection on the own personality and on the individual's personal history in combination with their effects on interaction. The focus here is creating value congruence – the individual nurse's beliefs, values and actions have to be consistent (see also Verplanken, 2004)
- (4) Ethics refers to the moral aspects of nursing. Frequently, there is ambiguity of values, interests, goals – not only due to the different “worlds” in the hospital (see above). Nurses then have to take moral decisions based on explicit and implicit ethical knowledge.

(Carper, 1978)

How this knowledge can be put into action depends on the organizational context (organizational structure and culture, power issues, technical possibilities, access to information), the group context and individual issues like motivation and abilities. Rosenstiel and Comelli (2003) cluster these determinants of individual behaviour in the organization as individual ability and motivation, social desirability and situational possibility. Only in cases where the individual can and wants to show a specific

behaviour – here i.e. using and sharing knowledge – and the group of colleagues supports that behaviour and the situation allows for it regarding resources, the likelihood is high that the behaviour will really be put into practice.

How these factors interrelate and which aspects are highlighted by the employees themselves is subject of the following chapters.

3 Method

3.1 Data collection

Both a comprehensive survey of up-to-date literature and qualitative research methodology were utilised in this study. The qualitative research data consisted of ten in-depth interviews with graduates of the health and patient care sector. The interviewees were recruited in one hospital in the south of Austria and are experienced psychiatric nurses with diverse professional backgrounds to ensure a broad perspective. All interviews were done in German.

All participated voluntarily and were informed about the purposes of the study and that their replies would be quoted using a pseudonym (a number.). Using an interview outline based on the research interests, the individuals were asked about (1) how knowledge transfer takes place in general, (2) when and where knowledge is shared or new knowledge created, (3) which problems occur, and (4) which improvements were suggested. By doing so, we followed the tradition of the problem based interview, which is *“a theory-generating method that tries to neutralize the alleged contradiction between being directed by theory or being open-minded so that the interplay of inductive and deductive thinking contributes to increasing the user's knowledge. The appropriate communication strategies aim firstly at the representation of the subjective approach to the problem, secondly the stimulated narratives are enriched by dialogues employing imaginative and semi-structured prompts.”* (Witzel, 2000)

3.2 Sample

Three out of 10 were male, which is roughly also the percentage in the general population of (psychiatric) nurses. Five individuals were between 20-30 years old, one between 31-40 years old, the rest between 41-40 years old. One person already worked in nursing over 20 years, two between 15 and 20 years, three between 6 and 10 years, the

rest between 2 and 5 years. Before taking their degree in psychiatric nursing, three interviewees had worked as assistants in psychiatric departments.

3.3 Form of analysis

The interviews were evaluated with the qualitative content analysis method according to Mayring (2000, 2004, 2007). The concept comprises nine steps:

- (1) Definition of the material: only parts relevant to the research objective are used
- (2) Analysis of the interview situation: one-on-one situation, four interviews lasted less than half an hour, the longest 74 minutes
- (3) Definition of formal characteristics of the material: transcript of interview; dialect was corrected to regular German; in a second step superfluous parts were deleted (breaks, thematically irrelevant issues, etc.)
- (4) Direction of Analysis: the focus was to analyze how the interviewees experience knowledge transfer in their professional surrounding
- (5) Theory-based differentiation of research question: four major issues were investigated – (a) how knowledge transfer takes place in general, (b) when and where knowledge is shared or new knowledge created, (c) which problems occur, and (d) which improvements were suggested
- (6) Definition of Type of Analysis: the replies were pre-categorized by (a)-(d), where applicable new categories were defined.
- (7) Definition of Entities for Analysis: typically, sentences were the smallest entities for analysis
- (8) Analysis: see (6), the replies were categorized and then abstracted
- (9) Interpretation.

In the next section, the results of step 8 are presented.

4 Results

In a first step, 13 categories were created by analyzing the content of the interviews:

- (1) Definitions for knowledge sharing and transfer (KST) ,
- (2) Current Situation,
- (3) Importance of KST,
- (4) Situations of KST,
- (5) Types of shared and available knowledge,
- (6) Knowledge acquisition,
- (7) Handling of KST,
- (8) Reactions to KST,
- (9) Barriers to KST,
- (10) Benefit of KST;
- (11) Consequences of lack in KST,
- (12) Emergence of know knowledge,
- (13) Suggestions for improvements.

In a second step, these categories were assigned to the basic aspects of knowledge management processes. Categories (1)-(4) relate to the procedural context, categories (5) and (6) to the input, categories (7) - (9) refer to the process design, categories (10) - (12) refer to the effects, whilst category (13) remains the same.

4.1 Procedural context

The interviewees' own definitions for knowledge sharing and transfer (KST) ranged from simply stating that there are various ones (Int. 7 / L 14), to learning from others (Int. 3 / L 4-5), communication between students and professionals (Int. 1 / L 13), interactions in the course of shift changeovers (Int. 4 / L 3), and the note that how knowledge is transferred is highly influenced by hierarchical issues (Int. 7 / L 9-10).

Interestingly, most state that KST is of high importance to them (Int.1 / L 15; Int. 4 / L 6; Int. 5 / L 3; Int. 6 / L 10; Int. 7 / L 19; Int. 8 / L 11; Int. 9 / L 14; Int. 10 / L 14, 129), but of rather less for their (especially older) colleagues (Int. I / L 16-17; Int. 5 / L6; Int. 6 / L 12; Int. 10 / L 18), and of even less relevance for the organization (Int. 6 / L 14; Int. 9 / L 22; Int. 10 / L 22). Others mention the opposite regarding colleagues and organization, which is also obvious in the subjective evaluation of the current KST practices.

Regarding situations for KST, team meetings and shift changes are mentioned frequently (for example Int. 3 / L 116; Int. 7 / L 17), also breaks (Int. 2 / L 118 - 119), errors (Int. 3 / L 30 - 31), or new situations (Int. 3 / L 55). Nevertheless, time, attention and interest (Int. 9) as well as the own obligation to ask (Int. 5 / L 37 - 38) are stressed as determinants for creating situations of KST. The obligation to inquire seems to be highly important as "being asked" is mentioned by four interviewees, and "when asking someone" is stated by nine as occasion to share knowledge. However, this is not regarded as a matter of course, since (new) knowledge is often acquired during free time (Int. 8 / L 70 - 71). Evidently, there are also situations where knowledge is shared without a trigger question – some regard the situation itself to induce KST, whether others want to listen or not (Int. 4 / L 38-39).

3.2 Input

Regarding available knowledge, experience is rated very highly (see for example Int. 7 / L 59; Int. 10 / L 54), but also additional courses (see for example Int. 1 / L 48; Int. 7 / L 40). However, frequently the fact is lamented that the latter have to be attended during

off-time and are not even paid (Int. 3 / Z 90; Int. 4 / Z 51; Int. 6 / Z 29; Int. 8 / Z 21 - 22; Int. 8 / Z 44; Int. 10 / Z 63). Therefore, the interest of the organization in continuing education of the nursing staff is questioned.

3.3 Process Design

KST in the hospital is in a very early stage for some (Int. 5 / L 13; Int. 10 / L 19), leading to everyone creating their own knowledge anew (Int. 8 / L 76 - 77). As for reactions to KST, some state that asking may lead to being perceived as ignorant (Int. 5 / L 30 - 31), that some (thus) never show not knowing something (Int. 2 / L 20-21), and that colleagues can be envious to knowledge (Int. 1 / L 54). In Int. 6, low interest of others is mentioned, in Int. 10 the lack of value put on “school” knowledge is highlighted since experience is more praised.

Barriers to KST are lack of time (Int. 1 / L 90 - 91; Int. 2 / L 121; Int. 7 / L 19; Int. 9 / L 80) and shortage of personnel (Int. 1 / L 89; Int. 3 / L 213, Int. 7 / L 100 - 101) as well as lack of interest (see above), knowledge protection (Int. 2 / L 88), and too little communication (Int. 4 / L 66; Int. 6 / L 17; Int. 7 / L 64 - 65; Int. 10 / L 69 and L 95). Moreover, certain structural issues (general: Int. 6 / L 61; shift plans: Int. 7 / L 84) and lack of organizational interest in knowledge acquisition and transfer regarding nurses make KST difficult to coordinate (Int. 7) and thus unstructured (Int. 8 / L 62). Also, there are no incentives for practicing KST (Int. 10 / L 93).

3.4 Effects

The benefit of KST is stated to be better (Int. 1 / L 101) and quicker (Int. 4 / Z 82; Int. 6 / Z 77) patient care, or simply keeping the current services up (Int. 1 / L 25). Also, an improvement of collaboration (Int. 7 / Z 93), higher employee satisfaction (Int. 1 / L 100) and a quality boost for both patient and personnel (Int. 2 / L 104-105) are possible. In Int. 3 and 8, learning from colleagues is stressed as being helpful since time-saving (Int. 8 / L 86) and providing security (Int. 3 / L 73-74).

Inexistent or limited KST would lead to harmful individual consequences: the feeling of not being informed enough is regarded as strain (Int. 3 / L 144; Int. 7 / L 89 - 90) that could even lead to burn-out (Int. 2 / L 97 - 99). Negative effects are also expected for the patient (Int. 4 / Z 77; also: Int. 5, Int. 9), for example due to longer stays at the hospital

(Int. 2 / L 101; Int. 6 / L 74) or because the patient also receives too little information (Int. 10 / L 98 - 99). At the group level, tensions are expected due to the experienced strain (see before; also: Int. 5; Int. 9) and less synergies created (Int. 8 / L 76 – 77). Also, there are organizational dangers, for example in case errors occur due to lack of communication.

3.3 Suggestions for improvements

The suggestions for improving KST practices are manifold and can be subdivided into individual aspects group issues organizational matters and leadership. Interaction, participation and communication play central roles next to time management requirements. The ideas are highly practical and focus on creating more possibilities for KST as well as a new positive understanding of it. As they focus very much on the context of the specific hospital, they are presented only in short here. A major issue was providing more time for KST by changing shift times and structures plus implementing fixed times for team meetings, which was mentioned by almost all of the interviewees. This has to be backed up by the leadership (Int. 8 / L 95; Int. 9 / L 116; Int. 10 / L 107 and 120 – 121; see also Int. 2 and Int. 3), and the necessary physical structures (meeting rooms) are needed. Moreover, the organization should promote continuing education. Also, a bonus system was discussed to reward active KST (Int. 8).

5 Discussion

Both a comprehensive survey of up-to-date literature and qualitative research methodology were utilised in this study. The qualitative research data consisted of ten in-depth interviews with graduates of the health and patient care sector. The interviews were evaluated with the qualitative content analysis method according to Mayring (2000).

The results of the interviews revealed that the respondents had a differing approach to the concept of knowledge in general. This may be one of the reasons why the implementation of a knowledge management system is difficult: in when it is unclear what should be shared and transferred, the system cannot reach its potential (Howaldt et al., 2004) The situation in the health care sector as well as the importance of efficient knowledge transfer was given varying degrees of significance by the respondents. Many of the respondents' comments contain specific suggestions for improvements, for example regarding shift design.

Lack of time and sometimes interest in communication is a major barrier to an efficient KST. Also, the organization itself is not perceived to be highly supportive. One approach to incorporate more aspects into one intervention would be to implement mentoring systems (Swap et al., 2001). By doing so, the organization would show the value and importance of KST, those who have experience would feel valued and their knowledge wanted. The necessary structural issues would have to be provided for by the organization and the team (time, rooms). By ensuring one-on-one communication, fear of being perceived as ignorant would be reduced by the formalized setting (see also Coiera and Tombs, 1998) of an experienced and less experienced nurse. Eventually, the sharing would become mutual, as the newer knowledge (out of adapted study programs) of the younger ones would naturally be discussed, so all could profit. A further approach would be to incorporate more multi-professional teams working on problems, like in cancer boards. That way, and also in mentoring systems, the members of the organizations feel their own relevance in the KST process much more, which increases the likelihood of it to happen (Kvarnström and Cedersund, 2006).

6 Conclusions

It was found that adequate evidence-based knowledge management requires sensible and sensitive handling of health care staff in respect to individual, general and organisational knowledge. If these requirements are met, staff contentment will increase and patient care will improve. As this qualitative research has shown, findings from interviews can shed light on the major obstacles to efficient KST in organizations. In the context of the hospital where this study took place, a common definition of KST is required, which has to be created in a shared process started by the management. By doing so, the organizations' interest in the knowledge of its employees would become apparent, increasing motivation and the feeling of being heard and valued. For future research, the main findings of this study should be analyzed on a broad quantitative level in order to analyze the most important issues so an adaptation of the current knowledge management system can be carried out efficiently.

Structured Abstract

Purpose – Undesirable blocking of bed capacity by non-acute patients because of systematically unresolved ways of their transfer to convenient external facilities gradually restricts instant availability of local healthcare services and evidently requires systematic solution. In the presented research, we propose and analyse different scenarios, according to which the clinical social workers (CSWs) can influence the overall hospital throughput.

Design/methodology/approach – We propose two-stage system dynamics model of hospital, distinguishing between acute medical and discharge related activities. According to our research hypothesis, CSWs could contribute both internally or externally. As hospital staff members, they extend HR capacity and decrease workload of medical workers. Outside the hospital, they can negotiate the real necessity of admission or allocate appropriate post-acute capacity. Because of complex dynamics and inherent complexity, we consider interactive computational modelling as convenient tool, supporting analyses, planning or design of healthcare and social policies.

Originality/value – Delayed discharges are usually presented as suboptimal capacity problem with related managerial constraints, striving to administratively relocate patients to momentarily free facilities. We are specific in the following ways: (i) orientation on psychiatric patients with high risk of relapse in case of discharge to inappropriate social conditions, (ii) explicit introduction of CSWs to discharging processes, which enhances this problem with social aspects and (iii) utilization of intuitive language of stocks and flows, which is understandable for all involved parties.

Practical implications – This research transforms topic related knowledge and data to the form of interactive strategic planning simulator. Presented studies were realized in close cooperation with psychiatric hospital, where CSWs form inherent part of

multi-professional teams, altogether with doctors and nurses. All findings were thoroughly discussed with practitioners and their feedback promptly incorporated to model.

Keywords – Social work, hospital performance, dynamic modelling.

Paper type – Academic Research Paper

1 Introduction

Average length of patients' stay is essential, but still rather misleading indicator of hospital performance. The reason is that this metrics incorporates two naturally uncertain phenomena - duration of medical treatment and unnecessary time, spent by improved patients in hospitals. Although the first one can be hardly modelled, not to say optimised, the latter is an excellent candidate for redesign. Thorough investigations of multiple aspects of delayed hospital discharges are subject of research interest for decades. The reason why structural and behavioural features of differently occupied hospitals are so intensively analysed, discussed and improved is generally high price and limited capacity of hospital beds, accompanied with shortage of qualified resources and still unclear relations between hospital and surrounding environment. The following findings represent the most frequently repeating conclusions from reviewed resources:

- Keeping treated patients in hospitals or their strict discharge are strategically and ethically unbearable. There is a need for multi-professional hospital teams, dealing with social matters of patients, discharged from acute care (Costa et al., 2012; McDonagh et. al., 2000; Mur-Veeman and Govers, 2011; Victor et al., 2000),
- Systematic institutionalization of discharging process requires design of new working positions, providing additional assistance in social domain (Challis et al., 2014; Connolly et al., 2009; Godfrey and Townsend, 2009; Majeed et al., 2012),

- Special emphasis during the transition from hospital must be given on socially weak and psychiatric patients (Allen and Read, 1997; Capdevielle and Ritchie, 2008; Carpenter, 2002; Heng-Ching and Hsin-Chien, 2008; Huntley et al., 1997; Maone and Rossi, 2003; Ryu et al., 2006),
- There must be transparent internal interfaces between the hospital front-end (treated) and back-end (discharge planning) patients and defined external bridges between hospital precedent and subsequent stages (Bachman, 2011; Bruce et al. 2005; Huby et al., 2004; Paradis, 1987; Shepperd et al., 2009),
- Post-hospital capacities must be timely synchronised with amount and diagnoses of patients, planned for discharge to post-acute care (Allen, 2012; Golden, 2011; Goldman, 1982; Kiesler, 1982; McMillen et al., 2005).

These recommendations can be implemented by financially feasible extensions of deficit capacities or through particular improvements of efficiency. The following examples characterise some viable strategies:

- Hospital at home (Mottram et al., 2007; Shepperd and Illiffe, 2002; Young et al., 2012), i.e. service, in applicable cases providing active medical treatment by health care professionals in the patient's home for a limited period. The eventuality can also serve as a hospital bypassing bridge between general practitioners (GPs) and post-hospital facilities.
- Holistic discharge management, incorporating this activity to everyday planning, structuring, leading and controlling processes (Combes, 2002; McKenna et al., 2000; Parkes and Shepperd, 2003). This option assumes the existence of multi-professional, rapid response teams, interacting with patients continuously from admission and planning discharges in close connection with actual health status. Such systematic support results in deterministic and predictable internal flow of patients

There are also promising findings concerning the improved clinical care. The motivation behind is that high-quality medical processes produce less amount of post-hospital care requiring patients (Chung et al. 1997; Pavlin et al., 2002). Another researchers study possibilities of single roles, administratively involved in discharge process. For example, GPs can limit delayed discharges by lowering the hospital admission rate (Kendrick and Conway, 2003). In some hospitals there are discharge liaison nurses, responsible for related administrative, advisory and policy-making matters.

(van Emden et al., 1999). Nurses, however, cannot take full responsibility for discharges, because their official duties are limited to the hospital itself (Armitage and Kavanagh, 1996). According to our opinion, important but still not fully recognized role in discharge process can play also clinical social workers (CSWs). This specific type of non-medical hospital staff focuses mainly on social aspects of patients' treatment (Beder, 2006; Clarkson et al., 2009; Cnaan and Kang, 2011; Gibelman, 1995; Gil et al., 2013, Tendai, 2008; Watkins et al., 2012). Even if the role of CSWs is declared by law, range of their practical duties and competencies differs from one hospital to another. Standardized and efficient institutionalization of CSWs is problematic especially in countries with disjoint administration of health and social services.

2 Hospital productivity and its structural components

The main goal of our research was to identify, design and justify viable and transparent ways of inclusion of CSWs to everyday hospital operations. The convenience of such arrangement was analysed with respect to hospital productivity, combining its quantitative and qualitative characteristics (Davies and Davies, 2011). This one-shot organization-wide measure can be informally defined as a degree of ability to produce defect-free goods or services. In the simplest steady form, productivity is a ratio of cumulated outputs to cumulated inputs, e.g. *patients/labour*. Consequently, the desired growth of productivity can be achieved either by increasing the number of outputs with the same amount of inputs, by reducing the number of inputs with unchanged outputs or by any applicable combination of the both strategies. There are the following two major approaches, how to realize such adjustments:

- Quantitative, i.e. add more resources (people, money) and extend infrastructure (capacity, technology),
- Qualitative, i.e. harmonize and optimize both core and advanced processes, identify and minimize waste, educate people and actively employ organizational knowledge.

Usually, managers improve the both components simultaneously in a form of integrated frameworks like Lean, Six Sigma or Theory of Constraints (Jones and George, 2013). Beyond the simplifying *output/input* interpretation, productivity can be also expressed as a generally nontrivial function of effectiveness and efficiency. The former quantifies activities, contributing to the final effect or output,

i.e. healthy and satisfied patient in our case. The latter express the ease of effect creation. For example, patient can be clinically successfully treated in a slow, expensive and frustrating way. According to our understanding, such process is neither effective nor efficient, although there is still a discharged and possibly healthy patient at its end. The hospital treatment process could be called as effective if the discharged patients and their relatives feel comfortable in all its stages. In accordance with such assumptions, we split the presented CSW problem into three stages and two internal sub-stages as follows:

- Pre-hospital, i.e. input part, where prospective patients are examined by GPs and in justified cases sent to hospitals,
- Hospital treatment, applied to all admitted patients. Because our interest is focused mainly on treated and ready to leave patients, we divided this stage into the following two phases:
 - Front-end, consisting of hospital admission, assessment and acute treatment,
 - Back-end, incorporating post-acute treatment and discharge planning,
- Post-hospital, i.e. output part, considering discharges to home, home care, residential care or any other locally available type of post-acute care.

Consequently, productivity of hospital can be affected by changes in any of these stages or their interfaces. Health and social care, in contrast to for-profit domain, maximize utility of stakeholders rather than own earnings. Because of existing fragmentation of the both sectors and fragile nature of healthcare utility, we believe that governmentally legitimated and properly institutionalized CSWs can safely accompany patients through all the above-defined stages and continuously maintain appropriate level of their satisfaction. Resultant value for patients is evident, so the related key question is how to break the existing structural, functional and temporal complexity in order to built-in CSWs into the existing system in the right way.

3 Methodology and experimental design

Considering all outlined aspects, we decided to analyse the problem of hospital discharges by means of interactive computational model, developed in the language of system dynamics (Forrester, 1961, Warren, 2007).

This powerful tool belongs to family of systems science methods and has numerous successful applications in economy and management. Prior to model realization, we created corresponding conceptual model, the key part of which is the Causal loop diagram (CLD) (Sterman, 2000), summarizing the overall dynamics of presented problem. In accordance with figure 1, behaviour of proposed model is determined by four loops, three balancing and one reinforcing. Limiting effect of fixed hospital capacity and staff workload, slowing down the discharge rate, are generic internal behavioural patterns. What is not visible in the diagram, but is fully implemented in the model, are complex relations between workload, management and productivity. Computationally they are represented with nonlinear functions of teamwork, leadership, motivation, improvement and quality.

Analysed role of CSW is expressed with the additional two balancing loops. The left one limits the admission of new patients in the pre-hospital phase, i.e. on the level of GPs, external social and non-acute medical care providing institutions. The right loop matches the discharge rate with available external capacity. Stabilizing effect of both control mechanisms is evident. With early corrective actions, CSWs-induced loops can suppress capacity disturbances and relief internal pressures.

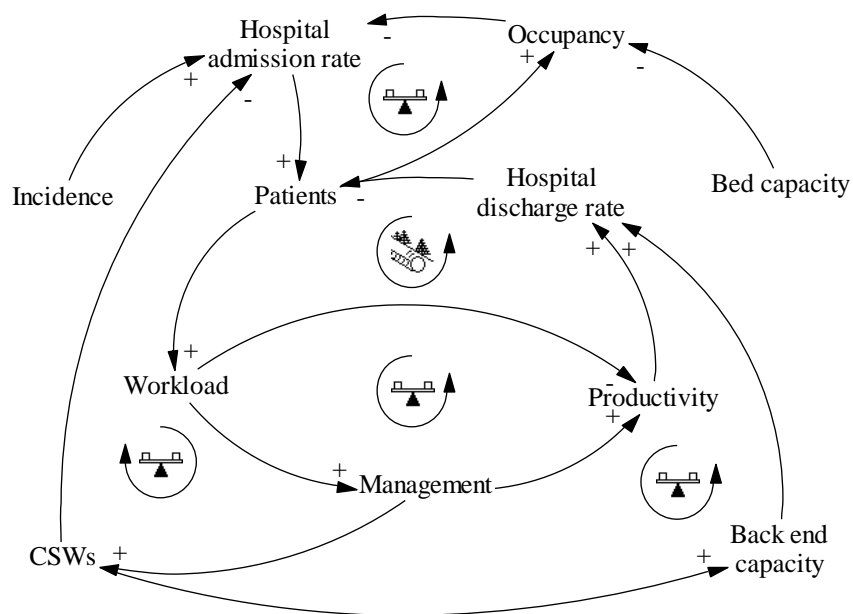

Figure 1 Conceptual Causal loop diagram of CSWs role in hospital

Resultant system dynamics model of patients flow is composed from the major diagnosis-dependent pathways, temporally divided into stages of introductory, acute, intermediate and post-acute care. Each phase is represented as a dynamically filled and drained stock of patients, controlled with parametrically adjustable valves. Similar formalization was proposed, e.g., by Wolstenholme et al (2008) or McKelvie (2013). In the desired stable configuration, the flow of inpatients is constant and equally distributed close to hospital effective capacity, i.e. admissions are approximately equal to discharges. If reasons for delayed discharges arise, patients start to cumulate in the affected stage. Such bottleneck slows down admission of new patients, which has multiple social and economic consequences.

Simplified functional diagram in SD-like notation is in figure 2. All valves (“sandglasses”) excepting the incidence rate are accessible also by CSWs. The flow of prospective patients from their homes or care facilities is primarily determined by incidence rate and partially also by readmission rate. CSWs, in cooperation with external medical and social workers, can partially close the upper left valve or even establish a hospital bypass. Thus the appropriate non-acute candidates for hospital care can be treated continuously in their original locations or moved directly from homes to any post-hospital type of care. Internal activities of CSWs, aiming to maximize the flow of patients through the hospital are oriented towards both its front-end and back-end stages. As a part of entry assessment team and based on knowledge of medical records, experienced CSWs can estimate future evolution of treatment and start to work on appropriate discharge option. Or, alternatively, from the very beginning they can prepare individual patients for the most convenient post-acute eventuality.

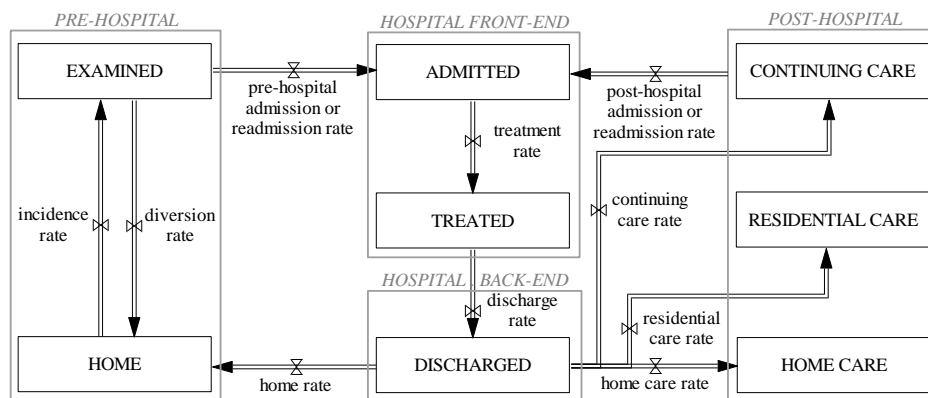

Figure 2 Simplified Stock and flow diagram of hospital in a wider context

Meanwhile, CSWs can play active role in post-hospital stage, either in planning of future capacities, prioritizing the waiting lists or participating in strategic development of this sector. Any long-time policy-making can be, however, realized only on the basis of exactly specified rules and responsibilities and in a close cooperation with local governmental both social and healthcare authorities.

4 Experiments

In the following experiments, quantity is characterized especially by numbers of patients in single stages and average durations of significant events, supposing fixed physical and process layout structure. Qualitative, i.e. efficiency related aspects, include satisfaction of patients and staff workload. In industries, dealing with specific services or intangible outputs, the quality of product is usually achieved through the quality of internal processes. Practically this means that sufficient number of motivated, relaxed, properly managed and continuously educated staff, equipped with appropriate tools and facilities can produce not only healthy, but also satisfied patients. In case of constant inputs, hospital operates around dynamic steady state. In adopted SD notation, this situation means smooth flow of patients through all its internal stages. Levels of patients' stocks are constant and reasonably below particular maximal effective capacities, derived during the structural design phase from historical data and with respect to maximisation of economies of scale. In practice, amount of incoming patients is time-varying. These changes are either inevitable, for example as a result of epidemically or seasonally increased incidence or induced, e.g. by slowed down medical processes or delayed discharging. The way of processing of external changes depends primarily on available infrastructural and HR capacities. Small fluctuations can be managed parametrically, i.e. through readjustment or redistribution of existing resources, supported with applicable extension of capacity. In such case, changes of stocks levels are managerially reflected shortly and without undesirable effects on patients' health status. Larger differences, however, cannot be handled in such way and require more complex restructuring, which is out of scope of this paper. Consequently, presented research deals with the typical case, when hospital operates just with a small reserve of capacity and any emergent changes must be solved with improved efficiency. The following cases analyse several typical scenarios, reflecting wide spectrum of applicable configurations.

4.1 Operations with constant input, appropriate constant capacities and without any contribution of CSWs

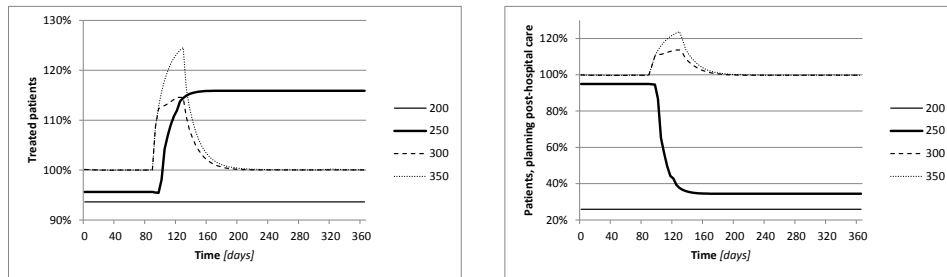

This example assumes ideal throughput, when all admitted inpatients are smoothly discharged to post-acute facilities. Input and output flows are equal, which leads to the constant levels of single stocks and minimal waiting times, workload and readmissions rate. Because all the below-presented graphical outputs are relative, it is useful to pinpoint their absolute, time-constant values here:

- Number of concurrently treated patients $N_T = 185$,
- Number of patients ready for discharge: $N_D = 25$,
- Number of patients, waiting for any non-acute post hospital care: $N_W = 30$.

It is evident, that in case of appropriate financing, there is no need for any changes.

4.2 Operations with bar input change, varying capacities and without any contribution of CSWs

To evaluate dynamic behaviour of hospital model, we increased amount of admitted patients for approximately 10% between days 80 and 120. Such rather unrealistic change is strong enough to discover system limitations and demonstrate its recovery possibilities. To study the role of capacity, we also performed system sensitivity analysis of this parameter. Because the effective capacity $C = N_T + N_D + N_W = 240$, we simulated behaviour for $C = 200, 250, 300$ and 350 with proportionally changing numbers of beds in all stages. Graphical representation of amount of treated and discharged patients is in figure 3. For insufficient capacities (i.e. $C < 240$), system is fully limited and cannot accept any additional inpatients. Logically, there are also no changes concerning the discharged patients. Their amount and resultant hospital productivity are low, because hospital back-end manages to distribute all treated persons to post-hospital facilities continuously. Curve for $C = 250$ shows such typical transient behaviour. Gradually loaded system cannot shortly incorporate additional patients and starts to cumulate them in the front-end. Their treatment is naturally delayed because of missing resources which, in turn, affects the hospital back-end similarly as in previous case. For higher capacities, however, the smooth long-time throughput is preserved, although there are capacity-dependent differences concerning the total number of processed patients. This happens because hospital with higher capacity can admit more patients, which lead to the sharp peak on corresponding graph. There is also clear capacity limitation effect for $C = 300$.

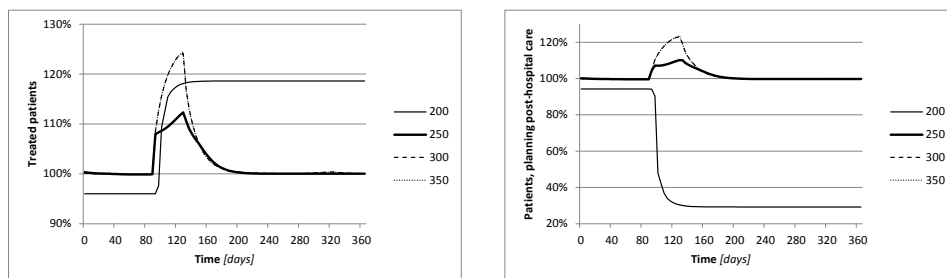

a) b)

Figure 3 Amount of patients treated (a) and discharge planning (b) with respect to available bed capacity and without involvement of CSWs

4.3 Operations with bar input change, varying capacities and entirely internal activities of CSWs

This analysis aims to recognize consequences of potentially rich internal role of CSWs, consisting - in accordance with figure 1 - of (i) partial extension of internal capacity with qualified undertaking of “social” duties of medical staff and minimization of related workload, (ii) active support of quality of care by establishment of partnerships with patients (clients) and their relatives, as well as (iii) distribution of collected findings among the remaining staff members. Figure 4 documents the achieved results. Positive role of CSWs recovers the previously lost throughput of patients - compare, e.g. graphs of treated patients for 250 beds in figures 3 and 4. The main positive is that this significant change is caused mainly by higher efficiency, because medical and structural resources remained unchanged.

a) b)

Figure 4 Amount of patients treated (a) and discharge planning (b) with respect to available bed capacity and with purely internally operating CSWs

4.4 Operations with bar input change, fixed capacity, internal and pre-hospital activities of CSWs.

Beyond the previously introduced internal duties, CSWs are active also prior to the hospital front-end, where strive to optimize the admission ratio through negotiations with GPs, because not every practical doctor is aware of other locally available medical facilities, than the hospital. Such effort can partially decrease the amount of inpatients.

4.5 Operations with bar input change, fixed capacity, internal, pre- and post-hospital activities of CSWs

This scenario maximizes possible utilization of CSWs with extension of their operations also to post-hospital area. There they observe free capacities and partially contribute to corresponding planning and management. Thus, requested non-acute places are available in the right time.

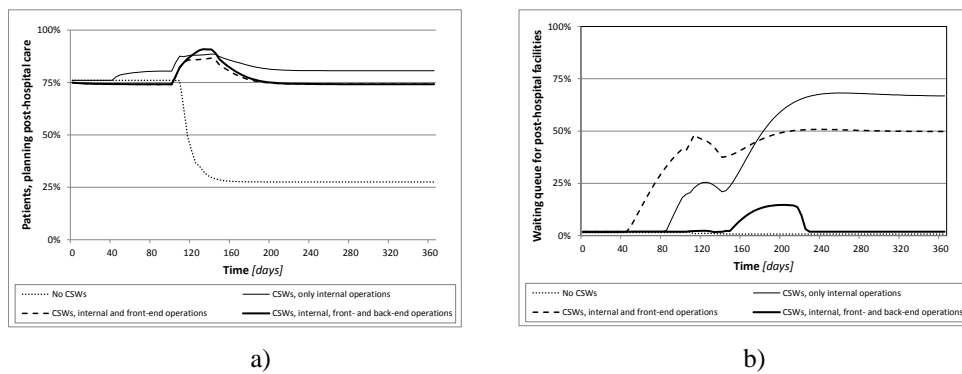

Figure 5 Amount of patients planning discharge (a) and waiting for available post-acute places (b) with respect to different involvement of CSWs. Total capacity $C = 250$

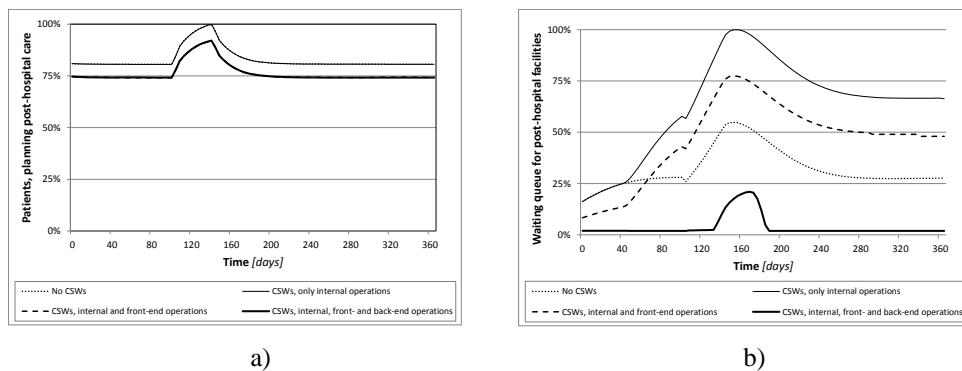

Figure 6 Amount of patients planning discharge (a) and waiting for available post-acute places (b) with respect to different involvement of CSWs. Total capacity $C = 300$

Comparison of effects of different types of CSWs utilization on amount of treated patients for different capacities is in figures 5 and 6. For clarity, all graphs have the same scale. In figure 5 with boundary capacity we can notice gradually summing positive effects of CSWs, compensating originally sharply falling throughput. In graphs of patients, planning post-hospital care, there is also visible the step difference in bed occupancy, given by pre hospital interventions of CSWs. Graphs of lengths of waiting queues visualizes the total instant availability of post-hospital facilities. Figure 5 a) gives approximately similar information as figure 4 a), i.e. that heavily loaded front-end resources cannot serve more incoming patents, which leads to considerable draining of back-end. As soon as CSWs start to act, the desired flow is recovered and demand for external post-acute services starts to grow. One can also notice that pre-hospital activities of CSWs don't have any real effect on waiting queue. This metrics can be improved only by active post-hospital operations, which are then able to serve the majority of demand (bolded solid lines in figures 5 and 6 b)). Figure 6 depicts efficiency of recommended arrangements for satisfactory capacity, quickly balancing input changes. Smooth flow always generates proportional excess of candidates for post hospital care. Supportive internal role of CSWs logically contributes to this trend. That's why their pre-hospital engagement just shifts down the whole waiting curve and only the active post-hospital operations can solve the problem of cumulation of waiting patients completely. Changes in post-hospital end are approximately two times slower, because of complex management of this part and low amount of dedicated resources.

4.6 Economic considerations

Acceptable amount of CSWs for given parametric configuration is also possible to estimate experimentally. Figure 7 illustrates the situation, when new CSWs are gradually included to hospital with fixed capacity $C = 250$ and indicates that optimal *CSWs:patients* ratio is between 1:30 and 1:50. From graphs b) in figures 5 and 6 it is evident that properly engaged CSWs can increase discharge rate up to 70% of patients, waiting for external post-acute placement. Let's suppose that in our concrete case this represents 15 patients. The costs difference between one day spent in hospital and in post-hospital bed can be estimated on 5% of monthly costs of one CSW position. The optimistic *CSWs:patients* ratio 1:30 says, that this hospital needs altogether 8 CSWs for assumed 240 patients.

Figure 7 Amount of treated patients with respect to amount of CSWs

As the additional monthly costs of unnecessarily occupied hospital beds, expressed in terms of CSWs expenses, are $15 * 30 * 0.05 = 22.5$, we can conclude, that CSWs services are also cost-effective.

5 Conclusions

We analysed the role of clinical social workers in problem of delayed hospital discharges. According to its system dynamic model, CSWs involved in multi-professional hospital teams can contribute to overall productivity by the following three strategies:

- Harmonization of internal operations, leading to (i) relief of socially oriented workload of medical staff, (ii) facilitation of transfer or treated patients' between hospital front-end and back-end and (iii) increase of satisfaction of patients and their relatives,
- Involvement in pre-admission stage, searching for applicable alternatives to hospital treatment,
- Demand driven planning and allocation of post-hospital capacities and contribution to development of related cross sector policies.

Our experiments justified positive effects of all these strategies on hospital productivity. Moreover, engagement of CSWs introduces also other, yet unquantified outcomes, arising from holistic character of our solution and shifting the task of discharges from purely hospital problem to the level of joint municipal and governmental health and social care planning. Transparent and interactive system dynamics framework contributes conveniently to practical applicability and user friendliness of developed computational model.

A prospective and participatory approach towards 'responsible' health research and innovation

Structured Abstract

Purpose – Non-publication of health research data results has serious negative impacts on people's lives. Ben Goldacre diagnoses and popularizes in "Bad Science" (2008) and "Bad Pharma" (2013) a vital "systemic failure" with many stakeholders and counterproductive practices involved so that information about randomized controlled trials (RCTs) are not put in the public domain to the extent that drug innovation is sufficiently effective. This paper presents a conceptual framework for understanding and supporting transformative knowledge-based change aimed at overcoming publication bias in clinical trials guided by the concept of 'Responsible Research and Innovation' (RRI).

Design/methodology/approach – When faced with high levels of uncertainty and complexity regarding future, scenario-based foresight offers itself as a promising system of inquiry. A 'system foresight' approach (Andreescu 2013) is based on the assumption that, firstly, inquiring into the future provides freedom to distance oneself sufficiently from the present; secondly, the future should be approached systemically; and thirdly, the processes whereby the future is explored should be participatory, i.e. as inclusive as possible.

Originality/value – The proposed methodology puts in evidence that in areas where complex decisions involving the coordination and the commitment of many different institutional systems and (large) organizations are at stake for transformative change, a strong prospective and participatory component is needed in order to provide a robust framework for 'responsible' governance of research and innovation.

Practical implications – The conceptual framework proposed was empirically applied as a structured stakeholder-based prototyping process within the context of the EU-funded project "UNCOVER". A value-based vision was laid out, together with procedural arrangements of feasible measures leading to pathways towards responsible future research and innovation in the realm of clinical trials.

Keywords – Responsible Research and Innovation; health innovation process; clinical trials, prospective approach; participatory prototyping

Paper type – Academic Research Paper

1 Introduction

1.1 The diagnosis: 'systemic failure' in health research and innovation

Results from clinical studies are an essential body of knowledge determining health research and policy making. Distortions in the publication and the dissemination of health research results have serious detrimental effects on people's health. Non-publication (i.e. not distributing results properly to stakeholders) may decisively reduce the advantage of systematic reviews of drugs, medical devices or procedures. It affects the knowledge base, patient value per outcome, and the level of public health. A recent review (Song, Parekh et al. 2010) concludes "that studies with significant or positive results are more likely to be published than those with non-significant or negative results." Non-publication of clinical trial results may lead to false conclusions about benefits and harms of medical interventions.

The sources of publication bias¹ are manifold. Song, Parekh et al. (2010) find that publication bias is often due to individual investigators' failure to write up and submit, which can be affected by pressure from research sponsors, preferences of journal editors, and the requirements of the research award system. Some scholars label "under-reporting research as scientific misconduct" (Rotonda 1990). Thus, the research system as a whole seems to fail to sufficiently consider ethical and societal effects of (non-) publication.

The available methods to prevent, reduce or detect publication bias target registration and publication of clinical trials to improve transparency and accessibility, primarily for systematic reviews. Self-regulation, voluntary agreements, good practice guidelines, and the like proliferate, yet the impact is limited (Glasziou, Altman et al. 2014). According to Strech (2012), the reasons against the obligation of complete registration and publication of trials lie in the protection of private data and commercial interests. This is particularly the case with industry-sponsored research (Melander, Ahlqvist-Rastad et al. 2003; Viereck 2009).

¹ *Publication bias occurs when the publication of research results depends on the nature and direction of the results. Because of publication bias, the results of published studies may be systematically different from those of unpublished studies. Publication biases can have different forms e.g. non-publication (never or delayed), incomplete publication (outcome or abstract bias), limited accessibility (grey literature, language or database bias), or other kinds of biased dissemination (citation, duplication or media attention bias). [Source: UNCOVER project]*

As Goldacre popularized in “Bad Science” (2008) and “Bad Pharma” (2013), there is a vital “systemic failure” with many stakeholders (public and private) as well as counterproductive practices involved so that information about randomized controlled trials (RCTs) are not put in the public domain to the extent that drug innovation is sufficiently effective and ultimately provides the best available treatment for patients.

1.2 In search for ‘treatment’

There are evidently systematic constraints on the consideration of societal needs and ethical aspects in the health research and (drug) innovation system which requires extending the scope and going beyond the research realm and addressing the whole “research and innovation process value chain”. The search for viable solutions to counter publication bias thus moves the attention towards future-oriented dimensions of responsibility that offer greater potential to accommodate uncertainty and allow reflection on purposes and values (Stilgoe, Owen et al. 2013). The necessary transformative shift in the governance of health systems towards more ‘democratic’ innovation calls for advanced approaches and methods of knowledge generation, use and exploitation with a stronger focus on participatory principles, i.e. engaging with a broader array of stakeholders.

This paper presents a conceptual framework for understanding and supporting change of current practice in (non-)publication of clinical trial results, guided by the concept of Responsible Research and Innovation (Von Schomberg 2011). The challenge is to adequately address a complex societal issue which encompasses several societal subsystems (health, science, economy, law, etc.). A transformative shift is called for and can be tackled by taking a prospective and participatory approach system approach. In the following, the general conceptual and methodological design will be presented and then its prototyping application for the case of publication bias in clinical trials.

2 Methodology and Design

We will first introduce the concept of Responsible Research and Innovation (RRI) as normative guidepost. Then system foresight, transformative scenario-building and participatory prototyping are proposed as systems of inquiry and vehicles for profound change towards more responsible policies and practices in health-related research and innovation processes.

2.1 Responsible Research and Innovation

Responsible Research and Innovation refers to the comprehensive approach that allows all stakeholders involved in the processes of research and innovation at an early stage (a) to obtain relevant knowledge on the consequences of the outcomes of their actions and on the range of options open to them, (b) to effectively evaluate both outcomes and options in terms of societal needs and moral values, and (c) to use these considerations as functional requirements for design and development of new research, products and services (van den Hoven 2013).

The RRI approach has to be a key part of the research and innovation process and should be established as a collective, inclusive and system-wide approach. So far, there is no coherent approach or guideline on how to integrate aspects of RRI in research and innovation processes (van den Hoven 2013).

2.2 System foresight

When faced with high levels of uncertainty and complexity as is the case with Responsible Research and Innovation in health, system foresight and transformative scenario-building offers itself as a system of inquiry.

Foresight is essentially a process of better understanding and preparing for the future. It explores what events or changes may occur and prepare accordingly to reduce risks and maximize opportunities. Whereas foresight is a broad concept which covers a wide array of prospective practices (Miles, Harper et al. 2008), larger-scale transformative change calls for 'system foresight'. System foresight (Andreescu, Gheorghiu et al. 2013) describes "a type of practice that

- has, as its object, large social institutions and the associated systems of organizations (such as education or Research, development and innovation);

- entails a participatory process involving diverse categories of actors and stakeholders; and

- aims to deliver, among others, a shared normative narrative of the future (often, a vision) as a guide to action. This normative narrative usually emerges as the result of some form of consensus among participants and therefore claims for itself a degree of representativeness or, at least, of inter-subjective agreement."

2.3 Transformative scenario-building

Scenario development comprises a set of methods for envisaging and exploring different potential ways the future may unfold. Scenario-building typically presupposes long-range futures in order to allow for structural, and hence more ‘profound’ change. A scenario-based foresight approach (cf. Andreescu 2013) relies on the following assumptions:

- In inquiring into the future, one must distance oneself sufficiently from the present to gain freedom which leads to better anticipation of the former.

- The future should be approached systemically and holistically with no part of the future system being considered as a priori more important than any other; and

- The processes whereby the future is explored should be participatory, i.e. as inclusive as possible. Distancing naturally makes room for a participatory and activist approach to the future. Whereas near, predictable futures are arguably sometimes best handled by experts, the latter’s role in the imagining or creation of futures appears less dependable.

Scenarios are thus convenient tools in the context of future thinking because several of their features enable broad participation (Bradfield 2005; cited in Andreescu 2013): they do not presuppose advanced technical skills from most participants, can accommodate a variety of inputs into the process, are quite flexible as a technique and format, and can be convincingly interpreted as a process-oriented endeavor.

Transformative scenario planning is a method or process to work with complex problematic situations that actors want to transform but cannot transform unilaterally or directly (Kahane 2012). It is thus useful for dealing with actors faced or associated with publication bias (see below) because of the following characteristics (Kahane 2012):

- Actors view the situation they are in as unacceptable, unstable, or unsustainable.

- Actors cannot transform their situation on their own or by working only with their friends and colleagues. Even if they want to, they are unable to impose or force through a transformation. The larger social-political-economic systems within which they and their situation are embedded is too complex – it has too many actors, too many interdependencies, too much unpredictability – to be shifted by any one person or organization or sector.

- Actors cannot transform their situation directly. Any attempt to implement a solution directly would only increase resistance and rigidity. So the transformations

must be approached indirectly, through first building shared understandings, relationships, and intentions.

2.3 Stakeholder Mapping and Participatory Prototyping

Scenarios rely on creative dialogue and participation. They should not only deliver fresh or original or heuristically useful insights, but also command the assent or the recognition of stakeholders (and often also of the communities whose voices they represent). Whether or not the transformative scenarios are actually followed by strategic commitments or policy action is less significant for their normative status.

Due to the weaknesses in clinical trial-related health research and innovation, the full potential of research and innovation is not tapped and which affects various actors as stakeholders at different levels and stages. Stakeholders are thus a central source for identifying feasible strategies associated with non-publication and its consequences, acting as barriers or facilitators. Stakeholder mapping identifies the relevant actors in a systematic manner. In the case of clinical trials, the mapping (Buchinger 2012) resulted in the following actor categories: journal publishers and editors, ethics committees, pharmaceutical industry, funding agencies, research institutions, trial registries, regulatory agencies, patient organizations, and political decision-makers. This landscape describes the “whole system” of stakeholders potentially involved in producing publication bias in the drug research and innovation process.

Based on ideas from participatory design, new constellations, issues and ideas are assumed to evolve from bottom-up co-creation amongst stakeholders. In participatory design, participants are invited to cooperate with researchers and developers during a creative process. They potentially participate during several stages of the process: they participate during the initial exploration and problem definition both to help define the problem and to focus ideas for solution, and during development, they also help evaluate proposed solutions.

4. Results

4.1 Prospective - participatory design and prototyping

The combined prospective and participatory approach for profound change was translated into a scenario-based multi-stakeholder dialogue and consequently

implemented as a prototype with the aim of identifying novel yet feasible measures to change practice towards producing robust health knowledge (Wagner-Luptacik et al 2013).

A small stakeholder team of about a dozen insightful and interested actors representing the “whole system” (cf. stakeholder mapping above) was convened. Due to the challenge of receiving positive response from all stakeholder groups, it was necessary to adapt the method and also include experts not directly involved yet sufficiently knowledgeable in the field to cover for absent stakeholder perspectives (e.g. industry).

The first step in scenario building with stakeholders was to observe what is happening and construct stories (= scenarios) about what could happen given a desirable long-term future vision. Scenarios are thought experiments or “heuristic devices” to break away from conventional thinking. As such, scenarios help identify threats, recognize opportunities and make choices about strategically important issues. Initial visioning about a desired distant future revolved around the questions: How kind of world do we want to live in? What kind of society do we want to create? The co-created vision can be described as guided by collaboration and communication (technologies), embedded in a clean and green environment with work-life balance and incremental changes. This reflects the notion of responsible innovation as “an endorsement of public values” (Taebi, Correljé et al. 2014). The vision served as the common basis for building scenarios on the focal question: „How can we minimize publication bias to maximize patient well-being, with a time horizon 2035?“ The resulting images present snapshots of possible futures - sketching boundary issues rather than fully characterizing all possible outcomes (Wagner-Luptacik et al. 2013).

In a second step, scenario enrichment aimed at discovering what can and must be done by whom to achieve a “systemic” solution for overcoming the detrimental effects of publication bias. Generating new insights about collaborative initiatives that might be pursued between stakeholders if this scenario 'world' became dominant – and considering how relationships might need to change to enable success. It thus had the specific purpose of helping to close the gaps between the current practices with the future vision. For this purpose, participants first developed options for separate action lines. They also drew conclusions about what each stakeholder will or can do and then explored opportunities and pathways for collaboration and joint actions. Though coming from different working

groups, the various activities converged towards one preferred scenario which ultimately tested positive for robustness and resilience.

During the next step – scenario consolidation - the various interventions produced in the previous scenario enrichment were clustered by an expert into several ‘blocks’. These blocks were classified into three major intervention types – ‘hard policies, ‘soft policies’ and general institutional context (Buchinger 2013). Whereas hard policy indicates public governance on the basis of legislation (including taxes, standards and other forms of binding rules), soft policy means public governance by guidelines, recommendations, declarations, self-commitment, voluntary agreements etc. Whereas hard policy changes behavior by immediately changing the choice set of addressees (i.e. hierarchical approach), soft policy changes behavior without (immediately) changing the choice set of addressees (i.e. market approach).

The co-created scenario resulted in the following measures to reduce publication bias: Hard policy basically refers to Mandatory Clinical Trial Registration with Facilitator WHO linking to Clinical Trial Registration Standards as complementary soft policy. Additional soft policies encompass Funding Policy and Journal Policy, both linked to Open Science & Web 2.0 as relevant institutional context, as well as Reward Policies linked to Empowerment as relevant institutional context.

The fourth and final step - scenario verification - allowed for final stakeholder participation by evaluating the consolidated scenario. Participants were invited to provide feedback on the three major intervention types and the various measures. They were also asked to rank the latter according to importance resp. power in changing undesired publication practice in clinical trials.

4.2 Practical implications

Responsible Research and Innovation features both a product and a process dimension (von Schomberg 2013). The participatory approach aimed to develop a deeper understanding of each other’s roles, concerns and potential for future action. The process facilitation focused on taking and maintaining a productive, adaptive and transformative stance throughout the process. The scenario-building process thus achieved two major outcomes. Firstly, by looking in a sustained and collaborative way into the future, it enabled novel insights about how needs for providing transparency about clinical trials and their outcomes might be addressed more appropriately and effectively in the future.

Secondly, the process provided a mechanism for considering the robustness of ideas in a range of possible futures - and in so doing might have helped build confidence in future collaborations between various stakeholder groups.

5 Conclusions

There is ample evidence that the non-publication of clinical trials results has serious detrimental effects on patients' treatments and consequently on society's health. "Problem space" and "solution space" involves many institutional systems and (large-scale) organizations as key stakeholders. This paper presents a combined future-oriented (= prospective) and stakeholder-oriented (= participatory) approach to prototype the necessary transformative shift. Whereas the prospective dimension emphasizes the long-term orientation and the potential of shaping a desired future, the participatory dimension emphasizes the adequate and timely inclusion of values by representative stakeholder 'voices'.

Contrary to thinking and acting in 'empty futures' (Groves), the concept of Responsible Research and Innovation (RRI) incorporates ethical and societal dimensions and thus opens pathways for 'desired futures', i.e. deliberate normative stances. RRI may thus be considered as a 'design' element (von Schomberg 2013) in research and innovation policies, programmes and practices. By laying out a clear vision and the procedural arrangements for governing future strategic conversations around issues of transparency and accountability in providing vital medical data, we hope to contribute towards (a) turning a 'problem' into a promise for more robust health-related knowledge, and (b) providing an exemplar of a coherent approach on how to integrate aspects of RRI in the governance of research and innovation processes.

The Role of New Media in Election Campaigns – Features in the Era Web 3.0

Eleonora Gabriela Baban *

Department of Marketing
The Bucharest University of Economic Studies
University Address: Piața Romană Street 6, Bucharest, Romania

Structured Abstract

Purpose – Currently in the “era of information” when information and technology represent “power”, the economic, political, social and business environment and not only these, have to adopt the challenges arising from the knowledge-based economy. In the contemporary context, information and technology have a decisive role in every individual's life, influencing his/her whole behaviour. When it comes to the political world, it may be mentioned that the use of new technologies in election campaigns (new media and social dialogue) have radically changed politics.

Design/methodology/approach – I propose an approach of new media in the context of the era Web 3.0. The paper is based on qualitative research, the main objective being that of investigating the impact of new media on social dialogue in the context of the era Web 3.0. By addressing a number of 10 questions already established to a group of 100 people (students at a University from Bucharest aged between 19 to 33 years) the role of new media in the context of the Web 3.0 is analyzed.

Originality/value – This methodology puts in evidence the role and importance of using new media in election campaigns by the actors of political life in the context of knowledge based economy. The main objectives of the study are: presenting new media in the context of Knowledge-based Economy (KBE) ; the definition of marketing in the contemporary context; highlighting the role and importance of political communication in the contemporary context; the analysis of the role of new media in the context of era Web 3.0. These objectives will serve as a basis for future research.

Practical implications – The outcomes of the application highlight the importance of using new media by political actors in order to obtain the electoral success by influencing directly the individual behaviour. Through the marketing research presented in this paper some ideas regarding the impact that new media have in the context of knowledge-based economy are presented. It is important to mention that some advantages and disadvantages of using new media in election campaigns have been identified, these issues being important for a campaign manager who aims at carrying out an election campaign.

Keywords –knowledge-based economy, new media, era web 3.0, political marketing

Paper type – Academic Research Paper

1 Introduction

The paper aims to make a brief presentation of the main features of new media in the context of era Web 3.0. In a contemporary context, information and technology have a decisive role in every individual's life, influencing his entire behavior. If we are referring to the political world, it can be mentioned that the use of new technologies in election campaigns (new media and social dialogue) has radically changed politics. In the last part of the paper the impact of using new media on voter behavior will be analyzed by presenting a qualitative research, because it is very important that “in an election campaign, it is essential for the candidate / party to know how to use the political communication tools, because this is the only way to get closer to voters, who need to be encouraged to grant the final vote” (Baban, 2013, p.435).

Depending on how the technology is used the Internet can be classified in “web 1.0, web 2.0, web 3.0, new media, etc.” (Toader, Grigorași and Frunză, 2011, p 179).

Toader, Grigorași and Frunză (2011) believe that in web 1.0 the website was just a tool, the information circulating unidirectional, and in Web 2.0 the Internet has become a virtual space “in which users interact and generate content” (Toader, Grigorași and Frunză, 2011, p 179). According to literature review, it can be said that nowadays web 3.0 aims at the dynamic framework of expressing communication, public relations and social dialogue.

By comparison, in the sphere of marketing one can also discuss about marketing 1.0, 2.0 and 3.0. Kotler, Kartajaya and Setiawan (2010) in the book entitled “Marketing 3.0: From Products to Customers to the Human spirit” present the “road” that the science of marketing has made in time. Thus, a shift has been made from an approach of marketing 1.0 (product oriented) to marketing 2.0 (consumer oriented) and marketing 3.0 (values oriented) (Kotler, Kartajaya and Setiawan, 2010, p 20).

Major changes in the last century have significantly influenced human behavior. If in the past they bought products to satisfy basic, elementary needs, now they purchase those products to satisfy their most sophisticated needs at a superior level.

It appears that the emergence of marketing 1.0 was favored by the Industrial Revolution and marketing 2.0 manifested due to technical development and technology. Currently, marketing 3.0 occurs due to the new wave in technology (Kotler, Kartajaya and Setiawan, 2010, p 21). But what is the new wave in technology?

Hogg, Howells and Milman (2007) consider that “some of the crucial issues which characterize consumers in the KBE relate to resources, firstly, to the new skills which they need in order to participate in the KBE; and secondly, to the assets, such as computers, that are needed to participate fully in many of the “virtual” aspects of the modern marketplace. Many of the electronic and technological tools needed to participate in the KBE require consumers to develop new technical skills” (Hogg, Howells and Milman, 2007, p. 153).

Kotler, Kartajaya and Setiawan (2010) believe that “technology allows people to express themselves and collaborate with other individuals” and “the new wave in technology gives people the opportunity to transform from consumers into proconsumers” (Kotler, Kartajaya and Setiawan, 2010, p. 21). But where can we find a proconsumer? A proconsumer can be found on Facebook, Twitter, YouTube, etc., becoming “both producer and consumer of information” (Sălcudeanu, Aparaschivei and Toader, 2009, p.28).

2 Overview of new media in the context of Knowledge-based Economy

Parent, Roy and St-Jacques (2007) believe that “knowledge is quickly becoming the prime source of wealth in the world, not only for corporation and individuals but also – and perhaps even more so – for nations and societies” (Parent, Roy and St-Jacques , 2007, p.81).

Becla (2012) considers that “the knowledge-based economy can be treated as an element of information society” (Becla, 2012, p.127). The same author presents several features of the KBE and information society, such as: (1). “the development of the information and telecommunicational infrastructure”; (2) “the advancement of the information sector”; (3) “the participation of information sector (information services) in the creation of the gross national product (GDP)”; (4) “the creation of useful information (scientific knowledge)”; (5) “the skilfulness level of filtering system to information by people”; (6) “the preparation of the educational system to information excess”; (7) “the range of information exclusion in society”; (8) “range and techniques of the effective interpersonal communication” (Becla, 2012, p.127).

In knowledge-based economy, information is “power”, the solutions of an effective communication being those organizational and technological conditions within organizations that rely on flexibility and rationality. Applying modern management the information gains more value which contributes to the effective achievement of

organizational communication. In KBE, information and knowledge as economic resources can be capitalized and improved. The main managerial challenges of information society are: the information offer is vast, what matters is people communicating with other people at great distances, with low costs, their number increasing significantly in recent years; consumption of information increases gradually, but surely; information is constantly used, however the offer is higher than the demand, which could lead to misleading potential users.

Gerstlé (2002) considers that political communication is currently “a field of knowledge in which the competition of main paradigms of political thinking and social sciences is fully reflected“; it is worth mentioning that “the behavior, the system, the interaction and dialogue allow labelling logics of analysis of political communication (Gerstlé, 2002, p 32).

In the literature review is presented the concept of “Internet – based services”, concept which “consider applications such as social networking websites (public or private), peer –to-peer networking, wiki applications, blogs, microblogs (e.g. Twitter) (..)”(Munive-Hernandez and Taticchi, 2012, p.1203). In the last decades, Webblogs (blogs) has gain popularity, being a new form and source of political news and information.

According to Kim (2011) “the Internet has been regarded as an important source of political knowledge and engagement in this line of research because the Internet has easily and cheaply available information” (Kim, 2011, p.976), because “new media is a growing force in the study of civic engagement” (Conroy , Feezell and Guerrero, 2012, p. 1535).

According to Touri (2009) “blogs offer an effective combination of expertise, real-time collective response to breaking news, and public-opinion barometer” (Touri, 2009, p.172). Campbell (2009) notes that “beyond a few specific examples of deliberate attempts at using new media for democratic communication, often on quite small, highly localised scales (...), an emergent focus of attention has been the increasing prevalence of blogs in number, content, and apparent impact on political communication” (Campbell, 2009, pp. 139-140). The same author notes that “in some developed democracies, the existence of vibrant and extensive political blogging networks is demonstrable, but their impact on wider political communication, even in election campaigns, is less so” (Campbell, 2009, p.140).

Jun (2012) considers that “political discussion in contemporary online environment may rather be interaction that generates exchange of political messages. Through such interaction among politically homogeneous Internet users, people can expose themselves selectively to political information” (Jun, 2012, p. 1452).

3 Analysis of the role of new media in the context of era Web 3.0

Jaffrin (2003) considers that “the Internet is bringing new means of communication. It is global, it is fast, and is growing rapidly. Reaching each corners of the earth, the Internet is making the world at once smaller and more connected, transmitting information at nearly real – time speed” (Jaffrin, 2003, p. 25). Also, Miller and al. (2006) quote by Neffati (2012, p. 245) notes that “the evolution of information depends on the nature of the economic, political, geographic, social, cultural and ethnic interactions which are strengthened by globalization and information network”.

A qualitative research was carried out in order to analyze the impact of using new media on voter’s behavior. A semi-directed interview was conducted on 100 people, with a discussion guide consisting of the following questions:

1. Do you believe that through websites candidates / political parties maximize their communication with the electorate in an election campaign? Please explain your answer.
2. Do you believe that new media (social networks, political blogs, etc.) provide the possibility of creating a direct connection between political actors and the electorate? Exemplify your answer.
3. Do you believe that this connection depends on how both voters and political actors adapt to communications means in the online environment? Please explain your answer.
4. Do you believe that political actors and voters need to follow certain rules of behavior in the online environment? Exemplify your answer.
5. Do you believe in an election campaign the Internet is a dynamic environment for sending electoral messages? Please explain your answer.
6. Do you believe that posts that candidates put on their blogs influence voter’s behavior ? Exemplify your answer.
7. Do you believe that those candidates who create their campaign message to voters according to their aspirations and values emotionally identify with them? Please explain your answer.

8. Do you believe that social dialogue between individuals is facilitated by the new wave of technology? Please explain your answer.

9. Do you believe that candidates, who promote technological innovation in an election campaign, can influence the final voting decision? Please explain your answer.

10. Please list what are the advantages / disadvantages of using new media by candidates / political parties in the era Web 3.0.

In the qualitative research gender structure is as follows: 17 % male respondents and 83% female respondents. Respondents are part of the following age groups: 1 % - 18 years old, 50 % - 19 years old, 37 % - 20 years old, 4% - 22 years old, 4% - 21 years old, 1 % - 24 years old, 1 % - 25 years old, 1% - 29 years old, 1 % - 33 years old.

Analysis of answers to the first question: At the first question respondents agreed that through websites candidates or political parties in an election campaign maximize their communication with voters; the following relevant opinions were distinguished:

“Yes , because communication becomes much easier and the information is transmitted faster” (Diana, 20 years old); “Yes , because now, political parties, candidates, supporters have accounts on different social networks and benefit from specialized websites that make information much cheaper than traditional methods of communication” (Simona, 20 years old); “Yes, as the Internet nowadays plays an important role in everyday life; people use it to get information on certain issues, for example, if a political party or a candidate has a personal blog, the voter can access that website and the communication does becomes effective given that both voter and candidate can transmit ideas quickly, with immediate feedback” (Cristina , 20 years old); “Yes , because it is an accessible method to those interested in finding out information about candidates / political parties, but it should not be the only source of communication with the electorate” (Georgiana , 20 years old); “Yes, because parties / candidates present their political offer more clear and in a more structured way, improving the communication with the electorate” (Marius , 19 years old).

Analysis of answers to question number two: 11% of respondents did not agree with the fact that new media offer the possibility of creating a direct connection between political actors and the electorate, and 89 % answered yes; the following relevant opinions being outlined:

“No, I don’t believe that new media offer the possibility of creating a direct connection between political actors and the electorate; indeed, through these media means

a connection is established, but an indirect one from my point of view, because one cannot compare an article on a candidate's blog, for example, with a dialogue face-to-face between the candidate and the voter" (Ionut , 22 years old); "No, because it takes a real interpersonal relationship and not a virtual one to create a direct connection candidate – voter" (Marius, 19 years old);

"Yes , I believe that new media offer the possibility of creating a direct connection between political actors and the electorate; through political blogs or Facebook voters can interact directly with politicians expressing desires and discontent" (Andrew, 19 years old); "Yes, because the ease and speed of sending messages online and in social networks creates the perfect environment for the transmission of personal thoughts and ideas" (Adrian, 19 years old).

Analysis of answers to question number three: 16% of respondents agreed with the fact that the connection created between candidate - voter depends on how both political actors and voters adapt to online communication means; 84% of respondents answered affirmatively; the following views were outlined:

"Yes , this connection depends on how both voters and political actors adapt to online communication means because through blogs they can invite political actors to direct conversations, through social networks, they can receive feedback at their posts, which can mean an approval, a positive response, support" (Marilena , 20 years old); "Yes, for this communication to be beneficial, people should be receptive and keep pace with technology in order to face the challenges coming from society, but also willing to seek relevant information" (Georgiana , 20 years old); "Yes, this connection depends on how both candidates and voters adapt to communication means because the more pieces of information they are willing to provide, the more the connection is stronger" (Claudia , 20 years old); "I believe that this direct connection depends on how the two sides adapt to online communication means , because if one party does not adapt in a positive way to online communication (nowadays, this type of communication being essential) then poor communication occurs between the parties, the connection created thus disappearing at some point" (Rodica, 20 years old); " No, I don't think that this connection depends on how both voters and politicians adapt to online communication means environment because I don't think there can be a direct connection, as long as there is only an exchange of ideas on a website, not a face-to -face confrontation" (Luana, 19 years old).

Analysis of answers to question number four: all respondents agreed that in the online environment, and not only here, political actors and voters need to follow certain rules of behavior; the following opinions were revealed:

“Yes , I think a certain decency must be preserved, namely adequate language” (Denisa , 24 years old) ; “Yes, I think that both online and in other case both political actors and voters must have a certain conduct” (Raluca, 25 years old); “Yes , they have to follow certain rules of behavior in order to strengthen a connection based on respect, so that the two sides can explain their opinions without insulting the others” (Alexandra , 19 years old); “Yes, rules of behavior need to be observed regardless of where they carry out their campaign because an elevated and respectful language is the basic element that facilitates effective communication” Cristina , 19 years old).

Analysis of answers to question number five: most respondents agreed that the Internet is a dynamic environment for sending election messages; the following views were outlined:

“The Internet is a primary factor for sending messages because many voters consult online news, blogs, social networks thus managing to form a positive or negative opinion about a certain candidate” (Valentin, 19 years old) ; “Yes, it is a dynamic environment due to the speed of sending information, but also because information circulates bidirectionally”(Alexandru, 33 years old); “In an election campaign it is very important for the information to be transmitted using new media in an effective way and in a timely manner so that the electorate is accurately informed, the Internet being a dynamic environment of sending messages on time, exactly when voters need them” (Rodica , 20 years old); “I think the Internet is the most dynamic way of sending election messages, given that it can be accessed anywhere; because of lack of time, people cannot participate in meetings organized by political actors and via the internet they can listen and read all the necessary details” (Ana -Maria, 20 years old); “Yes , as through the online environment the information transmitted reaches voters more quickly and has a much greater impact” (Maria , 20 years old); “Yes , because through social networks one can publish a large volume of information and the reaction of a large group of people can be easily monitored and evaluated” (Simona, 20 years old); “Yes, because in the online environment everything moves quickly , and if a message, an idea, a concept is good enough it will soon become popular” (Cristina , 20 years old).

Analysis of answers to question number six: all respondents agreed that the posts that candidates show on their blogs influence voter's behavior. The following opinions were revealed:

"Yes, a lot, because I believe that a good voter pays attention to all the details" (Andrea, 19 years old); "Yes , because it is very important for voters to get to know candidates better so that they form a solid opinion when granting the final vote" (Miruna, 19 years old); "I believe that the posts candidates show on their blogs influence voter's behavior because I believe that the information presented on the blog defines the candidate as a person" (Naziana, 19 years old); "Yes , these posts can have a certain impact on voters and can convince them, for this reason there are attempts to create convincing commercials" (Veronica , 19 years old); "Yes , posts made by candidates on their blogs can influence voters, though there are also people who are not easily influenced, so the quality of messages posted is very important" (Nicoleta , 19 years old); "The image that the candidate creates on his/her blog is a criterion that influences the choice of the electorate. For example, if on his/her blog the candidate does not speak only about politics, but also about his/her social life, he/she gets closer to voters, because voters want to get to know him/her as a person and not just as a politician, thus establishing a candidate - voter bond of trust" (Cristina , 19 years old).

Analysis of answers to question number seven: 62% of respondents didn't agree with those candidates who create their campaign message to voters according to their aspirations and values, who emotionally identify with them, and 38 % of respondents said yes; the following opinions were outlined:

"No, because these candidates can provide information which is not real in order to influence the electorate"(Cristina , 19 years old); "No, because voters are already used with these political clichés and with the same speeches" (Oana, 20 years old); "No, I think it is just a strategy of the candidate who wants to obtain more votes" (Mihaela , 19 years old);

"Yes , I believe that the campaign message is established by carefully studying target-voters" (Eliza , 19 years old); "Yes, because sharing the same set of values and aspirations can lead to harmonization of the connection between voters and candidates" (Anca , 19 years old); "Yes , I believe that candidates who create their electoral message according to the aspirations and of voters emotionally identify with them because

candidates want to find out the needs and desires of voters in order to come up with solutions to any problems “ (Roxana, 19 years old).

Analysis of answers to question number eight: the majority of respondents agreed that social dialogue between individuals is facilitated by the new wave of technology; the following relevant opinions were outlined:

“Yes , the new wave of technology has greatly facilitated social dialogue between individuals” (Monica , 19 years old); “Yes, because online environment allows fast communication between individuals” (Andra , 20 years old); “Yes , because candidates can now respond to voters faster and more efficiently, technological innovations helping both sides in the exchange of ideas” (Cristina , 19 years old); “By means of new technologies communication is effective and rapid, individuals are just a click away, which enormously saves their time” (Cristina , 19 years old); “Social dialogue can be facilitated by the new wave of technology as through social networks and blogs one can connect with other people from different parts of the country but also worldwide so we can learn more views on certain subjects” (Valentina, 19 years old); “Yes, I think the new wave of technology facilitates social dialogue between individuals because now you can communicate with low costs on all social networks whether you're at home or not, and much faster and easier” (Marilena, 20 years old);

“No , I think that the new technology eliminates emotion from communication, although it makes it easier; in a social dialogue, in addition to the information transmitted emotion transmitted between interlocutors plays a very important role” (Violeta, 19 years old).

Analysis of answers to question number nine: the majority of respondents agreed that candidates who promote technological innovation in an election campaign can influence the final vote. The following opinions were distinguished:

“Every promise has an effect. A part of the population, mostly younger generations will support technological innovation, while older generations and the disadvantaged population that has no access to technology will be more reluctant to vote for the candidate who supports technological innovation” (Georgiana , 20 years old).

“Depending on voters , some of them can be influenced, others not, depending largely on their aspirations and values” (Naziana 19 years old); “Yes, they can influence the final decision to vote by posts, arguments or projects that candidates can promote through technological innovation” (Liliana , 22 years old); “Yes, I believe that promoting

technology in an election campaign can influence the final decision to vote, each individual may be pleasantly surprised when the candidate keeps pace with what is new in technology” (Bianca, 20 years old); “Yes , because those candidates who promote and use new technology can spread information faster and reach voters, influencing them to grant the final vote through the content of those messages” (Marilena, 20 years old).

Analysis of answers to question number ten: question number ten identified the following advantages / disadvantages of using new media by candidates / political parties in the era web 3.0, as follows:

Advantages - rapid communication, accessibility, opportunity for a new method of transmitting the message, rapid and constant information, effective communication, visible slogans, low cost, the opportunity to receive immediate feedback, higher visibility, candidates / political parties can be easily promoted online, promptness of information, dynamic communication of election message, it is easier to interact online with younger population, complex and interactive information.

Disadvantages - the message sent is not accepted, older voters do not know how to use modern means of communication, messages sent can be false, information may not be accessed frequently, face-to -face interaction with voters is missing, in the rural areas not all people have access to the Internet.

4 Conclusions

Knowledge-based society is based on the existence of several driving forces that change the rules of the environment in which organizations operate. These driving forces are: globalization and information technology. Information technology includes in turn: knowledge / information, new media and computer networking. In a contemporary context where knowledge is the key element of any industry, new media promote online interaction between users, so knowledge / information becomes easier to access. Internet is the engine-factor of information society, globalization became a priority of the Internet which is the result of social interaction. Knowledge society is not possible without information society and therefore it should not be separated from it, knowledge meaning information.

From a theoretical perspective, this study aims to review literature in order to present the role and importance of new media in election campaigns in the context of era Web 3.0. In the last part of the paper, by presenting a qualitative research, the impact of using

new media on voter behavior was analyzed. Marketing research presented in this study may be useful for campaign managers who want to achieve an election campaign that can bring the results desired.

CSR disclosure on the WEB: an empirical analysis on the Italian context

Katia Furlotti*, Federica Balluchi

Department of Economics
University of Parma - Italy
v. J.F. Kennedy, 6 – 43122 – Parma

* *Corresponding author*

Structured Abstract

Purpose - The purpose of this research is to analyse the role covered by internet as a communication tools of social responsibility strategies implemented by Italian companies. The hypothesis that will be tested by research are:

HP1: Italian companies disclose their commitment to CSR on their websites, fully exploiting the potential offered by the Internet.

HP2: Sectors of activities affects the quality and quantity of the information disclosed and the way in which the information is provided.

HP3: Companies that have a specific website CSR section communicate a larger quantity of information than companies that give information in a not structured way.

Design/methodology/approach

We propose a descriptive research based on a quality/quantitative approach and is focused on empirical analysis on websites of the Italian listed companies. Websites are analysed on the basis of languages, map site, dedicated CSR section, and the content both for the general aspect of social responsibility and with specific focus on environmental responsibility and relationships with the community.

The phases of research process are:

- 1) formulation of research problem (purpose of study);
- 2) literature review relating to research problem and developing of a framework to identify the hypothesis;
- 3) empirical analysis and interpretation of the results;
- 4) conclusions.

Originality/value - The research intends to work in the path outlined by the international studies on CSR disclosure (many researches represent a key starting point: Coope, 2004; Esrock, Leichty, 1998; Morhardt, 2010; Morsing, Schultz, 2006; Sousa Filho, Wanderley, 2007; Tagesson et al., 2009; Xiao et al., 2004) in order to analyse the behaviour of Italian listed companies which will be analysed, in particular, with regard to the importance of the sector to which they belong in the choice of CSR disclosure via web.

This methodology puts in evidence the important use of the Internet as a communication tool, especially in recent years.

Practical implications - The research aims to highlight areas for improvement in CSR disclosure with focus on web communications.

Keywords - Corporate social responsibility, disclosure, internet, Italian companies.

Paper type – Academic Research Paper

1. Introduction

Corporate Social Responsibility Disclosure (CSR D) is the communication process of social and environmental effects of companies' economic actions with regard to all stakeholders interest. The formal commitment to inform and involve stakeholders needs an adequate flow of communication through suitable channels, focusing on relevant content.

In recent years, the recognition of a large and various groups of stakeholders has required the use of new media and the use of technological platforms has evolved over the years. In this sense internet is the best channel and it is used since 1990.

Several studies have demonstrated the importance of the internet platform for the diffusion of CSR information (see paragraph 2). This research intends to work in the path outlined by the international studies on CSR disclosure (many international researches on this topic represent a key starting point of this paper; i.e.: Coope, 2004; Esrock and Leichty, 1998; Morhardt, 2010; Morsing and Schultz, 2006; Sousa Filho and Wanderley, 2007; Tagesson et al., 2009; Xiao et al., 2004) in order to analyse the behaviour of Italian large companies, listed on the Italian Stock Exchange, which will be analysed, in particular, with regard to the importance of the sector to which they belong in the choice of CSR disclosure via web.

In other words, the main purpose of this research is to analyse the role covered by internet (website) as a communication tools of social responsibility strategies implemented by companies in Italy.

The hypothesis that will be tested by research are mainly three:

HP1: Italian companies disclose their commitment to CSR on their websites, fully exploiting the potential offered by the Internet.

HP2: Sectors of activities affects the the quality and quantity of the information disclosed on CSR and the way in which the information is provided by a company.

HP3: Companies that have a specific website CSR section communicate a larger quantity of information than companies that give information in a not structured way.

The research is a descriptive research and is based on a quality and quantitative approach; it is focused on an empirical analysis on websites of the Italian listed companies at 28 December 2013. Websites are analysed on the basis of languages, map site, dedicated CSR section, and the content both for the general aspect of social responsibility and with specific focus on environmental responsibility and relationships with the community (paragraph 3).

The research aims to highlight areas for improvement in CSR disclosure with focus on web communications

2. Theoretical framework

Corporate Social Responsibility Disclosure (CSRSD) can be defined as “the process of communicating the social, ethical and environmental effects of organisations’ economic actions to particular interest groups within society and to society at large” (Gray et al., 1987. See also Campbell, 2004; Gray et al., 2001; Mathews, 1993). The formal commitment to inform and involve stakeholders necessitates an adequate flow of communication through suitable channels, focusing on relevant content. CSRSD plays a key role in this commitment, and transparent reliable information is also widely considered important for legitimacy.

Corporate Social Responsibility (CSR), in fact, has become a key issue in recent years and the increased consideration for stakeholders implies a change in attitude and communication with them. The commitment to formal involvement by all stakeholders necessitates an adequate flow of communication in terms of channel and information relevance. In other words, disclosing social responsibility involves two key aspects; on one hand the firm meets commitments made to its stakeholders and on the other hand ensures a wider legitimacy through clear and reliable communication (Campbell, 2004; Cho et al., 2010; Deegan, 2002; Gray et al., 2001; Hess, 2008; Kaptein, 2007; Morhardt, 2010; Roberts, 1992). Full and reliable information is in fact a basic condition for development of the firm; profits and losses as well as how these are reached are made public knowledge and this creates the consensus necessary for the firm to flourish (Balluchi and Furlotti, 2013: 3 ff).

Companies have always used financial statements and traditional media (press

announcements, advertising campaigns on television and radio, newspaper and magazine trailers, bill boards and conferences) as communication channels.

In recent years, the recognition of a large and various groups of stakeholders has required the use of new media and the use of technological platforms has evolved. In this sense internet is the best channel and it is used since 1990.

Internet has been used in order to make the companies able to meet the needs of the stakeholders in an efficient way, providing great flexibility in the presentation and quality of the information (Bolívar, 2009: 179).

The last few years, have also been marked by the important diffusion of technologies that will support sociability and relationship: social networks, aggregators multimedia content created by users and blogs.

Several studies have shown the importance of the internet platform for the dissemination of information: Porter and Kramer (2006: 78 ff), DiPiazza and Eccles (2002: 127). Other studies have focused on the limitations of the instrument; for example, Esrock and Leichty (1998: 305 ff) revealed how the websites are not being used fully exploiting their possibility: although 80% of Fortune 500 companies have webpages that deal with at least one CSR question, sites are not used fully exploiting the potential of communication, in particular with regard to CSR issue.

In 2000, another survey by the same authors showed that this percentage has risen to 85% (Esrock and Leichty, 2000: 327 ff).

On the same topic, Coope (2004: 20 ff) highlighted how useful information are often hidden in the webpages and they are hard to find for the reader.

Other studies (described below) have attempted to correlate some company characteristics (i.e.: size, sector of activity, profitability, ownership structure, etc.) to CSR and, in particular, CSR by the web. Sousa Filho and Wanderley (2007) and Morsing and Schultz (2006) analyse general aspects of social communication on the web: and other researchers study the identification of some specific key variables that inspire the scope and content of CSR information on company websites (Tagesson T. et al., 2009). Esrock and Leichty (1998) and Adams (2002) refer to companies' size; Knox et al. (2005), Zeghal and Ahmed (1990) and Xiao et al. (2004) focus on the sector of activity to which companies belong; Belkaoui and Karpik (1989), Inchausti (1997) and Ng and Koh (1994) on companies' profitability; Adrem (1999) and Secci (2005) on the ownership structure of the companies.

This research intends to work on in the path outlined by the international studies mentioned in order to develop the analysis with reference to Italian companies, listed on the Italian Stock Exchange, characterized by large size which will be analysed, in particular, with regard to the importance of the sector to which they belong in the choice of CSR disclosure via the web. The assumptions outlined in the light of the theoretical framework are explained in the introduction (see paragraph 1).

3. Empirical analysis

3.1 Purpose

The purpose of empirical research is to analyse the role covered by internet (website) as a communication tools of social responsibility strategies implemented by companies in Italy.

Specifically, we arise the following research hypothesis:

HP1: Italian companies communicate information about their commitment to CSR on their websites, fully exploiting the potential offered by the Internet.

HP2: The sector of companies activities affects the CSR disclosure of a company.

HP3: Companies that have a specific section devoted to CSR communicate a larger amount of information than companies that offer information in a less structured mode.

3.2 Research methodology: definition of the sample

The universe of analysis consisted of companies listed on the Milan Stock Exchange, belonging to the STAR segment, on 28 December 2013 as recorded on the website www.borsaitaliana.it. Companies suspended from quotation or quoted on overseas markets were excluded; the final sample was of 66 firms (see Appendix for details).

The graph below shows the characteristics of sample in term of sectors of activity of companies. This information is essential in the light of the hypotheses being verified.

Graph 1 – Composition of the sample in terms of sector of activity

For HP2 Chemicals and raw materials, Health and Telecommunications are excluded because composed only by 1 firm.

3.3. Empirical evidence: data collection and results

The research examines the websites of the 66 companies using the grid shown in Table 1.

The time of survey (February 2013) is an important aspect of the research for the strong dynamics and for the updates of information.

Table 1. - Survey grid for the analysis of the companies websites.

WEBSITE STRUCTURE
Information in different languages
Site map
Navigation panel
CSR section
Direct link to the CSR section on the home page (for companies that have a specific section)
Number of “clicks” for accessing to the CSR section
Operating hyperlink
Number of sections (webpages, documents, etc.) dedicated to CSR
Format of presentation about CSR (text, audio, video, interactive resources)
Mistakes

WEBSITE CONTENTS
General aspects
Codes of ethic or guidelines
Social, environmental sustainability or intangible reports (social report)
Social performance indicators
Awards
FAQS section on CSR
Collaborations with external parties on CSR projects
Establishment of organizations that are dedicated to social responsibility in general
Projects about CSR (success or failure)
Commitments of social responsibility for the future
Environmental Responsibility
Environmental unit
Environmental Performance Indicators
Environmental policy statement
ISO 14001 Certification
Responsibility towards community
Welfare Policies
Document statement of ethics policy

The main results are shown below, making attention to the three hypothesis defined in our research.

HP1: *Italian companies disclose their commitment to CSR on their websites, fully exploiting the potential offered by the Internet*

The variables analyzed for testing hypothesis 1 refer to:

- the language used for give information;
- the presence of a CSR specific section;
- the number of pages dedicated to CSR;
- the structure of the website;
- disclosure on general aspects (code of ethics, social report, awards, ect.) and on responsibility towards environmental and community strategies.

Analisyng the availability of information in different languages, we observe that the majority of companies (65%) offers information both in Italian and in English language; 3 out of 66 companies (4.5%) disclose information in a single language, and 30.5% allows the choice between more than two languages (see Graph 2).

Graph 2 – Disclosure in one or more languages

More than half (51.5%) over companies surveyed (34 of 66) presents a special section dedicated to CSR on its website; among them, 53% have a immediately connection on the homepage, 23.5% use the heading “sustainability” and 15% of “social responsibility”.

45.5% of companies analysed, don’t present a CSR specific section and gives information scattered and less structured; 2 companies (3%) don’t give any infomation.

Different is the number of sections and pages devoted to CSR (see Graph 3).

Graph 3 - Presence of a specific section and number of web pages dedicated to CSR

The structure of website was assessed by analyzing the simplicity and the speed of browsing through maps or links.

The website of the companies of the sample are characterized by an important simplicity and browsing speed:

- 70% have a site map;
- 62% have a panel to search for information;
- 89% have a working hyperlinks.

In relation to the format of the presentation, more than half (58%) of the websites analysed use only text, the other presents also pictures, diagrams, graphs; 3 companies use also interactive documents (see Graph 4).

Graph 4 - Structure of the website

Referring to general aspects:

- 88% of websites contains a link to the code of ethics of the companie;
- 17% allows to download a social report.

In general, companies prefer to disclose on general aspects rather than disclose specific achievements in the field of social responsibility.

Only one company devotes a special section dedicated to frequently asked questions (see Graph 5)..

Graph 5 - General aspects

In terms of environmental responsibility and towards community, a few number of companies websites present in detail these topics. The most important information concerne (see Graph 6):

- ISO 14001 certification (41%),
- environmental policy (24%)
- and welfare policies put in place by the company (29%).

Graph 6 – Responsibility towards environmental and community

HP2: Sectors of activities affects the quality and quantity of the information disclosed on CSR and the way in which the information is provided by a company

The sectors of activity analyzed in more detail are those of industry, consumer goods, technology, finance and consumer services.

The data collected on the website structure and on general information are presented in the following graphs with refer to the single sector analyzed (Graph 7 and Graph 8).

Graph 7 - Structure of the website in different sectors

Graph 8 - General aspects

Regarding to the presence of information on ISO 14001 certification, policies and environmental documentation or information on welfare policies, the data collected are presented in the Graph 9.

Graph 9 – Responsibility towards environmental and community

HP 3: *Companies that have a specific website CSR section communicate a larger quantity of information than companies that give information in a not structured way.*

The final analysis compares the websites containing a specific section (34 companies) with websites that present CSR information in a less structured way (30 companies); 2 companies do not provide any information about CSR.

Regarding the number of pages dedicated to social responsibility disclosure, 93% of websites without the specific section devotes a few pages to this topic and 7% a discrete quantity.

With regard to companies with a specific CSR section, instead:

44% have a few number of pages about CSR;

38% a discrete amount of pages about CSR;

6% many pages about CSR (from 16-25);

2% more than 26 pages (see Graph 10).

Graph 10 - Number of pages devoted to CSR

80% of websites without specific CSR section uses a presentation by only format text; 38% of the websites have a section that uses more visual impact.

Other synthetic and less significant information relating to the structure of the website are presented in the Graph 11.

Graph 11 - Structure of the website

With regard to general aspects the results obtained can be represented as follows (Graph 12):

Graph 12 - General aspects

Finally, with regard to information concerning environmental and relations with the community, Graph 13 summarize the results.

Graph 13 – Responsibility towards environmental and community

4. Conclusion

Regarding HP1 (Italian companies disclose their commitment to CSR on their websites) is possible to underline a good availability of information regarding the CSR. The majority (65%) of the companies offers information in both Italian and English language. More than half (51.5%) has on its website a special section dedicated to CSR, although the majority of sites (64%) has a few pages dedicated to the theme of

sustainability (a number between 1 and 5). The businesses are not exploiting the full potential of the Internet as granted by approximately 2 out of 3 companies offer only minimal information on its website.

The simplicity and speed of navigation is very accurate in the websites analyzed: 70% of the companies have a site map and 62% offers a panel of navigation to facilitate the research of information; the percentage of sites that have operating links is 89%.

In terms of responsibility towards environmental and community, there are few websites that express these topics in detail. The most significant data are related to the presence of information on the ISO 14001 certification (41%), environmental policy (24%) and welfare policies (29%).

With regard to HP2 (sectors of companies activities affects the quality and quantity of the information disclosed on CSR and the way in which the information is provided), the sectors analyzed are those of industry, consumer goods , technology, finance and consumer services. The sector influences the CSR communication of companies, as in most of the aspects analyzed there is a prevalence of a particular sector than the other.

The industry and consumer goods, which are characterized by strong activity in environmental impact, offer a decent amount of CSR information but still insufficient. Enterprises belonging to these sectors should provide much more information than the others. In contrast, firms belonging to finance sector communicate information in a rather complete way, even if it is a sector with weak environmental and social impact. The areas of technology and consumer services were the ones that offer a less comprehensive CSR communication, many aspects are left out and not processed within the websites.

About HP3 (companies that have a specific website CSR section communicate a larger quantity of information than companies that give information in a not structured way), we can observe that it is fully confirmed. There is clear evidence that the websites that contain a specific section dedicated to social responsibility provide more information. This is because the companies that give much importance to CSR disclosure, usually submit information as complete as possible and easily detectable by the user.

The search can be developed considering a larger number of companies (for example considering all the listed companies and not only the ones belonging to the STAR sector) and a greater number of information (for example with regard to the relationships between company and different stakeholders such as employees, customers or consumers, and so on.)

Also the time variable represents an important limitation of the research. The data, in fact, are related to the month of February 2013 and the discussed results are usable for a specific period of time, since the information available can change very quickly with the risk of compromising the conclusions reached. This limit, however, represents a characteristic of a research whose purpose is to analyze the web site content.

Structured Abstract

Purpose – The purpose of this study is to verify the parental influence on the entrepreneurial intention of technical degrees students in Spain. In an economic crisis context such as the one Spain is currently suffering, entrepreneurship is often regarded as an opportunity for productivity increase and wealth generation, especially if it is technology-based. Therefore, the research of factors that may determine young engineers' attitude towards entrepreneurship is of great interest. Special attention is paid to parents' role as knowledge transferors, as their experience may have a positive effect on the entrepreneurial intention of their children.

Design – The proposed approach is the statistical analysis of a survey conducted on 1004 students in five different technical degrees at Universidad Politécnica de Madrid (UPM), the biggest technical university in Spain.

The survey explored the students' entrepreneurial intention and their perception of the support provided by their closer environment (family and friends) in case they decided to found a new company. Special attention is paid to the parents' current occupation as entrepreneur or civil servant, as this is believed to be relevant for the success of entrepreneurial knowledge and attitude transfer from one generation to the next.

Value – The existence of positive role models for entrepreneurship that through the transference of knowledge transmit the willingness to become self-employed have been found long before in the literature. Negative role models also exist, in the form of entrepreneurs that failed. In this research we present a new type of negative role model, which are the parents that work for the public sector. Empirical evidence is provided that, while self-employed parents grow children with higher entrepreneurial intentions, civil

servants tend to have children who do not feel the entrepreneurial professional perspective so intriguing.

Practical implications –A distinction can be made between the technological start-ups with high growth capabilities, which lead to productivity increase and wealth generation and those new companies in which the main scope is self-employment. In the foundation of the former is where technical universities can play a key role on economic development as a technology transfer vehicle to the society. However, universities can only foster entrepreneurial intentions in those students in which it is not hindered by their closer family. Therefore, it is crucial to assess to what extent parents' knowledge transfer can affect the entrepreneurial intention of technical degree students.

Keywords – knowledge transfer, entrepreneurship, family ties, technology-based companies, role models.

Paper type – Academic Research Paper

1 Introduction

Due to parents' role as knowledge transferors to their children, the existence of role models in the close family is determinant in the choice of the future professional career of young adults. This transference of knowledge and experience can take place either by *exposure*, in which the self-employed parents act as role models for their children, or by *closure*, providing financial or social capitals for the foundation of a new venture (Mungai & Velamuri, 2011).

The family, and especially father and mother, exercises great power over the desirability and feasibility for the process of the creation of a new company (Shapiro & Sokol, 1982). In this sense, determining the influence of the close family on the entrepreneurial intention and the transfer of business knowledge in students of technical degrees is the main objective of this study.

In a context of economic crisis, the founding of new technology-based companies is of the greatest importance (Hernández-Mogollón, 2014). Nevertheless, it has been stated that not all the entrepreneurial actions are of the same significance for economic growth (Shane, 2009). That is, necessity-driven entrepreneurship leads to founding of companies whose principal scope is the self-employment of the entrepreneur, and are usually regarded as low-value added companies with limited growth capabilities. On the contrary, high technology entrepreneurship (from the fields of Information Technology, aerospace engineering, bioengineered materials, nanoscience or advances in medical science, for

instance) can provide the economy with high-value added firms that foster economic growth.

However, there is a knowledge entry barrier for the foundation of such technological ventures. While entrepreneurial and managerial skills may be found amongst the population, the technical knowledge and expertise needed in technology-based companies are only found in individuals with engineering and other technical education and background.

In this research we analyze the influence of parental knowledge transfer to engineering students via positive and negative role models for their entrepreneurial intention.

2 Research framework

There are empirical evidences of parental transferences and support to their descendants across many different cultures. To cite a few examples, the transference of public working positions from parents to sons in Italy has been found by Scoppa (2009), the providing of material resources and services from parents to their young adult children in Taiwan and Philippines (Agree, Biddlecom, Chang, & Perez, 2002) or the inter-generational transmission of home ownership in the Netherlands (Mulder & Smits, 2012) have also been analyzed.

But the transferences from parents to children are not limited to tangible goods or working positions, being the choice of a professional career also influenced by them (Otto, 2000). In the case of self-employed parents, their influence on their children entrepreneurial intention has also been stated.

Research findings (Bosma, Hessels, Schutjens, Praag, & Verheul, 2012; Carr & Sequeira, 2007; Laspita, Breugst, Heblich, & Patzelt, 2012; Oren, Caduri, & Tziner, 2013) show a positive correlation between parental occupation as entrepreneurs and the likelihood that their children will become entrepreneurs themselves. They claim that parents are in a unique position to influence the future behavior of their children, becoming role models for them. Other studies have focused on the role model of the entrepreneur father and the influence it has on their children to become entrepreneurs. Lindquist et al. (2013) found that both biological and adoptive entrepreneur parents increase over 60% the chance of having children who are themselves entrepreneurs. It is

worth noting that the influence of the adoptive parents is twice than that of the biological parents.

Regarding the gender of the entrepreneur, many entrepreneur women look to their parents for advice, support and encouragement for entrepreneurship, while men want independence from their parents, especially from their father (Kirkwood, 2007). According to (Chlosta, Patzelt, Klein, & Dormann, 2010) a self-employed father increases the likelihood of children becoming entrepreneurs in the future, but moderated by aspects of his personality as the openness of the individual. Contrarily, mothers have been stated to be a more decisive influence in the choice of the professional career by Otto, (2000).

Nevertheless, the existence of a negative role model for entrepreneurial intention of descendants has been found by Mungai and Velamuri (2011). Whenever the father fails in his entrepreneurial activity, his children will be less prone to become self-employed, being this more pronounced in young adults.

As has been stated, the fact of having self-employed parents makes the likelihood of the children becoming entrepreneurs greater. Then, what could the effect of the parents employed by the public sector in the entrepreneurial intention of their sons be? It has already been mentioned than in collectivist cultures like the South of Italy parents who are civil servants help their descendants to become public workers themselves (Scoppa, 2009). This, together with the existence of negative role models for entrepreneurship provided by Mungai and Velamuri (2011), leads us to the research question of this study: Are self-employed parents a positive role model for entrepreneurial intention of engineering students while parents employed as civil servants are a negative role model? This issue has not been sought after so far, to the author's knowledge. The research question stated is depicted graphically in figure 1, with the two main hypotheses tested in this paper.

Figure 1. Model and hypotheses tested

There are several models for the development of the entrepreneurial action based on the intention of the individual. Here we rely on the Theory of Planned Behavior (TPB) model from Ajzen, (1991), which is described in the following.

Ajzen proposed in his theory that the intention is determined by three socio-cognitive factors: *attitude* toward performing the behavior, *subjective norms* concerning action, and *belief in one's ability* to perform successfully the behavior, in this case, the foundation of a new company. In a meta-analytic review of 185 empirical studies that applied the TPB, Armitage and Conner (2001) showed that it is effective in predicting both intentions and behaviors.

The TPB model is summarized in figure 2. Behavioral attitude is related to the level of attractiveness that the action has for the individual, which creates a favorable or unfavorable position to the behavior. Subjective norm represents the perception by the individual of the social pressure to pursue an action. Finally, perceived control is a factor that may facilitate or impede performance of the behavior, according to the perceived capability of the individual.

Figure 2. Theory of Planned Behavior model by Ajzen (1991).

The TPB model is used to provide the theoretical background of the hypotheses tested in this research. While H1 and H2 are based in the aforementioned research question, the sub-hypotheses H1a, H1b, H1c, H2a, H2b and H2c refer to the TPB model. The hypotheses under study are, hence,

H1. Self-employed parents act as a positive role model and knowledge transferors to their children, increasing their entrepreneurial intention.

H1a. Those students whose parents are self-employed, have a better attitude toward the founding of a new company.

H1b. Those students whose parents are self-employed perceive more support from their environment toward the founding of a new company.

H1c. Those students whose parents are self-employed show a higher perception of their capability for the founding of a new company.

H2. Parents employed in the public sector act as a negative role model and knowledge transferors to their children, decreasing their entrepreneurial intention.

H2a. Those students whose parents are civil servants have a worse attitude toward the founding of a new company.

H2b. Those students whose parents are civil servants perceive less support from their environment toward the founding of a new company.

H2c. Those students whose parents are civil show a lower perception of their capability for the founding of a new company.

3 Methodology

3.1 Procedure and variables

In order to explore how the family acts as a knowledge transfer asset for the creation of technology-based firms, a survey, addressing the different factors of entrepreneurial intention as well as information on the families, was created. This survey included items based on Ajzen's TPB (1991) and the three main factors that affect entrepreneurial intention, namely attitude towards the behavior, subjective norm and internal locus of control. These items were based on a previous study by Liñán and Chen (2009). As the main goal of the study was to explore differences according to the family influence, the survey also contained items concerning the parents' professional background, especially regarding if they were self-employed or civil servants. Other items explored if there were other people in the students' environment who carried out these kinds of jobs.

The study was conducted with engineering and architecture students of the Universidad Politécnica de Madrid (UPM), the biggest and oldest technical university in Spain. Data were collected at the beginning of the 2012/2013 winter semester during a four weeks period in five different degrees which count among the most traditional and

demanded ones at the UPM (Universidad Politécnica de Madrid, 2013), namely, Aeronautical Engineering, Architecture, Civil Engineering, Mechanical Engineering and Telecommunications Engineering.

3.2 Sample

Of the initial 1004 obtained answers, those of non-Spanish students were eliminated in order to maintain cultural homogeneity. As the items concerning the parents' profession were formulated in yes/no format and explored if the parent (not differentiating mother and father) was or was not e.g. a civil servant, those students who answered affirmatively for the civil servant and self-employed questions, were also left out. This way, the final sample considered for analysis comprised a total of 851 students. 67.3% of them are men and 32.3% women (0.4% did not give information about their gender), which is congruent with the fact that the number of men in technical degrees, and specifically at UPM, is usually higher than the number of women (Instituto Nacional de Estadística, 2012; Otero & Salamí, 2009).

As stated before, five degrees with great tradition in engineering studies and which count among the most demanded ones at the UPM (2013) were chosen for the present research. 31.7% of the sample were Aeronautical Engineering students, 18.3% were studying Architecture, 20.1% were enrolled in Civil Engineering, 24.2% in Mechanical Engineering and 5.6% were Telecommunications Engineering students. As differences may be expected according to the students' proximity to their graduation, and therefore entry into the labour market, data from students in their first and last semester of the degree were collected. This distribution was balanced with 50.9% of the respondents enrolled in their first and 49.1% in their last semester at university.

Concerning age, the sample had a mean of 20.52 years and a standard deviation of 2.90, being the youngest respondent 17 years old and the oldest 34.

4 Results

4.1 Descriptive results

If we consider the parents professional background, we find that 20.8% of the students claim that at least one of their parents has his/her own business. Parents who work as civil servants take up to 40.2% of the sample. Questions concerning other people in the closer

environment of the students were considered and it was found that 29.3% did not have anyone close who was self-employed. Similarly, 25.9% expressed the absence of civil servants in their close environment.

In this study, the impact of the family background and their knowledge transfer is considered, regarding the entrepreneurial intention of technical degrees students and the three main factors affecting it. These variables were measured through different items on a scale from 1 to 7. For these, we found in this sample that entrepreneurial intention was rated 3.57, this is, a medium score. If we look at the general means of the predicting factors we find that attitude was rated 4.87 meaning that entrepreneurship is viewed, in general, as an attractive professional option. The support respondents think they would receive from their parents and siblings is also high, with a mean of 5.64 in subjective norm. Finally, we found the lowest mean for the internal control factor ($\bar{x}=3.32$), which indicates that students see themselves as not very capable of creating and managing their own firm.

4.2 Data analysis

In order to analyze if the professional background of parents and social environment is affecting the entrepreneurial intention of technical degrees students, we conducted mean comparisons with Student's t-test. We compared the students who indicated that at least one of their parents was an entrepreneur, with those who stated that none of their parents was self-employed. The same comparison was carried out for possible sons/daughters of civil servants.

Table 1. t-test for entrepreneurial intention.

Family's professional background	N	Mean (1-7)	df	t
Parents with own business	177	3.91	844	-3.54***
Parents without business	669	3.48		
Parents civil servants	342	3.35	845	3.49***
Parents no civil servants	505	3.71		

***p<.001; **p<.01; *p<.05

Table 1 shows the results for the entrepreneurial intention variable. As can be seen, students who have parents with their own business have a significantly higher entrepreneurial intention than students whose parents are not self-employed ($t=-3.54$;

p<.001). Similarly, students with civil servants parents have a lower entrepreneurial intention than those whose parents are not employed in public services (t=3.49; p<.001).It can be therefore stated that the professional background of parents influences the entrepreneurial intention of their descendants, having children of entrepreneurs a higher intention to create their own firm and those of civil servants a lower intention.

For the rest of variables studied, the same pattern was found. As can be seen in tables 2, 3 and 4, students whose parents are entrepreneurs show a more favorable attitude towards entrepreneurship (t=-2.38; p<.01), feel more support (t=-4.29; p<.001) and see themselves more capable of doing it (t=-3.59; p<.001) than students whose parents are not self-employed. On the other hand, children of civil servants show lower means than students whose parents are not public employees in all of the three variables: attitude towards the behavior (t=3.12; p<.01), perceived support (t=3.19; p<.01) and internal control (t=3.67; p<.001).

Table 2. t-test for attitude towards the behavior .

Family's professional background	N	Mean (1-7)	df	t
Parents with own business	177	5.06	842	-2.38**
Parents without business	667	4.81		
Parents civil servants	341	4.71	843	3.12**
Parents no civil servants	504	4.97		

***p<.001; **p<.01; *p<.05

Table 3. t-test for subjective norm.

Family's professional background	N	Mean (1-7)	df	t
Parents with own business	177	6.06	841	-4.29***
Parents without business	666	5.54		
Parents civil servants	340	5.45	842	3.19**
Parents no civil servants	504	5.77		

***p<.001; **p<.01; *p<.05

Table 4. t-test for internal control.

Family's professional background	N	Mean (1-7)	df	t
Parents with own business	177	3.59	843	-3.59***
Parents without business	668	3.26		

Parents civil servants	342	3.15		
Parents no civil servants	504	3.44	844	3.67***

***p<.001; **p<.01; *p<.05

4.3 Discussion

As it can be seen in table 1, those students whose parents are self-employed rank higher in entrepreneurial intention, allowing for the acceptance of the first hypothesis of this study. This finding is not surprising, as it is in line with the results provided by (Bosma et al., 2012; Carr & Sequeira, 2007; Laspita et al., 2012; Oren Caduri, & Tziner, 2013), among others.

Contrarily, it has been found that parents who work for the public sector tend to hinder the entrepreneurial intention of their sons/daughters, as they have been found to have a lower mean in that item. That is, civil servants act as a negative role model regarding the foundation of new businesses. Therefore, the second main hypothesis can also be accepted. This is a far-reaching result, as to the authors' knowledge, it has never been assessed before.

Regarding the hypotheses linked with the Theory of Planned Behavior model, there is empirical evidence that supports H1a, H1b and H1c, stating that self-employed parents act as positive role models that increase their sons' attitude towards the creation of a new company, their perception of environmental support and their perception of their own capability, respectively.

With regard to the presence of negative role models, it has been found that sons/daughters from parents working in the public sector score lower in the three dimensions (attitude, subjective norm and perceived control) of the TPB model. Thus, hypotheses H2a, H2b and H2c are also confirmed.

5 Conclusions

The founding of innovative, technology-based companies with high growth potential would be of great importance in the context of the economic crisis that Spain is suffering. This highlights the important role of technical universities that feed the society with the professionals able to create such businesses.

In this research the results of a survey of engineering and architecture students from UPM, the largest technical university in Spain are presented. We analyzed how the parental occupation as self-employed or civil servant influences the entrepreneurial

intention of students from technical degrees. We posit that parents act as knowledge transferors to their sons/daughters, thus being determinant on their later career choice.

Our findings support that parents who own a business act as a positive role model towards the entrepreneurial intention of their children, while parents who work at the public sector are a negative role model.

These results obtained for entrepreneurial intention are also confirmed for the three dimensions that form the TPB Ajzen model. That is, a positive role model makes the students have a better attitude towards entrepreneurship, feel higher support from their environment with regard to the founding of a new venture, and feel more capable to succeed in case of creating a company. Contrarily, having parents who work as civil servants hinders the three dimensions of the model.

Ambidextrous organization and Innovative performance: testing the mediation effect of the internal networking

Lara Agostini, Roberto Filippini, Anna Nosella *

Department of Management and Engineering
University of Padova
Stradella San Nicola 3, 36100 Vicenza

Structured Abstract

Purpose - This paper has two aims: first to investigate whether an ambidextrous organization can be represented in a more integrated and complete way as a second order construct, reflected by contextual (managers social support and performance management context) and structural approaches (see figure below); second to examine whether internal networking mediates the relationship between the ambidextrous organization and its attitude to pursue high level of innovation ambidexterity.

Design/methodology/approach - To test our arguments, we carried out a survey in medium high tech industries, collecting data from a sample of Austrian and Italian firms. Data collection took place in 2011. In total, 185 useful questionnaires were received, resulting in an effective response rate of 13.5%. Structural equation modeling (SEM) with AMOS was used to examine the hypothesized model.

Originality/value - The results show that our second order theoretical model fits the data well and internal networking partially mediates the relationship between the ambidextrous organization and the innovative performance. This study contributes to the debate on organizational ambidexterity in at least two important ways: first, it shows that both structural and contextual approaches can be taken together and modelled as a second order construct, thus representing an holistic view of the ambidextrous organization. Second, this empirical study is one of the first to investigate the role that the ambidextrous organization has in fostering internal networking, which in turns affects innovative performance.

Practical implications - This study shows that the ambidextrous organization is not simply the result of either a structural solution or a contextual solution, but it should be made up of different organizational antecedents of ambidexterity that might complement one another. Together with the formal organizational structure, the role played by managers is fundamental since they foster employees to reach their objectives, to be empowered and to be free to decide how to divide their time and resources; furthermore managers should devote considerable effort to developing subordinates, giving creative challenges to their people instead of narrowly defining tasks..

Keywords – Ambidexterity, Internal networking, SEM

Paper type – Academic Research Paper

Introduction

Competitive pressure, rapidly changing and disruptive environments, frequent technological turnovers and shortening of product life cycles are all factors that characterize many industries in a globalized economy and require firms to continuously reconfigure structures and processes in order to sustain the current business and, at the same time, to generate innovations to meet or create future demands (Jansen *et al.*, 2008). In other words, firms should manage the tension between exploration activities that correspond to “the experimentation of new alternatives” and exploitation activities that refer to with “the refinement and extension on existing competencies, technologies, and paradigms” (March, 1991: 85). Here the concept of ambidexterity, defined as the capability of an organization to manage conflicting activities and tensions by achieving high levels of both simultaneously, comes into play as a possible solution to this concern (Nosella *et al.*, 2012). Since the pioneering work of Tushman and O’Reilly (1996), in both the academic and managerial practice there has been an increasing attention to this phenomenon, resulting in an increase of publications which mainly address the issue of antecedents and consequences of ambidexterity (Raish and Birkinshaw, 2008). As far as antecedents are concerned, literature has mainly investigated the effect that intra-organizational solutions can have on achieving ambidexterity; particularly, structural, contextual and leadership-based features have been analysed. Structural ambidexterity refers to the creation of separate organizational units specifically devoted to exploitation and exploration activities (Tushman and O’Reilly, 1996), while contextual ambidexterity emerges when leaders are able to shape an organizational context with proper degrees of performance management and social support (Ghoshal and Bartlett, 1994; Gibson and Birkinshaw, 2004). However, until now, few papers have empirically investigated the effect that adopting a structural design with elements of a contextual design has on innovative performance, even if there is an explicit call for research on this issue (Chang, Hughes, 2012). Indeed literature has outlined that an ambidextrous organization often contains both structural design and contextual elements (performance management and social support), thus emphasizing the importance of a simultaneous adoption of a comprehensive set of ambidextrous organizational approaches (Kauppila, 2010). Along this perspective, also O’Reilly and Tushman (2008) argue that the resolution of tensions requires organizations to be integrated around a culture which is shaped by top managers and tied up with an over-arching structure and complementary context. Starting from

these considerations, this paper focuses on the tension between radical and incremental innovation and aims at investigating whether an ambidextrous organization for innovation can be represented in a more integrated and complete way as a second order construct reflected by contextual and structural approaches.

Furthermore, recently some studies have provided evidence of the role these two ambidextrous configurations have in fostering internal networking for knowledge exchange, defined as the set of practices and methods through which individuals are linked together to create and share knowledge and experience (Ledwith *et al.*, 2012). For its nature, internal networking fuels innovation activities, in this way contributing to innovation ambidexterity, defined as the achievement of high levels of both incremental and radical innovation (Lin *et al.* 2011). Due to the often inconsistent use of the word ambidexterity (Lin *et al.*, 2011), for the sake of clarity we specify that ambidextrous organization refers to specific structure, context and behaviour that lead to innovation ambidexterity that thus is viewed as a “performance oriented outcome” (Lin *et al.*, 2011). Until now, the role of internal networking for knowledge exchange as a mediator between ambidextrous organization and innovation ambidexterity has not been investigated yet; consequently, this study also aims to examine whether internal networking for knowledge exchange mediates the relationship between the ambidextrous organization and its ability to pursue high level of innovation ambidexterity.

To test our arguments, we carried out a survey in the medium high tech industries, collecting data from 185 Austrian and Italian firms, using structural equation modeling (SEM). Results show that our second-order theoretical model fits the data well and internal networking for knowledge exchange partially mediates the relationship between the ambidextrous organization and the innovation ambidexterity.

The remainder of this paper is organized as follows. Next section presents the literature review and develops the hypothesized relationships. Then, the research methodology and analysis of results are presented before discussing them and illustrating implications of the study.

Literature review and research hypothesis

The ambidextrous organization

Since the founding work of Tushman and O’Reilly (1996), literature on management and organisation has addressed the phenomenon of ambidexterity that is defined as an

organisational capability that makes it possible to simultaneously manage opposing poles and tensions, such as: alignment vs. adaptability, comfort of the past vs. uncertainty of the future, exploitation vs. exploration of knowledge, radical vs incremental innovations. Being able to solve these contrasting tensions and thus realising ambidexterity has been demonstrated to contribute to superior performances (He and Wong, 2004; Gibson and Birkinshaw, 2004; Cao *et al.*, 2009).

The rapid emergence of the literature on the theme has caused an inconsistent definition of the construct (Lin *et al.*, 2011; Nosella *et al.*, 2012) which authors refer to as behavioral ambidexterity and structural ambidexterity (thus focusing on the organizational features that lead to the solution of tensions) or realized ambidexterity (thus concentrating on “the performance oriented outcome”, Lin *et al.*, 2011). In this paper we consider both perspectives, using the word ambidextrous organization in order to refer to structure and context, and innovation ambidexterity in order to encompass the achievement of high level of both incremental and radical innovation (Lin *et al.*, 2011; Chang and Hughes, 2012).

If on the one hand literature has investigated the performance implications of being ambidextrous, on the other hand there is an another growing body of research which has focused on investigating structural and contextual ambidexterity, as well as other factors and conditions that could lead to the development of this capability. Structural design refers to the creation of spatially separated units for solving contrasting tensions (Duncan, 1976; Tushman and O’Reilly, 1996; Benner and Tushman, 2003; He and Wong, 2004; Jansen *et al.*, 2006; Fang *et al.*, 2010), while the contextual solution sustains that organisations can solve constrasting tensions “by building a set of processes or systems that enable and encourage individuals to make their own judgments about how to divide their time between conflicting demands for alignment and adaptability” (Gibson and Birkinshaw, 2004: 211). In this last perspective, studies demonstrate that a context characterized by a combination of performance management and social support is associated with a higher level of ambidexterity (Birkinshaw and Gibson, 2004); performance management refers to a context where managers push employees to account for their actions and results, whereas social support is concerned with giving employees the security they need to perform their activities. In both solutions the abilities and the characteristics of leaders (Jansen, 2008) and top management teams (Lubatkin *et al.*, 2006) are critical as enabling factors of ambidexterity.

Most of the studies on this field analyse the impact that a single configuration – whether structural or contextual – has on firm performance, while there are few works that consider the possibility that structural and contextual ambidexterity are complementary alternatives that can coexist and alternate within the same organisation; in their review of the state of the art of the topic, Raisch and Birkinshaw (2008) suggest that the simultaneous effect of these approaches should be considered in order to understand how ambidexterity is likely to emerge. Along this vein, also O'Reilly and Tushman (2007) emphasize that resolution of tensions requires organizations to be integrated around a culture which is shaped by top managers and tied up with an over-arching structure and complementary context. To conclude, ambidexterity is a nested concept present at different levels into an organization which normally adopts both structural and contextual solutions (Birkinshaw and Gupta, 2013) interacting in a synergic way. Up to now, an integration of all the approaches is still lacking, “leaving an important gap in our knowledge of the theory and practice of ambidexterity” (Chang and Hughes, 2012). Building on these considerations, this paper aims at investigating whether an ambidextrous organization can be represented in a more integrated and complete way as a second order construct reflected by contextual and structural approaches. On these grounds, the first hypothesis is presented.

HYPOTHESIS 1: *Ambidextrous organization is a multidimensional, second-order construct, reflected by three first order ambidextrous organizational approaches (structural design, managers' social support, performance management context).*

Ambidextrous organizations, internal networking for knowledge exchange, innovation ambidexterity

The literature (Zhang and Zhao, 2006; Nilakanta *et al.*, 2006) has outlined that knowledge is a key element in business success; in fact, knowledge is one of the most strategically important asset in order to guarantee competitive advantage. Firms which introduce knowledge management practices will use their resources more efficiently and will be more innovative and perform better, as different authors sustain (Smith *et al.*, 2005; Darroch and McNaughton, 2002; Dougherty *et al.*, 2002; Hargadon and Sutton, 1997, Darroch, 2005). Particularly, many studies emphasize the fact that creativity and innovation are enhanced through the integration of different pieces of knowledge and

experience since existing ideas from one group of employees could be a novelty to another, thus leading to the development of potentially new products or processes. For this reason, firms more and more push individuals to interact and share knowledge with each other so that they can not only improve their capacity to solve problems (Nonaka *et al.*, 2006), but also create new knowledge (Van Den Hooff and De Ridder's 2004). A set of organizational mechanisms and practices have been suggested by the literature as a powerful method to favor the gathering and dissemination of knowledge in an organization, making it accessible to everyone. Using these practices would help individuals with different skills and experience to connect more easily in order to solve problems, learn new perspectives and generate powerful new ideas; internal networking for knowledge exchange has been proved to contribute to bringing together employees with different knowledge and background and to help teams connect with other people company-wide through network ambassadors (Ledwith *et al.*, 2012), thus being a powerful source of innovation.

Overall, as Bierly (2009) outlines, knowledge transfer and sharing are crucial to improve an organization's existing products, processes or services (exploitative innovation) and could lead to the development of new products and technologies in the case of exploratory innovation.

Investigating the role that internal networking and integration practices have in fostering innovation ambidexterity is a challenging issue which only recently has been addressed by the literature (Kamasak *et al.*, 2010). Gilbert (2006) and Westerman *et al.* (2006) are among the first authors who have posed the questions of how formal and informal integration mechanisms can increase the flow and recombination of knowledge in an ambidextrous organization. Furthermore, Kamasak *et al.* (2010) examine the impact that knowledge sharing, intended as a construct made up of the dimensions of knowledge donating and knowledge collecting, has on explorative, exploitative and innovation ambidexterity. The results of their studies carried out in a sample of middle- and top-level managers of Turkish companies show that knowledge collecting has a significant effect on exploitative, exploratory and innovation ambidexterity. As far as knowledge donating is concerned, results prove that it positively influences the ambidextrous and exploitative innovation in case it takes place within the same function, while it does not show impact in any kind of innovation when outside the function, thus being partially in contrast with previous mentioned findings. Finally, Nosella (2012) highlights that managing internal

knowledge creation is an important search strategy for both incremental and radical innovation and positively impact on ambidexterity.

Even if, as shown above, there are some papers dealing with the impact of internal networking for knowledge sharing on innovation ambidexterity, there seems to be little insights about its relationship with structural and contextual approaches. Among the fews, Jansen *et al.* (2009) show that connectedness, measured as the extent to which employees are networked to various levels of the hierarchy in their organization, influences employees' ability to share and recombine different sources of knowledge, thus mediating the relationship between structural ambidexterity and innovation ambidexterity. In this way a flow of knowledge between explorative and exploitative units is enabled and this bridge can favor the "search for new applications of exploitative efforts or help those organizational members who want to advertise their exploitative efforts in new areas" (Jansen *et al.*, 2009). Indeed, thanks to connectedness, organizational members share their experience, knowledge, and backgrounds. Subsequently, Andriopolous and Lewis (2009) find that structural solutions and integration mechanisms, which "stress interdependence between seeming opposites and enable coordination", should be used in order to solve paradoxes; integrative efforts enable the flow of knowledge between spatially separated units which otherwise would not be able to properly exchange and recombine it, in this way leading to innovation ambidexterity.

While the last mentioned studies deal with structural ambidexterity and integration practices, very recently the issue of contextual ambidexterity and internal networking comes up. Contextual ambidexterity has been analysed as antecedent of knowledge sharing at the level of interorganizational relationship, providing evidence of its positive impact (Ram and Im, 2008): in particular, the effect of contextual ambidexterity on performance is partially mediated by explorative and exploitative knowledge sharing in the case of the relationship with customers, whereas it is fully mediated for the vendor. Differently from the latter study, the paper of Clercq *et al.* (2013) carries out the analysis at the firm level, showing that the relationship between contextual ambidexterity and firm performance is positively influenced by firm's internal knowledge exchange; overall, to guarantee that "the simultaneous pursuit of alignment and adaptability leads to enhanced firm-level performance, the firm's different functional areas must freely share resources". Furthermore, also the paper of Lin *et al.* (2011) argues that a culture that promotes knowledge sharing has a positive impact on the emergence of innovation ambidexterity.

Building on these evidences, we can sustain that ambidextrous organizations, taken as a high-order construct, play an important role in fostering internal networking which in turns pushes the achievement of innovation ambidexterity. On these ground, the following hypothesis are presented.

HYPOTHESIS 2: *The more the firm uses internal networking for knowledge exchange, the greater the innovation ambidexterity will be.*

HYPOTHESIS 3: *Internal networking for knowledge exchange mediates the relationship between the ambidextrous organization and the innovation ambidexterity.*

Figure 1 depicts our research model.

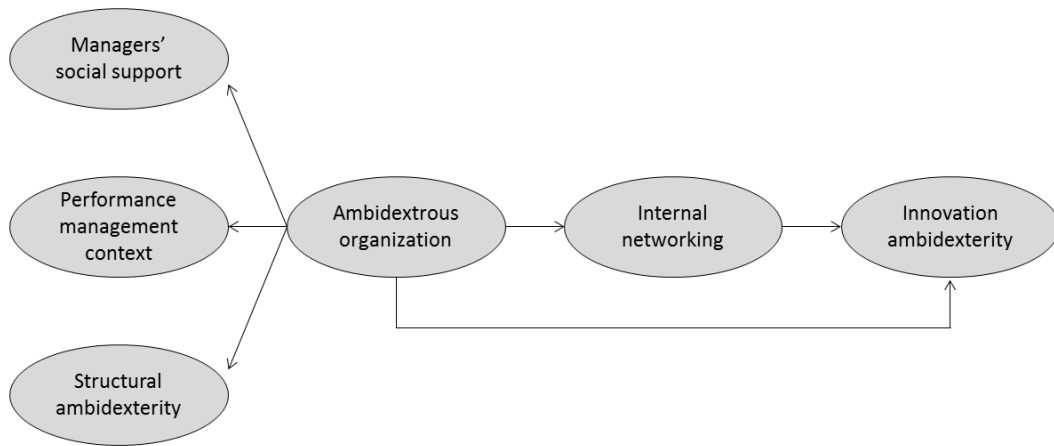

Figure 1: The research model

Research Method

Sampling and data collection

Data for this study were collected thanks to a survey in Italy and Austria. The target population frame consisted of high-tech companies with more than 50 employees and covering the specific two-digit NACE codes C20, C21, C25, C26, C27, C28, C29, C30, C32 (see the following table for a detailed description of the codes).

Table 1: Sectors included in the analysis

SECTOR	NACE CODE
Manufacture of chemicals and chemical products	C20
Manufacture of basic pharmaceutical products and pharmaceutical preparations	C21

Manufacture of fabricated metal products, except machinery and equipment	C25
Manufacture of computer, electronic and optical products	C26
Manufacture of electrical equipment	C27
Manufacture of machinery and equipment n.e.c. (not elsewhere classified)	C28
Manufacture of motor vehicles, trailers and semi-trailers	C29
Manufacture of other transport equipment	C30
Other manufacturing	C32

A total sample of 1370 firms was randomly obtained from Austrian and Italian commercial listings of firms having the characteristics described above. An on line self-administered questionnaire was used as the means for data collection; R&D managers served as respondents because they possessed the deepest knowledge about the R&D organizational and managerial design, the practices used to exchange knowledge for innovative purposes and the innovative performance. Companies were contacted by phone to introduce the research initiative, and an email, including the survey cover letter and an account for survey on line access, was sent to those who agreed to participate. In total, 185 useful questionnaires (85 Italian and 100 Austrian) were received, resulting in an effective response rate of 13.5%. The response rate is within the accepted range of typical response rate for this typology of study.

Data collection took place in 2010-2011.

Measure and operationalization

As far as independent variables are concerned, we used already well validated scales.

Social support context and performance management context were measured using the scale taken from Birkinshaw and Gibson (2004). The four-item measure for “Social support context” (SSC) captures the extent to which management systems in the organizations encourage people to challenge outmoded practices, and devote considerable effort in developing subordinates, pushing decisions down to the lowest appropriate level. The three-item scale for “Performance management context” (PMC) captures the extent to which managers use business goals and performance indicators to run their business.

The independent variable “Structural ambidexterity” (SA) was measured using 2 items taken from Jansen *et al.*, (2009), asking the respondents to indicate the extent to which they agree or disagree with some statements about the extent to which

organizations segment the activities involved in the innovation process into separated units.

As far as the mediation variable is concerned, internal networking for knowledge exchange (INK) was measured using the scale taken from Ledwith *et al.* (2012) and Nosella (2013). The three-item scale makes reference to the use of methods that help organizational members with different backgrounds and skills to connect in order to exchange knowledge and experience and to learn new perspectives.

The dependent variable, innovation ambidexterity (IA), was calculated as the multiplicative score between explorative and exploitative innovation, as suggested by the literature (Gibson and Birkinshaw 2004; Gupta *et al.*, 2006). Explorative innovation (EXR) and exploitative innovation (EXT) were measured using 4 items each, adapted from Atuahene-Gima (2005). The respondents indicated the extent to which they agree or disagree with eight statements about the extent to which organizations, over the last three years, acquired respectively new or improved knowledge.

All items for the constructs used in the present study were assessed on a 5-point Likert scale ranging from 1 (completely disagree) to 5 (completely agree).

Appendix 1 presents a detailed description of all items.

Statistical procedure

Our methodology consisted of an explorative and confirmatory factor analysis and a structural equation modelling (SEM) to test and measure our conceptual framework using the software R (package lavaan).

Results for the measurement model

Scale validation

To ensure that all criteria had the desirable characteristics of dimensionality, convergent and discriminant validity and reliability, we conducted several analyses.

Convergent and discriminant validity

Principal component analysis with promax was conducted to identify and confirm the different factors under each construct in our conceptual model. First, we run exploratory factor analysis (EFA) removing items with a factor loading lower than 0.4 or items which load with value greater than 0.4 in two factors. The results of the EFAs are shown in appendix.

Confirmatory factor analysis (CFA) was then run on all the items and it clearly replicated the intended factor structure, with each item loading on its intended factor. Thus, all items are significantly related to their underlying constructs, thus proving support for convergent validity; all standardized parameter loadings were significant (p-value < 0.001) and ranged from 0.4 to 0.8, with most of the items greater than 0.6 (see appendix 1). Furthermore composite reliability was assessed by checking whether the composite reliabilities exceeded 0.6: as shown in table 3, the requirement is satisfied by MSC, PMC, INK, EXR, EXT, thus indicating that items relate well within each latent variable. We further assessed discriminant validity by examining Cronbach's alpha, which shows alphas higher than the acceptable threshold of 0.60 (Nunnally, 1978).

Finally, unidimensionality was assessed by the overall model fit that can be tested using the comparative fit index (CFI), incremental fit index (IFI), Normed Fit Index (NFI), root mean square error of approximation (RMSEA), and normed chi square (i.e. χ^2 per degree of freedom) (Bryne, 1989; Hair *et al*, 2006). All the indexes (see appendix) indicate that the data acceptably fit the model. In addition, results provided strong evidence that the measures are of good quality .

Table 2 presents the correlations of the studied variables.

5. Model testing: analysis of the structural model

Ambidextrous organization was conceptualized as a second order model made up of three dimensions. The structural model was used to determine whether a high-order factor model is appropriate; results are shown in Figure 2. All standardized path coefficients were statistically significant at p-value <0.001, ranging from 0.765 to 0.923, supporting H1. The target coefficient (T) index is employed to assess the fit of the second-order

factor model relative to the first-order factor model, as suggested by Marsh and Hocevar (1985). The target coefficient is the ratio of the chi-square value of the first-order model to that of the second-order factor model, with an upper limit of 1.0. A target coefficient value of 1.0 was obtained, which indicates that the second-order factor model could completely explain the relationships among the first-order factors (Marsh and Hocevar, 1985). Furthermore, the fit statistics for the second-order model were CMIN=28.250; CMIN/DF=1.177;CFI=.990; NFI=.985; RMSEA=.031, thus indicating an acceptable fit.

(all the error terms are not shown for the sake of brevity)

†No p-value means that the parameter has been fixed at 1

Figure 2: Second-order representation of ambidextrous organization (AO) (Hypothesis H1)

When we tested for mediation, the following conditions had to be satisfied: 1) the independent variable must influence the dependent variable; 2) the independent variable must influence the mediator; 3) the mediator must influence the dependent variable; 4) the effect of the independent variable on the dependent variable must decrease in the presence of the mediator. Full mediation is reached when all the previous conditions are met and the influence of the independent variable becomes not significant in the presence of the mediator. If all the conditions are satisfied, but the influence of the independent variable is still significant in the presence of the mediator, there is only partial mediation (Baron and Kenney, 1986).

In order to verify our hypotheses 2 and 3, we used the decomposition of effects results, in which the total effect of an independent variable on a dependent variable is disaggregated into its indirect and direct effects (Tabachnick and Fidell, 1996). Figure 3 encompasses both direct and indirect paths whose standardized parameter estimates are shown.

Overall the model has acceptable fit indexes: CMIN=84.581; DF=60; CMIN/DF=1.410; CFI=.967; TLI=.958; IFI=.968; NFI=.898; RMSEA=.047

* Significance at p<0.05 level
 ** Significance at p< 0.01 level
 *** Significance at p<0.001 level

When taking into consideration the indirect effects, a significant indirect effect indicates that a relevant quantity of the independent variable's total effect on the dependent variable happens via the hypothesized mediator. Consistent with hypotheses, internal networking partially mediates the relationship between ambidextrous organization and innovation ambidexterity.

Robustness check

When using structural equation modelling, authors often compare the proposed model to competing models to determine which model fits the data best. In our proposed model (Model 1), internal networking partially mediates the relationship between ambidextrous organization and innovation ambidexterity. A full mediation model (Model 3), where the direct path from AO to IA was cut, and the direct model (Model 2) were tested (see Table 4).

Table 4: Comparison of different models

	Model 1 (hypothesized model)	Model 2 (direct model)	Model 1 (full mediation)
AO to IA	1.168 **	1.391***	-

AO to INK	.515***	-	.555***
INK to IA	2.992***	3.146***	3.743***
CMIN/DF	1.410	2.047	1.496
CFI	.967	.915	.960
TLI	.958	.892	.949
IFI	.968	.917	.961
NFI	.898	.850	.890
RMSEA	.047	.075	.052

As Table 4 exhibits the hypothesized mediational model (Model 1) has smaller chi-squares and RMSEA, and better fit indexes when compared to the other models. Particularly, Models 2 and 3 fit the data worse than the mediation model, as suggested also by the RMSEA. Taken together, information provided by the comparison of the direct effects and mediation models shows that the partial mediation model (Model 1) fits the data best. So we can conclude that data support the mediation hypothesis.

Discussion and conclusion

The results show that all our three hypothesis were supported: the various fit indexes consistently indicate that our second-order theoretical model fits the data well and internal networking for knowledge exchange partially mediates the relationship between the ambidextrous organization and the innovation ambidexterity.

This study contributes to the debate on organizational ambidexterity in at least two important ways: first, it shows that both structural and contextual approaches can be taken together and modelled as a second-order construct, thus representing an integrated view of the ambidextrous organization. This study shows that the ambidextrous organization is not simply the result of either a structural solution or a contextual solution, but it is made up of different organizational antecedents of ambidexterity that might complement one another. Here, together with the formal organizational structure, the role played by managers is fundamental since they foster employees to reach their objectives, to be empowered and to be free to decide how to divide their time and resources; furthermore managers should devote considerable effort to developing subordinates and giving creative challenges to their people instead of narrowly defining task. In this perspective, the resolution of tensions requires organizations to be integrated around a context which

is shaped by top managers and tied up with an overarching structure where units, devoted to innovative exploration and exploitation activities, are separated.

Second, this empirical study is one of the firsts to investigate the role that the ambidextrous organization has in fostering internal networking which in turns affects innovation ambidexterity. As far as behavioural elements are concerned, managers are hence called to shape values and norms to create a supportive context that promotes the creation of an internal networking, which plays a significant role in achieving innovation ambidexterity. Providing employees with clear and assessed objectives as well as empowering them with broad and challenging tasks push organizational members to connect each other to exchange knowledge, therefore finding solutions easily; along this perspective, putting in place a supportive and performance management context fosters internal networking, favouring knowledge management processes and increasing innovative outcomes. At the same time, the presence of separate units devoted to exploration and exploitation activities intensifies the need of integration mechanisms to connect employees belonging to the two units in order to have some cross benefits from the knowledge developed in the two mentioned areas.

These results answer to some of the calls presented in the literature on the theme. In particular, our findings represent a step towards the integration of all the ambidexterity approaches, as recently some authors (O'Reilly and Tushman, 2008; Chang and Hughes, 2012) recommended. In fact, we have statistically shown that structural solution, performance management context and social support load together in a high-order construct, which is a representation of an ambidextrous organization; consequently, the ambidextrous organization seems the result of three underlying dimensions which deal with structure and context. Of course, our attempt to simultaneously considering all the approaches together is an initial step that has some limits. In fact, we focus only on the paradox between radical and incremental innovations, thus looking at the ambidextrous organization as a way to solve this specific tension; many other tensions are present inside an organization and call for being managed, using different ambidextrous approaches, which makes the complexity of the interactions between different organizational units increase. Taking this nested view of the ambidexterity requires a qualitative approach, which could shed more light on the synergies and chosen approaches.

Furthermore, our findings show that the ambidextrous organization positively impacts on the ambidexterity innovation, also through the creation of an internal networking that

pushes individual to exchange knowledge and ideas, increasing the potential to generate innovations. On this basis, firm's managers are called upon to solve the tension between radical and incremental innovation through both designing the organizational structure and creating the right context that push individuals to solve problems and to be accountable for their objectives.

All these organizational features contribute to the creation of ambidexterity, since they encourage organizational members to interact, which leads to exchanging knowledge and creating powerful new ideas.

Acknowledgment

The research is part of the project "Developing organizational ambidexterity to foster the competitiveness of the Italian machinery industry" (cod. CPDA129273), funded by the University of Padua.

Structured Abstract

Purpose – This paper aims at evaluating the effects of the exploitation and exploration strategies on the economic and innovative performance of a local system of firms. Accordingly, this study embraces the exploration-exploitation dilemma (e.g., March, 1991; Benner and Tushman, 2003; Burgelman, 2002; Holmqvist, 2004; Katila and Ahuja, 2002) and differently from the extant literature we investigate the two above mentioned innovation strategies at the level of a system of firms rather than at a single organization's one. Specifically, we aim at empirically analyzing which strategy is more beneficial for those systems of organizations? Can systems benefit more by the introduction of new technology into existing products and processes or they can take more advantage by the continuous improvement of their technological knowledge base?

Design/methodology/approach – To reach our aim, an empirical research has been conducted on the 103 Italian Provinces, by measuring for each province both economic and innovative performance and indexes that capture the exploitation and exploration strategies. Specifically, focusing on the manufacturing sector, we use two different indexes, as: the inverse Gini coefficient of the distribution of firms by sector (two-digit level) in each province, which measures the heterogeneity across unrelated manufacturing sectors, and the inverse Gini coefficient of the distribution of firms within each two-digit sector in each province, which measures the heterogeneity across related manufacturing sectors. Furthermore, a set of control variables is included to account for other potential effects on provinces' performance.

Originality/value – Our results reveal that exploration strategies, as reflected by the agglomeration of industrially different organizations, have positive effects on the economic and innovative performance in a territory, as well as that this effect results greater when the exploration regards more similar industrial sectors. Our interest on the effects of the two strategies on a system of firms rather than on a single organization

significantly offers contributions both to the literature related to innovation strategies and to the studies on local economic growth. Specifically, while most of previous studies on innovation strategies adopt as level of investigation the single organization or dyadic collaborations, we focus on the exploitation-exploration balancing at the level of firms' geographical systems. Furthermore, analyzing which of the two strategies is more conducive for the territorial development and growth, allows us to give a contribution in the field of economic growth and regional development, answering the question on the relevance of heterogeneity in firms' competencies and capabilities for the competitive advantage of the local systems of firms (Boschma, 2005; Schamp et al., 2004).

Practical implications – Of course this study presents a number of practical implications, especially referring to the definition of innovation strategies and policies aimed at sustaining the economic and innovative outcomes of given territories. In particular, our findings suggest the importance of enhancing local development by favouring the establishment of organizations operating in different by complementary industrial sectors.

Keywords – Exploration, Exploitation, Local Development, Econometric analysis.

Paper type – Academic Research Paper

1 Introduction

Since the publication of March's (1991) pioneering article, the terms "exploration" and "exploitation" have increasingly come to dominate studies in the fields of innovation strategy, technology management, and economic growth (e.g., Aghion and Howitt, 1992; Allen and McGlade, 1986; Benner and Tushman, 2003; Burgelman, 2002; Holmqvist, 2004; Katila and Ahuja, 2002; McGrath, 2001).

According to He and Wong (2004) exploitation strategies trigger learning processes aimed at improving the product-market domains. Therefore, exploitation refers to learning gained via local search, experiential refinement, and selection and reuse of existing routines domains (Baum et al., 2000). As a result, exploitative innovations involve improvements in existing components and build on the existing technological trajectory (Benner and Tushman, 2002).

Differently, exploration refers to learning gained through processes of concerted variation and planned experimentation (Baum et al., 2000). According to Benner and Tushman (2002) exploratory innovation involves a shift to a different technological trajectory. Along the same lines, He and Wong (2004) defined exploratory innovation as technological innovation aimed at entering new product-market domains.

Following March (1991), exploitation and exploration strategies are strongly complementary and both essential for successful organizational adaptation, technological innovation, organizational learning, and even organizational survival. However, although both exploration and exploitation are essential for assuring organizations' competitive advantages in the short and long-term, the simultaneous pursuit of both appears very difficult. First, they compete for scarce organizational resources, since more resources devoted to exploitation imply fewer resources left over for exploration, and vice versa. Second, both types of actions are iteratively self-reinforcing, as exploration often leads to more exploration, and exploitation to more exploitation. Finally, the mindsets and organizational routines needed for exploration are radically different from those needed for exploitation, making them fundamentally incompatible (Gupta et al., 2006).

Recognizing the incompatibility of the two strategies, several authors stressed the need for a balance between exploitation and exploration strategies, leaving however an open question: which strategy is more beneficial for organizations? Can firms benefit more by the introduction of new technology into existing products and processes or they can take more advantage by the continuous improvement of their technological knowledge base? Furthermore, these dilemmas have been generally analyzed at the level of single organization (e.g., Benner and Tushman, 2002) or dyadic collaborations (e.g., Lavie and Rosenkopf, 2006), devoting few attention to the exploitation-exploration balancing at the level of firms' geographical systems. Thereby, this paper tries to cover this gap, by evaluating the effects of the exploitation and exploration strategies on the economic and innovative performance of a local system of firms.

We believe our interest on the effects of the two strategies on a system of firms rather than on a single organization significantly contribute to the existing literature. In fact, analyzing which of the two strategies is more conducive for the territorial development and growth, allows us to answer to another open question characterizing the studies in the field of economic growth and regional development, namely the relevance of heterogeneity in firms' competencies and capabilities for the competitive advantage of the local systems of firms (Boschma, 2005; Schamp et al., 2004). Exploration strategies have been found to have a higher effect on the level of knowledge heterogeneity, because those strategies span on a wider range of technological knowledge. On the contrary, exploitation strategies involve an intensive search along an existing knowledge dimension, producing a lower diversity in the knowledge system (Quintana-Garcia and Benavides-

Velasco, 2008). A fully understanding of the benefits and costs going along with the adoption of these distinct strategies at a territorial level still lacks, hence calling for further investigations.

To reach our aim, an empirical research has been conducted on the 103 Italian Provinces, by measuring for each Province both economic and innovative performance and indexes that capture the exploitation and exploration strategies. An econometric analysis on the 103 Italian Provinces over the period 1999-2010, controlling for an extensive set of control variables, is applied. Results reveal that exploration strategies positively influence the economic and innovative performance of a firms' geographical system, although this effect seems to be strengthened when firms share common technological expertise.

In the following session we present the research methodology, describing data, variables, and estimation method. Section 3 reports the empirical results, while Section 4 finally concludes.

2 Research Methodology

2.1 Data Sample

The data set is represented by the 103 Italian Provinces. To build our dataset we used different statistical sources: the Italian Office of National Statistics (ISTAT) databases; the European Patent Office (EPO) database; the Ministry of University and Research (MIUR) database, and the UNIONCAMERE database. Data on GDP, employment, population, and R&D investment come from ISTAT databases, data on university are extracted by the MIUR database, data on firms in two-digit and three-digit NACE codes come from the UNIONCAMERE database, and finally data on patents are provided by the EPO database. Data have been collected for each Province and refer to the period 1999-2010.

2.2 Variables

2.2.1 Dependent variables

As the phenomenon under investigation is the development and growth of local areas, we used as dependent variable the number of patents developed in each province, as an indicator of the innovative performance (see Jaffe and Trajtenberg (2005) and Acs et al.

(2002)); and the GDP, employment rate (Employment-to-population ratio) and unemployment rate as indicators of the economic performance.

They have been measured by:

Patent_p = Number of patent registered in province

$$GDP_p = \left(\frac{GDP_{region}}{N..employees_{region}} \right) \times N.employees_{province}$$

$$Employment_rate = \frac{Employees}{population} \times 100$$

$$Unemployment_rate = \frac{Unemployed_workers}{total_labour_force} \times 100$$

These variables have been measured in a time period of seven years and in particular for the years 2004, 2007 and 2010. Finally, in order to exclude endogeneity problems, the dependent variables are lagged of five years respect to the independent variable.

2.2.2 Independent variables

To capture the characteristics of the strategies carried out within the provinces, in terms of exploitation and exploration, the degree of a province's industrial heterogeneity has been measured by using the inverse Gini coefficient (Greunz, 2004; Paci and Usai, 1999; van der Panne and van Beers, 2006). The index aims at capturing the level of concentration of firms in a specific industrial sector and it has been measured over a period of seven years and in particular in the 1999, 2002 and 2005.

Specifically, focusing on the manufacturing sector, we use two different measures: 1) the inverse Gini coefficient of the distribution of firms by sector (two-digit level) in each province (invGini_{unrelated-sector}); 2) the inverse Gini coefficient of the distribution of firms within each two-digit sector in each province (invGini_{related-sector}). The invGini_{unrelated-sector} measures the heterogeneity across unrelated manufacturing sectors, as those characterized by a greater technological diversity. Instead, invGini_{related-sector} measures the heterogeneity across related manufacturing sectors, namely those characterized by a greater

technological similarity. Following Frenken et al. (2007), we assume that the related manufacturing sectors are those that share the same 2-digit NACE code.

The Gini index is defined as follows:

$$\text{invGini} = 1 - \left(\frac{\sum_{i=1}^{n-1} (Q_i - P_i)}{\sum_{i=1}^{n-1} P_i} \right)$$

Where:

- i indexes the manufacturing sector ($i = 1 \dots n-1$), classified into the two-digit NACE code for the $\text{invGini}_{\text{unrelated-sector}}$ and into the three-digit codes that share the same 2-digit class for the $\text{invGini}_{\text{related-sector}}$;

- $Q_i = \frac{\sum_{j=1}^i F_j}{CF}$

- $\sum_{j=1}^i F_j$ is the cumulative sum of firms in each manufacturing sector, classified into 2-digit NACE code/ 3-digit code, when the sector is ordered in increasing order;

- CF is the total number of firms.

- $P_i = \frac{i}{n}$

The inverse Gini coefficient ranges from a minimum value of zero to a maximum of one. Values of the index close to zero indicate that the industrial system in the province is specialized into a very few sectors, while values of the inverse Gini coefficient close to one indicate that the province industry specialization is spread across the different manufacturing sectors. Therefore, we assume that values of $\text{invGini}_{\text{unrelated-sector}}$ close to one reflect exploration strategies towards industries that are characterized by a greater technological diversity, while values of $\text{invGini}_{\text{related-sector}}$ close to one reveal exploration strategies towards industries technologically related. Values of the inverse Gini coefficient close to zero indicate exploitation strategies within the province.

2.2.3 Control variables

The analysis includes several control variables. First, in order to take into account the general economic conditions of the provinces, we use a dummy for provinces localized in the Northern Italy, generally considered as a more advanced and developed area (Mariotti et al., 2008). Three other controls have been included that may affect the province innovative performance. Specifically, the first variable refers to the presence of universities within the province area, which are considered as sources of new knowledge (Benneworth and Hospers, 2007; Cooke and Piccaluga, 2004). The second variable measures the R&D expenditure in the area. The index is defined as follows:

$$R \& D_p = \left(\frac{R \& D_r}{F_r} \right) \times F_p$$

Where:

- . $R \& D_p$ is the amount of R&D investments in region p where the province p is located.
- . F_r is the total number of firms in region r .
- . F_p is the total number of firms in province p .

R&D expenditure has been frequently used as a proxy for the local capability to generate new knowledge and innovation (Cohen and Klepper, 1991; 1992; Frenken, 2007). We control also for sectors, by introducing a dummy variable for high-tech sector (Head et al., 1995).

Finally, we control for the scale of local economic activity, measured by the total number of firms located in the province, that is a determinant of some type of cross-fertilization and economic advantages, usually called urbanization economies (Henderson, 2003).

2.3 Model and measurements

In order to estimate the relationship between the economic and innovative performance and exploitation and exploration strategies carried out within the province, proxied by the variables presented in Section 2.2, we apply a non-linear estimator, i.e.

negative binomial. The reason for choosing such estimator is because of the special feature of our dependent variables.

The descriptive statistics together with correlation matrix are shown in Table 1 and Table 2, respectively.

Table 1. Descriptive statistics.

3 Empirical Results

The results of negative binomial estimation of effects of exploitation/exploration strategies on the economic and innovative performance for Italian provinces over the period 1999-2010 are reported in the Table 3 and Table 4. In particular, Table 3 reports the effects of the exploration strategies across industries that are characterized by a greater technological diversity on the economic and innovative performance of the Italian provinces. Table 4 reports the effects of the exploration strategies across industries technologically related on the economic and innovative performance of the Italian provinces. Results show a positive a significant relation between the strategies of

exploration and two of the local performance indicators: the GDP that is a measure of the local economic performance, and the patent application, that is a measure of the innovativeness of the province.

Table 3. Negative binomial estimation of the effect of exploration strategies across technologically unrelated industries on the economic and innovative performance (1999-2010).

	Patent	P> z	GDP _p	P> z	Empl_rate	P> z	Unempl_rate	P> z

Central	-.6646297 (.1366196)	0.000	-.083949 (.0527804)	0.112	-.070632 (.0208808)	0.001	.3402452 (.0706866)	0.000
South	-2.047982 (.1411257)	0.000	-.4268026 (.0531106)	0.000	-.3442234 (.022152)	0.000	1.073546 (.0672972)	0.000
M _{tech}	.9191724 (.4803183)	0.056	.2388702 (.1910832)	0.211	.005481 (.0735845)	0.941	.3438435 (.3312133)	0.299
L _{tech}	.5661076 (.4798646)	0.238	.1463752 (.1903738)	0.442	.0051691 (.0733688)	0.944	.3305159 (.3310775)	0.318

Results show a positive and significant relation between the exploration strategies across technologically related industries and three of the local performance indicators: GDP and the unemployment rate, which are measures of the local economic performance; and patent application.

An interesting result is that the correlation coefficients assume greater values in the second model than in the first model. Therefore, we can conclude that exploration strategies have more positive effects on the economic and innovative performance in a territory when the exploration regards more similar technological sectors.

4 Conclusions

This paper has contributed to the debate on effects of the exploitation and exploration strategies on the economic and innovative performance of a local system of firms.

Our study on the effects of the two strategies on a system of firms rather than on a single organization significantly offers contributions both to the literature related to innovation strategies and to the studies on local economic growth. Specifically, while most of previous studies on innovation strategies adopt as level of investigation the single organization or dyadic collaborations, we focus on the exploitation-exploration balancing at the level of firms' geographical systems. Furthermore, analyzing which of the two strategies is more conducive for the territorial development and growth, allows us to give a contribution in the field of economic growth and regional development, answering the the question on the relevance of heterogeneity in firms' competencies and capabilities for the competitive advantage of the local systems of firms.

Our results prove that exploration strategies have positive effects on the economic and innovative performance in a territory and such effect is greater when the exploration regards more similar technological sectors.

Sustaining Growth in the 21st century: Knowledge Sharing & Opportunism in Joint New Product Development

Richard CM Yam

Department of Systems Engineering & Engineering Management
City University of Hong Kong, Hong Kong
Tat Chee Avenue, Kowloon Tong, Hong Kong

Structured Abstract

Purpose - Knowledge sharing in joint new product development (NPD) with business partners has been recognized by researchers on its crucial role for sustaining organizational growth in the 21st century. In joint NPD, huge amount of information and knowledge are being interchanged among firms. Organizations worry that knowledge sharing (KS) would invite opportunism; i.e. knowledge being copied, stolen or leaked to outsiders or even competitors. This empirical survey study investigates the relationship of contract, commitment and opportunism during knowledge sharing among business partners in NPD.

Design/methodology/approach – 312 valid responses were collected and data was analysed by using structural equation modelling. Our findings indicate that commitment among contractual business partners provide strong support to enhance knowledge sharing in NPD. Knowledge sharing itself will not directly affect product performance. But the enhanced knowledge sharing process among the committed contractual business partners facilitate the NPD team. The extensive sharing of innovative knowledge could help the committed NPD teams with contractual binding to achieve consensus and cohesive understanding of knowledge quickly. This would help the NPD teams to respond quickly to the rapidly changing market with better product performance.

Originality/value – Researchers have recognised the importance of corporate collaboration in NPD to sustain growth for firms in today's highly competitive global markets. However, the worry of opportunism for knowledge sharing with business partners in NPD has threatened many business collaborations. This study has shown that knowledge sharing among the committed contractual business partners will suppress rather than increase the chance for opportunism in NPD.

Practical implications – Managers engaged in joint NPD activities should commit seriously with their contractual business partners by sharing more innovative knowledge. This would reduce rather than increase the chance for opportunism and lead to better product performance. This finding is important for firms to work collaboratively in NPD for sustaining growth in the 21st century.

Keywords: contract, commitment, knowledge sharing, opportunism, sustainable growth

Paper type – Academic Research Paper

1. Introduction

In the 21st century, firms need to strive in developing new products for growth. Successful firms can seize new market opportunities by working collaboratively with their business partners to continually introduce new products. In addition, sharing updated knowledge with their business partners and adopting outsourcing strategies allow them to sustain competitiveness. A wide variety of knowledge are generated, disseminated and exchanged among firms during the new product development (NPD) process. However, industrial experience and research findings indicated that opportunism often exists in NPD. Firms worry that knowledge sharing in NPD invites opportunism. Many of them look for protection by building up complex contracts and good collaboration. They hope that this can help to improve knowledge management and product performance. Scholars acknowledged that transactional mechanism, e.g. contract, can suppress opportunism between business partners through legal actions (Liu et al., 2008; Luo et al., 2009) and relational mechanism, e.g. commitment, can nourish cooperation among business partners.

2. Literature review and Research Model Development

2.1 Contract and commitment

When a contract is signed by two or more firms and put into execution, it brings in sense of commitment between the signed business parties (Holm et al., 1999). A close and valuable business relationship can be gradually developed. When a signed contract is implemented, it is just one in a series of events that gradually committed the firms to a valuable and close business partnership. A signed contract can give power and obligation to firms for committing to other parties. This can help to achieve certain goals that are beneficial to the development.

Hypothesis 1 (H1) is proposed as: Contract is positively associated with commitment.

2.2 Contract suppresses opportunism

Contracts propose special behaviour patterns and specify duties of both parties, along with penalties for agreement violation. The explicit statements and binding conditions can help to curb opportunism (Poppo & Zenger, 2002). Through legal forces, contract can prevent opportunistic behaviors. Contracts can extend the context to control and monitor the collaboration. This can help to minimize opportunism.

Hypothesis 2 (H2) is proposed as: Contract is negatively associated with opportunism in NPD

2.3 Commitment reduces opportunism

By having commitment within the relationship, firms may be able to reduce the risk in knowledge sharing during NPD. Commitment could lead to the development of mutual interests and trust that the partners would treasure in their relationship. This can help to mitigate opportunism and nourish cooperation (Kim, 2000). Commitment is a necessary basic ingredient for long-term relationship between business partners. Firms are willing to make short-term sacrifices to get long-term benefit. Having a good commitment can reduce opportunism as parties would not expose to get a short term benefit only.

Hypothesis 3 (H3) is proposed as: Commitment is negatively associated with opportunism.

2.4 Commitment enhances knowledge sharing

A high level of commitment builds trust among business parties (Wuyts & Geyskens, 2005). In return, commitment would encourage knowledge generation and dissemination. It provides strong signals of willingness to communicate, share and exchange critical information and knowledge for supporting business growth to business partners. Improving the level of commitment in a relationship can encourage partners to share knowledge and information. Firms in highly trust relationship would not afraid to share knowledge and believe in the knowledge that they have received.

Hypothesis 4 (H4) is proposed as: Commitment is positively associated with knowledge sharing.

2.5 Opportunism inhibits knowledge sharing

Lee and Whang (2000) voiced out that firms concern about the confidentiality of their shared information being leaked to competitors. Researchers have pointed out that information or knowledge in the form of procedures, work practices, training and design are critical sources of opportunism. As the amount of disadvantages can be estimated, firms would prefer to keep the knowledge to their own.

Hypothesis 5 (H5) is proposed as: Opportunism is negatively associated with knowledge sharing.

2.6 Knowledge sharing improves knowledge interpretation and responsiveness

Critical information and knowledge tend to be exchanged earlier in the design and production phases to enhance efficiency and allow more innovations to be incorporated into product design and production processes (Baiman & Rajan, 2002). Involved individuals and teams must communicate among each other with an open dialogue about the knowledge required for all parties to reach a common understanding as the foundation for integrated. The integration of knowledge is critical to planning and implementing an interpretation and a collective response.

Hypothesis 6 (H6) is proposed as: Knowledge sharing is positively associated with knowledge interpretation and responsiveness.

2.7 Opportunism suppresses knowledge interpretation & responsiveness

Opportunism would cause business partners to have hesitation to trust the knowledge and information that they have received. For interpretation, they need time for filtering the knowledge that they receive and choosing the appropriate knowledge to compromise. This would lead to a slow responsive time. The hesitation and verification would delay the knowledge interpretation and responsiveness.

Hypothesis 7 (H7) is proposed as: Opportunism is negatively associated with knowledge interpretation & responsiveness.

2.8 Knowledge interpretation and responsiveness improves product performance

Firms with ability to interpret the related specialized knowledge of their employees know it is crucial to implement a collective response (Sutcliffe & McNamara, 2001). Achieving a common interpretation can help to get a faster response. The product performance would be better as it can fit the market needs. Achieving a cohesive understanding of knowledge within a short period of time is important. If the involved parties spent too much time to interpret knowledge, they may miss the opportune moment.

Hypothesis 8 (H8) is proposed as: Knowledge interpretation and responsiveness is positively associated with product performance.

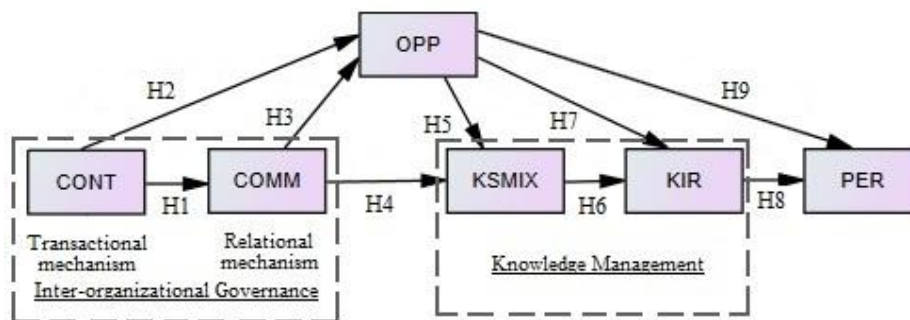

2.9 Opportunism suppresses product performance

Opportunistic problems cause skeptical behavior among NPD personnel to share more information and knowledge with others (Lee and Whang, 2000). The spiral effect would slow down the level of knowledge sharing among different parties. Firm's mind and thought would be limited. The end result may affect the creation of new products and product quality.

Hypothesis 9 (H9) is proposed as: Opportunism is negatively associated with product performance.

3. Research Model

By consolidating the above literature and discussions, the research model is proposed in Figure 1:

CONT: Contract

COMM: Commitment

OPP: Opportunism

KSMIX: Knowledge sharing (knowledge generation and knowledge dissemination)

KIR: Knowledge interpretation and responsiveness

PER: Product performance

Figure 1 : The Research Model

4 Research Method

An on-line survey was conducted to test the research hypotheses. Invitation e-mails were sent to target respondents with a hyper-link to the survey questions. This on-line survey reduces time and manual tasks for respondents in completing and returning the questionnaire. Invitations were sent out to 1350 samples. After a four-month survey period and data scrutiny, 312 completed and valid responses were collected, representing

a 23.1% response rate. Follow-up interviews were conducted to verify the survey findings.

5 Findings and discussion

Figure 2 shows the model with data testing result. Regression weights and significance between constructs are shown in Table 1. Model Fit Summary is shown in Table 2. The fit indices suggest that the data fit the model quite well. The result of our hypotheses testing is shown in Table 3.

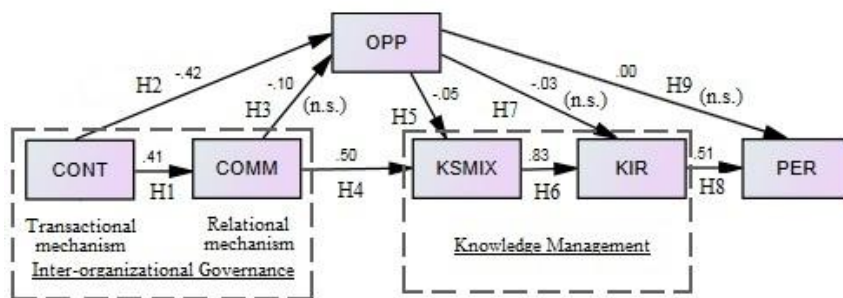

Figure 2: Model with testing result

Table 3: Summary of hypotheses tests

Hypotheses		Results
H1	Contract is positively associated with commitment in NPD	Supported
H2	Contract is negatively associated with opportunism	Supported
H3	Commitment is negatively associated with opportunism	Not Supported (ns)
H4	Commitment is positively associated with knowledge sharing	Supported
H5	Opportunism is negatively associated with knowledge sharing	Supported
H6	Knowledge sharing is positively associated with knowledge interpretation and responsiveness	Supported
H7	Opportunism is negatively associated with knowledge interpretation & responsiveness	Not Supported (ns)
H8	Knowledge interpretation and responsiveness is positively associated with product performance	Supported
H9	Opportunism is negatively associated with product performance	Not Supported (ns)

Briefly speaking, the effect of opportunism within inter-organizational governance and knowledge management is less than the prediction. This reflects that the weight of opportunism within the relationship is less. So firms are encouraged sharing knowledge as benefits are far more than risks.

However, opportunism is always exist and unavoidable. Therefore, it is important for firms to learn how to minimize opportunism. Interviews with specialists in the field were conducted for discussing the test results. Respondents pointed out that the role of inter-organizational governance is very important in NPD. Governance mechanisms can control and align incentives. Inter-organizational governance includes “Transactional Mechanism”, e.g. contract, which generally provides a formal legal and institution framework and “Relational Mechanism”, e.g. commitment, which focuses on the role of the informal social interaction and socially embedded relationships. Formal and informal mechanisms are effective in governing the partnership complementarily. Contract actually

is a protection for the involved parties for their intellectual property and confidential knowledge. Gradually, commitment and trust can be built among business partners. Apple Inc. is an apparent example for demonstrating the importance of collaboration and knowledge sharing among business partners. The Apple's collaborating success has significant impact to the market and change people's way of living. The commitment allows extensive knowledge sharing among partners which enhance more NPD with no worry of opportunism. In the past, Apple Inc. is a technology company which focus on computer only. Programming and hardware were the main themes that they put a lot of effort to develop. In order to meet customers' needs; Apple Inc. makes the mobile phone and computer into one device through business collaboration in NPD.

6 Conclusion

The research results indicate that the existence of inter-firm governance measures is important to regulate collaborative business activities. Once firms have signed up a clear contract, they would commit to their business partners to jointly develop new products through knowledge sharing, interpretation and use of knowledge. Sometimes, business environment has become too complicated for inter-firm collaboration to be governed by transactional mechanism solely. Relational mechanism is therefore crucial to supplement transactional mechanism for supporting inter-firms activities. The complementary effects of contract and commitment are important to build up trust among business partners to avoid opportunism in NPD.

Structured Abstract

Purpose- By studying and analyzing mutual relationship between two main topics – Knowledge Cities and the quality of life- this paper aims at determining the relationship between Knowledge Based Urban Development (KBUD) pillars, leading to successful emergence of KCs (economic, Socio-cultural, Enviro-urban, and institutional development), and the domains of quality of life; economic, social, urban, and environmental. It also aims at setting a scale for observing and analyzing the mutual relationship to facilitate reading, finding, and analyzing the gap between citizens' satisfaction with the quality of life and the results achieved in terms of the KBUD pillars. This helps decision makers to orient decisions in the right directions, achieving balance between both, and – thus- positively reflecting on cities sustainability.

Design/methodology/approach- To achieve the aim, the research adopts the following:

- Determining the different concepts and pillars of KBUD, and their assessment models.
- Determining quality of life factors, indices, and measurement model according to EU report (Quality of life in cities).
- Selection criteria for cities investigated.
- Determining an approach for analyzing and connecting quantitative results (method of KCs assessment) and the qualitative ones (method of assessing quality of life in European cities).
- Proposing a tool for the observation and analysis of mutual relationship between KBUD pillars and the quality of life potentials.
- Formulating the previous conclusion in a diagram/compass to facilitate extracting the mutual relationship.

Originality/value- The challenge before social development lies in the interaction of different development parameters for the purpose of making a society characterized by quality of life; the ultimate development goal. If such premises do not achieve quality of life results, then they are unable to achieve their goals. KBUD is a global fact proven by the end of the last century. Thus, knowledge-related value is the driving power of civilization.

So, the value of this research is attributed to the scarcity of studies related to the mutual relationship between the quality of life and Knowledge economy-based cities.

Practical implications- Reaching an approach for monitoring and analyzing the mutual relationship between the potentials and pillars of KCs and the different aspects of the quality of life supporting the theoretical and practical aspects as follows:

In theory: deducing the mutual relationship between the quality of life and KCs. The authors think that the quality of life is a concept that has analytical efficiency and capacity for handling problems and aids in setting an integrated approach for achieving knowledge-based developmental aims.

In practice: Proposing an observation tool for clarifying the mutual relationship between the quality of life and KCs to decision makers to help them boost the efficiency of decision making for achieving the quality of life to city residents; thus positively reflecting on the sustainability of cities.

Keyword- Knowledge Cities, quality of life, Knowledge Based Urban Development, pillars

Paper type- Academic Research paper

1. Introduction

Knowledge cities are important as 50% of the world's population now live in cities. After WWII, more than 50% of GDP of many industrial nations turned from physical development to knowledge-based development. Thus, knowledge-related value is the driving power of civilization.¹³ In 1996, the Organization for Economic Co-operation and Development (OECD) coined the term Knowledge City (KCs). Consequently, several developed countries sought to develop and adapt some aspects in their cities to be upgraded to knowledge-based economic cities. The aim was achieving sustainability, safe economic growth, environmental preservation, and a high quality of life level. The quality of life is a novel global issue that is attracting increasing attention in developed countries. The quality of life approach is one that looks holistically at issues, and is the prospective answer because it aims at setting a number of factors that reflect the social, psychological, economic, urban, and hygienic status of local residents. It also helps evaluate the occurrence / possible occurrence of change in such regions. Quality of life methodologies are gaining increasing global interest. In recent years, world organizations focused more in the quality of life issues and methods of their assessment such as: The UN's Human Development Index; social organizations such as The Ontario Social Development Councils " Quality of Life in Ontario" project; sustainable development organizations such as Hamilton-Wentworth, Seattle; organizations interested in health (e.g., Pasadena, Ontario Healthy

Communities Coalition), and organizations interested in municipal governments (e.g., Jacksonville Community Council, the Federation of Canadian Municipalities).

Hence, the research studies the mutual relationship between the potentials of KCs and the different aspects of the quality of life in cities to observe the extent of quality of life achieved by knowledge cities

2. Knowledge Based Urban Development concepts and pillars

In the late 1900s some urban development concepts were developed. Several experts stated that the future of cities and urban regions lies in the attraction, generation, and enhancing of knowledge, innovation, and creation (Yigitcanlar, 2011). In the middle of this, some new concepts emerged:

- Knowledge Economy: defined as economy depending on knowledge production and usage as an input in production. The term was first coined by the OECD IN 1996 (Hogan, 2011; Yigitcanlar, 2007).
- Knowledge society: this term defines a society which is developed in parallel with knowledge development. The knowledge society is a human development era, i.e., the knowledge society replaced the industrial society in several developed countries (Ironfiled, Read and Higgins, 2013).

This was followed by the emergence of the concept of KBUD. Knight was the first to coin such concept. He indicated the KBUD is a process where citizens take part in developing their cities through enhancing cultures and knowledge production in the city (Yigitcanlar, 2007). Yigitcanlar described KBUD as the knowledge development model in the knowledge economy era. It aims at achieving the following (Yigitcanlar, Lonnqvist, Kapyla and Salonijs, 2012):

- Sustainable urban development (Yigitcanlar and Sarimin, 2010; Yigitcanlar, Lee, 2009).
- Designing a knowledge city that encourages, produces, and expands knowledge work. This methodology can be considered a process of city transformation and innovation (Yigitcanlar, Lee, 2009).
- Boosting the quality of life through providing services needed for achieving social development (Yigitcanlar, Velibeyoglu and Martinez-Fernandez, 2008).
- Achieving a strong, safe knowledge economy that achieves the quality of life and makes the city vivid in terms of cultural activities (Yigitcanlar, 2007).

2.1 The main pillars of Knowledge Based Urban Development

Knowledge Based Urban Development may be regarded as a four-pillar model (Yigitcanlar, 2010):

- Economic development.
- Socio-cultural development.
- Environmental urban development.
- Institutional development.

2.1.1 Economic Development

The first KBUD pillar is economic development (Yigitcanlar, 2010). It aims at creating a knowledge-based economy that depends on knowledge creation, assessment, and marketing. Success in domestic economic development is closely related to the ability of a city on adaptation to knowledge economy. Literature indicates that upon determining the economic development level of a city in the knowledge economy era, the main variables/indices related to the economic structure are selected as follows (Yigitcanlar, 2011):

- Gross Domestic Product.
- Growth in domestic product.
- Spending income available.
- Foreign investment.

As for indices related to knowledge economy performance, they indicate:

- Spending on R&D, patents, knowledge workers, and knowledge-intensive services.

2.1.2 Socio-cultural development

It aims at achieving progress towards creating a knowledge economy that generates, distributes, publishes, and uses knowledge and information; which is the economic and cultural activities driving power. So, it is necessary to increase individuals' skills as a means for social development (Yigitcanlar, 2011). The benefits of social development go beyond economic growth and achieving life quality in public services (such as health and education) to maintaining cultural, social, and environmental values which distinguish cities and attract/expel the creative class of knowledge workers (Yigitcanlar and Velibeyoglu, 2008).

According to literature, the main indices used in assessing socio-cultural fall under socio-cultural capital indices (Yigitcanlar, 2010):

- Educational attainment in the city.
- Main university stature in the city.
- Social and cultural diversity in the city.

2.1.3 Environmental urban development

It aims at achieving environmental preservation along with meeting society needs. So, it seeks achieving sustainable urban development and quality of life in knowledge societies (Yigitcanlar, 2011). Sustainable development indices include (Yigitcanlar, 2010):

- Environmental status of the city.
- Sustainable urban development.
- Mitigating the effect of climatic changes.
- Sustainable transportation.

2.1.4 Institutional development

Institutional development, from the KBUD perspective, seeks to gather all active parties for organizing and facilitating knowledge-intensive activities needed for the strategic planning for creating a knowledge city (Yigitcanlar, 2011). The main institutional development indices revolve around two groups; governance and planning (Yigitcanlar, 2010):

- Electronic governance.
- The ability to develop.
- Strategic planning.

The second group, community leadership, includes:

- Local & regional.
- Establishing brand of the city.
- Community participation.

2.2 Knowledge based urban development assessment models

Several economic organizations – such as the OECD, The World Bank, and the European Commission – provide guidance to developed and developing countries for

building knowledge-based economies through KBUD. Here, five models for assessing and analyzing KBUD were observed (Sarimin, Yigitcanlar and Parker, 2010):

- The most admired knowledge cities model (Makci).
- The KBUD analysis model.
- The KBUD characteristics model.
- The ALERT model.

Here, the Makci model is used in assessing knowledge-based urban development. The Most Admired Knowledge Cities Award is an international award aiming at determining the best knowledge cities in the year. The award was established in 2006 by The World Capital Institute. The MAKCI model is essentially a model for evaluating knowledge-based urban development in terms of economic positions, represented by the financial capital; the urban social positions, represented by the identity capital; and the organizational positions, represented by the tools capital. There are eight indices in this regard (The World Capital Institute and Teleos, 2009; Sarimin, Yigitcanlar and Parker, 2010):

2.2.1 Identity Capital

All formal and informal elements in the city that have contributed and/or are contributing to determine the city's identity, its clarity and differentiation (i.e. historic profile, city characterization, infrastructure, and utilities).

2.2.2 Intelligence Capital

Refers to the city's systems capacity to sense, make sense of and respond to external agents and events which are significant to the city's welfare (i.e. city's strategic planning agencies, city public/private future centers, prospective studies etc).

2.2.3 Financial Capital

Refers to the city's articulation of monetary denomination of production value dimensions which elicit economic sustainability within the capital system (i.e. macro indicators: investment, GDP, tax system, un/employment etc).

2.2.4 Relational Capital

Refers to the city's articulation capital that provides cohesion and makes social integration possible (i.e. ethnic diversity, individual health habits, intellectual and cultural habits, etc).

2.2.5 Human Capital (collective base)

Refers to the collective cultural fitness and team based value generating capacities of all citizens that contribute to the city's system of capitals (public health, social welfare intellectual heritage, civic culture, innovation and entrepreneurial capacities).

2.2.6 Human Capital (Individual)

Refers to value generating capacity of individual citizens that contribute to the city's system of capitals (health: biological inheritance and physical development; education :holistic personal development).

2.2.7 Instrumental Capital (tangible)

Refers to the material-based means of production through which other capitals leverage their value generating capacity. Instrumental capital includes natural existing before the settlement and infrastructure.

2.2.8 Instrumental Capital (intangible)

Refers to the knowledge-based means of production through which other capitals leverage their value generating capacity (i.e. organization and production systems in electronic and non electronic repositories).

3. General concepts and frameworks of the quality of life

The quality of life is a novel global issue that is attracting increasing attention in developed countries. The quality of life approach is one that looks holistically at issues, and is the prospective answer because it aims at setting a number of factors that reflect the social, psychological, economic, urban, and hygienic status of local residents. It also helps evaluate the occurrence / possible occurrence of change in such regions. The same methodology will be adopted in handling quality of life issues: definition, quality of life indices, and the assessment method.

3.1 Definition of quality of life

While there is no consensus as to what quality of life is, several definitions listed below provide an overall sense of what is meant by the term (Anderson, 2004):

- “the degree to which a person enjoys the important possibilities of his or her life” (Centre for Health (Promotion, University of Toronto)
- “the products of the interplay among social, health, economic and environmental conditions which affect human and social development” (Ontario Social Development Council)
- “a feeling of wellbeing, fulfillment or satisfaction resulting from factors in the external environments” (Jacksonville Community Council)
- “a popular expression that, in general, connotes an overall sense of wellbeing when applied to an individual and a pleasant and supportive environment when applied to a community. Quality of life is a global outcome that is highly valued by all populations” (Healthy People 2010, Draft Objectives).
- Quality of life is a term used by government synonymously with sustainable development, because it is felt to be more easily understood by the general public. (DETR, July 2000, Local Quality of Life Counts, p 5)

The concept of the quality of life includes the quantitative and the qualitative criteria on the individual and society levels. The qualitative criteria on the individual level are: (Satisfaction about life, feeling happy, ...), whereas on the level of the society :(The ability to participate and to have effect, the amount of correlation between the person and the individual and the society,...).On the society level, (measuring the environmental, economical and social status,...), thus the quality of life can be considered two-dimensional matrix. It is clear in the table (1).

Table (1): The elements of the quality of life (Jones, 2002).

	On the individual level	On the society level
Personal/ qualitative (Feeling)	How the person feels towards himself and his status	How the person feels towards his society, and his ability to participate and affect the decisions of the society concerning the quality of life.
Objective/quantitative (Cases)	The professional cases like education.	The economical, social, environmental, cases, and the governmental efficiency.

A comprehensive definition for the term "the quality of life, can be deduced from all the above, and the research can adopt it: The quality of life is the outcome of the interaction between the social, economical, constructional, and environmental cases which affect Man (Mostafa, 2008).

3.2 *Quality of life Indices*

The process of developing urban communities is the essence of solving their problems. Knowing whether such development positively influences the quality of life was not clear due to lack of its indices. Now, decision makers and society partners are looking for evidence for determining outputs to reach good measurable results. The quality of life approach is one that looks holistically at issues, and is the prospective answer because it aims at setting a number of factors that reflect the social, psychological, economic, urban, and hygienic status of local residents. It also helps evaluate the occurrence / possible occurrence of change in such regions. Quality of life methodologies are gaining increasing global interest. Quality of life indices help understand how to act on the individual and the collective levels and what we feel. It helps answer three questions: where were we? Where are we now? Where do we want to go? (Jones, 2002).

3.3 *Quality of life measurement methodology*

The quality of life measurement methodology depends on the 2013 EU report "Quality of life in cities" results.

The request of the Directorate-General for Regional and Urban Policy to get a snapshot of people's opinions on a range of urban issues. Earlier surveys were conducted in 2004, 2006 and 2009. This survey included all capital cities of the countries concerned (except for Switzerland), together with between one and six more cities in the larger countries. In each city, around 500 citizens were interviewed. A total of 79 European cities were used in this analysis. In addition to these, the surroundings areas of Athina, Lisboa, Manchester and Paris were analyzed. The report therefore refers to "83 cities", though a more accurate terminology would be "79 cities and 4 surrounding areas". A complete list of these is included below as well as the list of questions asked. These cities have been classified according to the population size of their "urban centre" into 6 categories:

- S 50 000 – 100 000 inhabitants

- M 100 000 – 250 000 inhabitants
- L 250 000 – 500 000 inhabitants
- XL 500 000 – 1 000 000 inhabitants
- XXL 1 000 000 – 5 000 000 inhabitants
- Global More than 5 000 000 inhabitants

These classifications are used in the analysis when relevant. The results from the four surrounding areas introduced in the survey are included in the report under the following names: “Paris surroundings”, “Lisbon surroundings”, “Athens surroundings” and “Manchester surroundings”. This survey was carried out by the TNS Political & Social network in the then 27 Member States of the European Union, as well as Croatia, Iceland, Norway, Switzerland and Turkey, between the 15th of November and the 7th of December 2012. Some 41,137 respondents from different social and demographic groups were interviewed via telephone (landline and mobile phone) in their mother tongue on behalf of the European Commission, Directorate-General for Regional and Urban Policy. The methodology used is that of Euro barometer surveys as carried out by the Directorate-General for Communication (“Research and Speechwriting” Unit)². A technical note on the manner in which interviews were conducted by the Institutes within the TNS Political & Social network is appended as an annex to this report. Also included are the interview methods and confidence intervals.

4. Method of selecting cities and the proposed observation and analysis method

The research studies the mutual relationship between the potentials and pillars of KCs (the quantitative aspect) and the different aspects of the quality of life in cities (the qualitative aspect) being studied- as well as setting the different criteria for selecting cities.

4.1 Selection criteria of cities

The research selects three cities according to the following criteria:

- Located in the EU territories.
- MAKCI Award winner.
- Studied in the EU report " Quality of life in cities".

Hence, three cities were selected: Manchester, 2010 MAKCI first place; Barcelona, 2010 MAKCI third place; and Zurich, 2010 MAKCI forty place.

4.2 Method of connecting KBUD pillars and quality of life potentials

The research proposes a method for connecting KBUD pillars (as in the MAKCI report), and their relationship to the EU quality of life report, as in table (2).

Table (2): Connecting the quantitative and qualitative aspects of knowledge cities

KBUD pillars and quality of life potentials	MAKCI Report Quantitative aspect	Quality of life measurement questions Qualitative aspect
Economic development	<ul style="list-style-type: none"> ▪ Financial capital 	<ul style="list-style-type: none"> ▪ It is easy to find a job in [CITY NAME]. ▪ It is easy to find good housing at a reasonable price in [CITY NAME].
Socio-cultural development	<ul style="list-style-type: none"> ▪ Relational capital ▪ Human capital (collective) ▪ Human capital (individual) 	<ul style="list-style-type: none"> ▪ Health care services, doctors and hospitals. ▪ The presence of foreigners is good for [CITY NAME]. ▪ Foreigners who live in [CITY NAME] are well integrated. ▪ I feel safe in [CITY NAME]. ▪ I feel safe in my neighborhood. ▪ Generally speaking, most people in [CITY NAME] can be trusted. ▪ Generally speaking, most people in my neighborhood can be trusted
Environmental-urban development	<ul style="list-style-type: none"> ▪ Instrumental capital (tangible) ▪ Identity capital 	<ul style="list-style-type: none"> ▪ Public transport, for example the bus, tram or metro. ▪ Sports facilities such as sport fields and indoor sport halls. ▪ Cultural facilities such as concert halls, theatres, museums and libraries. ▪ The state of the streets and buildings in your neighborhood. ▪ Public spaces such as markets, squares, pedestrian areas. ▪ Green spaces such as parks and gardens. ▪ Availability of retail shops. ▪ Schools and other educational facilities. ▪ The quality of the air. ▪ The noise level. ▪ Cleanliness ▪ [CITY NAME] is committed to fight against climate change (e.g.: energy efficiency, green transport)
Institutional development	<ul style="list-style-type: none"> ▪ Intelligence capital ▪ Instrumental capital (intangible) 	<ul style="list-style-type: none"> ▪ The administrative services of [CITY NAME] help people efficiently. ▪ Generally speaking, the public administration of [CITY NAME] can be trusted.

4.3 Tool for the observation and analysis of mutual relationship between KBUD pillars and the quality of life potentials

Using the proposed tool, the MAKCI report and the EU quality of life report percentages are observed as in fig. (2). It is worth mentioning the strong and relative agreements were added to facilitate observation and comparison as in fig (3). The difference between

achieved results was observed, and reasons of occurrence of such difference were analyzed as in table (3).

Fig (2): Method of laying the results of the EU quality of life report survey questions (European Commission, 2013)

Fig (2): EU quality of life report (modified by the authors)

Table (3): The proposed tool for observation and analysis

City	Pillars	Makci	Quality of life (strongly agree + somewhat agree)	Makci / quality	cause

From the above, and after selecting cities, results were observed and analyzed as in table (4).

Table (4): observation and analysis of mutual relationship between KBUD pillars and the quality of life potentials of case study cities

City	Pillars	Makci	Quality of life	Makci / quality	cause
Barcelona	Socio cultural development	89.5%	71%	-19%	<ul style="list-style-type: none"> Foreigners who live in Barcelona are well integrated (50%). Health care (66%).
Zurich		70.5%	85%	+14.5%	
Manchester		84.3%	85%	+0.7%	
Barcelona	Physical Environment and Urban Development	90%	65%	-25%	<ul style="list-style-type: none"> Quality of air (31%) , cleanliness (58%) and climate change (53%). Public transport (69%), sport facilities (65%), school and education facilities (62%).
Zurich		75.8%	92%	+16.2%	
Manchester		89.5%	74%	-15.5%	<ul style="list-style-type: none"> cleanliness (57%) sport facilities (67%) and

					The state of the streets and buildings in your neighborhood (68%). ▪ school and education facilities (73%).
Barcelona	Economic Development	78%	33%	-45%	▪ It is easy to find a job in Barcelona (37%). ▪ It is easy to find good housing at a reasonable price in. Barcelona (28%).
Zurich		80%	30.5%	-49.5%	▪ It is easy to find a job in Zurich (55%). ▪ It is easy to find good housing at a reasonable price in Zurich (6%).
Manchester		85%	37%	-48%	▪ It is easy to find a job in Manchester (31%). ▪ It is easy to find good housing at a reasonable price in Manchester (43%).
Barcelona	Management and Governance	85%	48%	-37%	▪ The administrative services of Barcelona help people efficiently (45%). ▪ Generally speaking, the public administration of Barcelona can be trusted (51%).
Zurich		75.8%	79%	+3.5%	
Manchester		88.5%	68%	-20.5%	▪ The administrative service of Barcelona help people efficiently (69%). Generally speaking, the public administration of Barcelona can be trusted (67%).

N.B: Authors argued that a 5-10% difference is a balanced one.

5. Conclusion

Through the study, the research managed to observe the mutual relationship between the potentials of KBUD and the quality of life. Results were analyzed based on these potentials, as follows:

5.1 Socio-cultural development

- Analyzing the mutual relationship in Barcelona case, there was a negative imbalance between the socio-cultural development and the quality of life; a difference of 19%. This is due to citizens' dissatisfaction with health care. Also, foreigners were not satisfied; 50% satisfaction.

- In the Manchester case, a balance was detected between socio-cultural development and the quality of life; a 0.7% difference.
- As for Zurich, a positive balance was found; 14.5%.

5.2 *Environmental urban development*

- A negative imbalance was observed in Barcelona; 25%. This can be attributed to citizens' dissatisfaction with the quality of air (31%), city cleanliness (58%), systems of protection against climatic changes (53%), public transportation (69%), sport establishments (65%), and educational facilities (62%).
- As for Manchester a negative imbalance was observed; 15.5%. This is attributed to citizens' dissatisfaction with city cleanliness (57%), sports facilities (67%), and educational facilities (73%).
- As for Zurich, a positive imbalance was observed.

5.3 *Economic development*

- A negative imbalance was observed in the three case studies. This is attributed in the case of Barcelona to dissatisfaction with employment (37% satisfaction) and 28% satisfaction with finding a residence suitable for income.
- As for Manchester there is dissatisfaction with employment (31% satisfaction), and 43% for satisfaction with a suitable residence.
- As for Zurich, there was a 6% satisfaction with finding a suitable residence, and 55% satisfaction with employment.

5.4 *Institutional development*

- A negative imbalance was observed in the case of Barcelona; 37% difference. Citizens' satisfaction with administrative services is 45%, and 51% satisfaction with the public administration of Barcelona.
- As for Zurich a state of balance was observed.
- As for Manchester a negative state of imbalance was observed; a difference of 20.5%. This is attributed to citizens' dissatisfaction with administrative services; 69% satisfaction. Citizens' satisfaction with public administration was 67%.

Structured Abstract

Purpose – Smart Services are now an emerging phenomena that is based on intelligent technologies which are widely used for better customer. Smart Service is supposed to be an IT-service based on rich intellectual capital, realtime tools, sophisticated analytics, and automation (definition based on Cisco approach from (Smart Services, 2011). Individual Knowledge Structuring (IKS) is a significant part of any design activity, as it forms together and within critical thinking an analytical preface to a synthesising process. We argue that the current palette of individual knowledge structuring techniques and their cognitive impact affect the effectiveness of requirement engineering procedures.

Design/methodology/approach – The aim of this study is to show how the repertoire of IKS is affected by individual cognitive style (Witkin, Moore, Goodenough and Cox, 1977; Palmquist and Kim, 2000). We have done an experiment with 79 students to discover the impact of the cognitive style features on the knowledge structuring. From the plethora of cognitive style characteristics three parameters have been chosen: field dependence/ field independence (FD/FID), impulsivity/ reflectivity, and narrowness/ width of the category. The point is that we received totally different knowledge models from respondents with different cognitive styles peculiarities. In this paper we aim to introduce our findings on this issue.

Originality/value – The paper proposes new approach to using cognitive psychology for the knowledge analytical activity for requirement engineering. The proposed findings are based on wide survey and experiments of the authors. The paper contributes to a wider use of knowledge engineering methodologies for smart service design and development. Individual Knowledge Structuring helps to develop a holistic conceptual service model. In this paper we aim to overcome the limitations of traditional approach and to enrich the repertoire of the methods that can be used by service designers and analysts to broad the understanding of the customer needs and service capabilities issues.

Practical implications – The essential attributes of Smart Services are that they deliver better insights and predictability through software enabled tools predictive analytics, and intelligent automation. Smart Services design and development needs thorough requirements engineering process (Ralph, 2013) that involves all the palette of knowledge

engineering techniques and methods. The paper contributes to business service science and practice by introducing recommendations for service analysts at the crucial phase of the design and development process. Such approach merges the cognitive ergonomics issues with knowledge engineering.

Keywords – knowledge structuring, visual models, cognitive approach, requirements engineering, knowledge engineering.

Paper type – Academic Research Paper

1 Introduction

Smart Services are now an emerging phenomena that is based on intelligent technologies which are widely used for better customer. Smart Service is supposed to be an IT-service based on rich intellectual capital, realtime tools, sophisticated analytics, and automation (definition based on Cisco approach from (Smart Services, 2011)). The essential attributes of Smart Services are that they deliver better insights and predictability through software enabled tools predictive analytics, and intelligent automation. Smart Services design and development needs thorough requirements engineering process (Ralph, 2013) that involves all the palette of knowledge engineering techniques and methods. The primary measure of success of any software system or service is the degree to which it meets the purpose for which it was intended. So requirements engineering (RE) is the process of discovering that purpose, by identifying stakeholders, their needs and knowledge, and documenting and mapping these in a form that is amenable to analysis, communication, and subsequent implementation (Nuseibeh and Easterbrook, 2000).

Individual Knowledge Structuring (IKS) is a significant part of such RE design activity, as it forms together and within critical thinking an analytical preface to a synthesising process. We argue that the current palette of individual knowledge structuring techniques and their cognitive impact affect the effectiveness of requirement engineering procedures.

The paper contributes to business service science and practice by introducing recommendations for service analysts at the crucial phase of the design and development process. Such approach merges the cognitive ergonomics issues with knowledge engineering.

This paper presents the main results of the KOMET (Knowledge and cOntent structuring via METHods of collaborative ontology design) project which was devoted to developing methods of using group visual ontology design in research and education with regards to the respondents' individual cognitive styles. The group ontology design was tested in the medical domain (smaller group) (Gavrilova, Ravodin, Bolotnikova and Kotko, 2012) and computer science (informatics) domain (larger group of participants).

2 About KOMET Project

The KOMET project was aimed at developing a paradigm of data and knowledge structuring with regard to individual cognitive styles, using recent advances in knowledge engineering and conceptual structuring, aimed at creating structurally holistic knowledge bases for various areas of science and technology.

This aim was decomposed into such objectives as:

- research of correlations between the expert's individual cognitive style and the peculiarities of the expert's subject domain ontology development,
- research of correlations between the expert's individual cognitive style and the group ontology design (including design performed in groups consisting of experts with either similar or different cognitive styles), and
- research of formal ontology evaluation methods from the cognitive ergonomics point of view and informal evaluation by peers.

The idea of using visual structuring of information to improve the quality of understanding and mentalization among research colleagues is not new (Shneiderman, 1996). For more than twenty years, concept mapping (Grosslight, Unger, Jay and Smith, 1991; Sowa, 1984; Jonassen, 1998; Conlon, 1997) has been used to compile maps and mental models that support the process of knowledge sharing.

Ancient scholars used diagrams and figures to describe taxonomies and other complex sets of terms. As such, the visual representation of general domain concepts facilitates and supports understanding of both substantive and syntactic knowledge. Many scholars, especially those who also teach sciences courses, operate as knowledge analysts or knowledge engineers by making visible the skeleton of the studied discipline and showing the domain's conceptual structure (Kinchin, 2005). This structure is frequently represented by a so-called "ontology".

An ontology is a set of definitions we make in understanding and viewing the world. The visual approach to presenting an ontology is not only compact but also comprehensive. It makes ontology a powerful mind tool (Johanssen, 1998; Gavrilova and Voinov, 1996). One particular role of ontology is to act as “cognitive prosthesis” (Sutcliffe, 2003) or an example to stimulate the designer’s imagination.

By definition, ontology is a declarative representation of a certain precise domain specification, including the glossary of the domain terms and the logical expressions describing the meanings and the relationships of these terms, thus allowing structured sharing of knowledge related to the domain (Gruber, 1993). There are numerous definitions of this milestone term (Neches, Fikes, Finin, Gruber, Patil, Senator and Swartout, 1991; Gruber, 1993; Guarino and Giaretta, 1998; Gómez-Pérez, Fernández-López and Corcho, 2004).

However, the ontology-based approach to knowledge representation in requirement engineering and smart services design is a relatively new development.

Many researchers and practitioners have argued about the distinctions between ontology and a conceptual model. We propose that ontology corresponds to the analyst’s view of the conceptual model, but is not de facto the formal model itself. There are more than a hundred techniques and notations that help to define and visualize conceptual models. Ontologies are now considered as the most universal and shareable forms of such modelling.

Of course, the ontologies are inevitably subjective to a certain extent, as knowledge by definition includes a component of personal subjective perception; however, using the ontologies developed by others is a convenient and compact means of acquiring new knowledge. At the same time, collective ontology development experience allows the participants in the process to gain the fullest possible understanding of the subject area.

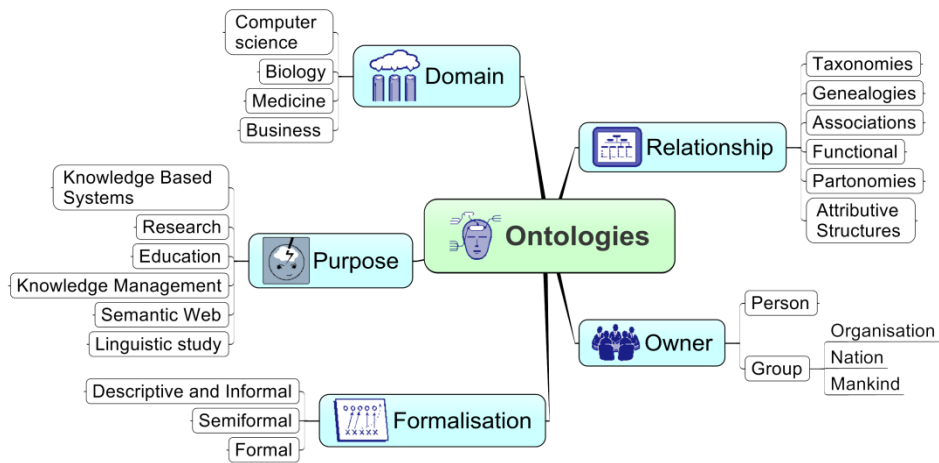

Figure 1. Summarizing the ontology classifications in a mind-map

Meta-ontology provides a more general description dealing with higher-level abstractions. Figure 1 illustrates different ontology classifications in the form of the mind map. This representation may be called the knowledge map. Such maps are graphical tools for organizing and representing knowledge. Later in this paper and in our study we will use two particularly appropriate forms of knowledge maps: mind maps (Buzan, 2005) and concept maps (Novak, 1998; Novak and Canas, 2006).

Knowledge maps are now widely used for visualizing ontologies at the design stage, while ontology editors (like Protégé) facilitate the development stage.

3 Individual Cognitive Style and Knowledge Structuring

There is a thriving industry devoted to publishing cognitive-style tests and guidebooks for teachers, and many organizations offer professional development workshops for teachers and educators built around the concept of learning styles (Peterson, Rayner and Armstrong, 2009). The cognitive-styles view has acquired great influence within the education field.

However, we will use the concept of cognitive style only for the predefined aim. As the aim of the KOMET project was to develop a paradigm of structuring data and knowledge with regard to individual cognitive styles, we had to choose the appropriate parameters or features of cognitive style.

The cognitive styles explain and describe how an individual acquires knowledge and how an individual processes information. The cognitive styles are related to problem solving, and generally to the way that information is acquired, structured and used.

Among the main features of cognitive style (Hayes and Allinson, 1998) we can name:

- field dependence versus field independence;
- impulsivity versus reflection;
- narrowness versus width of the categories;
- rigidity versus flexibility;
- levelling versus sharpening;
- scope of cognitive equivalence;
- visual/audio/kinesthetic preferences, etc.

Three characteristics have been chosen from the plethora of cognitive style characteristics described in the literature (Kholodnaya, 2004): field dependence/field independence (FD/FID), impulsivity/reflection, and narrowness/width of the category.

According to the definition by Witkin (Witkin, Moore, Goodenough and Cox, 1977) FD/FID is “a structuring ability of perception”. The field-independent style is defined by a tendency to separate details from the surrounding context. It can be compared to the field-dependent style, which is defined as a relative inability to distinguish detail from other information around it. The FD/FID characteristic can be interpreted as a proxy of the structuring capability of an individual mind. The characteristic of this style does influence the structuring process as a whole (e.g. ontology development “from scratch” in the research setting described in this paper), and even more it affects the restructuring process (the merging of individual ontologies). FD/FID exerts considerable influence on the collective problem-solving process. In dyads where members have cognitive styles differentiated by the FD/FID characteristic, the final solution is usually closer to the variant suggested by the FID participant. The FID dyads experience difficulty in developing common decisions on arguable points, while the FD dyads are more successful in coming to agreement in collective problem solving.

Psychologists in our research group were used to working with on-line text based on the popular modification of Witkin’s method of “embedded figures” which is aimed at the search for a simple figure hidden within the complicated one (Witkin, 1971).

The impulsivity/reflection characteristic considers the amount of information collected prior to making a decision: impulsive individuals are able to make decisions on

a considerably bounded information basis, while the reflective individuals are more inclined to make decisions considering completely full information on the respective situation. For assessing the respondents' impulsivity/reflection features, the "similar pictures comparison" (Kagan, 1966) method has been used.

As for the narrowness/width of the category, the main difference between the extreme poles of this characteristic is that narrowly categorizing individuals are inclined to restrict the area of application of a certain category, while the broad categorizers are, conversely, inclined to include a plethora of more-or-less related examples into a single category. The psychologists that help us with the experimental part advised us to use a modification by Pettigrew (1958) and Fillenbaum (1959): their method of so-called "average judgment". The procedure is based on respondents' opinion on the minimum, average and maximum evaluations of a concept or category.

4 Research Approach and Methodology

The study of expert's individual cognitive style was divided into four consecutive steps:

1. Identifying the significant individual cognitive style characteristics on the basis of the on-line testing results, using the software developed by Elena Kotova and Andrew Pisarev.
2. Creating the "informatics" research domain ontologies using the Protégé (Protégé) tool and estimating the ontology metrics using the COAT software environment (Gavrilova, Bolotnikova and Gorovoy, 2012).
3. Merging individual ontologies in face-to-face group ontology design.
4. Performing statistical analysis in order to find out significant relationships between the young researchers' (experts') individual cognitive style characteristics and the ontology metrics.

The second part of the research was performed using the same test sample and included ontology development in/with the use of the Protégé tool. All the tested students were given the task of developing an ontology for the informatics domain. They did it by using visual mapping approach.

The quality of the developed ontologies was assessed by two methods:

- An expert method, where the ontology analyst and domain experts (both professors in computer science) assessed the quality by such criteria as completeness, imbalance, relevance, etc.
- A formalized method, where any ontology was assessed by a set of quantitative metrics using COAT software.

The formalized method was preferable as it was free from experts' and analysts' subjective interpretations and had the potential to be automated.

For step 3 the KOMET-DILIGENT collective ontology development was designed (Gavrilova, Leshcheva, Bolotnikova, Blagov and Yanson, 2013). This methodology enriches the findings of the Neon Project (Neon Project).

All the individual and collective ontologies (both in dyads and in small groups of 3-5 members) were analyzed. In the KOMET project, specificity of the collective ontology development has been researched. The test sample consisted of the students of the Saint Petersburg State Polytechnic University, Institute of Information Technology and Control Systems (IITCS), attending the intelligent systems development course. The experiments were also aimed at figuring out how the collective categorization style is being developed.

5 Cognitive Ergonomic Metrics

The individually designed ontologies were assessed by an augmented set of metrics (such as minimal depth, absolute width, etc.) suggested in Bolotnikova, Gavrilova and Gorovoy (2011). In evaluating the quality of the designed ontologies, the following two aspects are most important: (1) correctness and depth of reflection of the subject domain, and (2) ergonomic aspect of the ontology representation from the point of view of quality and human speed of perception.

As an example further we describe two metrics. The notation used to describe the metrics is the following:

“g”, a graph representing an ontology; the concepts (classes and exemplars) of the ontology are the graph nodes, the relationships between the concepts are the graph edges;

“G”, a set of all the nodes g;

“E”, a set of all the edges g.

A minimal depth:

$$m = N_{j \in P}, \quad \forall i (N_{j \in P} \leq N_{i \in P})$$

where $N_{j \in P}$ and $N_{i \in P}$ are the path lengths j and i from the set of paths P of the graph g .

An absolute width:

$$m = \sum_j^L N_{j \in L}$$

where $N_{j \in L}$ is a number of nodes of degree j from the set of nodes L of the graph g .

Many aspects affect the quality of an ontology from the cognitive point of view. The COAT software environment provides calculation of more than 20 metrics. Metrics of this kind were first proposed by the research group of Aldo Gangemi (Gangemi, Catennaci, Ciaramita and Lehman, 2006). The ontology evaluation based on these metrics is formal but it helps to assess the ontology quality. The complete list of metrics was presented in detail in two works (Bolotnikova, Gavrilova and Gorovoy, 2011; Gavrilova, Bolotnikova and Gorovoy, 2012).

These metrics can help to understand what should be corrected in the description of the subject domain in order to improve it from the point of view of cognitive ergonomics or better perception. Thus it is supposed that each next version of the ontology will be better and it can be perceived faster by users.

The metrics can also be used in evaluating ontologies of the same subject domain produced by different people/teams. The calculated metrics help to estimate which of them is better from the point of view of cognitive ergonomics and to choose the best of them if the evaluations of other important criteria differ insignificantly.

6 Analysis of the Individual Construction Affected By Cognitive Style

The research sample for the described study was consisted of 79 students, enrolled in the intelligent systems development course. All the tested students were given the task of developing an ontology for the informatics research domain. Due to the professional specificity of the sample, a bias toward narrow, reflective and field-independent test persons was found in the sample. However, a statistically significant Spearman's negative correlation between the FID score and the time of the first answer in the Kagan was calculated, showing that the sample was dominated by the fast FID and slow FD respondents.

The two methods mentioned above were used for assessment of the result.

On the basis of the literature review and the practical ontology development experience, the following hypotheses are suggested:

Hypothesis 1. *Individuals belonging to the FID extreme point of the FD/FID cognitive style characteristic tend to have highly developed cognitive structuring capabilities; thus, the quality of ontologies developed by the FID individuals would be higher.*

Hypothesis 2. *Impulsive individuals tend to develop superficial ontologies lacking sufficient categorization in the upper level, while the reflective individuals tend to develop deeper ontologies.*

Hypothesis 3. *Ontologies developed by the individuals described as “imprecise” in the Kagan impulsivity/reflectivity test results tend to be more complex.*

Hypothesis 4. *The “narrowness/ width of the category” cognitive style characteristic exerts significant influence on the ontology width: the “wide categorizers” tend to develop broader ontologies.*

The correlation between the cognitive style and ontology metrics values was assessed by Spearman’s coefficient (rank correlation). The significant correlation between the metrics and such features as field dependence/ field independence was not found.

Hypothesis 1 was not confirmed, as no significant correlation between the FD/FID metric and the quality of the ontologies was found; this result gave rise to optimistic feelings about the whole project, as it shows that it is possible to teach any individual to develop ontologies of a high quality.

Hypothesis 2 was partially confirmed: the “90% line depth” metric demonstrated significant positive correlations with the time of the first answer in the Kagan test, thus showing that reflective test persons tend to develop deeper ontologies; however, no significant negative correlation between the time of the first answer and the ontology width was found.

Hypothesis 3 was confirmed, as the number of mistakes in the Kagan test demonstrated a significant positive correlation with the values of the “Average number of parents of a graph node” metric that characterizes the ontology complexity.

Furthermore, the number of mistakes in the Kagan test demonstrated significant positive correlations with the metrics of the “Minimal depth of the ontology” and the “Families branching coefficient” and significant negative correlation with the weighted leaves branching coefficient.

Hypothesis 4 was fully supported: the broad categorizers developed bigger ontologies in terms of the number of concepts, achieved mainly by the greater number of “children” of each parent concept.

Respectively, the results of the “Average judgments” test demonstrated significant correlations with such metrics as the “Average ontology width”, “Number of leaves”, “Absolute cardinality of families”, etc. These results also demonstrated significant correlation with the root-mean-square deviation of the average ontology width. This result shows that the number of concepts belonging to the neighbouring levels and to different branches is significantly different, indicating imbalance in the ontologies developed by the wide categorizers.

Despite the objectivity of the quantitative metrics-based method of ontology assessment, this method has the significant drawback of being too formalized and lacking semantic analysis elements. Having augmented the quantitative metrics-based analysis by a semantic analysis performed manually, we found that the ontologies developed by the field-independent test persons tend to have simpler and clearer structure. However, this simplicity and clarity tends to be achieved by truncating the concepts that do not fit into the developed ontology, thus sacrificing the ontology’s completeness and integrity for formal logical consistency.

As for the collective ontology development, including wide categorizers into a group together with a FID individual can be useful, with the wide categorizers generating a plethora of sub-classes and the FID participant restructuring these. This hypothesis has been tested on the stage of research dedicated to collective ontology development.

So, the following relationships between the respondent’ individual cognitive styles and the peculiarities of respondents’ subject domain ontology development have been identified as a result of the research:

- Considering the “impulsivity/reflection” scale, the reflective individuals tend to develop deeper ontologies.
- The ontologies developed by the imprecise individuals (as defined in the Kagan test) tend to be more complex.
- The “narrowness/ width of the category” cognitive style affects the ontology branching coefficient, i.e. the ontology width.

7 Collective Ontology Design

An objective of this study was to establish how the collective categorization style was developed. Specificity of the collective ontology development has also been researched, both in dyads as well as in the groups of 3-5 persons.

The KOMET-DILIGENT collective ontology face-to-face design methodology proposed within the KOMET project uses the following algorithm (Gavrilova, Leshcheva, Bolotnikova, Blagov and Yanson, 2013):

1. Preliminary individual ontology development by the participants and consequent mutual ontology matching.
2. Ontologies analysis, merging and alignment.
3. Ontology revision and redesign.

Students first developed individual ontologies and then were asked to develop a collective common ontology on the same topic, “computer science”. The time allowed was one hour.

The experiments aimed at figuring out how a collective categorization style was developed. Two strategies were identified:

S1, a strategy of collective ontology development “from scratch”, and

S2, a strategy of common ontology development on the basis of two or more individual drafts.

These strategies were affected by the peculiarities of analyzing and merging individual ontologies in the collective ontology development methodology suggested and previously explained by the authors.

The second strategy, S2, is of greater practical interest. In this case the respondents effectively applied all three basic ontology engineering operations (matching, merging and alignment).

The experiments have shown that merging usually follows either of the two scenarios:

1. Absorption scenario (60-70% of all the tested groups);
2. Compromise (synthesis) scenario (30-40% of the tested groups).

The absorption scenario has been researched by us in more detail, as this scenario was used more often than the others. The implications of this scenario have led to the design of two models:

A disjunctive model, in which the higher power ontology absorbs the lower power one, with further merging of the same-degree nodes in the resulting ontology.

A conjunctive model in which the reduction of nodes leads to the resulting ontology including only the disjunction or intersection of the same-degree nodes.

Comparison of these scenarios with the cognitive styles of the test participants revealed the following relationships:

- Field-independent (FID) test persons tend to prefer the conjunctive scenario.
- Field-dependent (FD) test persons tend to prefer the disjunctive scenario.

Figures 2, 3 and 4 illustrate the experiment and demonstrate the variation from the synthesizing scenarios. This variation is the best alternative, with collective effort showing the synergetic effect of “jumping” to a higher level of abstraction. The higher level always demonstrates deeper knowledge and better understanding of the domain specifics. These ontologies can be criticized as they were developed by young researchers. However, our experiment was targeted at the study of collaborative ontology design, not the production of a serious domain ontology.

8 Conclusions

This paper addresses the conceptual limitations of traditional research communication and proposes using a visual metaphor for illustration and presentation of the research state-of-the art and main findings.

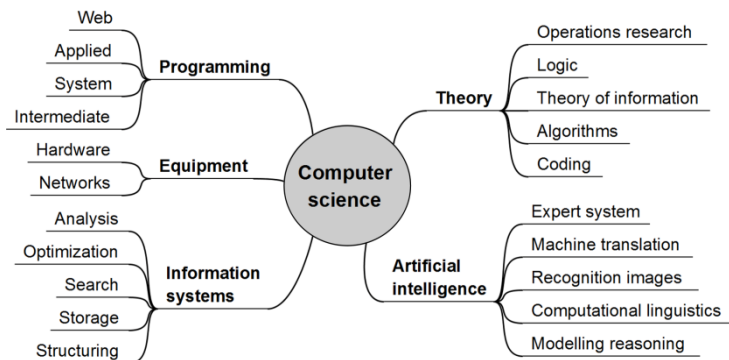

Figure 2. Example of individual A ontology of computer science

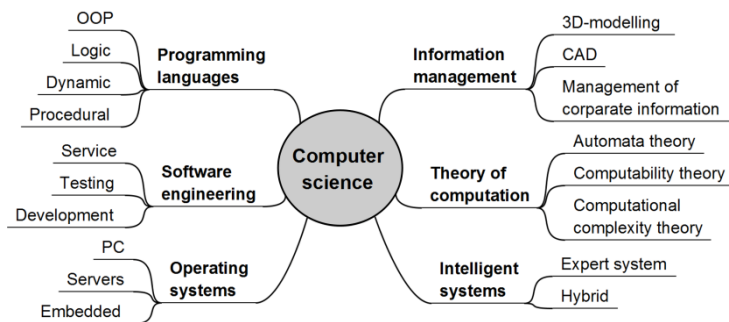

Figure 3. Example of individual B ontology of computer science

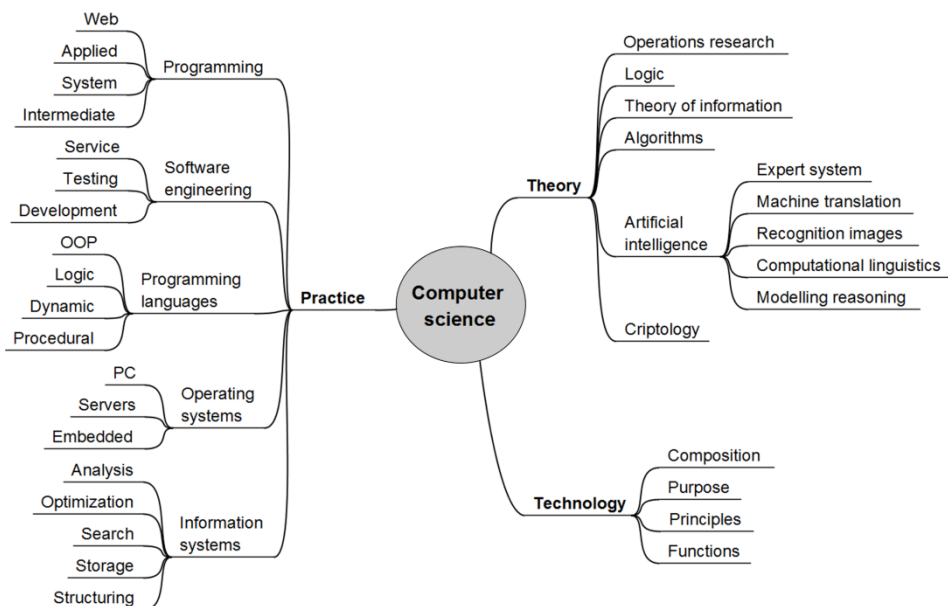

Figure 4. Collaborative AB ontology of computer science

Finally, the impact of individual cognitive styles on team ontology development can be taken into consideration in such areas where team intellectual work with ontology development as a possible method can be used, e.g. requirement engineering, smart services R&D or management consulting.

Using visual inspection of the ontology it is possible to detect gaps and misunderstandings in the state-of-the-art knowledge level and cognitive model of the domain knowledge. However, there is as yet little consensus on the useful design and orchestration of such structures. Furthermore, in many cases it is not known what the structure of socially legitimate knowledge patterns looks like, or how a particular instance

of a knowledge model deviates from that “ideal” state (e.g. guru’s view) (Cross, Parker, Prusak and Borgatti, 2001). However, researchers are individuals, and they may disagree among themselves.

The study described here is only a first step in the interdisciplinary research field dedicated to the inquiry into the affect of the expert’s individual cognitive style parameters on the group structuring design activity. Our results are therefore of a preliminary nature.

Group ontology design, both in dyads and groups of more than two participants, is performed either “from scratch” or on the basis of the drafts prepared by the members of the group individually.

Merging of the individual drafts into a single group ontology follows either an absorption or compromise scenario, or a synthesis scenario. The absorption scenario of the merging of ontologies can be implied from either a conjunctive or a disjunctive model.

From the different cognitive styles, the field-dependent participants tended to prefer the disjunctive model of merging ontologies, with the higher power ontology absorbing the lower power one and further merging of the same-level nodes in the resulting ontology.

The field-independent participants tended to prefer the conjunctive model, with the node reduction leading to the resulting ontology, with the conjunction or interception only of the same-level nodes.

Despite the preliminary character of the research results, all the findings can be used in organizing collective ontology development, data structuring and other group analytical work. Our work presents a novel approach on collaborative ontology development from the psychological point of view. Knowing of the cognitive personal peculiarities helps to leverage the subjectivity of the individually-designed ontologies.

Using recent advances in knowledge engineering and a human factors approach, we aim at creating new consistent ontologies for smart service requirements engineering. Especially it is important for the knowledge portal maintenance services.

Acknowledgements

The authors are thankful to Andrew Pisarev (programmer), Elena Kotova (psychologist), Eugene Blagov and Ekaterina Bolotnikova who helped both with the

experimental part and at the stage of paper preparation. The KOMET project was funded by the Russian Foundation for Basic Research (grant 11-07-00140).

Structured Abstract

Purpose – Integrating sustainability into the banking activity, *i.e.* taking a broader view of how actions affect future generations, stakeholders and the environment, is an increasingly necessary but extremely challenging issue currently facing financial institutions. It is thus becoming ever more important to understand the key determinants of sustainable banking and how they inter-relate with each other. As such, our aim in this research is to build a cognitive map, in particular a fuzzy cognitive map (FCM), to model, dynamically analyze and test the reciprocal influence of key factors underlying sustainable banking.

Design/methodology/approach – We propose an approach which explores the applicability of FCMs in the context of sustainable banking. FCMs have been shown to be of particular use in the handling of complex decision problems characterized by lack of information or unavailable data. They constitute a methodological framework that should allow for a reduction of omitted determinants with regard to sustainable banking, as well as a greater understanding of the relationships between them.

Originality/value – This methodology puts in evidence the value of applying FCMs to the structuring of the process of sustainable banking. We know of no previous work which has done this; and believe this first effort in the application of cognitive mapping

techniques to the identification of the key determinants of sustainable banking will be an important contribution to both theory and practice.

Practical implications – The outcomes of the application of FCMs to sustainable banking can be expected to contribute to the literature, not only in what refers to sustainability strategies in the banking sector, strategic knowledge asset management and operational research, but also at a methodological level. As neuro-fuzzy systems, FCMs are able to incorporate experts' knowledge, holding powerful and far-reaching potential to analyze and model complex decision problems, such as those considered in this paper. We anticipate implications and practical applications for both bank managers and policymakers aiming to increase the efficiency of their decision making in the context of sustainable banking.

Keywords – Sustainable Banking, Problem Structuring Methods, Fuzzy Cognitive Maps, Knowledge Management, Expert Systems.

Paper type – Academic Research Paper.

1. Introduction

The 21st century has brought greater business diversification to the banking industry, such that most of the major banks in the industrialized world are now complex financial organizations offering a wide range of services to international markets, and strategically controlling billions of dollars in cash and assets. Making use of technological advances, banks have been working to identify new market opportunities, implement new strategies, and increase their levels of customer retention (*cf.* Reis *et al.*, 2013). And as the globalization and diversification of the financial industry increase, these challenges become bigger: the changes in the environment become faster, the competition more fierce, and the need to adapt greater (Cole, 2011; Ferreira *et al.*, 2012). It is anticipated that over the coming years the banking sector will become even more complex, and that in the future it will no longer work in the same manner all over the world. The requirement for survival, therefore, is of a posture of learning, whereby banks are able to adapt to the demands of the external environment with greater agility. At the same time, from an academic point of view, it becomes increasingly pressing to understand the effects of these ongoing changes in the global economy, as well as the role of banks in particular, as their importance in the business community increases (Stephens and Skinner, 2013; Ferreira *et al.*, 2014).

There has been growing discussion about the integration of sustainability into the banking activity, in both academia and business practice. Recent analyses have shown

that sustainable, values-based banks, which predominantly base their decisions on the needs of people and the environment, are outperforming traditional mainstream banks in terms of financial indicators such as return on assets or growth in loans and deposits (for a fuller discussion, see Ramos *et al.*, 2011; Rebai *et al.*, 2012; Fatemi and Fooladi, 2013; Stephens and Skinner, 2013). Results such as these have put sustainability at the forefront of banks' managerial concerns, and at the same time made researching sustainable banking an imperative.

The integration of sustainability concerns in banking has essentially been taking two forms: (1) socially and environmentally responsible initiatives (*e.g.* support for cultural events, charitable donations, recycling programs and support for improvements in energy efficiency); and (2) the integration of environmental and social considerations into product design, mission and business strategies (*e.g.* the integration of environmental criteria into lending and investment strategies) (Jeucken and Bouma, 1999; Bouma *et al.*, 2001). This second dimension highlights the importance of incorporating sustainability into banks' competitive strategies and decision-making processes on a larger scale, since financing environmentally and socially responsible projects can be expected to ultimately lead to changes in the business landscape as whole, as sustainable and sound enterprises are helped to prosper (Stephens and Skinner, 2013). Indeed, a major shift has already happened, as banks have come to realize that poor environmental performance on the part of their clients can represent a threat to their profitability. There is an increasing concern among banks over clients' environmental performance, which has been acting as an additional driver of sustainable banking, leading banks to develop mechanisms to assess their customers' ethical and environmental risk exposure, in order to protect themselves from potential losses.

Despite the above arguments, integrating wider concerns over stakeholder and the environment into the banking activity is not as simple as it might appear. In fact, given the considerable number of decision makers involved, and the large variety of sustainability determinants to be considered, this integration can actually be a very challenging undertaking. It becomes imperative, therefore, to understand these determinants, and how they inter-relate with each other, to promote (or inhibit) the consideration of sustainability in banks' strategic decisions. A fuller understanding of this hitherto largely underdeveloped topic is not only of academic interest, but of great utility to the decision makers involved. Ultimately, it can be expected to help support not only

the development of more sustainable banking, but more sustainable business ventures in general.

Our first research question thus pertains to the key determinants of sustainable banking and the manner in which they inter-relate with each other. Identifying and understanding the conditions that underpin sustainable banking and clarifying the links between them is crucial to the enhancement of value creation and achieving the desired sustainability goals. Existing research on these conditions or indicators “*is yet speculative, due to a shortage of standard definitions and relevant data*” (Kauko, 2010: 191), which highlights the need to not only identify them, but also to develop a framework for their representation and categorization, such that they can better be used to create value. Our second research question thus seeks to determine whether a knowledge-based representation of sustainable banking can be created, and having been developed, whether such a framework can enhance value creation.

In seeking to analyze these questions, an approach using *Fuzzy Cognitive Maps* (FCMs) is employed. This approach simultaneously allows the pursuit of a third research goal, which is to test the applicability of FCMs in the context of sustainable banking. FCMs have previously proven useful in handling complex decision problems characterized by lack of information or unavailable data (*cf.* Carlucci *et al.*, 2013; Gavrilova *et al.*, 2013). Indeed, “*FCM is a well-established artificial intelligence technique, incorporating ideas from artificial neural networks and fuzzy logic, which can be effectively applied in the domain of management science*” (Carlucci *et al.*, 2013: 208). This methodological framework should allow not only for a reduction in the number of omitted determinants, but also for a greater understanding of the relationships between them. We know of no previous work applying FCM to structuring the process of sustainable banking decisions; and believe this first effort in the application of cognitive mapping techniques to the identification of the key determinants of sustainable banking will be an important contribution to both theory and practice.

The remainder of the paper is structured as follows. The next section presents a brief review of the literature on sustainable banking. Section 3 presents the research problem and the methodological background. Section 4 explains the steps followed during the construction of our FCM, and section 5 concludes the paper.

2. Previous studies on sustainable banking

It is commonly claimed that the current economic crisis has triggered a sharp increase in competition, an assertion which is backed by research (e.g. Ferreira *et al.*, 2011). Wu (2012: 303) refers to the “*chain effects of the financial ‘tsunami’*” that was the Global Financial Crisis, and the fact that “*financial institutions in particular have encountered more competitive challenges worldwide*” as a result of it. In this climate, it becomes increasingly necessary for financial and banking institutions to have a clear and clearly understood mission, as well as agreed upon objectives, on the basis of which they can determine the strategies and tactics that will be used to achieve them (Ferreira *et al.*, 2012). This implies substantial progress in banks’ abilities to mobilize, explore and evaluate tangible and intangible resources, in line with the opportunities offered by its (ever changing) context. As highlighted by Carmeli (2004: 111-112), “*the real source of competitive advantage is underlined by the organization’s ability to consistently meet environmental changes [...]*”.

It is precisely with regard to this challenge that integrating longer term considerations into the banking activity plays a fundamental role. The current demand from the external environment appears to be that of sustainability, and banks need to develop the organizational agility to integrate this into their strategic decision making processes. Simply performing traditional activities such as attracting and investing savings is no longer enough. New responsibilities – environmental and social – are demanded of banks, and arguably the best way forward is to look at these as business opportunities, rather than risk factors.

Delineating and implementing a “sustainability strategy” is only possible when there is an ability and willingness to consider and involve stakeholders in decision making processes. *Figure 1* identifies banks’ main internal and external stakeholders.

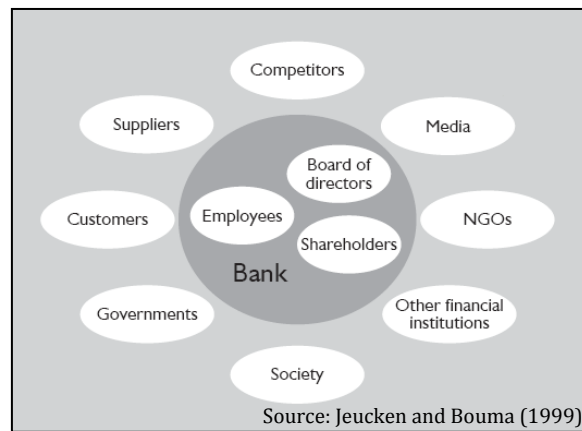

Figure 1. Sustainability strategy and (internal and external) stakeholders

Immediately, a challenge can be identified: the number of stakeholders is considerable, and they all constitute potential decision makers. However, they do not necessarily have the same interests and priorities, making decision making in general, and with regard to sustainability issues in particular, unlikely to be easy. A further challenge emerges when it becomes apparent from the literature that the determinants of sustainable banking have not yet been clearly identified, let alone defined and understood (Kauko, 2010). Understanding these determinants and their relative importance, however, is fundamental to our comprehension of banks' ability to consider sustainability in a strategic manner. This integration of sustainability in banking further implies a solid long-term commitment on the part of bank managers toward the creation of both value and of a more responsible society.

Given the social and economic relevance of this issue, it is not surprising that it has been attracting increasing interest in the literature (*cf.* Jeucken and Bouma, 1999; Bouma *et al.*, 2001; Rebai *et al.*, 2012; Fatemi and Fooladi, 2013; Stephens and Skinner, 2013). However, and their undeniable merit notwithstanding, the insights provided by these contributions have been unable to fully identify and define the determinants of sustainable banking, or the relationships between them. Indeed, most of the existing research presents the end results of sustainable banking practices, but does not explain why they emerge or how they can be improved. A further limitation of the existing research relates to the methodological frameworks used. Most of this research relies on parametric analyses, which, as highlighted by Garland and Gendall (2004) and Ferreira *et al.* (2011), have

limited ability to provide practical contributions to sustainable relationship management. In particular, the process by which the determinants of sustainable banking are identified and articulated in such studies arguably appears somewhat arbitrary (Pan *et al.*, 2012).

Given these limitations, the recourse to modern approaches, such as FCMs and neural networks, constitutes a promising avenue in the field of sustainable banking. Although themselves not perfect, these “new” approaches hold the potential to identify the “missing links” between determinants, and consequently enhance value creation by increasing the transparency and our understanding of decision situations.

Our framework sees sustainable banking as a complex decision problem, where the determinants of sustainability are strongly dependent on diverse stakeholders with different and conflicting values and preferences. As such, it assumes a process-oriented position and will be developed with the direct involvement of professionals from the banking industry.

3. Research problem and methodological background

3.1. Research problem

This study aims to analyze the conditions and key determinants that support sustainable banking; since, as previously noted, integrating sustainability into the banking activity is not an easy task. Not only are there a considerable number of decision makers with different and conflicting values and preferences involved, but there are also a large number of determinants of sustainability to be considered. While it is true that this makes the integration of sustainability in banking strategies and decisions more challenging, it is also true that this is an increasingly pressing issue for these financial institutions. A better understanding of the determinants of sustainability and the ways in which they are interlinked, will help bank managers and decision makers to enhance value creation through better, more informed decisions, at the same time as sustainability objectives are moved forward.

3.2. General overview of the methodology

Although there can be many ways to consider decision problems and decision making situations, when these are multifaceted and multiple criteria are involved, additional demands are placed on the methodological approach adopted. Cognitive mapping has

been argued to be particularly adapted to such situations, not only because it allows the modeling of complex relationships between variables in multifarious phenomena (Carlucci *et al.*, 2013), but also because, as visual tools, maps “*facilitate the representation and communication, support the identification and the interpretation of information, facilitate consultation and codification, and stimulate mental associations*” (Gavrilova *et al.*, 2013: 1758). Indeed, by directly involving participants and fostering discussion between them in order to come to a consensual group map, this methodology promotes greater processual transparency, improves understanding of the decision problem and reduces the likelihood of omitted variables (Peña *et al.*, 2008; Ferreira *et al.*, 2012).

Within cognitive mapping, “Fuzzy Cognitive Maps” (Kosko, 1986, 1992) in particular have been extensively applied to contexts and decision problems characterized by high levels of complexity (*e.g.* Kardaras and Mentzas, 1997; Stylios and Groumpos, 1999; Tsadiras *et al.*, 2003; Kok, 2009; Salmeron, 2009 and 2012; Papageorgiou *et al.*, 2012; Carvalho, 2013). The novelty in FCMs lies in complementing cognitive mapping with fuzzy logic. In FCMs, the relationships between criteria can be represented by positive and negative causality at the same time; the intensity of which is then translated into a number which can go from -1 to 1. The resulting map thus allows for dynamism, by including feedback links between the different variables/criteria (Carlucci *et al.*, 2013), as represented in *Figure 2*, where C_i is criterion or variable i and W_{ij} represents the extent to which criterion i influences criterion j . This relationship (W_{ij}) can be of positive, negative or null causality, depending on whether C_i causes a move in the same direction, the opposite direction or has no impact on C_j .

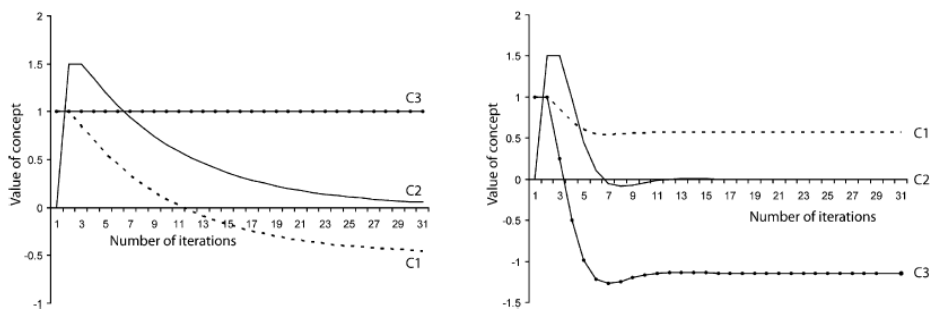

Figure 2. Example of a typical FCM

Source: Salmeron (2012: 3706).

The mathematics behind FCMs can be summarized in the following equation (see equation 1), where $A_i^{(t+1)}$ is the activation level of criterion C_i at time $t+1$; $A_i^{(t)}$ is the activation level of criterion C_i at time t ; $A_j^{(t)}$ is the activation level of criterion C_j at time t ; W_{ji} is the weight of the interconnection between both criteria; and f represents a threshold activation function (Mazlack, 2009; for further details, see also Stach *et al.*, 2005; Papageorgiou *et al.*, 2012; Glykas, 2013).

$$A_i^{(t+1)} = f \left(A_i^{(t)} + \sum_{j=1}^n A_j^{(t)} \cdot W_{ji} \right) \quad (1)$$

Mazlack (2009) clarifies that the overall impact of a change in the value of a particular criterion is given by a new state vector A_{new} , which is obtained by multiplying the previous state vector A_{old} by the adjacency matrix W . “The resulting transformed vector is then repeatedly multiplied by the adjacency matrix and transformed until the system converges to a fixed point. Typically it converges in less than 30 simulation time steps” (Carlucci *et al.*, 2013: 213). Aiming to exemplify this type of exercise, Figure 3 shows the results of a simulation carried out by Kok (2009).

Source: Kok (2009: 125).

Figure 3. FCM stabilization and value convergence points

A ranking (*i.e.* “strength of impact”) of criteria is then obtained, reflecting how the system is perceived in the FCM. This allows: a) the impact of changes in the value of any single concept to be assessed; b) the strength of the impact of concepts on each other to be determined; and c) “what if” questions to be formulated, in order to ascertain the impact on the system as whole of changes, addition or removal of some concepts.

The most common challenge in applying this kind of methodology relates to the difficulty of getting group members (in this case, experts from banking institutions)

together in the same place at the same time, for what are relatively long sessions required to develop a joint cognitive map. Although this is an issue to be taken seriously, we considered that the potential benefits of the application of FCMs to the field of sustainable banking, in terms of contribution to both theory and practice would greatly outweigh this challenge. To the best of our knowledge, this study constitutes the first attempt to identify key determinants (and the “missing links” between them) of sustainable banking using cognitive mapping techniques. We anticipate practical implications for bank managers and policymakers who aim to increase the efficiency of their decisions in terms of sustainable banking.

4. Construction of the fuzzy cognitive map

In this section we present a step-by-step discussion on how the FCM approach was used to identify key determinants of bank sustainability, and the dynamics between them.

4.1. Participants involved

With regard to the participants in this type of study, Yaman and Polat (2009: 387) argue that “*using a group of experts has the benefit of improving the reliability of the final model*”. As such, we sought to set up a professional panel, in this case constituted by banking experts. After several unsuccessful attempts, due to availability restrictions and incompatible schedules, we were finally able to form a panel with seven participants. This final group was comprised of three regional directors, two bank branch managers and two bank branch front office employees, from the five largest banks operating in Portugal. Although “*the expert panel number is quite difficult to establish and no study has been conclusive with respect to it*” (Salmeron, 2009: 276), seven can be considered a very reasonable number of participants for this kind of research in particular, since “*the consultant [i.e. facilitator] will relate personally to a small number (say, three to ten persons)*” (Eden and Ackermann, 2001: 22). Furthermore, the group’s heterogeneity allowed different perceptions on sustainable banking to be confronted, enriching the discussion underlying the whole process. The expert panel was brought together during an intensive 7-hour meeting, which was conducted by an experienced facilitator assisted by an ICT technician.

4.2. Identifying concepts and quantifying relationships

The group meeting started with an initial clarification of the research objectives and a presentation of the principles of FCM. The aim was to ensure a common understanding of the purpose of the session among the participants. Having established this common ground, the group was asked the following trigger question: “*Based on your own values and professional experience, what are the determinants of sustainable banking?*”. This provided the focus for discussion and allowed the “post-its technique” to be applied. This technique consists of writing what the decision makers consider as relevant criteria on post-its (*i.e.* one criteria per sticker), and sticking them on a large piece of paper (Ackermann and Eden, 2001). The process is grounded on continuous debate among the expert panel members and should be repeatedly executed until they are collectively satisfied with the outcomes achieved. In the next stage of the process, the post-its are organized by areas of concern (or clusters), which allows for additional discussion on the meaning and significance of each criterion. Once the areas of concern have been defined, each cluster is then carefully analyzed, so the post-its can be reorganized in a means-end-based structure (*i.e.* the most important/strategic concepts are put at the top of the cluster and the least important are put at the bottom). *Figure 4* illustrates the process followed in this study.

Figure 4. Snapshots of the “post-its session”

Once there is agreement within the group with regard to the form and content of the cognitive structure developed, this phase of the process is considered to be concluded, and a “strategic” or “collective” map is obtained. In our study, the final version of the map, which is partially illustrated in *Figure 5* and represents the group’s agreement on the key

determinants of sustainable banking, was developed using *Decision Explorer* software (www.banxia.com).

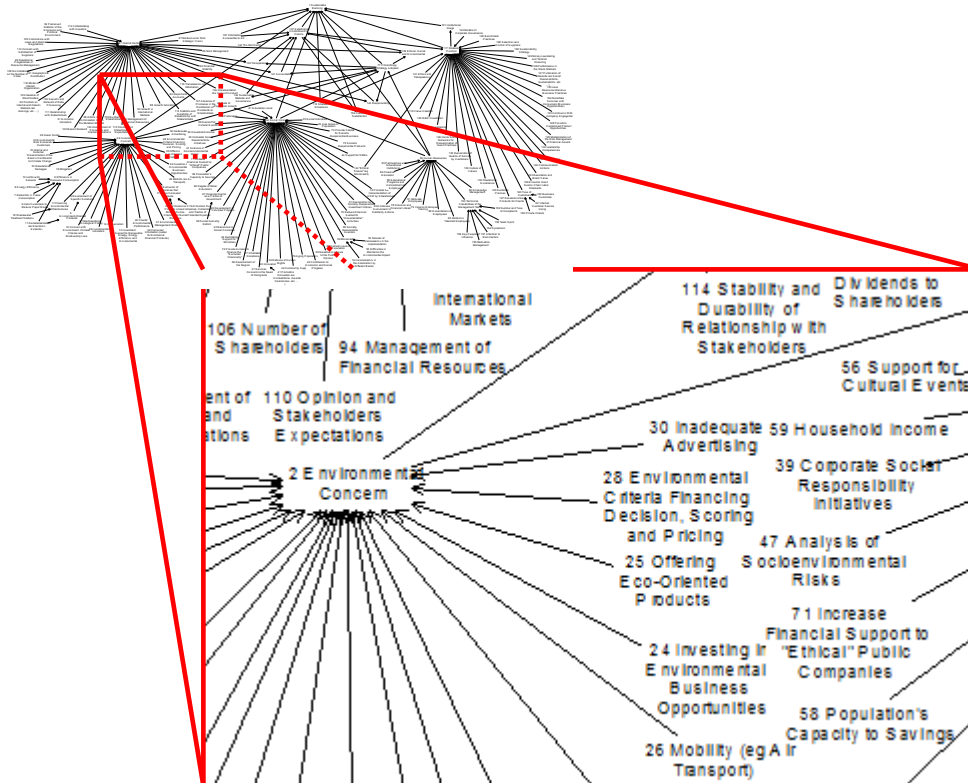

Figure 5. Part of the collective map developed

The final version of the map contained 167 determinants of sustainable banking, and for this reason could not be totally displayed in this paper. However, the contribution of this approach goes beyond the mere identification of criteria. It adds value by allowing vast amounts of information to be analyzed; and through the insights brought by the experts involved in the process (Ferreira *et al.*, 2014). The process is (and was in the current study) inherently subjective, but in practical terms, cognitive map allowed the panel members to be provided with a holistic view of sustainable banking, which they considered extremely useful.

In moving forward in the construction of a FCM, the agreed upon collective map was rebuilt using the *FCMapper* (<http://www.fcappers.net>) and *Pajek* software (<http://pajek.imfm.si/doku.php>). As complements to *Decision Explorer*, these two

software packages allow the intensity of the links between variables to be dynamically analyzed. *Figure 6* presents the new layout of the cognitive structure, where the numbers stand for the determinants of sustainable banking previously identified.

Figure 6. [Initial] Structure of the FCM

The panel members were provided with *Figure 6* and asked to analyze the intensity of the links. *Figure 7* illustrates this analysis, which was performed for all the clusters and where the intensity of each link ranges between -1 and 1 (*cf. subsection 3.2*).

Figure 7. *Quantification of relationships*

These degrees of intensity expressed by the group were then introduced in a 167 x 167 adjacency matrix. Again, size restrictions mean that this matrix cannot be displayed in this paper. However, *Figure 9* exemplifies the matrix used: N_i stands for criterion i and e_{ij} represents the intensity degree between criteria i and j , as defined by the expert panel on a collective basis.

	N_1	N_2	...	N_{N-1}	N_N
N_1	0	e_{12}	...	e_{1N-1}	e_{1N}
N_2	e_{21}	0	...	e_{2N-1}	e_{2N}
...
N_{N-1}	e_{N-11}	e_{N-12}	...	0	e_{N-1N}
N_N	e_{N1}	e_{N2}	...	e_{NN-1}	0

Source: Stach *et al.* (2005: 380).

Figure 8. *Adjacency matrix*

The development of the adjacency matrix served to promote additional discussion on the results and helped define the study recommendations (Yaman and Polat, 2009; Salmeron, 2012; Carlucci *et al.*, 2013).

4.3. *Interpreting the research outputs*

Several static and dynamic tests were carried out throughout the study; and, “*through a proper neural network computational model, [...] what we can get is an idea of the ranking of the variables in relationship to each other according to how the system is perceived in the FCM*” (Carlucci *et al.*, 2013: 216). This criteria interaction allowed the most relevant determinants of sustainable banking to be presented in *Table 1*.

Table 1. Major determinants of sustainable banking [based on centrality]

Determinants	Reference	Outdegree	Indegree	Centrality
Social Concern	34	1.80	28.10	29.90
Strategic Position	117	1.799999952	25.2	26.99999995
Internal Factors	87	4.10	22.70	26.80
Environmental Concern	2	1.50	17.40	18.90
Human Resources	50	2.40	8.90	11.30
Commitment to Clients	137	2.599999905	6.1	8.699999905
Philanthropy Strategy Adopted	77	5.00	2.60	7.60

These results are, naturally, context-dependent, meaning that they could have been different had the panel of experts been another or had the session had a different duration. (for details, see Ferreira *et al.*, 2014). However, it is important to note that in addition to the results themselves, the approach followed allowed for discussion among experts and promoted a better understanding of the determinants that influence sustainable banking.

A centrality index was calculated for each criterion comprised in the FCM. Due to the high number of criteria (*i.e.* 167), only the ones with greater indices were included in *Table 1*. In particular, *Social Concern*, *Strategic Position* and *Internal Factors* present the highest centrality indices (*i.e.* 29.90, 26.99 and 26.80, respectively). The way each criterion contributes to the calculation of these indices offers real insight into the dynamics behind sustainable banking, supporting the premise that “*FCMs are simple, yet powerful tools for modeling and simulation of dynamic systems, based on domain-specific knowledge and experience*” (Papageorgiou *et al.*, 2012: 45).

As Salmeron (2009: 275) points out, “*from an Artificial Intelligence perspective, FCMs are supervised learning neural systems, whereas more and more data is available to model the problem, the system becomes better at adapting itself and reaching a solution*”. Indeed, the results obtained in this study suggest that FCMs hold great potential for operational planning and improvement of sustainable banking, which is of prime concern for banks and society at large.

4.4. Limitations and recommendations

The knowledge-based representation of sustainable banking resulting from the construction of the FCM allowed the group members to: (1) identify objective and subjective determinants of sustainable banking; (2) identify key feedback loops and analyze the dynamics of the system; (3) engage in meaningful discussion throughout the meeting; and (4) provide insights that can improve our understanding of sustainable banking.

Naturally, this proposal is not without its own limitations. As already pointed out, the process followed is subjective in nature and its context-dependence discourages direct extrapolations. In addition, and as argued by Stach *et al.* (2005: 372), “*FCM development methods are far from being complete and well-defined [...] the development of FCM models almost always relies on human knowledge [...] and] strongly depend on subjective beliefs of expert(s) from a given domain*”. Balancing pros and cons, it should be underlined, however, that these limitations are arguably more than compensated by the exchange of ideas underlying the negotiation process and by the insights brought to the system by the panel of experts, which might go undetected by simple applications of statistical methods alone (*cf.* Stach *et al.*, 2005).

5. Conclusion

There has been significant progress in the field of sustainable banking in recent times. Notwithstanding, existing contributions fall short of clearly identifying the cause-and-effect relationships between the determinants of sustainable banking. A knowledge-based representation of sustainable banking has been identified as a research priority for the development of sophisticated decision support systems, because, as noted by Kim and Lee (1998: 303), “*knowledge engineering is one of the most important tasks in developing expert systems. One of the primary objectives [...] is to develop a complete, consistent and unambiguous description of the knowledge base*”.

Based on this premise, and taking a constructivist standpoint, this paper made use of FCMs to, through the discussion and negotiation of a group of experts: identify the main determinants of sustainable banking; define them; determine their interactions; create a visual map of the whole system; and analyze its dynamics.

The results of this study can be expected to contribute to the literature, not only in what refers to sustainability strategies in the banking sector, strategic knowledge asset management and operational research, but also at a methodological level. By reducing the number of omitted criteria and increasing our understanding of the relationships between variables, this study strengthens previous claims that fuzzy logics (and FCMs) can provide an important alternative for overcoming some of the limitations associated with the methodologies currently most in use in the industry (*cf.* Keršulienė and Turskis, 2011; Glykas, 2013). Indeed, sustainable banking decisions are characterized as being complex, subjective, and fuzzy in themselves; which makes them a particularly appropriate context for the application of knowledge-based frameworks. FCMs, as neuro-fuzzy systems, are able to incorporate expert knowledge; and as such hold powerful and far-reaching potential to analyze and model complex decision problems, where there is scarcity of information or data, as is often the case in sustainable banking situations.

As discussed, our proposal is context-depend and not without its own limitations. Therefore, it would be of interest for future research to: (1) replicate the study with another set of banking experts, in order to determine the robustness of the research outcomes; (2) replicate the process followed within another country; (3) compare the results obtained from different methodological applications (see Xu and Ouenniche, 2012); or (4) extend the proposal to other contexts. Any such advance in our understanding of sustainable banking, can be used to create (or improve) new strategies.

Structured Abstract

Purpose –The main objective of the paper is to present the model of management system supporting knowledge processes and integrating economic, social and environmental factors in the activity of machine-building enterprises. Successful management in all areas of enterprise’s activity is determined by processing of adequate knowledge in business activity. Machine-building enterprises are crucial elements in creating sustainable growth by decisions at all stages of new product deployment. The great importance for machine-building enterprises is reducing the level of operational risk. It means the need to have the adequate knowledge to improve chances of profitable contracts and to avoid unfavourable ones.

Design/methodology/approach – The model and the system structure were worked out on the basis of research study undertaken in machine-building enterprises. The studies were conducted as qualitative research in 38 Polish machine-building enterprises located in Silesia, recognized as small and medium-sized companies (the target group for which the system was dedicated). The research was conducted in the form of direct interviews with managers using structured questionnaires. As a result the model of knowledge management system was determined and the IT system supporting knowledge management in machine-building enterprises on the basis of the proposed model was worked out.

Originality/value – The value of undertaken research was the model of an information system supporting knowledge management in the execution of contracts in machine-building enterprises. The integration of such solutions as: expert systems, case-based-reasoning, knowledge object management system, dynamic research simulation system enables taking into account economic, social and environmental factors in decision-making processes at all stages of a contract execution.

Practical implications – The model and the proposed IT system support decision-making processes in such areas as: construction, supply, production, distribution and service. The functionalities of the system enables supporting employees responsible for the process of a contract execution, especially project and top managers. At all stages of projects’ execution managers have the opportunity to take into consideration economic, social and

environmental factors in decision-making processes. The important IT tools implemented in the proposed system, in the context of sustainable development, are risk management in the entire contracts' execution and the support in the selection of managers and project team members.

Keywords – sustainable growth, knowledge management system, expert system, machine-building industry enterprise.

Paper type –Practical Paper

1 Introduction

The operation of a manufacturing company is determined by a combination of production factors such as raw materials (environmental resources), financial resources (economic factors) and workload (social factors). The activity of a company brings about such effects as goods or services and waste materials of different type (e.g. pollution). According to the sustainable growth theory, it can be assumed that while accomplishing their objectives, the companies can simultaneously reduce their impact on the environment. The realization of sustainable growth principles at the company level means that the economic and ecological systems are combined. The management, in line with the sustainable growth principle, necessitates the introduction of such planning strategies and company operation policy which would be able to predict a potential, negative impact of such a policy and to undertake measures to counteract it or at least considerably reduce its consequences. An effective realization of the sustainable growth concept in Polish manufacturing companies can be only successful when the strategic realization of vision and mission as well key decision-making processes are supported by multivariate tools and processes of knowledge management which allow for the criteria and conditions involving the principles of sustainable growth.

Effective and efficient realization of knowledge management processes is a key factor contributing to a more productive operation of a company, in particular with respect to manufacturing companies which make use of high-tech solutions and where a product is dedicated to a specific customer (Jashapara, 2006; Kisielnicki, 2008; Kowalczyk, Nogalski, 2007; Szmaj, 2013). A complicated system of internal processes in such companies (Dohn and Gumiński, 2012; Dohn and Gumiński and Zoleński, 2011) necessitates the application of IT solutions which support knowledge-based processes, i.e. knowledge acquiring, storing, transferring and processing in the operation of a company

as the best supportive instrument of decision-making processes which require both quantitative and qualitative processing (Nonaka and Takeuchi, 2000).

The paper presents the research model, the results of the carried out research studies in the selected Polish machine-building companies, the model of knowledge management system and the IT system based on it. The worked out system is dedicated to small and medium-sized machine-building companies. The main objective of the proposed model of knowledge management system is to support decision-making processes during the realization of a contract portfolio and also to facilitate the realization of company's management strategy in terms of its sustainable growth.

2 Literature review

2.1 Knowledge management background

Nowadays organizations recognize that knowledge and its effective development, deployment and exploitation represent a fundamental source of sustainable competitive advantage (Schiuma, 2009; Schiuma et al., 2008).

The literature on the subject offers many approaches to the problem of knowledge management, viewed both from the theoretical perspective and from economic, practical experience (Nonaka, Takeuchi, 1995; Davenport, Prusak, 1998; Hall, Paradise, 2005). In some approaches knowledge management is treated as information technology (knowledge management software) and others treat it as a management philosophy which has little to do with economic practice (Ferrari, de Toledo, 2004). As it was proved by J.Pfeffer and R.Sutton (2002), in practice there is a big discrepancy between the accumulated knowledge and the ability to apply it. It results from the fact there are no approved models or procedures which might assist the companies as a kind of guide. Such a situation might be the direct result of differently understood interpretation of knowledge and the management of knowledge, in particular when viewed from the perspective of theoreticians or practitioners of management. A comprehensive approach to the problem of knowledge management has been proposed by G.Probst, S.Raub and K.Romhardt (2004). In this approach, knowledge is treated as a core around which the whole structure of knowledge management is built. The authors claim that this is the only concept which allows us to translate the problems of management into the problems connected with knowledge, making knowledge the basic category of management.

Sveiby and Lloyd (2009) conclude that the main features of the organization that enters the phase of knowledge organization are: intangible assets and exploiting the limited resources of the knowledge era. Grover and Davenport (2001) argue that the processes of knowledge management are located between information and the sources of income in the organization (e.g. services rendered or sold products), aiming towards the acquisition of knowledge, the definition of knowledge and the knowledge transfer (Roblek et al. 2014).

2.2 Fundamentals of sustainable development in business environment

Over the years, many business organizations, governments, local agencies, and non-governmental organizations have been promoting sustainability, encouraging the establishments of regulations, activities for sustainable production and consumption, education processes (Lukman, and Glavie, 2006).

One of the key challenges which the sustainable growth is facing is the fact that it requires a new and innovative approach to decision-making and to the way of thinking. While the advances in the fields of knowledge and technology contribute to the economic development, they are also offering some potential to provide assistance in solving the risks and hazards threatening the stability of social relations, natural environment and the economy. New knowledge and innovation in technology, in management or in public policy is challenging for the organizations and forces them to make new choices in everyday business operation, in particular with respect to products or services and in view of the impact on the natural environment, people or national economies.

The literature provides many approaches and many definitions of sustainable growth.

But understanding sustainability is a complex task. Berke (Berke, 2002) believes that sustainability may be the next paradigm or "framework to dramatically shift the practice of local participation from dominance by narrow special interests toward a more holistic and inclusive view".

On the other hand (Roosa, 2008) is asking himself the following question: is "sustainable development" a policy, a set of policies, a management philosophy, an agenda, a new set of solutions, a new set of problems, or all of these? Can sustainability, an abstraction, be defined and how could it possibly be measured? What solutions, if any, does it offer? Is sustainability worth pursuing?

Undoubtedly the concept of sustainable development needs to be incorporated into the policies and processes of a business (Dally, 1990). It will require new cultural orientation and extensive refinements to systems, practices, and procedures. Besides the imperatives of creating a sustainable and profitable business are compatible to the best interest of human society and the natural environment. The sustainable view of a business is that the business world is a part of the natural and social system. It is intertwined and has dramatic implications in the absence of one or the other (Wong, 2010).

In view of the above, one can argue that the concept of sustainable growth is a new proposition of a new and qualitatively better form of conscious and responsible individual and social life, where the development is taking place together with and in accord with the surroundings, both social and natural, and where the ecological limitations and social expectations are taken into consideration. The functioning mechanism of the concept of sustainable growth can be narrowed down to the realization of three basic objectives (Skowroński, 2006):

- 1) ecological – which consists in preventing the degradation of the environment and the elimination of environmental risks,
- 2) economic – which means that basic material needs of humanity should be satisfied with the use of engineering and technology friendly to the environment,
- 3) social and humanitarian – which ensures social minimum (liquidation of famine, poverty and misery), health protection, the development of spiritual aspect of man (culture), safety and education.

2.3 Impact of knowledge management on sustainable growth

Taking into account the main assumptions of both knowledge management and sustainable growth, one can argue that although they are two different disciplines, some aspects of knowledge management overlap the activities characteristic for sustainable growth.

The empirical authors' studies show that in various sectors of industries, the prudent use of knowledge while factoring in the importance of societal demands and the conservation of the ecosystem will derive great returns to the stakeholders of the organization.

Table 1 presents the relation between the process of sustainable growth and the results of knowledge management (Wong, 2010).

Table 1

Framework of sustainable development versus knowledge management

	Sustainable development (SD) activities	Sustainable development (SD) impacts	Knowledge management (KM) outcomes
1	Commitment to Stakeholders	Staff	Positive Responds to KM Initiatives

3	Redefining Policies and Legislation	Structure	Re-engineering Processes
4	Awareness and Changing Mind-set	Shared	Values Learning Organization
5	Mobilizing Science and Technology	Systems	Knowledge Management Systems
6	SD Practices to Foster Social and Human Capital	Style	Business Transformation
7	Measurement, Review, and Recognition	Strategy	Reward and Recognition

Source: Wong, 2010

Many authors emphasize that knowledge can be considered as critical foundation for sustainable development innovation (Laszlo and Laszlo, 2002; de Sousa, 2006; Sheng and Sun, 2007; Brzóška, 2012). Mohamed and Stankosky say that sustainability now acquires its meaning in the midst of a knowledge-centered worldview that remains intrinsic in what it could be termed as the socio-scientific order. Such a knowledge-centred worldview and its domains of action, the socio-scientific order, being unified on the basis of a uniquely epistemological premise of unity of knowledge, is also of an extensively ethical and moral kind. Nonetheless, they presuppose that achievement of these goals all at once is impracticable. Consequently, the aim should be founded on a reasonable compromise that considers the proportionality of the contribution of each of these elements to sustainability. Therefore, striking the balance between economic growth and environmental issues is highly recommended by investigators such as Daily and Huang (2001), who emphasize the importance of ecological sustainability, but call for a balance amongst economic development, technological progression, and natural resources protection.

2.4 Specificity of Polish machine-building industry enterprises

Machine building industry is a branch of heavy industry. The machine building sector covers the production of machines used in other branches of industry. The products fabricated by this sector involve among others the machines for mining industry, steelmaking, energy production, agriculture and also machine tools and engines.

The sector combining the manufacturers of machinery and equipment in Poland has a very wide range of suppliers from different branches of industry. You can distinguish here the suppliers of basic production means such as: energy, water and other public services, suppliers of raw materials and other materials or components for the production of final products as well as the suppliers of machines and equipment used in manufacturing processes. An overwhelming majority of machine tool manufacturers produce their machines from ready-made intermediates. Hence, the rising trends in competitiveness or production quality is largely determined by the suppliers of purpose machines: CNC machine tools, welding machines, bending machines, grinding machines, etc. It should be underlined here that a significant contribution of the suppliers to the generation of costs in companies and their dependence on the quality of raw materials and intermediates offered by the suppliers. The customers in the sector of machinery and equipment can be divided into several groups: individual customers, private companies, the ones which purchase products from this sector to apply them further in the manufacturing of their own final products, e.g. automotive, building construction or mining sector, as goods applied in supporting processes: storing, transport, institutional customers, wholesalers and home or overseas dealers – intermediaries in the trade of machines, own subsidiaries (Matusek, 2013). With respect to factors which determine the financial result of the analysed companies, it should be singled out among others such factors as the share of the buyers in the sales value for a given company, knowledge of the buyers about market offer and the number of competitors in the sector.

In the sector involving the manufacturers of machinery and equipment, the greatest impact on the competition state is exerted by buyers. These are usually institutional customers who have perfect knowledge about the market and specific, growing expectations involving safety, quality and also ecological conditions of machine operation (Matusek, 2013; Kramarz M., Kramarz W., 2011).

Business processes are realized in line with the standards formalized in the quality management system, safety management system and environmental management

system, whereby the machine building manufactures can ensure proper functioning in accordance with the principles of sustainable growth.

Furthermore, the buyer-companies purchase products in large quantities, making the manufacturer dependent on them to some extent. The most important competitiveness factors involve the level of technology and innovation. Innovative activities have principally the character of product or process innovations, and therefore, in order to be viewed as competitive, the companies must ensure knowledge acquisition, storing and transferring, in particular by the engineering staff (designers, top management and supervising staff) (Matusek 2013).

3 Research methodology

3.1 Characteristic of research procedure

In order to work out a model of knowledge management in Polish machine-building companies, a research procedure was proposed in which three basic stages were singled out (Fig.1):

1. The first stage consisted in the studies carried out in the selected companies of machine building industry, involving the analysis of the implemented procedures of information processing to support the management as well as the analysis of knowledge sources. This stage was divided into two parts. In the first part questionnaire studies were carried out which were to answer the following questions:
 - what are the key business processes in the investigated companies?
 - how is the information system organized in the investigated companies (formalization level, applied procedures)?
 - what elements of the sustainable growth concept are reflected in the realized business processes in the investigated companies?
 - which management systems are applied and what is their application scope (quality management, environmental management, safety management, risk management)?
 - to what extent the implemented management procedures allow for the principles of sustainable growth? Where and what type of necessity

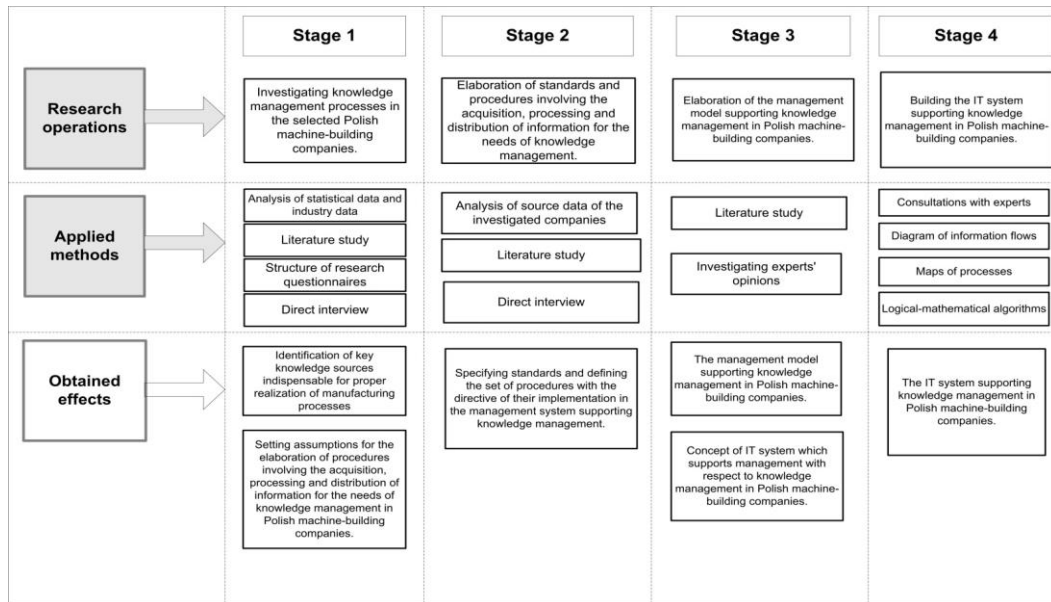

occurs in the order realization process which involves frequent application of “non-routine” information sources¹?

- what information tools and to what extent are applied in the customer’s order realization by the investigated company?

In the second part the prepared research questionnaire paper was to answer the following questions:

- are there any procedures of information processing which support the management of knowledge, and what type of procedures?
 - what are the potential sources of knowledge in the investigated companies?
 - what are the key areas of knowledge, allocated accordingly to its main recipients?
 - what are the applied solutions, methods and tools in knowledge management processes, i.e. knowledge acquisition, storing, transferring and processing in the activity of other investigated companies, and, basing on the above, how are the deficits determined involving the support of knowledge processes with IT solutions?
2. The second stage consisted in the elaboration of knowledge extraction procedures and the methods of its formalization and registration in the investigated companies, which, in effect, yielded the specification of standards and a set of procedures with the directive of their implementation in the field of knowledge management.
 3. The third stage consisted in building of the management model with respect to knowledge management, and ultimately the IT system supporting the knowledge management in Polish machine building companies.
 4. The fourth stage consisted in the elaboration of the IT management system supporting knowledge management in the machine-building companies.

¹ *Non-routine sources of information are understood as e.g. the necessity to create non-standard reports, solving untypical problems, need to contact external experts etc.*

Source: own preparation

Fig. 1. Research model

The carried out research studies in the selected machine-building companies had a qualitative character. The investigation studies of that type are frequently carried out with the help of such tools as questionnaires for collecting data, interviews for in-depth analyses of problems, focus groups, observing the work in progress (Liebowitz et. al., 2000). Such tools offer the opportunity to make other observations and to understand how the management of knowledge is perceived by employees.

The research studies were conducted in the form of directed interviews with the representatives of the companies with the use of structured research questionnaires. The group of respondents was made up by owners, company managing directors, managers of units responsible for the development of new products and for the implementation of technologies (e.g. engineering department, technological preparation of production).

The questions involving the sources of knowledge and the application of the instruments supporting knowledge management were grouped allowing for knowledge management processes, i.e. acquisition, storing, transferring and application of knowledge. The respondents were assessing the level of current use of a given instrument in the scale from 0 to 6 (Likert's scale), where 0 meant no use and 6 meant intensive use of the instrument.

In addition, the respondents assessed the target state, i.e. they assessed the implementation necessity of a given solution in the investigated company.

3.2 The selection of the research sample

The research studies involved the sector of medium-sized and large machine-building companies from the Silesia voivodeship (due to the highest concentration of companies of that type in the area of Upper Silesia). The studies covered 38 companies (which accounts for 9.5% of the total number of machine-building companies in Poland), allowing for the size of the company and its economic activity sector.

The selection of companies was premeditated and was made basing on the following:

- size of the company (sale volume, employment level);
- industrial sector in which the company is operating;
- expenditure on research and development projects;

Basing on the accepted research assumptions and the declaration of non-objection of the company owners involving the access to information and consent to carry out research studies, 4 groups of companies (altogether 38 companies) were singled out, and the knowledge processes realized in those companies were subjected to research studies. The group comprised small-sized and medium-sized companies (it is the target group for which the system is being elaborated) including:

- general purpose machine-building companies (8),
- mining machine-building companies (15),
- machine-building companies for defence industry (6),
- machine-building companies for automotive industry (9).

Table 2 Characteristic of research sample

Assumption	Result
Classification criteria defining the population of companies	<ul style="list-style-type: none"> – size of company – medium-sized and large companies (employment level above 50 people), – industry sector in which the company is operating (machine-building companies for mining industry, for defence industry, machines and equipment for automotive industry, machine tool-building companies), – location of the company – Silesia voivodeship , – level of technological advancement – medium or high.
Population of companies	402 companies (acc. GUS data on 31.12.2010)

Research sample	38 companies (9.5%), including: <ul style="list-style-type: none"> – 15 companies from mining sector – 8 companies from machine tool-building sector – 6 companies from defence sector – 9 companies from automotive sector.
Method of data collection	Direct interview with the use of a research questionnaire with the members of top management staff

Source: own preparation

3.3 Research results

The main objective of the carried out research in the selected Polish machine-building companies was to elaborate methodological assumptions needed to build a management model with respect to knowledge management in a machine-building company and to determine the scope of problems and elements which should be taken into account in the elaborated model. In addition, the research studies made it possible to determine the functional range of the IT system which supports knowledge management in a machine-building company.

By and large, the conducted research analysis in the selected machine-building companies rendered the acquisition of effects with respect to the following:

1. Identification of the structure of IT system and management processes.
2. Identification of key processes realized within the management of contracts portfolio in particular functional areas (designing, supply, distribution, supporting processes), allowing for the factors determining the sustainable growth of a machine-building company.
3. Identification of knowledge processes supporting the management of contracts portfolio (acquisition, storing, transferring and utilization of knowledge).
4. Determining knowledge deficits in key business processes in the realm of contracts portfolio management.
5. Determining the applied information solutions supporting the management of contracts portfolio.

In effect of the analysis of management systems in the investigated machine-building companies, the following information were determined:

1. Structure of management processes,
2. Management methods and tools,

3. Formalization level of routine and non-routine information indispensable for management,
4. Applied management systems (of quality, environment, safety),
5. Applied IT solutions supporting the management,
6. Functional range of the applied and planned for implementation IT solutions.

Table 3 presents the information involving the applied management systems, the number of used management systems independently for each group of companies.

In 36 companies (out of 38 subjected to research) the quality management system was introduced in line with the standard ISO 9001. It should be emphasized that in the majority of companies this standard is a foundation on which management processes are based. In the majority of the investigated companies there was a high level of specificity as to formal scopes of activities allocated to managerial and technical positions. Due to the cooperation with overseas contractors, the certification complying with other standards was implemented in some companies.

Table 3 Applied management systems in the analyzed machine-building companies

Management state	Group A	Group B	Group C	Group D
Quality management system in compliance with ISO 9001	13	6	8	9
Quality management system in compliance with other standard	2	3	2	7
Environment management system in compliance with ISO 14001	2	2	1	5
OHS management system in compliance with PN 18001	7	3	4	6

Source: own preparation

The system of environmental management being in compliance with ISO 14001 and the system of OHS management being in compliance with PN 18001 were only implemented in 10 investigated companies.

The quality management systems and connected with them certificates are viewed as an instrument used to create the image of a company and to enhance the competitiveness of its products. In some cases appropriate certificates are required by contractors. The usefulness of quality management systems for the perfection of processes realized in a company is assessed as high, but only in the areas where the formalization of procedures is well-founded. The implementation of formalized, detailed

procedures is sometimes confronted with certain mental barriers, with respect to both employees and the management staff. Getting used to very far-fetched formalization takes time. It should be also emphasized that detailed formalization of procedures is not always possible and justified. Besides, also high costs and large labour intensiveness generated by the implementation and maintenance of these systems are indicated.

It must be underlined that there were considerably fewer implementations of environmental management systems or OHS management systems. The said systems were introduced later so they can become common in the analysed companies in the future. In terms of the realization of the sustainable growth strategy in the analysed machine-building companies, the environmental management and OHS management should be formalized.

With respect to the analysis of knowledge management processes in the analysed companies, the following information was collected:

- key factors for the development of a company,
- the scope of decisions and activities in the selected sector of knowledge management,
- applied and provisioned for implementation methods and tools supporting knowledge processes (knowledge acquisition, codification, transfer and utilization),
- knowledge deficits in knowledge management processes (acquisition, storing, transferring and utilization of knowledge) supporting the management of contracts portfolio.

The respondents from top management level indicated to very different advancement level of knowledge management in their companies. In some companies full cyclic knowledge audits were carried out in recent years, and in other cases the respondents emphasized the need to carry out knowledge audits without specifying any definite realization period. In many cases the interviewed managers accentuated the significance of information and knowledge as the key factors contributing to the development of company, yet as to implementation, the management of knowledge was treated by them as an issue which can be dealt with in the future. The managers rightly affirm that the infrastructure of knowledge management requires a lot of financial expenditures and time, and the positive effects show up relatively late.

Knowledge acquisition is a significant component of knowledge management in every company. The companies of machine-building industry should be particularly open to new technological solutions and to new solutions involving modern methods of organization and management. The carried out research studies illustrated the following knowledge deficits with respect to knowledge acquisition:

- lack of procedures of knowledge acquisition involving the problems with contract realization,
- insufficiently refined procedures involving knowledge acquisition from customers,
- lack of the verification of significance level of the codified knowledge,
- limited potentials allowing to take over the hidden knowledge from employees,
- insufficiently refined procedures involving the acquisition of knowledge about the experience of employees and experts connected with the realization of contracts.

Knowledge storing in manufacturing companies is taking place in three knowledge repositories: in the minds of employees (in the form of implicit knowledge), in documentation in paper (in the form of explicit knowledge) and in computer databases (in the form of codified knowledge). Of particular importance in the analysed companies is the unique knowledge of the employees involving engineering and technology, being stored in their minds as implicit knowledge which should be processed into a codified form.

The carried out research studies show the following knowledge deficits involving knowledge storing:

- insufficiently refined procedures involving the storage and updating of electronic documents,
- insufficiently refined procedures and tools involving the storage and updates of the knowledge on contracts,
- limited knowledge resources about the competence of employees and external experts.

The transfer of knowledge in a company allows the employees to access knowledge resources indispensable in various technological or managerial processes. To satisfy such an objective, it is necessary to ensure appropriate IT infrastructure for knowledge transmission. The transfer of codified knowledge is realized mainly through electronic communication channels. And the transfer of non-codified knowledge is realized mainly

in the form of formal and informal meetings of employees, knowledge fairs and mentoring programs.

The carried out research studies exhibited the following deficits involving knowledge transfer:

- insufficiently refined procedures involving the formation of task force teams within the scope of contracts being in progress,
- insufficiently refined procedures involving internal trainings and lectures,
- limited infrastructural potentials involving the exchange of knowledge between employees.

The use of knowledge requires that the effective realization of the remaining processes of knowledge management is ensured, i.e. the processes of acquisition, storing and transfer of knowledge. The use of knowledge presupposes an appropriate processing of knowledge resources for a definite objective supported by various IT systems which involve among others data management systems, knowledge management systems and new generation systems.

The carried out research studies indicated the following deficits involving the use of knowledge:

- limited utilization of assessment tools for realized contracts,
- limited utilization of codified knowledge in the implementation of process innovations,
- limited utilization of codified knowledge in the implementation of product innovations,
- insufficient potentials in the access to contextual technological and managerial knowledge during the realization of contracts portfolio.

The analysis involving the applied IT solutions demonstrates that none of the analyzed companies introduced a fully integrated IT system supporting the management. The analysis concerning the applied methods and tools of knowledge management shows that the changes in the functionalities of the applied IT solutions in machine-building companies are unavoidable and they are viewed as an on-going process resulting from the adaptation of business processes in a company to dynamically changing internal and external conditions. The respondents expect functionality in systems which are not fully integrated, but appropriately prepared to satisfy the needs of a given company. The

effectiveness criterion for the systems integrated with respect to knowledge management illustrates that the financial and non-financial expenditures are too high as compared to the obtainable effects.

The carried out research studies revealed a huge diversity range of IT tools implemented in the analysed machine-building companies in terms of the assortment and scale of production, organizational structure and economic-financial condition. The analysis shows that there is a great deficit of IT applications with respect to management support in the majority of the investigated areas. In order to define necessary measures to be undertaken to provide machine-building companies with IT technology, it is necessary to conduct a detailed analysis of technical requirements as well as to define internal and external capabilities and conditions for the implementation of IT solutions. The assessment involving the utilization of IT tools in the analysed machine-building companies obtained from the top managerial staff shows that there is limited satisfaction with the functionality of the implemented IT solutions and cautious approach to their further development.

4 The model of knowledge management system supporting sustainable growth in machine-building industry enterprises

4.1 Assumptions to build a management model supporting knowledge management

Taking into account the operating conditions of Polish machine-building companies, the assumptions involving the fabrication of knowledge management support model in a machine-building company were defined in detail. These assumptions on the one hand allow for external conditions connected with the aspect of competitiveness facing the company, and on the other hand they allow for internal conditions connected with the range and scale of business processes realized in line with the principles of sustainable growth. Basing on the carried out analyses, the following assumptions of the model structure were accepted:

1. The concept of the model is based on a fundamental assumption that the support of knowledge management processes should contribute to better effectiveness of contract realization, which is related with better efficiency and prowess of business process realization in the area of supply, production, distribution and supporting processes with the principle of sustainable growth taken into consideration.

2. The support of knowledge processes ensures the access to contextualized knowledge involving decision-making problems in all functional areas connected with the realization of contracts portfolio.
3. The model allows for the following internal and external engineering-organizational conditions of knowledge management in machine-building companies:
 - machining-assembly type of production has discrete character of high complexity,
 - a great share is made up by unit production, including the production of large machines, mainly as the make-to-order production,
 - the activity of the analysed companies is particularly sensitive to the changes of economic situation. The sensitivity to downturn is higher and more violent than the reaction to the improving economic condition,
 - proper operation of a company is conditioned by high competence of the employees in terms of engineering and organizational skills, principally in the field of production preparation (designers, technologists, the staff of the production organization department),
 - with the unit production, the viability of the company's operation is affected by many different low-stability factors, in particular such as order portfolio, parameters of contracts signed with customers (the price of a unit product can be very different), contract parameters with suppliers and subcontractors (prices can be very different).
4. The processes supporting knowledge management allowed for in the model encompass the scale and range of the applied IT tools, needs involving necessary changes of these tools and the changes of engineering-organizational conditions involving the operation of the analysed machine-building companies.
5. The model allows for the existing state of knowledge deficit with respect to IT tools supporting knowledge processes, i.e. acquisition, storing, transferring and utilization of knowledge in all processes of contract portfolio management (designing, supply, production, distribution, supporting processes).
6. The tools supporting decision-making processes in particular functional areas allow for economic, social and environmental criteria.

4.2 Description of the management model supporting knowledge management

For the needs involving the construction of the model of management support system concerning knowledge management, a general structure of works carried out in the process of contract realization in machine-building companies was accepted:

1. Preliminary offer – is supposed to find out if a company is able to execute the order. If yes, as the following step the estimate price is quoted, where the experience from the execution of similar products in the past plays an important role.
2. Proper offer – when the estimate price of the future machine is accepted by the buyer, the department of design and technology, basing on the accepted assumptions, works out the required construction and production technology. The above information is transferred to the procurement department where potential suppliers of materials and components needed for the production process are identified. Basing on the above procedures, the price of the mechanical construction together with labour costs are determined.
3. Realization and control over contract execution – after the agreement has been signed between the company and customer, the execution of contract is taking place, i.e. details of constructional and technological requirements are defined, orders are made by the procurement department and/or work outsourcing is taking place, as well as the production with the use of company's own resources. Simultaneously, the progress in the execution of the realized works is controlled on a regular basis.

In each of these stages one of the key tasks (frequently ignored in practice) is risk management and compliance with the strategy of sustainable growth. The authors constructed a model (Fig.2) which is oriented on the processes ensuring the settlement of a knowledge management system which would facilitate business processes realized in machine-building companies and enhance their effectiveness. The constructed system is supposed to enhance the usability of knowledge indispensable for the realization of a contract and to concentrate on important information which are crucial in terms of the value of the realized processes. Hence the model was based on the concept of Porter's value chain. A functional approach to the process realization was applied, and then the processes were divided into the processes of designing, supply, production and distribution. At the same time the said processes are realized within the frames of the

existing company structure and they take advantage of the results of previously executed contracts stored in the knowledge repositories at all management levels.

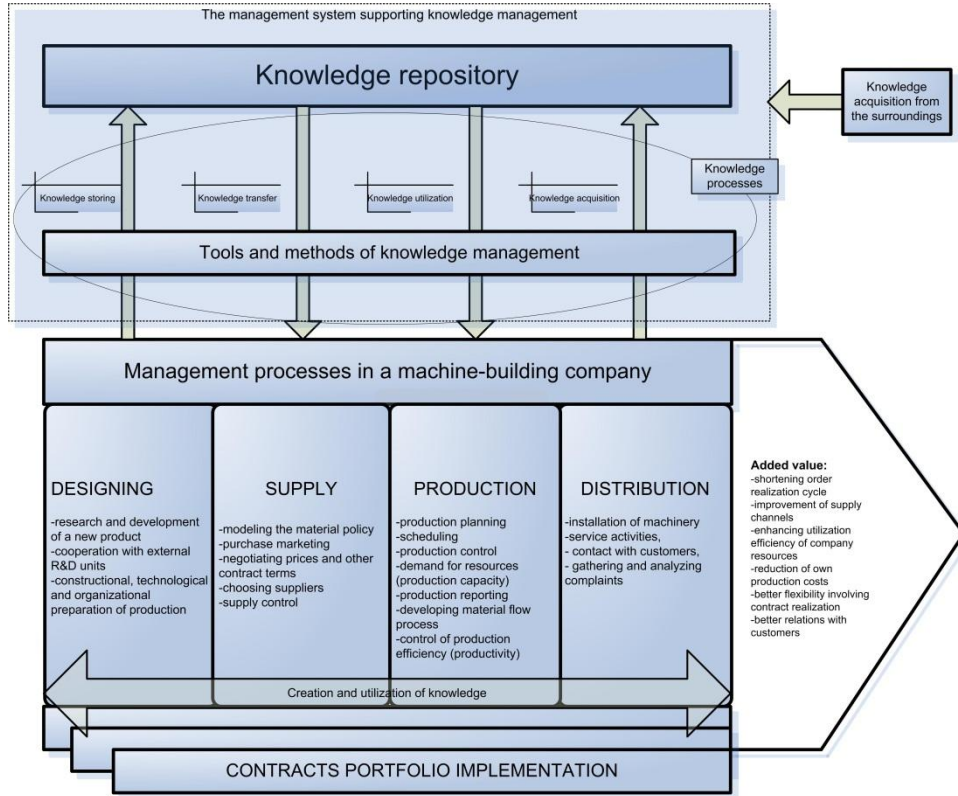

Fig. 2. Model of the management system supporting knowledge management

4.3. The computer management system supporting knowledge management in a machine-building company

Basing on the prepared model, an IT system supporting knowledge management in machine-building companies was worked out. A general structure of the system was presented in Fig.3.

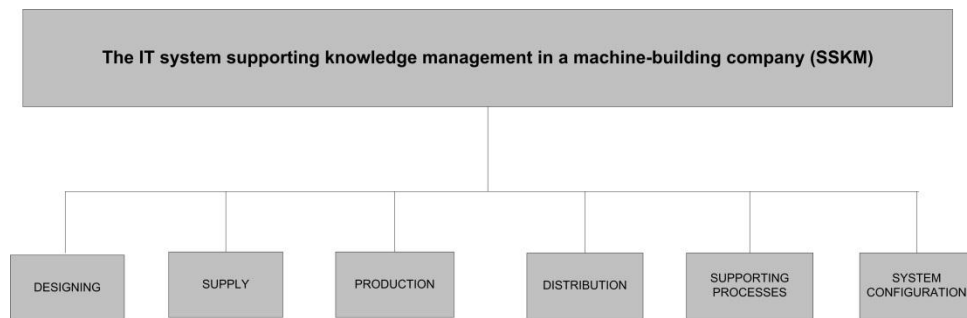

Fig. 3. Main modules of the management support system involving knowledge management in a building-machine company

Source: own preparation

The module “DESIGNING” comprises the following options:

- preliminary analysis of contract,
- support of designing processes,
- management of contract risk involving designing.

The module “SUPPLY” comprises the following options:

- analysis of suppliers,
- management of contract risk involving supply.

The module “PRODUCTION” comprises the following options:

- support of contract realization involving production scope,
- management of contract risk involving production.

The module “DISTRIBUTION” comprises the following options:

- customers,
- service,
- management of contract risk involving distribution.

The module “SUPPORTING PROCESSES” comprises the following options:

- database about contracts,
- risk management of contracts portfolio,
- human resources management.

The module “SYSTEM CONFIGURATION” comprises the following options:

- users of the system,

- work environment of the system,
- safety of the system.

The presented structure of IT system has been focused on supporting decision-making processes with respect to contracts portfolio management. It results from the need to provide a comprehensive support of knowledge processes in the preparation, realization and control of contracts to ensure their efficient realization in line with the principles of sustainable growth. The contracts which comply with specific requirements of a customer should be approached individually making use of the company's knowledge resources with the overall objective to support in the best possible way the realized business processes. In order to ensure effective storing of knowledge and its processing within the frames of the elaborated system, appropriate tools supporting knowledge processes must be allocated (Table 4).

Table 4 - Allocation of tools supporting knowledge processes to the management processes of contracts portfolio in a machine-building company in the System Supporting Knowledge Management

Management processes of contracts portfolio	Knowledge processes			
	Knowledge acquisition	Knowledge storing	Knowledge transfer	Knowledge utilization
Designing	KOMS (record of individual experiences of employees, record of good and bad practices used in designing area). ES (acquisition and codification of knowledge in the form of expert system rules) CBR (codification of experience in the form of cases)	KOMS (storing experiences in the hypertext form) CBR (storing knowledge in the form of verified cases)	KOMS (updating and sharing knowledge with system users) RM (updating and sharing knowledge on risk with system users) CBR (possibility of knowledge sharing through the access to cases-base, training staff on the basis of verified cases)	KOMS (use of electronic procedures to monitor business processes in designing) ES (preliminary analysis of engineering-organizational conditions of contract realization) ES (preliminary estimation of contract price) ES (preliminary legal analysis of a contract) CBR (simplification of the estimation process of the introductory contract price, fast and reliable response to the customer's queries)
Supply	KOMS (record of good and bad practices in supply, codification of procedures used in supply) ES (acquisition and codification of procedures used in	RM (storing knowledge on risk in supply area) KOMS (storing experiences in the hypertext form) CBR (storing knowledge in the form of verified cases)	RM (updating and sharing knowledge on risk with system users) KOMS (updating and sharing knowledge with system users) CBR (possibility of knowledge sharing	ES (preliminary selection and assessment of suppliers) KOMS (use of electronic procedures to monitor business processes in supply area) IPCS (supporting the

	supply area) SDRS (supporting the interpretation of system archetypes in supply area) CBR (codification of experience in the form of cases)		through the access to cases-base, training staff on the basis of verified cases)	value judgment of experts in supply area) CBR –(support for designers, purchasing dept. staff, ensuring high supply level, lowering the number of complaints, high quality of goods)
Production	KOMS (record of good and bad practices used in production area. Codification of procedures used in production area) ES (acquisition and codification of procedures used in production area in the form of expert system rules) SDRS (supporting the interpretation of system archetypes in production area)	RM (storing knowledge on risk in production area) KOMS (storing experiences and description of good practices in the hypertext form)	RM (updating and sharing knowledge on risk with system users) KOMS (updating and sharing knowledge with system users)	KOMS (using experience involving the realization of contracts portfolio) KOMS (using experience, good and bad practices in production area) ES, KOMS (use of electronic procedures for business processes monitoring in production area) ES (preliminary analysis of resources availability) SDRS (analysis involving the impact of disruptions on production process) IPCS (supporting the value judgment of experts in production area)
Distribution	KOMS (record of good and bad practices used in distribution area. Codification of procedures used in distribution area) ES (acquisition and codification of procedures used in distribution area in the form of expert system rules) SDRS (supporting the interpretation of system archetypes in distribution area)	RM (storing knowledge on risk in distribution area) KOMS (storing experiences in the hypertext form) KOMS (storing good practices in service area)	RM (updating and sharing knowledge on risk with system users) KOMS (updating and sharing knowledge with system users) KOMS (sharing good practices in service area)	KOMS (analysis of customers' complaints) ES, KOMS (use of electronic procedures for business processes monitoring in distribution area) ES (supporting the analysis involving possible decisions in distribution area) IPCS (supporting the value judgment of experts in distribution area) KOMS (use of good and bad practices for servicing needs)
Supporting processes	KOMS (record of good and bad practices used in supporting processes. Codification of procedures used in supporting processes) ES (acquisition and codification of experts' knowledge in the form of expert system rules) SDRS (supporting the interpretation of system archetypes)	HRM (storing information about external staff and experts) RM (storing knowledge on risk involving supporting processes) KOMS (storing experiences in the hypertext form) ES (storing knowledge about the structure of business processes in the form of interactive decision trees)	RM (updating and sharing knowledge on risk with system users)	KOMS, ZZL (localization of knowledge sources, searching information on experts and expert opinions) RM (monitoring risk involving supporting processes) HRM (selection of designers team for contract realization) HRM (selection of project manager for contract realization)

Applied tools:

CBR – Case-Based Reasoning

ES – Expert System

KOMS – Knowledge Objects Management System

RM – Tool supporting risk management

HRM – Tool supporting the management of human resources

IPCS – Interactive paired-comparison system

SDRS – System of dynamic research simulation

4.3.1 A tools supporting risk management

Due to a specific character of the analysed machine-building companies and consequently a higher level and scope of a potential risk, it is extremely important to identify risk factors connected with the realization of contracts portfolio. The identification of risk factors of a single contract should be approached as an iterative process, and therefore it should be carried out in several steps, both by the people responsible for the realization of the contract and by the remaining people involved. The tool makes it possible to enter the information involving risk factor, basing on the selection from the list of risk factors, basing on the previously entered information (involving the completed contracts) in a given area and the category of risk.

The tool supporting risk management in a machine-building company can facilitate the realization of the following functions:

- storing knowledge on risk factors allocated to a specific contract, allowing for engineering, economic, ecological and social aspects,
- qualitative analysis of risk factors allocated to a given contract,
- analysis of the information on the assessment of risk factors at the stage of preliminary identification, at the verification stage after the proposition of preventive measures has been worked out and at the stage following the realization of contract,
- storing experience from the risk analysis as the outcome of a comparative analysis of risk factors during the realization of a contract and after its realization.

4.3.2 A tool supporting processes of human resources management

The proposed tool supporting processes of human resources management is used principally to improve the management effectiveness of contracts portfolio as a feedback from the customers of machine-building companies. The tool comprises 4 main functionalities:

- file of employees,

- file of external experts,
- competence matrix of employees,
- allocation of human resources to contracts.

By the implementation of the tool supporting the management processes of human resources, the following objectives can be obtained:

- enhancing the effectiveness involving the utilization of knowledge, skills and experience of external employees in the realization of specific contract tasks, allowing for the principle of sustainable growth,
- facilitating the analysis of human resources of a company and work demand, allowing for specific competence within the frames of contracts being realized,
- refining the monitoring and assessment processes of employees involved in the realization of contracts,
- ensuring the backup of expert knowledge in the preparation of solution concepts,
- enhancing the competence and qualifications of employees which allow for engineering, economic, environmental and social issues,
- ensuring an optimal selection of internal and external trainings for the employees in line with the identified knowledge deficit in particular processes,
- ensuring effective allocation of tasks between employees and augmenting the transfer of knowledge,
- enhancing the engagement and participation of employees in the realization of contracts,
- raising the formalization level of management processes of human resources in effect of the introduction of electronic procedures and documents.

4.3.3 Structure of the hybrid system Case Based Reasoning CBR and the expert system

Case Based Reasoning makes use of specific knowledge stored in the situations experienced in the past, referred to as cases. The CBR method is applied for the solution of new problems through the adaptation of the results which have been already applied for the solution of previously encountered problems. A new problem is solved by finding a similar case in a set and by applying the solution associated with the found case. The CBR system is characterized by the ability to learn through the storage of solutions of previous problems and sharing them for the solution of new problems in the future. The

operation cycle of the system based on CBR method can be described by means of four main processes (Aamodt, Plaza, 1994):

1. Retrieving the most similar case or set of cases,
2. Reusing the knowledge comprised in the found case for the solution of the problem – in many instances the solutions proposed by the system will have to be modified. A new solution is generating a new case in the cases-base.
3. Revising the proposed solution,
4. Retaining the experiences for further utilization for the solution of new problems.

The main objective of the CBR method is to find in the base the cases which are most similar to the one defined by the user. In many practical applications, a new problem is codified in the form of a query whereof form depends on a specific solution. The query can have the form of text, pairs of 'question-answer' type, database queries. Frequently, it is not possible to find one single, most suitable case for a given problem. Therefore, in the next algorithm step the solution must be adapted to the current situation. Usually, the new worked out solution is written down in the cases-base and then it can be applied in the future. While building the model, a hybrid of reasoning system was applied on the basis of cases and expert system. The expert system supports CBR at the adaptation stage of the found cases. The rule-based expert system RSE has been designed to cooperate with small knowledge modules which can be integrated, forming a larger knowledge base. The knowledge in the RSC system has the form of standard Horn rules. The rule-based expert system consists of three basic modules: a module supporting the interactive edition of knowledge bases, a reasoning-calculating module (an interpreter of rules), a clarification module (offers the clarification involving the run of the reasoning process and its results). The system being created supports the process of supplier selection when there is a necessity to change the supplier of material/services, to outsource certain activities to respective suppliers in order to enable the realization of the order made by a client, at the stage of designing, selection of designers, components and subassemblies.

Another problem to be considered involves the choice of technology which can facilitate the search of similar cases. The method most frequently quoted is the nearest-neighbour method and inductive retrieval. The nearest-neighbour method attempts to find similar cases, searching the neighbourhood of a given problem. An inductive retrieval is an alternative to the method described above. This method is applied in so called learning

systems and in systems which make decisions on the basis of decision trees. The nearest-neighbour method is a relatively simple technique of searching similarities. Yet, it has a drawback, which is the searching speed. To find the best match, the question (in the form of case) has to be compared to every question written down in the base. Furthermore, the similarity is determined by comparing each of the attributes. In effect the method is becoming inefficient when the number of cases is very large. In the proposed system this drawback can be minimized by preliminary filtration of the cases.

4.3.4 Knowledge object management system and rule-based expert system

The knowledge object management system (KOMS) enables the registration and ordering of knowledge presented in the form of unified, standard elementary objects. An elementary knowledge object combines together a unified formal structure and the possibility to register different types of data (text, graphics, numbers and others, also more complex ones e.g. any objects of MS Office package). Knowledge objects can be ascribed different attributes: describing, classifying and valuing, verbal and numerical (e.g. ordinal number, updating time, information source, significance assessment, credibility assessment). Elementary knowledge objects can be combined with one another with superiority-inferiority relations or with any other hierarchical or network relation. Also the registration of free objects, unrelated to other objects, is possible.

Computer support involving the realization of sequence (single path) procedures, described by a sequence of consecutive, executive instructions given always in the same order, can be narrowed down to the interactive feeding and searching of information (in particular the descriptive or graphic ones) which the executor needs in further activities. Knowledge in the Knowledge Object Management System is organized in the form of hypertext in the way ensuring that the user, depending on current, individual needs and has access to information of an appropriate level of specificity.

The procedures with selection instructions (multipath ones), in which the composition and order of activities depends on some situations unknown in advance, are supported by KOMS, providing descriptive information interactively and by the Rule-based Expert System RSE which is reasoning backwards. The selection of the first action is made by the expert system, basing on the information about the initial state of the factors which have influence on the realization of the procedure. In further steps, the expert system asks the executor a question about the result of the previous action and

about possible changes of other factors which may have influence on the run of the procedure, whereupon it selects another action.

The rule-based expert system RSE can work with knowledge modules stored in Horn rules tables. Standard Horn rules are the implications with one conclusion whereof conditional parts have the form of the conjunction of statements. Apart from the standard system which is reasoning forwards and backwards, the RSE consists of three modules: tools supporting the interactive edition of knowledge bases, a reasoning-calculating calculation spreadsheet and the tools for graphic presentation of knowledge and visualization of reasoning paths. Using these modules, expert microsystems were created to cooperate with small knowledge bases containing from a dozen to several dozen rules created by the user and related to the currently carried out tasks.

4.3.5 Interactive Paired Comparison System

The Interactive Paired Comparison System IPCS supports the creation of significance ranking of objects subjected to qualitative assessment. The description of sustainable growth frequently involves the significance assessment to be conducted with respect to various phenomena which are not similar to each other. The direct ordering (ranking) of the significance of a numerous set of various objects is difficult since in such a case the information about all objects must be retained in the memory. It is not necessary when objects are compared in pairs. Yet the standard comparing method of two objects in pairs is very labour-intensive. To order a set of n objects, $(n^2-n)/2$ comparisons must be carried out. In the IPCS system an innovative, interactive, paired comparison method developed by the author was applied, which consists in combining the comparative assessment of two objects with the current sorting of the set. The choice of pairs and the order of comparison result from the sorting algorithm (realized by the IT system), and they depend on the responses given by the user in the preceding comparisons. In effect, the number of comparisons can be reduced to the value below $n \log_2 n$ comparisons. For example, to create a ranking of 100 objects, it is enough to carry out no more than 534 comparisons instead of 4950 when the standard method of paired comparison is applied.

4.3.6 The system of dynamic research simulations

The system of dynamic research simulations SDRS is used to investigate hardly predictable behaviour of complex systems, basing on the models of system mechanics. P.M. Senge presented the concept of system diagrams (Senge, 2006) which characterize typical structures and behaviour of systems, or in other words, system archetypes. System archetypes include among others such concepts as: growth barriers, investing and deferred benefits, short-term improvement before long-term deterioration, harmful corrective measures, anomalous benefits of a leader, avalanche-style escalation, oscillations in the systems with feedback (“bullwhip effect”), ‘tragedy of the commons’. These archetypes well characterize the conditions of sustainable growth. The system diagrams proposed by P.M. Senge illustrate in a simplified way the most important features of systems, in particular positive and negative feedbacks. The simplifications that occur in system diagrams are in some cases too large, whereby the behaviour of the systems can be incorrectly understood. The system of dynamic research simulations enables a more precise representation of system archetypes. In particular in SDRS it is possible to allow for nonlinear relations and to distinguish between dynamic properties of objects, such as dead time, inertia, accumulation in time.

4 Conclusions

The development of world economy is enforcing the widespread use of IT tools supporting the management of knowledge. The changes taking place in machine-building companies with respect to the functionality of the applied IT solutions are unavoidable and are viewed as a continuous process resulting from the adaptation of business processes in these companies to the dynamically changing internal and external conditions. The proposed model of management support involving knowledge management and the IT system built on the basis of this model and dedicated to Polish machine-building companies is the response to such a demand.

In effect of the carried out research involving knowledge management in machine-building companies, the diagnose the IT system was undertaken in the investigated companies to determine functionality deficits with respect to knowledge processes and to define the indispensable functionalities of IT tools which should be implemented in the IT system supporting knowledge management. As a result of the carried out research studies involving the analysis of quality management system, risk management and

environmental management, the model was built which in a coherent way comprises the engineering, economic, social and ecological factors and conditions and which is a tool to be applied for supporting business processes in the operation of a machine-building company in terms of sustainable growth.

The proposed concept of a model has been focused on supporting business processes taking place during the realization of contracts portfolio. The structure of the model reflects the needs involving the support of knowledge processes in the preparation, realization and control of contracts portfolio in all execution areas (designing, supply, production, distribution, supporting processes).

The implementation of the proposed IT system in a given machine-building company must be preceded by the adaptation process of knowledge bases and to some degree the functional structure. Of great significance is the commissioning stage of the project within which a thorough pre-realization analysis should be carried out, and which will define the factors determining the effective implementation of the system in a specific internal and external conditions.

Structured Abstract

Purpose – The problem we are concerned with in understanding modern developments are short-sighted managerial decisions. The question is: What kind of “knowledge” is necessary to support, improve and enable meaningful decisions in an organization? Why and when would it be essential to gain additional knowledge? How could it be provided or processed? Considering that the information society is trusting too much in computational techniques, we analyse the relation between algorithms and actions to be taken in a new way, and argue that we need an enhanced education of managers to improve their decision making towards ecologically sound innovation, and thus sustainability.

Design/methodology/approach – We propose to design a scientifically founded and justified method for a sound understanding of the relation(s) between justifying arguments (leading to decisions), and their relation to reality, i.e., the underlying (unconscious) classifications and categorizations, and the impact they have on handling a complex reality. This method, resting upon research in model theory and systems theory, can be turned into locally applicable heuristics to improve decision making, and impact evaluation. It is a sort of enhanced multidimensional semantics to settle the question: When and why is it impossible to reduce managerial decisions to simple information processing algorithms?

Originality/value – Our methodology puts in evidence that purely economic arguments, which are used to justify decisions, are definitely incomplete. Our approach can also explain how certain disadvantages in the organizational context come about, namely by misuse of algorithms, and suggest what can be done to solve this kind of problems. As a consequence, we argue that we need dynamical and open systems for developing and integrating knowledge, also to support innovation arising from cooperation across organizational boundaries.

Practical implications – The main result will be to show how our analysis of the relation between language, information/knowledge and reality can be applied to support the coming about of good decisions as a basis for ecologically sound and successful innovation, and thus sustainable development of an organization. The proposed new way both of “documenting” knowledge as well as “arguing” within an organization can help to reach not only better decisions but also new ways of understanding the coming about of,

for example, economic success, and how to balance the local institutional logics of professionals and the proposed managerial decisions effectively.

1 Mindless Adopting as Organizational Foresightfulness? Introducing a New Ecological Approach to Decision-Making in Organizations

Today, in an age of mounting competition and vast technological change, we may easily gain the impression that in business, at least in the context of toggling enterprises, innovation is understood to be the one and only “magic cure” and the essential ready to go tool to solve any problems as soon as there are economic signs of mischief within an enterprise. If an enterprise wants to do better than anyone else and be relevant to their customers (as far as this is assumed and understood to explain the business success or profit of that enterprise), there is a need for “innovation” in the sense of new approaches and perhaps even “capabilities” within its organization to be able to go on. The question, however, is: How should we go on in practice, i.e., without having too much to alter in our own thinking and quasi-natural explanations about the world?

So, one usually proposed idea which may lead to competitive advantage of an enterprise via creating innovation is to bring together cross-functional teams from within that enterprise to work towards a common goal to improve the situation. These teams should span both across multiple disciplines and across lines of business and industries as the story goes. However, can we really rely on just bringing those groups of professionals (and their “institutional logics”, Thornton, Ocasio & Lounsbury, 2013), together and wait till they solve our most complex problems?

Well, of course, looking from outside upon the matter “communication” of knowledge is important. Yes, and there should be a good climate or culture of cooperation and all kinds of social aspects need to be taken care of as well. But is this really enough? Yes and no! We should not just believe in “blind evolution”. We still need to develop an “eye for the essential”. This means that letting language “take care of itself” (when we translate

from one field of specialists to another) is not enough. An “ecological stance”¹ to take care of the interaction between individuals and the “changing” environment in which they live, e.g., a business ecosystem understood as a complex adaptive business environment where self-organization, emergence, co-evolution and adaptation are at work, may be helpful. This will allow for a good combination of knowledge, i.e., “content” as well as “action” in sense of application, innovation and fostering the transfer of expertise, phantasy and problem solution capabilities.

In his famous book “The Black Swan: The Impact of the Highly Improbable” Taleb (2008, p. 111) refers to Bastiat in writing that “if both the positive and negative consequence of an action fell on its author, our learning would be fast.” This point is both positive as well as dangerous, if we do not think ahead and keep our language open ended, i.e., keep it unsaturated, so that new meanings or interpretations can be used to give a new view. Thinking ahead means that we have to connect the causality of actions with our explanations, i.e., the “if, then” from the factual area with the “if, then” from the realm of argument, thinking and logic. If we do not see the connection between action and result both logically and causally, we shall not be able to learn nor feel any responsibility for our actions. Taleb (ibid.) goes on to point out: “But often an action’s positive consequences benefit only its author, since they are visible, while the negative consequences, being invisible, apply to others with a net cost to society!”

Before going into detail about the “ecological style” and the “ecology” of persuasion within an enterprise and its environment, and therefore the “ecology of decision-making”, as far as it depends on more than logic, we want to provide a sort of framework for the analysis of such a persuasion. This could help us to depict how the knowledge or rather expertise available within a profession group, like HR, IT, marketing or finance specialists, within an organization can be identified and conveyed (translated) to another group, especially to managers. Consequently, it may provide a new way of conveying (translating) content by combining the latter with social knowledge, and emotional understanding and evaluation as pointed out by Damasio (2003), and thus means of selection for acceptability.

So, one of the main aims of our contribution is to provide both an argumentation and a practical tool for the enhancement of knowledge of the decision-makers in an organization as also Pisano & Shih (2012) call for. The point is that we need much more

¹ Tsoukas (2005) calls it “style” with respect to considering complexity in organisations.

in the managerial boards than just the intuition of generalists with a “feeling for the future”. Decision-makers in organizations need to be able to visualize the future in a way which allows them to act appropriately and in a corrective manner as they go along (decide and act). Thus, built upon our former theoretical and practical investigations we want to suggest and argue for a new way of how and why to provide the knowledge, not just the information, for decision makers in organizations. But this means in the sense of Taleb (ibid.) that they have to stay open minded and not just to believe in the existence of the white swans when black ones may be around as well.

One point should be clear: We seem no longer to be able to simply rely on bringing together groups of professionals, and managers themselves are of course also a kind of professionals, to solve the most obvious, urgent or complex problems. We think that one of the important problems concerns the communication or processing not only of information but of knowledge to provide a valid basis, or “ecosystem”², for decision making within an organization, especially towards innovation.

Considering modern economic developments, especially with respect to the management in and of enterprises, we can easily find examples where we can wonder what is going on there, both in the sense of not agreeing upon outcomes or rather results of measures on the one hand, and thinking about the arguments that seem to justify those results despite of the fact that we do not like them. Quite often the so called “initial success” of a measure applied in an organization leads to transpose the technique(s) into other fields and we expect positive results there as well, or at least positive parameter values which we think are signifying positive results. This non-reflected adopting (isomorphism in the New Institutionalism, DiMaggio & Powell, 1983) built upon a short term evaluation can lead in the long run to economic disasters, as Pisano and Shih (2009, 2012) argue by considering and analysing the long term consequences of applying the managerial technique of outsourcing not only for individual enterprises but also for the whole American national economy. Consequently, Pisano and Shih (ibid.) claim that we need a new education of (top) managers. In developing their argument, we want to add that it is also necessary to find out what could be done about this kind of so called “short sighted” managerial decisions and why.

² Expressions like “ecosystem” or other metaphors from ecology need to be transposed carefully and the term “eco” in all those connections should not just be identified with environmentalism which would be too narrow for our purposes or context. In general, we should be careful about metaphors, especially if borrowed from other fields of research, with respect to explanation and prediction of causal developments.

To solve this problem and to ground further practical steps in organizational practice theoretically, we have developed a framework of analysis resting upon (1) modern system theory, and in this context on research in complexity, e.g., in Santa Fe, (2) model theory and (3) semantic logic (Barwise & Etchemendy, 1994) as well as most recently on (4) the work of Nowak (2012) who allows us to provide a new point of view upon the evolutionary selection mechanisms, especially in the context of cooperation, enforcement and acceptance of actions as well as arguments. Nowak's (ibid.) selection mechanisms are linked up with the logical acceptance of arguments, and establish the connection between reality and language to process relevant information in a way we propose to consider systemically with the help of our framework of analysis called LIR (Language – Information – Reality). However, LIR is not only a means of investigation but also of application as positive results in the practice of organizational development prove (Augl & Hochrainer, 2007; Gatarik & Born, 2012).

We have already referred to Pisano and Shih (2009, 2012) and want to stress again that we need to identify a way allowing us to process that kind of information which is relevant for knowledge necessary for an improvement of decision making in organizations to be able to find decisions whose results will be valid and ecologically acceptable in a long period of time, and thus will provide sustainable success of an enterprise and its environment.

2 The New Ecological Approach of Decision-Making in Organizations Taken Apart

2.1. Reflexivity and Causality

Taking up the idea, or metaphor, that the knowledge of a firm is situated in the heads of its employees we tend to “get hold” of those heads. What is essential at this point is to use the distinction between an explanatory use of this idea and its descriptive use. The practical consequence of such a distinction is that in the context of organizational life we are guided by the metaphor and look primarily at the knowledge that, implicitly, is prevalent in a firm and more or less preserved as experience within the set of employees. We definitely can look at it and think that we can transport it, sometimes indirectly by providing experience that leads to some insight. There is enough discussion available in

the literature to know about the obstacles and all the techniques to get hold of this knowledge without being really able to “put the finger on it”. Of course, a lot of this knowledge can also be put into words as we can observe experts who use their notes and/or hand them out to their colleagues. However, if we look carefully, we will find out that these notes are something like “road marks” to reproduce results or experiences which help the experts in orientating in the(ir) world and act due to their own experiences respectively. Using notes is more or less comparable with the use of a static map, a map which does not depict the world literally. We still need a kind of extra knowledge which allows us to evaluate and correct the results of our actions. So, the real point is neither just processes (causal connections) nor just structures (reflexivity in the language). However, it is appropriate to see the distinction as an expression of the difference between explanations, which need not be taken literally descriptive as they necessarily are simplifications built upon a certain aspect of analysis, and thus need to be re-interpreted (by some kind of extra knowledge) into the reality, and processes, which can be used as literally action guiding conceptions, though they eliminate creativity, and thus flexibility and innovation when the moment of reflexivity is missing.

We argue that most of our problems stem from a kind of misconception how knowledge comes about and how it applies properly when we, again, have to look for “selecting” and for selection mechanisms (e.g., cooperation as discussed below) what kind of knowledge is appropriate with respect to a problem and its long term solution in an organizational context. But how to achieve this selection and is it not arrogant and preposterous in some sense to think one can select the necessary kind of knowledge in accordance with a problem and its solution appropriately (and beforehand)? This would mean that we select admissible solutions in advance.

2.2. Refining and Combining Background Knowledge towards Flexibility and Innovation in the Model-Theoretic Systemic Framework of Analysis LIR

Knowledge, as we want to emphasize, mediates between language and reality and defines our dealings with information which by itself is codified linguistically and which determines the relation/reference of language onto reality. In the communication of knowledge, we have to take into account the multidimensional background knowledge of an addressee – see the knowledge components or rather the knowledge roles experiences/expertise E, common sense/user knowledge/folk knowledge F,

rules/routines/knowledge by calculi K, structure/explanatory/model knowledge M in Figure 1.

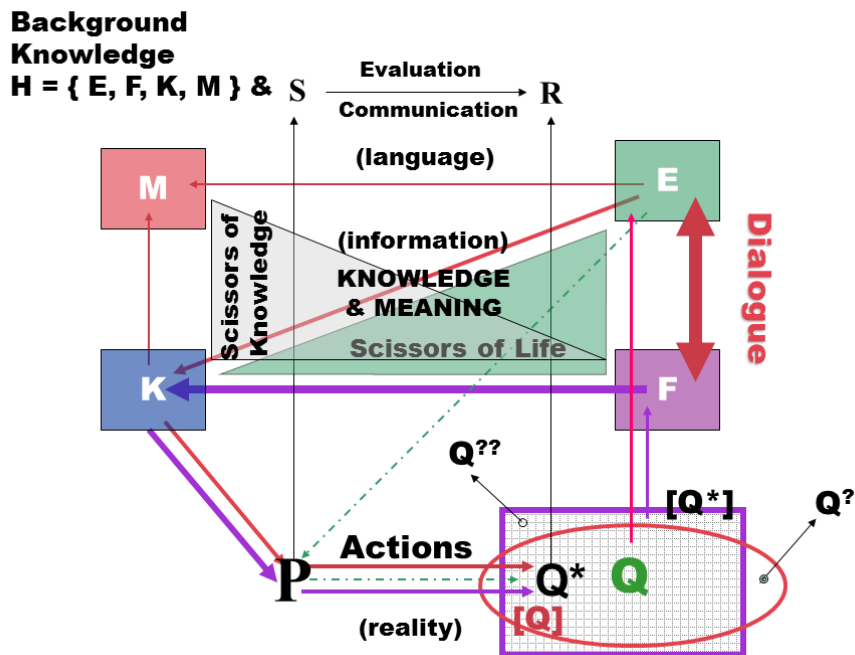

Figure 1: The model-theoretic systemic framework of analysis LIR (Language – Information – Reality) with the Scissors of knowledge and life

If we want to communicate the changing of a state P into a new state Q (in the world, in our attitude, in our understanding and in knowledge) or even if we want to make it understandable or want to produce the insight into this transition in the head of an employee/addressee, we have to explicate the means of representation in use (e.g., a language) and clarify which components of the background knowledge are responsible of relating the signs of the language onto special sections (selected parts) of the world. The causal connection of a situation or problem P and another situation, a solution Q, after the search/quest for some “holy grail” of knowledge within the given world is linguistically mirrored in the acceptance of the passing from a description of P as stimulus S to a description of Q as response R, and is a foundation of communication.

The state transitions from P to Q correlate with the fact that the transition from S to R in language is (logically) admissible. This acceptance of language can be amplified or

weakened by changing the relevant components of background knowledge which are responsible for acceptance and sense making in language. The real acceptance and therefore the success of the communication of knowledge (especially if we are dealing with building up or transferring new points of view or even new frames of reference) depend on the interplay of the respective components {F, K, E, M} of the background knowledge summarized and depicted as H. The Scissors of Life and Knowledge therefore concern the difference in the acceptance of (problem) solutions Q according to the use of the background knowledge F, E, M applied to the routines or rules K for causally producing or bringing about Q.

Roughly speaking, this means that the classical form and the set of documentations of information and of the rules, routines or procedures K for handling and using information do not suffice to grasp completely the expertise E present in people, e.g., due to manufacturing experience and the epistemic resolution level generated by this experience, and especially do not grasp the innovative potential of correction via background knowledge E, which is essential in *applying knowledge correctly* (in Figure 1 depicted as a difference between the outcome Q? provided and evaluated by an expert via knowledge E and the outcome Q?? provided by a lay-man via knowledge F). This potential of expertise is necessary to prevent the rules/routines from being overused or exploited in an unreflective manner, and therefore can lead to wrong applications of knowledge and especially of explanations.

2.3. The Form of Life in the New Organizational Ecology of Decision-Making

The following idea conforms to the conception of “Knowledge as a Commons” introduced by Hess and Ostrom (2007). The term Commons refers to “a resource shared by a group of people and it is often vulnerable to social dilemmas” (Hess & Ostrom, 2007, p. 349). It was recently taken up by Pisano and Shih (2009, 2012) as they introduced their concept of Industrial Commons as a way how to restore competitive advantage not only of the United States.

In our context it would mean that if we look at the interplay between expertise and experience given in E and the common sense or cultural knowledge given in F (see Figure 1) and then introduce an organizational structure and culture based on reflection and communicative cooperation to support this interplay, we can enable sharing experience/expertise and thus conveying knowledge via dialogue in order to change the

relation between E and F and transform the given background knowledge in F into an extended F^* by enriching the epistemic “resolution level” of the available background knowledge (see the discussion of von Foerster to link understanding with experience by acting in von Foerster, 1993, especially pp. 101-103). Applying an extended background knowledge F^* to the routines K (see Figure 1, especially the triangle $K|F|E$) can produce new (problem) solutions Q^* , i.e., innovation, which still can be accepted in F by way of simply applying the techniques that lead to success in every-day life but cannot be corrected by knowledge F.

Practically, an organizational structure and culture which cultivate knowledge as a Commons can enforce the necessary dialogue and the sharing of experiences/expertise between E and F, and in this way they can essentially influence the success of problem solutions of a system. We think that this dynamical dialogue can improve developments of a system, especially in supporting innovation in the realm of routines and rules K, and as a further consequence it can improve the competitive advantage and the general survival not only of a specific organization (understood as a regional “knowledge node”) but also of its environment, e.g., a region, as a whole.

3 Applying the New Ecological Style of Decision-Making in Organizations as a Chance for Creating Innovation Ecosystems

In the sequel, we want to apply the extended framework LIR (see Figure 2) in a more concrete manner, i.e., as a process model, to implicitly define the idea of an ecosystem of innovation. It may resemble in some sense the Canvas method (Osterwalder & Pigneur, 2010) but it goes far beyond especially with respect to its model-theoretic background and foundation in combination with the systemic approach by Senge (2006), and especially with respect to cooperation as mechanics of evolution according to Nowak (2012).

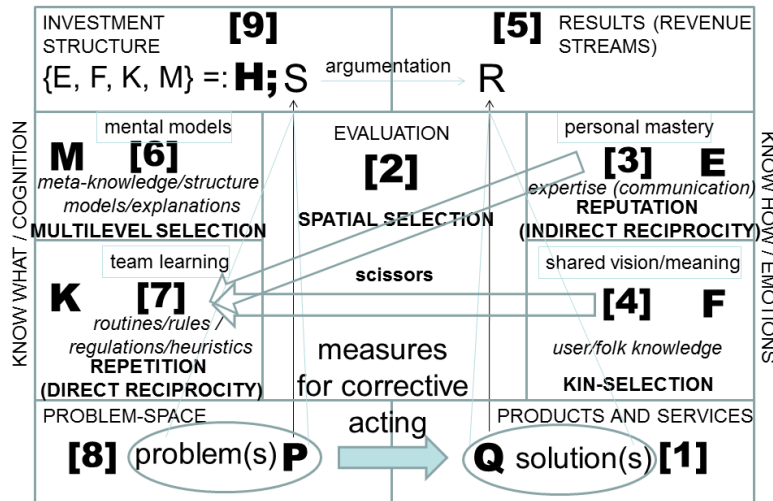

Figure 2: LIR (Language – Information – Reality) as a process model to analyse and understand the coming about of successful innovations via ecosystems and as model to support innovation ecosystems³

Let us therefore start with an observed, given result Q [1], e.g., a successful product or any other *accepted* problem solution within a set of them [Q] (see in Figure 3). This is where evolution theory comes in and the way in which it is extended by Nowak (2012). We do not only want to explain why the elements of the set Q are accepted but also how they are selected, and why they are successful in the evolution of mankind. Nowak (ibid.) explains this with the help of “mechanics of cooperation” built upon five rules.

So, there are (available) problem solutions or products which are accepted (according to agreed-upon values) by the members of an enterprise as well as people in its environment (not necessarily just customers), i.e., there are “evaluations” at hand [2] connected with these products [Q] in a realm of a “social network” where individuals interact with each other more often than others. Nowak (2012, p. 271) calls this spatial selection [2] and formulates the first rule: “The benefit-to-cost ratio must exceed the average number of neighbours per individual.” These systems specific value propositions (to bring in the systemic approach of Senge, 1999, 2006, 2008) provide a connection or a link to all other factors/elements of the scheme LIR and in a loose way correspond to the

³ The numbers in Figure 2 depict the path of the analysis and not the causal path from problem P to solution Q. The cooperation supporting evolutionary terms repetition, reputation, spatial selection, kin-selection and multilevel selection originates in Nowak’s *SuperCooperators* (2012).

5th discipline (Senge, 2006). By “loose” we mean that we apply the idea of “family resemblance” of Wittgenstein (1953) which roughly means that the concepts in use (stemming from Canvas, Senge and LIR) overlap, i.e., they are not identical in the sense that there is one single thread that makes up the “rope” (of argument) as such (to use a well-known metaphor of Wittgenstein’s).

Since it is our aim to reproduce the acceptance of a set of problem solutions [Q] via innovation resting upon expertise in E, we have to consider the internal structure of the social networks. Therefore, the next step in the analysis of the coming about of a set of good problem solutions [Q], i.e. accepted products or services, and thus the economic success of an enterprise, is to identify the [3] reputation (or indirect reciprocity) as a further rule of cooperation” introduced by Nowak (2012, p. 270) to support successful selection in evolution (as a competition and survival advantage of an enterprise explaining the acceptance of products or services on the market, so to speak). This second rule is at work when there are repeated encounters within a group of players especially with background knowledge E. Indirect reciprocity according to reputation for the exchange of knowledge leading to better results of the application of a set of rules in K via expertise in E is essential in the context of generating innovation. We must face forthcoming encounters. In the human society, Nowak (ibid.) argues, indirect reciprocity relies to a great extent on communication. He and his group found that “indirect reciprocity” can only “promote cooperation if the probability of knowing someone’s reputation exceeds the cost-to-benefit ratio of the altruistic act.” The altruistic act manifests itself in exchanging knowledge for creating an innovative problem solution, and presupposes trust. This is his second rule to support cooperation which he illustrates by the phrase: “I scratch your back and someone will scratch mine.” In our framework LIR reputation or indirect reciprocity corresponds to personal knowledge [or experience] in E (if we are looking for knowledge-based creativity). Here it is essential to take into account “nodes of knowledge” which also correspond to the idea of “personal mastery” (Senge, 2006), i.e., we have to find out where knowledge is relevant for creative problem solutions (experiences and expertise) and where it is concentrated such that it can be transferred or communicated. We are looking for the knowledge which we think is essential for the generation of problem solutions.

Thereupon, following our path of analysis of coming about accepted and innovative problem solutions in form of products and services, we concentrate on “kin-relationships”

[4] as the third selection rule introduced by Nowak (2012, pp. 271-272) which we can combine with cultural and social “folk-knowledge” F as the background knowledge which is important for the common use and acceptance of results Q as well as containing the possibility of cultural and in a broad sense ecological corrections with respect to the “acceptance” of proposed solutions. It is also the place where “ethics” (understanding “how far we can go”) can come into the picture. Nowak (ibid.) concentrates on the bonds of family and of common ancestry as decisive. We cooperate with close kin and defect with strangers, and there are, of course, dangers in it, too. Nowak (ibid.) formulates it as his fifth rule and calls it Hamilton’s rule: “The coefficient of relatedness must exceed the cost-to-benefit ratio of the altruistic act.”

Only afterwards, step [5] in Figure 2, we should analyse the “results” as often considered and argued by the top management to be causally produced and characterized by well selected parameter values. They must, however, not become the core or drive of invention.

In [6] we introduce a sort of view from outside which makes up the explanatory power M and corresponds to Senge’s “mental models”. These can make up what we consider as a *European competitive advantage* due to a host of cultural diversity in E and F. In Nowak’s terms this is called “multilevel selection”. As the fourth rule of cooperation it recognizes how, in some circumstances, selection acts not only on individuals but also on groups. According to Nowak (2012, p. 271) “multilevel (group) selection allows for the evolution of cooperation provided that one thing holds good: the ratio of the benefit-to-cost is greater than one plus the ratio of group size to number of groups.” As a rule it works well in many small groups but not so well if there are few large groups.

In general, our aim is to reproduce success of an enterprise in understanding the way in which this success comes about, and to explain that it does not depend on the manipulation of monetary parameter values in the first line: These values concern primarily the use of rules K via background knowledge F, i.e., the extended and innovative knowledge is missing. In the context of reproducing success of an enterprise it is also important to recognize the distinction between innovation and creativity by way of analysing the connection of experience in E to explanatory knowledge in M. leading to expertise with its innovative power.

What is furthermore relevant are in [7] the rules, routines and procedures in K in accordance to LIR which can be understood as the visible “core activities” of an

enterprise both in the production as well as the relation to the common sense knowledge F and therefore to Senge's "shared meaning" [4]. The step [7] corresponds to the fifth rule of cooperation by Nowak (2012, p. 270) called "repetition" or "direct reciprocity". Nowak (2012, p. 270) illustrates it by the sentence: "I'll scratch your back and you scratch mine." According to Nowak (ibid.), "direct reciprocity can lead to the evolution of cooperation only if the probability of another encounter between the same two individuals exceeds the cost-to-benefit ratio of the altruistic act." The production of results Q based upon a pure relation between K and F is the real core and point of critique in our analysis (see Figure 3).

In the sequel, we should look at the "original problem space" [8] and the available resources for possible solutions where the special knowledge of an enterprise and of other knowledge nodes, especially from other firms comes in.

The last (but not least) factor of analysis concerns the "investment structure" [9], such that one can calculate R from S by using relevant background knowledge $H = \{F, K, E, M\}$, structural hypotheses and extra knowledge by content (expertise).

Caveat: The approach is not safe against the possibility of misuse, i.e., of "freezing" in the knowledge about some system (organization and its environment), if we use the tool as a sort of static, universal language. In order to prevent mistakes, we need pre-knowledge, engagement and motivation. Each knowledge node has its own epistemic resolution level. Solutions, which are created, are understandable by the cultural autonomy of the single nodes. If, however, we use some digital technique for networking, we have to apply them in such a way that they just take over routines and leave open elbow room for individual exchange of experience and common creative problem solutions. It definitely must not replace real-life communication and we must take care to build up human attitudes to produce real success of communication, which is not solely reduced to rules, roles or norms. One must not overlook the fact that success cannot be reproduced by simply adding up the success of the producing parts. Senge summarizes this idea in "The Necessary Revolution" (2008), where he also takes care of the importance of ecology.

To understand the limits of the applicability of LIR as a process model, if it is just used as a means for the identification and analysis of, for example, business models (as in the case of the so called Canvas method by Osterwalder & Pigneur, 2010), we also need to take into account the Scissors of Knowledge and Life, or Meaning (see Figure 1): We

are rather looking for an extension of the local background knowledge F to some specific background knowledge F*, which guarantees the successful (and reflective, i.e., open for corrections) use of rule/routines/heuristics to (re-) produce results (products, solutions) with the help of the use of common sense background knowledge (as guiding our decisions in real life actions). F* will contain the specific knowledge/skills prevalent in a space (social network or region⁴), which is more than just a receipt to produce “results” on the basis of selected/prefixed parameter values. What is created is consciousness about the meaning/sense of the results of our analysis of business and “knowledge” models (Weick, 1995, 2009; Rullani, 2012). The aim, of course, is to prevent mistakes in the application of rules by evaluating “results” according to the background knowledge E and F*.

The idea leading further into this direction is to identify the necessary problem solution knowledge (explaining the local acceptance of results) and to yield the foundation for a “Geography of Knowledge”. Geography concerns the relation between a map and the reality it refers to (and therefore the reliability of maps in order to be used for our orientation in some world). This idea is depicted in Figure 3, which is the theoretical basis for our extension of the original scheme LIR as a process model. C combines E and F as common-sensical knowledge and is realized in Commons. A combines K and M and concerns abstracted knowledge.

4 Final Reflections on the New Ecological Approach towards Organizational Decision-Making in Order to Support Innovation Ecosystems

In this chapter we want to discuss a short example which recombines classical attitudes in science with the ecological style in the sense of Toulmin, and gives a new meaning to the ideas of Tsoukas and others arguing in his line but in a broader context and with a greater chance for practical application on the one hand and reflection on the other. Furthermore it helps to identify the place or rather space where communication and use of expertise are essential for creating innovation ecosystems, and how innovation is linked to creativity.

⁴ Consider in this context the story of Swatch in Switzerland analysed by Schulz (1999) or Wegelin (1999) as an example.

The ecology of decision making comes into play when all components in Figure 3 are dynamically interconnected, i.e., when the top level illustrating justifying argumentations $S \rightarrow R$ and the bottom level illustrating causality $P \rightarrow Q$ are connected properly, and the need for a switch of knowledge roles expertise E , user knowledge F , rules K , and meta-knowledge M is taken care of as well as the need for an endeavour/an active and constructive striving to understand something well, and not just to wait for a translation into one's own epistemic world.

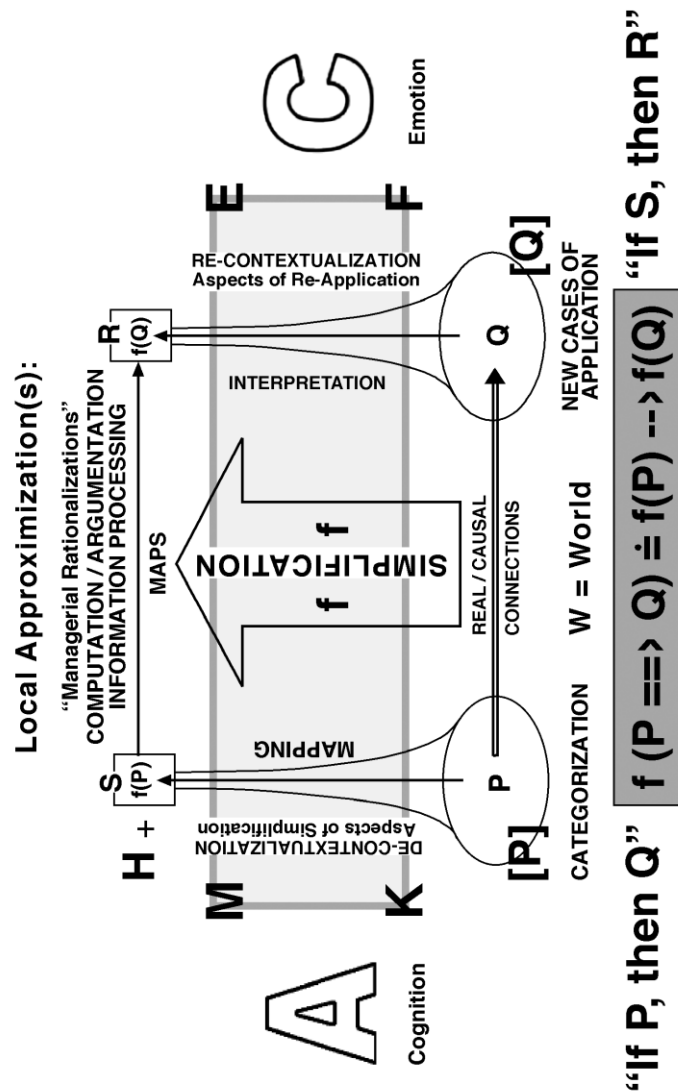

Figure 3: The core of the model-theoretic systemic framework of analysis LIR (Language – Information – Reality)

In Figure 3, P designates a given or constructed or assumed problem or any kind of starting situation that should either be transformed causally or by the application of systematic means of production into some result Q or some proposed solution in quest of which we were searching. The abstract mapping f from the bottom (the reality part) to the top level signifies the use of some means of representation (a language or a map) and especially the simplifications which we use to map reality onto this means. Thus, via feedback we create (quasi-) equivalence classes of similar cases in reality by bracketing them into [P] or similarly [Q]. This kind of reductionistic approach is an epistemic technique and should be called de-contextualization and not mixed up with ontological approaches. The top level uses background knowledge H consisting of all or some of the knowledge components invented to classify our knowledge and to process information encoded in signs (also parameter values if they stem from measurements). But the processing of information corresponds only in a middle realm of experience to our causal experiences which is expressed by the formula to capture a locally approximative homomorphism (a structure preserving mapping). The most important part is re-applying or projecting the top level onto the bottom level. Whereas the relation between [P] and S or $f(P)$ from bottom to top is many-one, the other relation, i.e., top-down, is one-many, which means we need a “corrective” interpretation of application provided by experience and expertise E in using rules K, and especially dialogue between experts in E and users in F (to enrich background knowledge F), not only within the same group of professionals but also with the members of the surrounding world (ecology) in general.

Figure 3 is in some sense the elaboration of the famous quote by Bateson (“The map is not the territory.”), which goes back to Korzybski, i.e., it elaborates the idea of how to understand the ecology of decision making, and therefore to know where the limits of some of those techniques are we are usually told to be inescapable.

But now let us fill the abstract framework with a fictitious example such that no living people might be affronted: Consider a country where there has been some change in the political situation. Originally, there had been factories with some technical knowledge, e.g., in producing cars. Now, there is a firm from some culturally completely different country but, of course, for technical application this might be irrelevant. To have a plant to assemble parts of the cars there would pay off, the management thought. All they had to do was to write a good programme how to assemble the parts and then let go. This corresponds with the set of rules K used by the workers to be hired in that country who

had some background knowledge F together with relevant technical experience. But where did the decisions of the management come from why did they think that their decision could be reduced to some formal understanding of the economic situation. Their background knowledge was, of course, specific economic knowledge with some weak understanding of what was essential in producing a car. After some time in the country there appeared some problems in context of repairing cars. The background knowledge of assemble line workers was not enough to solve the problems, the old sources for knowledge and teaching were gone, and no new ones could be built up, no one would invest in knowledge and expertise. One point is that in the beginning there was background knowledge in form of special expertise of the workers available. The picture or map in managers' heads was just a shortcut in explaining the success in the beginning, and this picture was parasitic on the pre-knowledge of the workers to cut the story short, the foreign firm gave up and withdrew their plant again. The original country had lost in two areas: Firstly, they had spent money to support the foreign firm because they promised employment. The foreign firm made profit but gave up after some time. But the original country also had lost the knowledge of the people, who were there to have the technical know-how to operate the system, and they did not invest in any education comparable or necessary, and they did not have anything by themselves to compensate the loss of employment. Now, this is a fictitious story and you can neatly explain what was going on within the framework in Figure 3.

The ecology of decision-making should be self-explaining: We have to take into account all the relevant factors in Figure 3 to reach good decisions with the chance to correct actions $P \rightarrow Q$ if the results Q are not really acceptable.

Tsoukas (2005) quotes Toulmin (1990) to stress that the ecological style of decision-making needs to embrace complexity by reinstalling the importance of the particular, the local and the timely. We therefore have to acknowledge connectivity, recursive patterns of communication, feedback, non-linearity, emergence, and ineffability.

One of the most important topics Tsoukas (ibid.) stresses is to think through the difference between verbs and nouns, i.e., as we like to put in between processes and explanatory structures, in Figure 3 the relation between E and M or in general the right side of communal knowledge C comprising F and E, and the left side of abstract or explanatory knowledge A comprising K and M.

Finally, with the help of LIR we can provide arguments why the ecological stance, approach or style is useful and we can explain it, and not just derive from some cases where it is successive, and then will find that the cases for the success have not been well identified. With the help of LIR, we can recombine classical approaches with new techniques, technologies, and an understanding of their limits. In this way, LIR can support emergence of innovation and help to evaluate the results of new applications.

5 Conclusions

There are three main practical conclusions which can be drawn with the help of the introduced ecological approach to organisational decision-making and which provide evidence for its applicability:

(1) Whenever we try to reproduce “results” in practice and try to invent more or less formal rule systems or even expert systems (in the sense of Artificial Intelligence), we must not institutionalize them as a means to replace creativity. Instead they should be used as a means to take over from routines K and create elbowroom to re-enforce real creativity as a necessary precondition for innovation, flexibility; and thus, sustainability in *Innovation Ecosystems*.

(2) Whenever we think we have identified rules K to produce results in a strict way we might remember that they rest upon simplifying categorizations of parts of reality (Figure 3), and the success of the application depends on our ability to use them reflectively which explains their real success.

(3) Strictly following a set of rules is not enough to reproduce success. It is not its real explanation. But instead it is the creative and innovative coping with reality by cooperation of people with different kinds of expertise. This is where the five rules by Nowak concerning the mechanics of cooperation create a competitive advantage and survival in evolution.

Acknowledgements

This contribution would not have come into existence had it not been for Prof Dr Rainer Born’s support and encouragement. I cannot thank him enough for all the inspiring discussions conveying insights into the complex matter, and, in general, for his unfailing willingness to help.

Structured Abstract

Purpose –This paper aims to contribute to the exploration of micro-foundations for innovation in autonomous team-based firms. It describes how different types of management control systems influence the innovation performance of teams through an extensive field study of a large scale agile implementation. It reveals the moderating role played by different kinds of managerial control systems and by perceived time pressure on teams in the relationship between a team’s absorptive capacity and its innovation performance.

Design/methodology/approach – A total of 44 individual semi-structured interviews were used to collect data over three separate data collection stages conducted from August to November 2013. All data were triangulated with the qualitative content analysis results of free comments from 121 people, covering different agile roles in the same organizations as above, and embedded in a survey performed in August 2013. Due to the complexity of the topic and the lack of prior studies investigating the effect of agile implementation on team learning and innovation capabilities, an abductive research approach (Peirce, 1931) was selected as a suitable method.

Originality/value – The empirical results indicate that a team’s beliefs on the importance of learning strongly influence its self-regulated learning behaviours. They represent the configuration of AC meta-routines underlying the concept of absorptive capacity (Lewin et al., 2011) at the team-level, conducive to teams’ exploration activities. Moreover, the antecedents for a team’s exploitative and exploratory innovation activities are presented and two types of managerial controls for driving exploitative innovation activities are identified. Additionally, team-level absorptive capacity was analysed, since it is a less explored, but important construct, leading to a team’s exploitative product innovation.

Practical implications – This study’s findings have a number of implications for practice. The results imply that autonomous team-based organizations may be better off not using

one single standard control system to manage all their teams. In fact, beyond securing a team's access to knowledge, management needs to provide teams with differentiated means to develop necessary competencies and capacities for understanding, assimilating and using the knowledge they retrieve. In addition, management should influence a team's beliefs by valuing the tasks requiring innovation and transmitting sustainable values to teams through their mission and vision statements.

Keywords – Agile, innovation, knowledge stock, control mechanisms, self-regulated processes

Paper type – Academic Research Paper

1 Introduction

Increasingly, the capabilities of organizations to create and transfer knowledge are being identified as a central element of organizational advantage. Kogut and Zander have proposed: "...that a firm be understood as a social community specializing in the speed and efficiency in the creation and transfer of knowledge" (1996: p.503). Adding to theory of the firm, the knowledge-based view contrasts transaction cost theory grounded in the assumption of human opportunism and the resulting conditions of market failure (e.g., Williamson, 1975); the knowledge exchange perspective instead argues that organizations have capabilities for creating and sharing knowledge that give them distinct advantage over other institutional arrangements, such as markets. Some researchers have used this notion to explain the very existence of the firm, especially forms such as the multinational company (Kogut and Zander, 1996, 2003) as well as strategic alliances (Lane and Lubatkin, 1998). However, research regarding the impact of knowledge on performance is arguably scant and characterised by broadness and diversity (Foss, 2007) and a call for more research to build the micro-foundations in the field has been issued (Felin and Foss, 2005; Foss, 2007; Foss, 2011). This 'knowledge governance approach', KGA, focuses on governance mechanisms and their impact on the creation, retention and sharing of knowledge. These governance mechanisms entail aspects such as organization structure, job design, reward systems, information systems, standard operating procedures, etc. This approach focuses on the crucial antecedents to knowledge processes. KGA identifies two research gaps related to the governance of knowledge-intensive firms and, the relationship between knowledge and competitive advantage.

In line with the KGA approach, the aim of this paper is to contribute to the exploration of micro foundations for innovation, especially teams' self-organization of

innovation activities. To this end, a specific set of practices that have gained recent popularity in R&D organisations - agile methods – serves as an empirical starting point to explore the impact of governance mechanisms on knowledge processes and subsequent impact on firm performance. From the view of the present study, agile methods represent a specific set of governance mechanisms that potentially have an impact on knowledge processes. In turn, these knowledge processes have a potential effect on crucial aspects of the firm's competitive advantage. Using an abductive approach from a knowledge-based perspective, two sources of data from a large R&D organisation have been explored. Firm performance in this R&D setting regards both refinement of the old as well as creation of the new, i.e. innovation.

A central contribution of this paper regards the implications of Agile and its main components. The self-regulated team is a key component, making the findings related to research regarding teams and their learning, regulation, and assimilation. The results illustrate that agile implementation has a clear impact on knowledge processes and that these knowledge processes are micro foundations for exploration and exploitation. Testable hypotheses are made based on empirical data together with extant literature. These findings contribute directly to our understanding of the effect of agile methods on a team's self-regulated learning and their knowledge stocks, as well as the knowledge-based micro foundations of competitive advantage. In the present study, Agile serves as a vehicle to pinpoint and illustrate potential micro foundations of general knowledge governance structures and their significance for competitive advantage, which builds on March's (1991) work on exploration and exploitation. The present exploratory study is focused on specific agile practices that are not necessarily used in all organisations. Generalisation of findings and subsequent hypotheses are thus made for the knowledge processes and their identified antecedents on a level of abstraction that is argued to be important beyond mere agile practices.

2 Theoretical background

2.1 Micro Foundations of the Knowledge-Based View

A number of researchers have suggested that knowledge exchange may facilitate socio-economic outcomes. These researchers base their arguments on separate theories and do not necessarily claim a knowledge-based view. These theorists can be found in

social capital research (Nahapiet and Ghoshal, 1998; Subramaniam and Youndt, 2005) and creative climate research (e.g., Scott and Bruce, 1994; Kylén and Shani, 2002). Nahapiet and Ghoshal (1998) claim that the special capabilities of organizations for creating and transferring knowledge are identified as a central element of organizational advantage. In their perspective, social capital is especially useful since its value also extends beyond the boundaries of the firm. Partly based on Nahapiet and Ghoshal's research (1998), in Subramaniam and Youndt's (2005) view, social capital is not only a conduit of knowledge transfer; it also refines the evolving body of this knowledge. Social capital was found to positively influence incremental innovation, as well as radical innovation. Research on the creative climate indicates support for the proposition that knowledge exchange and communication facilitate innovation. The research on creativity initially focused on organizational environments either hindering or supporting individual creativity (e.g., Scott and Bruce, 1994). Their findings support that leader-member exchange, innovative role expectations, resource supply and systematic problem solving style, as well as a climate that supports innovation are significantly related to individual's innovative behaviour. Kylén and Shani (2002) support the positive effect of a knowledge creation interaction climate on the self-rated efficiency of the product development process, while a defensive interaction pattern has a negative effect on efficiency. Defensive interaction patterns are characterised by withholding knowledge and not sharing good ideas. Knowledge creating interaction patterns were characterised by learning from mistakes, listening patiently, and having openness to knowledge. Although these aspects are related to efficiency, they regard the product development process and could, thus, also relate to innovation processes. However, there are some fundamental issues when attempting to create synergies from this research. Summarising their 2002 review of research on the knowledge-based view, Eisenhardt and Santos state that this research is very useful for understanding internal knowledge transfer, but that it is less helpful in dealing with performance issues since this research stream does not address key issues of strategy such as the nature of competitive advantage and implications for firm performance. In Eisenhardt and Santos' review of knowledge-based research, only two studies of knowledge transfer between business units (i.e., Brown and Eisenhardt, 1998; Lord and Ranft, 1998) actually measure performance. Hence, only indicative research regarding the link between KBV and innovation is present in extant literature. Underlining the breadth and diversity in the field, Foss (2007) notes the multitude of

interests, disciplines, methods, results, and philosophical underpinnings treated in this research. Cutting across these areas, Foss (2007) calls for more research to build the micro-foundations in the field, something that had previously been lacking. This approach was coined as the ‘knowledge governance approach’, KGA, and focuses on the deployment of governance mechanisms and their influence on knowledge processes (i.e. the creation, retention and sharing of knowledge). These governance mechanisms entail formal aspects of management of the organisation, e.g. organization structure, job design, reward systems, information systems, standard operating procedures, accounting systems and other coordination mechanisms. A basic claim in this approach is that the mechanisms are crucial antecedents to knowledge processes. KGA addresses two main research gaps: (1) the governance of knowledge intensive firms and, (2) the relationship between knowledge and competitive advantage. From the view of the present study, agile methods represent a specific set of governance mechanisms that potentially have an impact on identifiable knowledge processes. In turn, these knowledge processes have a potential effect on firm competitive advantage.

2.2 Agile scrum methodology

Agile methods consist of a group of practices for software development created by experts (Agerfalk and Fitzgerald, 2006). Agile practices face an unpredictable world relying on “people and their creativity rather than on processes” (Nerur et al, 2005, p.75). In particular, Scrum is the best-known agile method. It is illustrated as a software development process which relies on self-organizing teams and is divided in short iterations called “sprints”, lasting from one to four weeks (Rising and Janoff, 2000). A team’s activities are organized based on the product backlog (Moe and Dingsøy, 2008), which contains the product feature list, prioritized by the product owner (Cohn, 2009)., According to scrum principles, teams attend several ceremonies during a sprint:

- Sprint planning, at the beginning of the sprint, during which the product owner gives the list of prioritized features to the teams (Cohn, 2009);
- Daily stand-up meetings in order to discuss the team’s work progress, plans for the ongoing day and potential impediments (Moe and Dingsøy, 2008);
- Demo or Review, at the end of the sprint, to show the product owner, management and other teams what was completed during the sprint;

- Retrospective meeting, at the end of each sprint, to reflect collectively on how teams are performing and how to improve (Cohn, 2009).

The key factor for Scrum's applicability is that the system development process is extremely complex (Schwaber, 1997). Its results can be influenced by many aspects, so planning ahead, as the waterfall approach prescribed, in this case turned out not to be suitable (Moe and Dingsøy, 2008). Therefore, Scrum is organized to adapt to change, relying on strict mechanisms of process controls, with short and frequent feedback loops and continuous planning (Moe and Dingsøy, 2008). Moreover, the higher the project's complexity is, the more the controls result indispensable to increasing its flexibility, reliability and responsiveness and to controlling the risks (Schwaber, 1997). It has been debated that agile software development approaches are best fit to explore new fields and to support people having innovation and creativity as their highest priorities (Highsmith, 2002). Nevertheless, there is a remarkable lack of studies investigating how creativity and innovation develop in software development in general and how they are influenced by agile methods (Conboy and Morgan, 2010). This is in line with Dybå and Dingsøy's, (2008) literature review on agile scrum methodology, which reported only one case study of Scrum prior to 2006 and stated that most studies on agile methodologies were centered on the phases of introduction and adoption of agile methods (Dybå and Dingsøy, 2008), whereas fewer studies investigate its effect on innovation (Abrahamsson et al., 2009). Moreover, Dybå and Dingsøy (2008) also discovered that the applied research methods, in particular for data collection and analysis, were not rigorously described. Hence, they reported the need for more reliable studies in agile research to analyze its benefits and limitations. This paper aims to fill this gap and focuses on how agile teams self-organise their innovation activities. So at least one important question arises from the discussion reported here:

RQ1: What are the organizational factors and the self-organizing team's characteristics that influence their innovation performance?

3 Research design

3.1 Research setting

Four organizations within the same international company in the telecommunications industry were selected, following a purposeful sampling (Patton, 1990). Three of these

firms dealt with feature development activities and selected scrum methods for organizing their work, while the other firm developed product concepts and adopted a lightweight approach to Scrum. The product development activities were endorsed by cross-functional and cross-product teams made up of 7 people on average with different previous competences as designers, testers and system analysts. According to scrum principles, each team's work was organized in three-week iterations called scrum sprints. These organizations started the agile transition in 2011, which was considered completed by the end of 2012 when all their people were assigned to different agile teams. Our analysis started in August 2013, so one year after the complete transition.

3.2 Research method

An abductive approach (Peirce, 1931) was selected in consideration of the topic's complexity and the shortage of rigorous studies investigating the long-term effects of agile implementation on team learning behaviors. Moreover, all results were triangulated with a secondary data source, consisting of free comments taken from a global survey launched for the same organization in the same time period. This helped to increase the reliability and validity of the study's results.

3.3 Data collection

A total of 44 individual semi-structured interviews were performed by the research group, trying to comprise the different agile roles in the four organizations involved. The first round of interviews included the main agile roles (product owners, scrum masters, agile team members) and high level management, selected through a purposeful sampling (Schatzman and Strauss, 1973). In contrast, the second round of interviews involved middle level managers that were added to the initial sample, following a theoretical sampling (Draucker et al, 2007), in order to examine the origins of agile control mechanisms acting over the agile teams. As a third stage, some old participants were contacted again to confirm specific concepts, and other agile team members were interviewed to validate the emerging ideas. Data collection ended as saturation of data was achieved. Different interview templates were developed for the different roles, in order to focus attention on peculiar aspects related to the interviewees' roles. Each interview lasted almost 60 minutes and was recorded, transcribed and sent for confirmation to the interviewees.

3.4 Data analysis

The selected approach was inspired by abductive reasoning (Peirce, 1931). This was particularly suitable due to the lack of studies in the literature and the researchers' lack of experience on the topic. The researchers' aim was to generate new ideas and theoretical models to describe the impact of agile on team learning behaviours. The analysis started with as few preconceptions as possible, but with a solid background in organizational learning studies and agile characteristics in order to remain sensitive to interpretations and meanings on related emerging concepts (Glaser, 1998). Thusly, the literature was used as a fundamental source to shape emerging concepts, as suggested by Glaser (1998). In particular, literature review, endorsed after the first interviews, focused on control mechanisms, self-regulated learning/innovation strategies and absorptive capacity. The coding processes (Glaser, 1992) were performed on the entire data set in order to detect different themes, cluster them into categories and sub-categories and obtain a codebook. In particular, the coding process relied on different stages of analysis.

First, open coding was performed through a repeated reading of all data and an in-depth line-by-line examination in order to identify provisional concepts (codes). Relying on an external independent researcher, the identification of codes was performed twice from scratch. The first time it started from the analysis of team member interviews and the second time from those of middle managers. The categories were obtained by clustering the identified codes through comparison and analysis of belonging to a specific analysis dimension.

Axial coding (both hierarchical and non-hierarchical) was executed to organize identified concepts into macro categories, as well as to define related categories and hierarchical relationships with respect to their categories. During this process, the relevant literature studies results were considered as another source of 'data' and constantly used in the definition of emerging categories to be integrated in the nascent theory (Glaser, 1992). As a result, macro categories were detected and linked to the appropriate theoretical concepts enabling the development of the theoretical framework represented by the initial codebook that was generated.

This process was helped by the use of a qualitative data analysis program (MAXQDA 10plus®). The same codebook was then applied to the secondary source of data. It was enriched with new categories as new themes emerged in the text. Additionally, again with the support of MAXQDA®, the code co-occurrence models described as the applications

of “two or more codes to a discrete segment of text from a unique respondent” (Namey et al., 2007, p.145) were generated. This evidenced potential linkages between the codes belonging to the innovation category and the ones related to the other categories in the developed codebook. In fact, ignoring the context that derived from the underlined associations between codes, accidental code co-occurrences could emerge in models developed. So, in order to identify code co-occurrences that truly describe multiple concepts the analysis of relationships with the innovation codes was further analysed through a strict examination of the text done by means of the following steps:

- all the clusters of codes that resulted directly involved were identified through the overview of coded segments involved in code co-occurrence instances;
- the text corresponding to the overlapping parts in each cluster above was read to understand the nature of the relationships between codes in terms of causality, mediation, and moderation;
- paradigm models (Strauss and Corbin, 1990) were developed by scanning all the clusters and showing emerged relationships between the codes related to team innovation and the most significant one influencing them.

All the identified linkages between different codes, and consequently categories in the models, were validated and enriched through the analysis of previous literature studies. This facilitated: 1) identification of each team’s core behaviours, 2) comprehension of the influence each team’s core behaviours and environmental factors had on their innovation; 3) extraction of variables from the codes, and 4) the formulation of testable hypotheses.

4 Results and discussion

In this section, the results of the cross-case analysis over the four organizations involved are reported through the presentation of a preliminary evidence-based model describing how teams handled their innovation activities. The crucial relationships among the most relevant concepts belonging to the innovation category and the others from the selected key categories are shown here. This has been done by distinguishing between the performance of exploratory and exploitative product innovations in order to improve our understanding of the limits and constraints involved in both types of innovation, allowing us to generate different hypotheses for them.

4.1 Overview of identified codes tied to teams' exploratory and exploitative innovation activities

Two codes emerged for the description of each team's innovation performance and were identified as indicators of the team's exploitative and exploratory innovation performance. A brief description of them follows in Table 1. In the next section, the antecedents of these codes are presented.

Table 1: Overview of identified codes tied to teams' innovation performance

Code	Brief description	Main quotes
<i>Absence of product improvements since people are losing competence</i>	This refers to a team's exploitative product innovation performance. It confirms that teams were generally very aware of their limits due to the lack of proper knowledge in relation to the existing product domain.	<i>"Hence, I feel there is not that much space or possibilities for innovation, because you have to know a concept really good to understand its limitation. If you are new to an area, then you cannot see the limitations. To know where you want to go, you have first to realize where you have been."</i>
<i>Absence of new product ideas within teams</i>	This refers to a team's exploratory product innovation performance. It underlines the team's low ideation performance in the product domain.	[What are Innovation opportunities in Agile team? What kind of innovation is it?] <i>"The innovation opportunities, I think, are very limited; the times when we have seen innovation with items we worked at as a team, the suggestions have come from outside the team, like pre-study author or by testing with another organization".</i>

4.2 RQ1: Overview of identified antecedents of teams' exploratory and exploitative innovation activities

The list of antecedents to *"absence of product improvement since people are losing competence"* and *"absence of product ideas within teams"* is provided in terms of the codes having a direct or indirect effect on them. Their description is complemented by the information of their category and sub-category within the developed codebook and is enriched with exemplificative quotes (see **Error! Reference source not found.**).

4.3 Paradigm model for teams' exploitative product innovation performances

The relationships among the above codes belonging to different categories and a team's exploitative product innovation performance were explored in the data set. Their

nature was identified and distinguished in term of causality, mediation, and moderation. The following model relied on a further triangulation of results coming from the secondary source of data that was used for validation and is displayed in Figure 1.

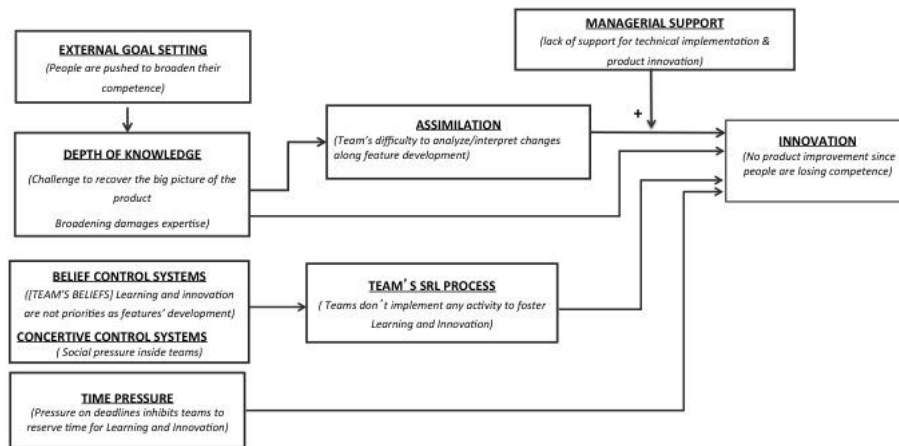

Figure 1: Paradigm model for teams' exploitative product innovation performance

Direct and indirect antecedents to the concept “no product improvement since people are losing competence” are displayed. The model explained the linkage between exploitative innovation performance and: 1) the depth of a team’s prior related knowledge, 2) the way the agile teams assimilate new product knowledge related to the current product development, 3) the team’s self-regulated behaviour for innovation and learning. Moreover, it highlighted the team’s external and internal conditions influencing these results: 1) the managerial support for technical implementation and product innovation; 2) the pressure on deadlines; 3) the external goal setting for the team’s competence broadening; 4) the team’s belief and internal normative controls.

Category	Code	Brief description	Main quotes
External goal setting	<i>“people are pushed to broaden their competence”</i>	This concept describes the new working condition for teams since the agile adoption. Compared to before, when people in teams took care of impacts on a specific part of the product, now they are asked to implement features affecting different product areas. In order to facilitate the transition to agile, the managerial roles in the organization put in place a strong communication policy encouraging people to embrace new learning domains and to always broaden their competences.	<p><i>“One benefit is that designers are together with testers, that we reduced handovers, and we find a lot of problem earlier than in waterfall way.”</i></p> <p><i>“On the other hand difficulties come when you are forced into new areas without having the knowledge in that area” [Team member]</i></p>
Team depth of knowledge	<p><i>“challenge to recover the big picture of the product”</i></p> <p><i>“knowledge broadening damages expertise”</i></p>	<p>These concepts refer to the way a team’s and a person’s knowledge stocks are becoming renewed following the agile transition. It reports a team’s problems to collect relevant information to obtain the whole picture and connect what team members already know with what they are acquiring.</p> <p>Moreover, the concept of <i>“knowledge broadening damages expertise”</i> tells about the team members’ difficulty to delve into the new knowledge they are acquainting due to the rapidity of the information change they are involved in along the continuous iterative development.</p>	<p><i>“I think I had a better overview about what was going on, I was involved in having a sort of big picture, but now there are lots of different teams in different locations working with these things so you can’t be more aware about this big picture and lose the overview” [Team member]</i></p> <p><i>“I’m learning a lot because of these new areas all the time to work with, but my feeling is that we are learning small pieces from all the places, you are not good in anything, you know a little bit of that and a little bit of that, you are not succeeding in being good in anything, you are not expert in anything. This is the downside of it” [Team member]</i></p>
Team absorptive capacity	<i>“teams’ difficulty to analyse and interpret changes along the feature development”</i>	This is related to a team’s difficulty to follow the rhythm of the feature impact changes they are called to work on due to their low	<i>“Teams need a longer time to understand which subsystem will be affected by a new feature, this is not an efficient way of working” [Team</i>

		familiarity with the product and its intrinsic complexity.	member]
<i>Managerial support</i>	<i>“lack of support for technical implementation and product innovation”</i>	This concept gives the idea of managerial behaviour towards teams regarding product learning. In the agile implementation, managers in the organization intended self-regulation of teams in a broader sense, giving them complete autonomy in their activities. In fact they removed any form of guidance and direction facilitating their work and replaced them with a stronger focus on knowledge sharing within the teams and in the organizations.	<p><i>“Before when we worked in the waterfall, we had a competence area where we were quite taught now we really don’t know how to do, we need to ask a run or we need to find out by yourself, we don’t have a real support. We have a lot of areas with not one supporting so it could take some time. You need to get into, it could take weeks.”</i> [Team member]</p> <p><i>“People should have the personality and mindset to share, they need to understand that through sharing they can help the team itself to be better”.</i> [Line Manager]</p>
<i>Team belief control system</i>	<i>“learning and innovation are not priorities as developing features”</i>	This concept tells about the strong focus on feature development teams have inhibiting them to spend time for learning and innovation. The huge amount of routines they follow in their implementation of agile are mostly conceived to foster product development activities and influence teams’ belief leading them to perceive feature development as their highest priorities. This is in line with what reported in Edmondson (1999).	<i>“Our team learning opportunity is not much, we have been working with 2 features at the same time, we had pressure for deliver those features and we don’t have much time to dedicate to learning. It is not the priority as developing and delivering features so we don’t spend time on learning”.</i> [Team member]
<i>Team concertive control system</i>	<i>“Internal social pressure inside the teams”</i>	This concept reveals the presence of “concertive control” within the life of agile teams, in agreement with what reported by	<i>“But I must say that I think the innovative part may be impacted negatively if you do it that way, I’ve the control on what you decide so there is a pressure to go</i>

		Whitworth and Biddle (2007) who identified this as one of the most common dysfunction of agile teamwork. The concept of concertive control in self-managing teams was introduced by Barker (1993) in describing the dominance of normative group control that may become constrictive to the individuals within it.	<i>through this kind of work package as quickly as possible especially if you are in a team and you cannot follow up on each other about what people are doing and everyone knows what everyone else is doing. For the innovation it is important to have freedom and time to think” [Team member]”</i>
<i>Team self-regulated learning processes</i>	<i>“teams don’t implement any activity to foster learning and innovation”</i>	This concept confirms the scarce attention that teams devote to innovation and learning activities.	“[Product Innovation opportunities in the Agile context]: <i>There is no specific activity for that”</i> . [Scrum master]
<i>Time pressure</i>	<i>“pressure on deadline inhibits teams to reserve time for learning and innovation”</i>	This concept is referred to the feeling of stress and strong involvement in feature development loops that the agile team members experienced. This is clearly seen as an inhibitor for any other activity than feature development one.	<i>“Concerning the stress, you feel, in agile the way of working is stressful. The management wants us to deliver code every day for testing to find out if new code breaks legacy functionality. But the delivery process is not good enough, when people make mistakes you have to roll out back and many people are waiting for you. It is not so effective this way of working. It should be modified somehow.” [Team member]</i>

Table 2: Antecedents to the code *“absence of product improvement since people are losing competence*

4.3.1 Analysis of the relationships with the concepts related to the following categories: external goal setting, depth of knowledge, knowledge assimilation and managerial support.

The relationships among the above categories could be interpreted in the following way. Team members were strongly encouraged to stretch their product competences by working on different product areas and covering roles other than their own within the team. Due to their limited time to absorb new product changes in areas where they did not have familiarity, they experienced some difficulties in connecting the new product concepts to the overall picture of the product. Additionally, people were inhibited to sustain their core competences with updated information leading them to hardly maintain their product expertise. The lack of solid product background inhibited the assimilation of new concepts coming from the team's enlarged product development activities and the generation of new product improvements since they did not feel able to master any product change. This was worsened by the absence of any external team support for technical implementation, thus making innovation happen within the team. This is supported by the following statements:

“For smaller improvement of the product, the difficulty is that the competence of the product is more spread out now. We have fewer experts, everyone gets a broader competence but not as in-depth as before. Previously we had more people with a deep competence in a specific area, now it's lacking, we don't have really expert people. So it's more difficult to understand how improvement or innovation can affect the system.”

“I don't know but my feeling is that this way of working is not that good for coming up with good ideas for improvements. We have this called cross-functional teams and it has been very pushy that every member should be able to do everything. As results of that the newcomers in the area, doing them for the first time, do a lot of the tasks. Those persons cannot come up with good improvements. They are fully occupied with learning the block and see how things are working, trying to implement things”.

Building on Coleman's (1990) distinction between macro- and micro-levels of analysis, it is possible to say that all previous relationships have been largely described by

scholars, but limited to the macro-level of analysis. Our study explored the same relationships but at the micro-level of analysis. We investigated the effects of a team's knowledge stocks, absorptive capacity and managerial support on its exploitative innovation performances. In detail, the positive relationship between a team's depth of knowledge and its exploitative product innovation performance is in line with the results obtained by Van Wijk et al., (2012). Additionally the relationship between a team's depth of knowledge and its absorptive capacity is aligned with the results described by Cohen and Levinthal (1990), Volberda et al., (2009 and Lane et al., (2001). However, the relationship between a team's absorptive capacity and its innovation performance follows what was stated in Cohen and Levinthal (1990), Zahra and George (2002) and Volberda et al. (2009). The effect of managerial antecedents on absorptive capacity is reported in Zahra and George (2002), Dijksterhuis et al. (1999), Kogut and Zander (1992), Lenox and King (2004) and Volberda et al., (2009). Hence, the following hypotheses are proposed:

H1: A team's depth of knowledge positively influences its (exploitative) product ideation performance.

H2: A team's knowledge assimilation capability significantly mediates the effect of its depth of knowledge on its (exploitative) product ideation performance.

H3: External technical support positively moderates the relationship between a team's knowledge assimilation capabilities and its (exploitative) product ideation performance.

4.3.2 Analysis of the relationships with the concepts related to the following categories: belief control systems, concertive control system, and teams' self-regulated learning process

The relationship among the above categories can be explained in the following way. A team's priorities were mainly focused on feature development activities that consequently absorbed most of their working time. Moreover, team identity seemed built on the need to accomplish product development deadlines which were constant, continuous and close to each other. So, within the teams, the dominance of normative group controls limited team members' freedom to embrace activities other than product development. All above it inhibited teams from planning any activity to foster learning and product improvements. The following quotes clarify these concepts.

“Now we are working with new products and we have to learn how they work – at least so much that we can see where and how to do the implementations. But to really understand the product (to be able to do improvements) that takes time and how to propose that for an OPO (before you have knowledge about the product you even don’t know if you can propose/do any improvements – spending time of investigation without any outcome isn’t so popular I guess..[sic]). Teams don’t spend time on digging the product, people are just making features.”

“Our team learning opportunity is not much, we have been working with 2 features at the same time, we had pressure for deliver those features and we don’t have much time to dedicate to learning. It is not the priority as developing and delivering features so we don’t spend time on learning.”

Individual value component motivation for engaging in a metacognitive activity, and in more cognitive strategy use, entangles people’s goals for the task and their beliefs about the importance and interest of the task itself (e.g., Ames & Archer, 1988; Dweck & Elliott, 1983; Eccles, 1983; Meece et al, 1988; Nolen, 1988; Paris & Oka, 1986). In the case of agile teams, it seems they have developed the feeling that meeting the continuous deadlines of both the agile framework and the project is something crucial for them to achieve, due to the effect of their induced belief systems. These team belief systems could be explained by their constant involvement in the huge amount of agile routines (see Edmondson 1999), which are mostly conceived to foster project development activities and by the presence of external managerial belief control systems which are used to define and reinforce people’s basic values guiding the organization towards a specific direction (Simons, 1994). Therefore, even though the connection with managerial belief is not evident in the data driven model, looking at the high level management beliefs in the data set, the following code emerged clearly: *“It is more relevant to be efficient than learning and innovating”*. In fact, some high-level managers stated the following.

“My view about the main problem is that we need to be more efficient to produce more and then to be able to innovate. Becoming more efficient is a condition to have innovation in place, we need to implement end users performance improvements and it is hard to get things into the product because, the demand is there but the capability was low”.

“Long term objectives are: we want to half the lead time, improve four times the output, improve ten times the quality, and increase the motivation as in the dialog. In this phase of life cycle, these aspects are more important. The quality is extremely important. Concerning innovation, we don’t have any measurement because they should be innovative to reach all of this !”

Having complete responsibility for feature development from beginning to end, team members felt it worth it to devote their effort to feature development, according to Deci and Ryan (1985, 2000). This led to internalized demands from external environment beyond any explicit managerial request, so that team behaviour resulted self-regulated yet not intrinsically motivated. This kind of motivation, called introjection, refers to the condition where an individual embraces an external regulation but not accepting it as its own (Deci and Ryan, 1985). Hence, team behaviour is not connected to external rewards; rather it aims to establish internal monitoring and applies sanctions and rewards to itself (Deci and Ryan, 1985). Applied to self-managing teams, concertive control develops through the values and norms of team members who enforce this control on each other and all team members are expected to conform to it (Barker 1993). Consequently, people within the agile team may suffer from the team’s normative control and become constricted in the decision of how and if to engage in learning activities (Whitworth and Biddle, 2007). However, people could still be committed to creative cognitive processes and try to solve problems creatively if they have the feeling that the organization gives importance to their work and provides work-related support in tasks requiring innovation (Baer & Frese, 2003; Zhou & George, 2001). Even if, as in this case, there is no empirical evidence about the relationship between a self-regulation mechanism and managerial support, the concept *“lack of support for technical implementation and product innovation”* was clearly identified in the data set and described previously as antecedent of product innovation performance. Moreover, since the concept regarding ideation performance *“absence of product improvement since people are losing competence”* includes the shortage of a team’s depth of knowledge, this leads to considering the effect of a team’s knowledge stocks on the team’s self-regulated learning and innovation behaviours. This is in line with what was reported by Butler and Winne (1995) for individual self-regulated learning process, who argued that: “as self-regulating learners engage in academic tasks, they draw on knowledge and beliefs to construct an interpretation of a task’s properties and requirements. Based on the interpretation they

construct, they set goals.” (Butler and Winne 1995, pp. 248). Drawing on the preceding discussion, the following hypotheses are then proposed.

H4. A team’s self-regulated behaviour for innovation significantly mediates the effect of its belief on the innovation importance and its (exploitative) product ideation performance.

H5. A team’s belief on the importance of innovation is positively influenced by external managerial beliefs.

H6. A team’s self-regulated behaviour for innovation significantly mediates the effect of its internal social pressure on its (exploitative) product ideation performance.

H7. External technical support for innovation positively moderates the relationship between the effect of a team’s belief on the importance of innovation and its self-regulated behaviour for innovation.

H8. External technical support for innovation positively moderates the relationship between the effect of a team’s internal social pressure on the importance of innovation and the team’s self-regulated behavior for innovation.

H9. A team’s self-regulated behaviour for innovation significantly mediates the effect of its depth of knowledge on the importance of innovation and the team’s (exploitative) product ideation performance.

4.3.3 Analysis of the relationships with the concepts related to time pressure

The relationship with the time pressure category can be described as follows. Pressure from current project deadlines and from the short feedback loops, prescribed by implementation of the agile scrum framework, inhibited teams from dedicating part of their working time to learning and innovation activities. Since people were losing their product competence, they felt that their capability to come up with new product improvements was strongly reduced. The following statement from the interviews reports what is claimed above:

“Before we had experience and time for product ideas. Before we had more knowledge about the product (the ones we were responsible of). We got better information about the project (all features) as a whole and could plan/coordinate features/deliveries in a better way.”

This basic finding is in line with what has been reported by other scholars on the effect of time pressure over creativity, when time pressure is perceived as a constraint for

cognitive resources (Andrews and Smith, 1996; Kelly and McGrath, 1985). Thus, time pressure may limit creative cognitive processes in the production of new ideas or in problem-solving activities (Amabile et al, 2002; Scott & Bruce, 1994). However, our empirical results show quite explicitly that team members feel time pressure due to their cognitive resources and are inhibited in their responses to the events (Byron et al., 2010). So, reduced familiarity with the product induced a high level of time pressure, considering the control levers teams are subject to, pushing them towards continuous deliveries. In fact, the concept of ideation performance embeds a lack of proper knowledge, the effect of which is worsen by the presence of time pressure regarding deadlines. Hence, the following hypothesis is proposed:

H10. Time pressure negatively moderates the relationship between a team's depth of knowledge and its (exploitative) ideation performance

4.4 Paradigm model for teams' exploratory product innovation performance

Linkages in the data set between a team's exploratory product innovation performance and the other codes belonging to different categories were analyzed in order to characterize the connection in terms of causality, mediation or moderation. The model presented here clarifies the antecedent to the “*absence of product ideas within team*” concept by describing the relationship between exploratory innovation performance and the team's self-regulated behaviour for innovation and learning. This model resulted much simpler than the previous one, considering that the exploratory innovation seemed to be out of the scope of an agile team's activities. In fact, it did not emerge so frequently in the respondents' interviews, and when it did, confirmed by its own nature, it was not tied to: 1) the way agile teams cumulate their own product competence from the current project development activities; 2) the existing team's knowledge stock; 3) the external conditions imposing teams high rhythm to follow the evolution of the existing product.

Figure 2: Paradigm model for a team's exploratory product innovation performance

4.4.1 Analysis of the relationships with the concepts related to the category teams' self-regulated learning process

The above relationship can be explained in the following way. Teams did not plan for any collective effort to spend on product innovation and learning activities leading them to achieve relevant innovation performance. This was in line with the previous model reporting that a team's priorities were mainly focused on feature development activities that absorbed consequently the most of their working time. Moreover, a team's belief seemed built on the need to accomplish product development deadlines which were constant, continuous and close to each other. A team member reported the following statement:

[What are innovation opportunities within your team?]" *I can see no innovation within my team. We don't produce any ideas.*"

In the case of exploratory product innovation performance, there is no trace of any linkage with: 1) a team's prior related knowledge, 2) a team's knowledge assimilation capability, 3) concertive and belief control systems and 4) the time pressure connected to the project development activities as found for product exploitative innovation. In fact, in this latter case, the opportunity for teams to exploit product/technology are tied to the short window of this opportunity due to the high rhythm of work and the different perceptions about the value of the opportunity itself among people in the teams. Moreover, the missed connection with the depth of a team's knowledge could be explained by Argote's (1999) and Stuart and Podolny's (1996) findings revealing that the depth of knowledge stock may be an obstacle in the development of radical new products. In fact, organizations basing the development of exploratory innovation on in-depth knowledge may fall in the competency trap (Levitt and March 1988), and result in generating core rigidities (Leonard-Barton 1995) that inhibit them from developing a focus on exploratory innovations. Hence, the following hypothesis is posed.

H11. A team's self-regulated innovation behaviour positively influences its (exploratory) product ideation performance.

5 Managerial Implications and Conclusions

This study answers a call for further research into building micro-foundations in the knowledge-based approach (Felin and Foss, 2005; Foss, 2007; Foss, 2011). This

'knowledge governance approach', KGA, focuses on governance mechanisms and their impact on the creation, retention and sharing of knowledge. The results of this study describe and illustrate that Agile has a clear impact on knowledge processes and that these knowledge processes are micro foundations for exploration and exploitation.

The empirical models describing the antecedents for the a team's exploitative and exploratory innovation activities within the agile context were presented. This was carried out under the form of two paradigm models as outcomes of the applied abductive approach in conjunction with a set of research hypotheses. The models contribute to current studies in the literature on the effect of agile implementation on the innovation performance of teams and organizations, whereas the proposed hypotheses identify opportunities for future research and empirical studies.

With our preliminary findings, we have identified two forms of controls that managerial roles should take in order to drive exploitative innovation activities within agile teams. These controls are: 1) managerial support acting as moderator in the relationship between a team's assimilation capability and its product exploitative innovation, yet also as a means to mitigate the effect of concertive controls inside teams and shape more balanced team beliefs by valuing the tasks requiring innovation and transmitting sustainable values to agile teams; 2) external goal setting to solve the trade-off between the need to broaden a team's competence and the possibility for people to retain their core competences.

Therefore, we suggest that there is a need for researchers to build on the interactions between managerial roles in the agile context and the team. In this paper, we have provided rigorous documentation of the different codes that emerged from agile teams and their stakeholders related to the integration of innovation within the agile framework. In this way, we have facilitated a rapid advancement in the field of innovation in the agile context, while also identifying research avenues for further studies.

Knowledge management in project environment: the way to improve the value of the enterprise organization

Antonio Bassi

Department of Innovation Technology
SUPSI – Scuola Universitaria della Svizzera Italiana - Swiss
Manno, Galleria 2, CH

Structured Abstract

Purpose – This paper aims to study the improvement of project success in organizations by integrating knowledge management strategies with project management practices in a typical project lifecycle, assuming that the projects are the tools by which organizations achieve the strategic objectives.

The knowledge created in the projects environment in almost any case is lost due to inefficiency of the processes of the enterprise organization. This leads to inefficiency in developing processes already done in previous projects.

The proposal highlights the importance of an efficient approach to knowledge sharing demonstrated on a project management level.

Design/methodology/approach – I propose an approach for improving the profitability of the projects through the management of an integrated system of knowledge management in the enterprise organization. The approach involves the definition of the organizational processes of knowledge management that integrate with ISO 21500 project management and the ISO 10006 relating to quality management in project management. I propose the creation of a new area of knowledge ("Knowledge Management") with a process in four of the five process groups (Planning, Executing, Monitoring and Controlling, Closing) in which all the processes defined in the standard are grouped together.

Originality/value - This methodology highlights the need to manage all the knowledge that is generated within a project, from the organizational point of view (historical information, best practices, knowledge of the processes, lessons learned ...) and from personal point of view (experience, knowledge management practices, lessons learned, ...), in order to improve organizational processes, reduce the time of project management and reduce the cost of the project. One of the main objectives is to achieve the continuous improvement in project management.

Practical implications - The outcomes of the application, through the management, in a centralized way, of the knowledge produced in all the projects managed by the enterprise organization and the knowledge obtained by all the people who participated in the projects, allows to reduce time and cost of project management, a better organization of the projects, the growth of intangible capital of the organization and work towards continuous improvement of the organization.

Keywords - Project Management, ISO 21500, ISO 10006, Knowledge Area, Continuous improvement, lessons learned, historical information, Knowledge Transfer, Project Lifecycle, Project Success.

Paper type - Practical Paper

1 Introduction

The Project Management, or rather the science through the definition of processes and rules, governs the management of projects and it is an incredible system that generates knowledge through which organizations, if properly structured, can grow and progress. The Project Management has the primary responsibility, within an organization, to make sure that the projects under his directions, comply with the objectives for which they were started. Projects are the tools by whom companies reach the strategic objectives for which they were created .

The management of the knowledge, produced by a project during its development (eg, planning, execution, control, ...), is one of the most relevant elements in the context of project management, but, unfortunately, it is also one of the elements on which the organizations hardly invest.

If we take as a reference the study that the Standish Group has been pursuing for many years, with the publication of the CHAOS report, which analyzed more than 30,000 projects managed throughout the world in different market sectors, we will note that there are wide margins for improvement to ensure that projects can be more productive and can enable to pursue the same objectives for which the organization was founded.

From the last analysis (2010) it can be seen that the 21 % of the projects is closed before its natural conclusion, 42% comes to an end without having complied with some of the goals such as time, cost and quality. In this context, only 37 % of projects are completed in accordance with the schedule. If you enlarge the scope of the analysis and take as reference the data from 1996 you will observe is in 14 years there has been an improvement in the success of projects by only 10%. If we think about how technology tools, in the same period, have provided in terms of communication, software for business planning, systems analysis to evaluate the performance of the projects, ... , we will see that technology and capacity management of the projects have not growth together.

CHAOS Report - Standish Group

We assess what may be the causes of these unsatisfactory results. There is certainly, among the main causes, low management skills by the project managers, due to a lack of training in the field of project management and the lack of some of the essential attributes that a project manager must have, which should be appointed as soft skills such as leadership, communication skills, problem solving, coordination, but, of course, the main cause is due to the organization and consequently its management. The organization first needs to establish a culture of project management within the organization. The culture of project management is different from other cultures that coexist in an organization. In this context it is possible to find (ie) the culture of marketing, sales and purchases, which are types of vertical culture, develop, (ie) within the directorates or departments. The culture of project management embraces the whole organization for which we can define as horizontal to develop a project one needs to cooperate with all the structures of the organization (marketing, sales, purchasing, legal, finance, operations, ...) and not only with the technical departments which are generally the most involved.

1.1 Project management culture

What does it mean to define a culture of project management within an organization? It means to develop tools and methods for managing projects, communicate and monitor the proper implementation. You cannot use ready-made tools that can provide answers to the organization because every organization is different, and these tools and methods can be defined and applied only through a knowledge of the business organization, processes and project management methodologies. To do this, we could use the ISO norms that have been defined to manage projects and/or activities related to them. They can be referred to the following standards:

- ISO 21500 - *Guidance on project management*
- ISO 10006 - *Quality management systems - Guidelines for quality in projects*
- ISO 31000 - *Risk management - Principles and guidelines*
- ISO 21502 - *Project and program management portfolio - forthcoming.*

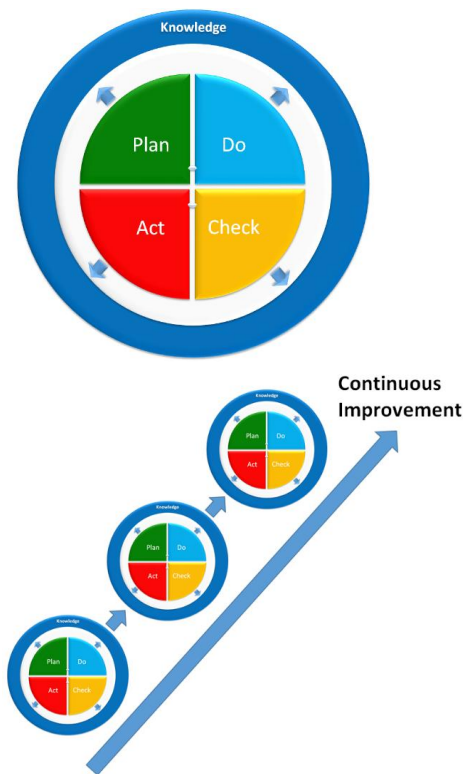

We can add to this list the *ISO 10007 - Quality management systems - Guidelines for configuration management*, for the management of all the documents that are produced by the project during its development. Certainly it cannot be apart from the fact that there must be a strong commitment by the management of the company so the whole organization to operate with unity of purpose .

Culture also means a continuous progress through the improvement of the management of all activities and processes, but how is it possible? The answer is in the management of everything that, in terms of information, is generated in a project: we need to manage the knowledge generated through which you can improve and progress in management activities.

The processes improvement in an organization

This graph could easily integrate the Deming wheel or Deming Cycle, the Plan-Do-Check-Act (PDCA), in order to capitalize the knowledge acquired in a project. This tool is also the basis for continuous improvement of organizational processes through the looping of the PDCA and the use of historical information from previous projects.

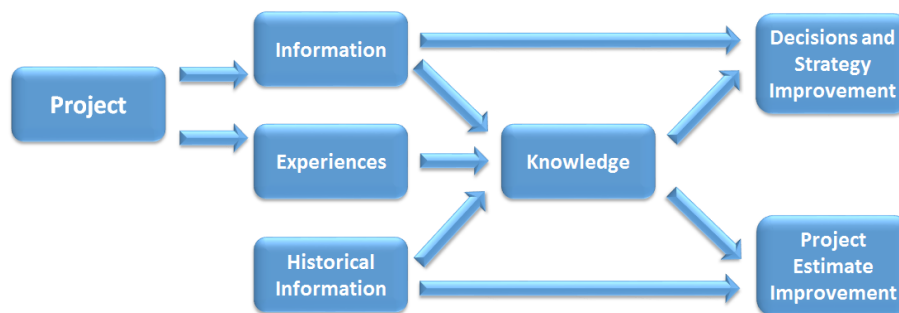

The continuous improvement of knowledge and organizations

2 The importance of knowledge in project management

Let us reflect on what are the implications of such a solution with regard to the management of projects. The collection of historical information of the projects, if it is done correctly, can allow definite savings for projects that will follow if you compare similar projects to those already done in the past you will be able to reuse some components with a double result:

- Reduction of planning time for the reuse of some elements of the project plan;
- Better planning as there it would be based on final data and not on estimates.

Another benefit is due to the experience that is gained by the individual and by the same organization in project management. This experience, if properly exploited, will allow you not to take decisions or solutions that have been proved wrong in the past, allowing, at the same time, through a critical analysis of past performance, the identification of what are the processes and the correct decisions.

Knowledge development cycle

We try to assess what may be the costs and benefits related to use and reuse this model of knowledge. If the processes of project management have been designed in accordance with the logic of knowledge management, thanks to modern communication tools evaluating the cost equal to '0' because the collection and management should take place as already established practice. If you want, however, to quantify the cost estimate, it is approximately 0.005 % of the total cost of the project. Meantime, concerning the benefits, these are more difficult to quantify because they are a function of the type of project to be managed. The benefits will be higher in similar projects to those that have already been done in the past and will strive to '0' for highly innovative projects for which there is not historical information. Therefore it could be said that the benefits can be measured in a scale ranging from 5% to 35% of the time and cost of the planning phase of the project which is estimated at approximately 20% of the total project.

ES . Project Budget = € 1,000,000.00

Storage cost = € 5,000.00

Benefits = from € 10,000.00 to € 35,000.00 (for each project)

The data were obtained from the international community of project managers through a questionnaire. So you can understand the great benefit to be achieved by an organization.

At this point the question arises why organizations don't evaluate this knowledge. The answer is related to maturity, risk appetite and the perspective of management. The management is not often able to recognize the benefits that can be gained from the application of new tools in the medium long term but he focuses on those who are current expenditure that attempt to break down in any way to get the savings. In this way it has, effectively, a reduction in costs on current projects but he can't see the cost savings that would be obtained compared with a minimum initial investment.

Agreeing that is necessary to have a proper knowledge management in the context of project management we see what might be the objectives that is possible to pursue:

- Reducing time and cost of project management ;
- Improving of organizational processes.

It is now necessary to define an organizational infrastructure that enables us to store, manage and exploit all the knowledge acquired by the stakeholders in the organization and management of projects.

3 The new model

The current rules related to the world of project management provide the factual basis on which we can establish the policy of knowledge management in a project. You can start from the ISO 21500 processes that structures the world of project management in 10 areas of knowledge and 5 process groups. The areas of knowledge describing how to manage and plan projects with regard to its main objectives, except for the first area of knowledge 'Integration', in which the plans are integrated and defined the rules of the project, describes the processes that allow you to define and control objectives in relation to:

- scope
- time
- cost
- quality
- risk
- communication
- stakeholders
- procurement
- Human resources.

These same processes are then grouped into 5 process groups that determine how to manage the project:

- initiating
- planning
- executing
- monitoring
- closing.

In ISO 21500 we can find a useful diagram that represents, among other things, the management of knowledge in a project, but unfortunately the activities related to it are

poorly structured and therefore it is too often rejected its use. We start from this point to build the processes and associated activities to develop knowledge management in projects.

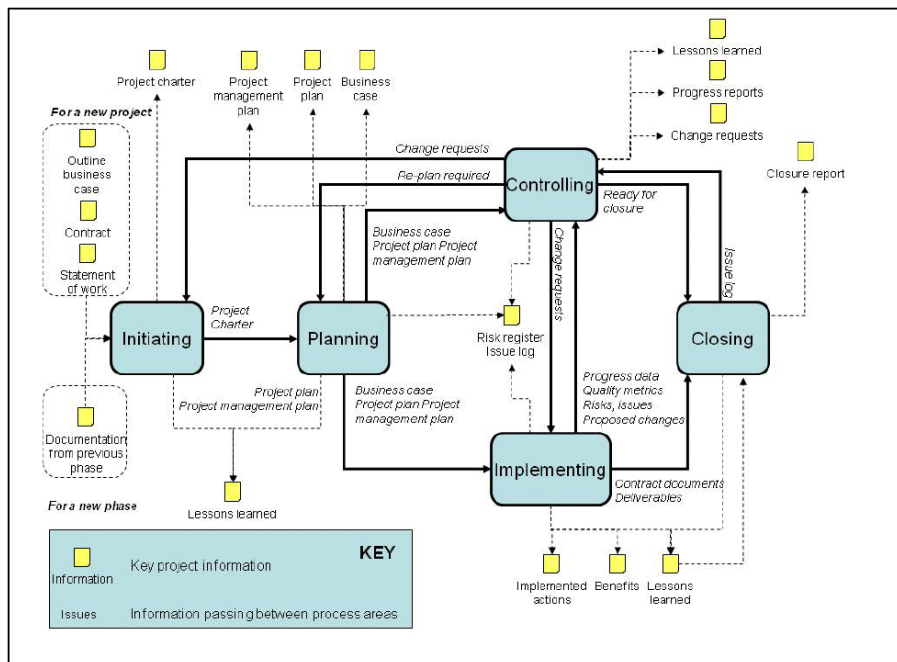

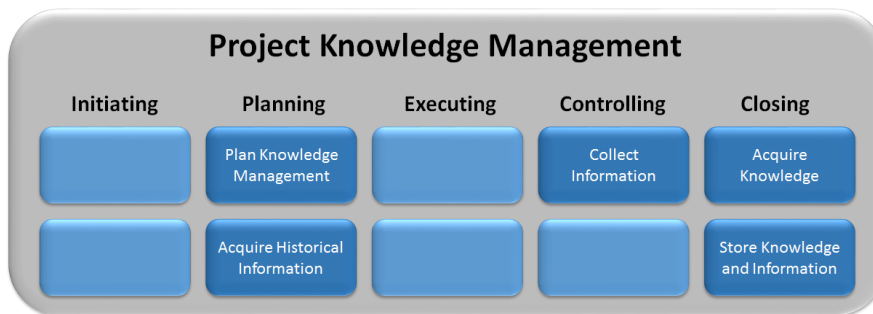

Diagram of documentation in the process of ISO21500

To improve the management of knowledge in project management we start from the definition of a new area of knowledge that is in addition to the 10 previously described. The new area of knowledge is called 'Project Knowledge Management' and consists of 5 processes that refer to three groups of procedures listed above (Planning, Monitoring and Closure).

The description follows the pattern defined by standard ISO21500 in such a way that it can be easily integrated by those who want to make use.

The processes that are added with this knowledge area are:

- Knowledge Management Plan ;
- Acquire Historical Information ;
- Collect Information ;
- Acquire Knowledge ;
- Store Information and Knowledge .

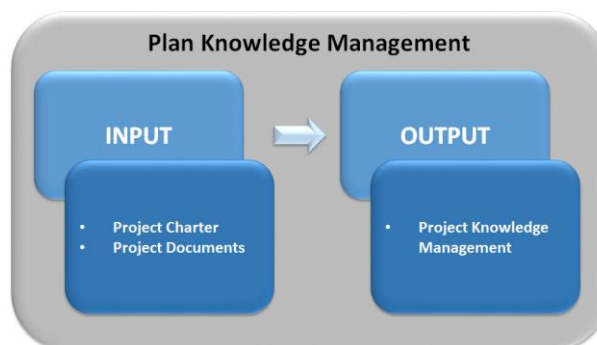

The new area: Knowledge Management

3.1 Knowledge Management Plan

As we can find in all the other areas of knowledge, in the context of planning processes it must be defined the strategy with which the knowledge, gained from previous projects and the current generated by the project, will be managed. The definition of the strategy starts from the analysis of the organizational structure in respect of the definition of the processes that govern it, for the analysis of the ways in which knowledge is managed within the organization, continuing with the assessment and the definition of the characteristics of the project from the point of view of the requirements, deliverables and development strategy of the project as defined by the governing bodies of the projects within the organization.

We suggest you to use an integrated system that enables the management of the project and, at the same time, helps managing the entire knowledge flow, such as a web-based platform that manages the plan and control the project and it is a tool of sharing and exchanging information so that, once closed the project, automatically, all the information generated are automatically archived.

The process 'Knowledge Management Plan'

Input

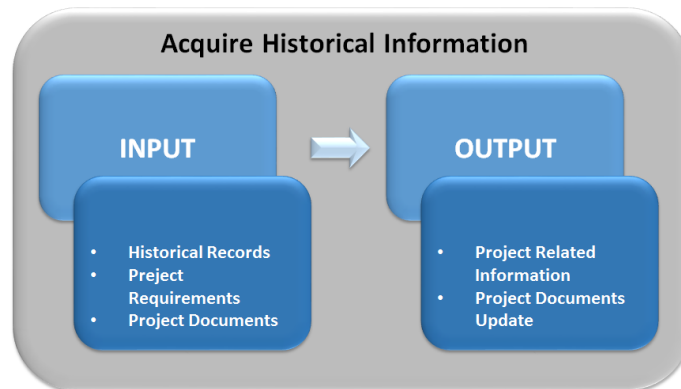

- Project Charter – documents that formally authorizes the existence of a project and provides the project manager with the authority to apply organizational resources to project activities, provide all the initial information issued by the sponsor of the project from the point of view of the requirements, objectives, constraints, stakeholders, risks, quality ...
- Project documents – documents of projects, as defined in ISO and other international standards, contain two main documents: the project management plan and the project plan;
 - o Project Management Plan – defines the guidelines by which the project will be managed. It is defined by the project manager and his team, it is based on the culture of the organization and on the characteristics of the project in terms of complexity, duration and commitment ;
 - o Project Plan – a document that defines the planning of the project. The plan is developed based on what is defined by the project management plan.

Output

- Project Knowledge Management – the plan shows the strategy by which the knowledge will be managed within a project. The plan should be integrated with the organization's processes that already dominate the collection, cataloging and dissemination of knowledge, eventually integrate them based on what are the peculiarities of the project, as well as integrate with Project documents.

3.2 Acquire Historical Information

One of the first tasks that must be developed once the project has been started is to acquire historical information generated by previous projects for the actual project because they may be used in the planning processes. The historical information enhances the planning of the current project using the experience gained in similar projects or even can offer the opportunity to take advantage of planning elements. In both cases there may be important advantages in terms of savings (time and cost) and reduction of the uncertainty of future performance of the project. We will rely, in fact, on the final data because of the result of previous executions and not on a simple planning characterized by uncertainty.

The process 'Acquire Historical Information'

Input

- Historical records – historical information from previous projects. In these records there are stored not only the knowledge generated by the management of the projects, formal and non-formal documents, but also the experience gained by those who have worked on the project in terms of better alternatives, things that could be done in a different way, solutions to problems and conflicts ...
- Project requirements – expresses the requirements that must be met by the project and are part of the definition of the scope of the project. On these basis the project is able to define which are the historical information that must be retrieved to be made available to the project;
- Project documents – have been already been defined in the process 'Knowledge Management Plan'.

Output

- Project Related Information – Information filtered by historical information that can be used by the project in its planning and management according to the characteristics and requirements of the project;
- Project Documents Update – update of the project documents regarding any changes to the management of the documentation.

3.3 Collect information

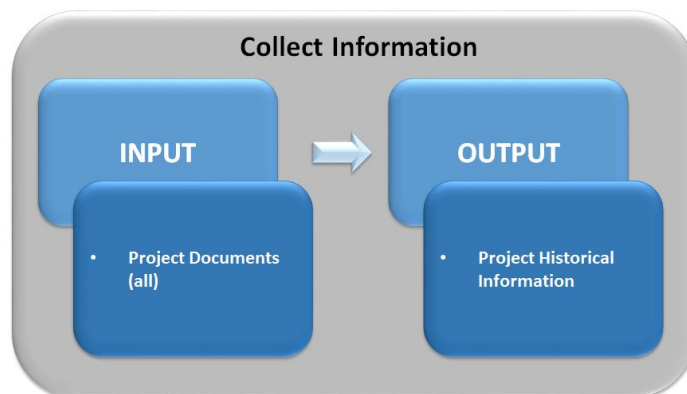

In the normal course of development of the project project documents and other related documents are generated and modified, such as:

- Minutes meeting;
- Presentations;
- Notes/memo;
- Reports;
- Contracts.

To this list it must be added any audio and video recording of meetings and/or events related to work.

All this information must be continuously collected and stored. We must not, in any way, get to the end of the project without have made the collection of documentations yet because, for long projects, the probability to 'forget' some extremely important information increases proportionally to the duration of the project.

This process has been included in the processes of monitoring and control, not for its control function but for the characteristics of this group of processes that have been developed until the project is ended, so it is the appropriate place for this type of activity

Process 'Collect Information'

Input

- Project Documents (all) – in this case, unlike the other processes not only the two main project documents, such as the Project Management Plan and the Project Plan, are taken into account but also the documentation produced by the project to be cataloged and archived .

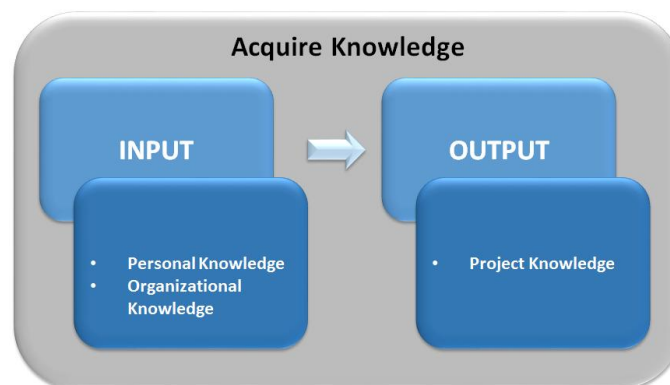

Output

- Project Historical Information – all the information collected within the project (plans, reports, records, memos , ...) are stored and cataloged within the historical information of the project to be made available for the current project, for the later stages, and for other projects that will be managed by the organization.

3.4 Acquire Knowledge

At the end of the project the experiences in the management of the project by the stakeholders and the organization, in terms of successful models must be acquired, so it can be replicated, or in case of failure, so improved, while providing a critical analysis and hypothesis of improvement so new projects do not follow a wrong way and have directions on how to improve the management and imagine new solutions.

It is strategically important to define the tools and techniques that can best support the collection of these knowledge elements, and in some cases, eventually, may be desirable the help of a psychologist for the collection of personal experiences

Process 'Acquire Knowledge'

Input

- Personal Knowledge – collection of knowledge and experience gained by all the participants of the project which could be significant for the management of future projects of the organization.
- Organizational Knowledge – collection of experiences/knowledge gained by the organization as parts of the project that is ending. The collection may be related

to the information that led to the change in the processes or improvement of activities and procedures.

Output

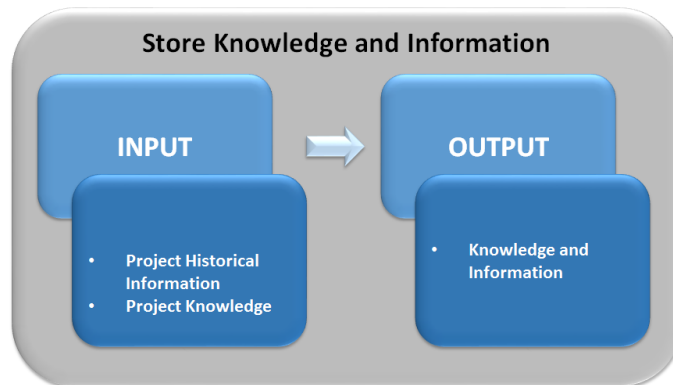

- Project Knowledge – document or management system that collects all the knowledge expressed in terms of experience, that has been generated within the organizational structure and management of the project.

3.5 Store Knowledge and Information

Once the project is ended, all the information that have not been collected so far, must be gathered, such as:

- Formal customer acceptance;
- Documents project closure;
- Sign off;
- Closed contracts.

To these elements it will be added also the collection of knowledge/experiences of each participant in the project and by the same organization. With this information the organization will be able to grow and improve their organizational processes in order to achieve the highest level of organizational maturity model defined by the continuous improvement.

Process 'Store Information and Knowledge'

Input

- Project Historical Information – collection of all closure documents of the project in addition to all the final versions of project documents that are closed to completion.
- Project Knowledge - as defined in the process Acquire Knowledge

Output

- Information and Knowledge – storage of all information including the various levels of knowledge that have been generated.

3.6 Use of Information

All information collected, as we have already said, can be gained from the projects to be undertaken in order to improve their planning or to improve the estimates in order to reduce time and cost, but in addition to these advantages may include even those resulting from the improvement of processes and procedures. In this case it is assumed that the organization is sufficiently structured to be able to have a central project management office also called PMO (Project or Program or Portfolio Management Office). This body will be in charge of analyzing the documentation produced by the projects run by the organization in order to improve:

- Processes for the management of projects;
- Checklist to guide the project team in the performance of their activities;
- Improvement of metrics for project management;
- List of the risks associated with mitigation and management;
- Improvement of the criteria for tailoring the projects;
- Template of projects;
-

In an organization doesn't have a PMO it is be the project manager and his team that will analyze the documentation in order to define the optimal management strategy of the project.

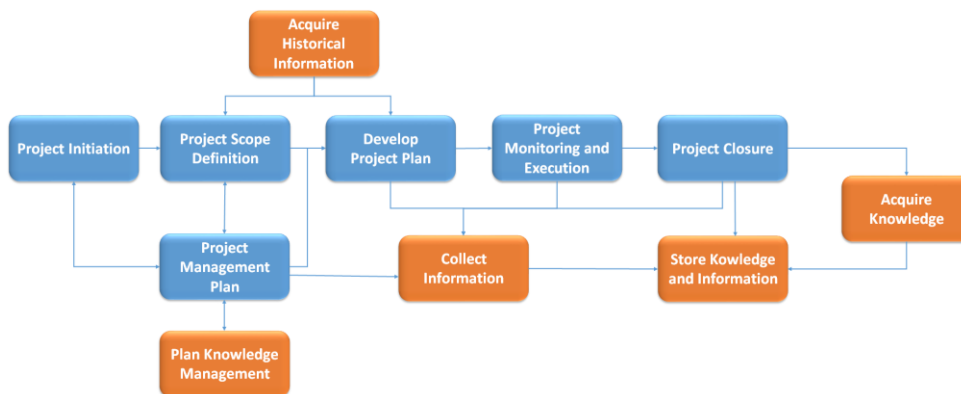

3.7 The reference model

The processes which have just been defined must be contextualized within the design of the processes by which a project is managed. The definition of a unique model is almost impossible because there is not a single model, the process model is defined in

terms of the scope of the project, the organization's culture and experience of the project manager. The only thing you can do is to define the relationship of the new processes in the context of the macro processes of project management. The following figure shows, in blue, the macro processes of project management, unchanging from project to project, and, in orange, the new processes.

The five processes of knowledge management can be grouped into 3 groups:

- Strategy - Project Knowledge Management – defines the strategy for knowledge management in the project;
- Collection of knowledge – collect information and Acquire Knowledge – collects the information and knowledge to feed the knowledge of the organization;
- Knowledge management - Acquire Historical Information e Store Knowledge and Information – distributes the information to feed the processes of planning and gathering of knowledge to feed the knowledge of the organization.

The reference model

4 Conclusion

To take advantage in the knowledge generated within a project in terms of information and experiences we should proceed in these ways:

- Definition of knowledge and project management organizational culture that defines rules and tools to manage the knowledge in relation to the projects management;
- Definition of the organizational processes that support the collection of knowledge in an organization.

Only through organizational culture and processes management, the organization will be able to obtain a costs, duration and risk reduction in project management as well as a reduction in the uncertainty of the results. In this way the project will be able to pursue the strategic goals of the organization with effectiveness and efficiency.

Structured Abstract

Purpose – The article aims at presenting a study into strategies of strengthening the resistance in a network supply chain of metallurgic products. The research was carried out in the years 2011-2013. Network supply chains include key chain links for building the resistance. These chain links affect material flows of the whole supply chain through silencing disruptions. Those predisposed to form a strategy strengthening the resistance of the whole network supply chain are organizations fulfilling the assumptions of material decoupling points.

Design/methodology/approach - The research is carried out in two stages: the stage of constructing an analytical model and the stage of constructing three simulation models corresponding to the distinguished variants of strengthening the resistance based. The first stage of the research aimed at indicating possible variants of the strategy of building the resistance of a network supply chain. At the second stage the authors carried out simulation experiments based on three models built in the management system dynamics technique (VensimDSS). The proposed methodology required constructing original tools for measuring disruptions and factors strengthening the disruptions in the form of cards for measuring disruptions.

Originality/value –The value added is grouping of disruptions in risk factors distinguished in terms of the frequency of the occurrence of disruptions and their results. The authors proposed and defined the notion of zones of strengthening disruptions. The zones are formed from sets of factors strengthening disruptions with similar influence on disruptions. In modelling of material flows in the context of the strategy of strengthening the resistance the authors proposed an assessment of the efficiency through elements of logistic customer service: the completeness, the punctuality of realized orders. In simulation experiments, the authors strived to reduce lost sales resulting from deviations in punctuality and completeness.

Practical implications – The proposed approach of gathering knowledge which will allow modelling material flows and constructing the strategy of strengthening the resistance of a network supply chain was verified in a selected organization fulfilling the assumptions of the material decoupling point of a network supply chain of metallurgic products. The IT system composed of a module for identification of disruptions in

material flows and a simulation model is a proposal dedicated to organizations controlling material flows in a network supply chain in the conditions of disruptions.

Keywords – gathering knowledge, material decoupling point, network supply chain., resistance.

Paper type – Practical Paper

1 Introduction

The first stage of knowledge management is knowledge acquisition in the organization and in its environment (Probst, Raub, Romhardt, 2002). Information turns into knowledge when it is interpreted and related to a context by its holder. Knowledge management in supply chains refers to a wide spectrum of issues, including the manner of decision making in particular organizations, gaining and processing knowledge about customers, etc. Relatively little attention is devoted in the research to factors causing deviations from the planned material flows. Gathering knowledge about disruptions is an essential task of the flagship enterprise whose part is to silence disruptions so that they will not transfer to the subsequent supply chains. The flagship enterprise controls material processes in supply chains, coordinates tasks performed by participants of the network and, having knowledge on disruptions in the entire supply chain, stands a chance to strengthen its resistance.

The paper presents the idea of gathering knowledge in order to strengthen the resistance of a network supply chain.

The first part of the paper indicates approaches to building the resistance of a supply chain which have been presented for the past years in the literature. The first part was closed with the expression of the research hypotheses. The second part indicated the author's idea and the resulting methodology of gathering knowledge within the range of disruptions in material flows, referring to contemporary solutions in this field. The worked out methodology was applied in a network supply chain of metallurgic products. The obtained findings were used for developing standard strategies of amplification of the resistance.

2 The resistance of a network supply chain

The complexity of the relations in contemporary supply chains results from dynamic changes in the environment as well as variable recipients' needs. Because of the fact that contemporary supply chains are characterized with a complex structure on each stage of creating the value added, in this paper they will be defined as "network supply chains". Creating network relations is especially justified in extremely innovative sectors and in those industries where products are diversified according to the recipients' needs (Brzóška, 2013; Chan, Wang, Luong, Chan, 2009). Harryson, Dudkowski, Stern (2008) point out that not only the number of network relations but also the variability of their forms constitute the basis which provides the foundation for organizations to develop new ideas and skills using their key competences and resources.

When defining the role of each link in the network it is worth looking at the graph theory. Determining the centrality of the node according to the degrees of tops (numbers of relations built on the entry and the exit by a given organization) often also means the assessment of the popularity or influentiality of nodes. The centrality according to the degrees of tops is useful for determining which nodes are the key ones from the point of view of spreading information or affecting the nodes situated in the immediate vicinity. Another indicator of the role of a node in a network is mediation. Mediation shows which nodes are the most important from the perspective of communication between nodes. Large mediation nodes are potential points of loss of cohesion of the network. Lin, Yang and Arga (2009) notice that the position of a node in the relational sense means authority essential for exerting efficient influence on other participants of the network. Taking into account the social networks theory in characterizing the network it can be noticed that the social status of the node reflects its authority in the form of one-sidedly directed emotional ties - respect, liking, recognition (Czakoń, 2012). Hagedoorn, Roijakkers, Van Kranenburg (2006) remark that the centrality and the popularity of nodes in a network creates a potential for exerting influence on other members of the network. The central link in the network, fulfilling the above-mentioned conditions, is defined in the paper as the flagship enterprise.

During the life of a flagship enterprise networks have features which predispose them to create new relationships. Consequently, these nodes more often than others decide about adding new nodes to the network. The phenomenon of preferential addition of results when creating a network in which a small number of nodes has a very high degree

of networkness. The remaining nodes of such a network have a considerably lower degree of networkness. Preferential adding usually results in the phenomenon of small worlds (cliques).

When referring these features of the flagship enterprise to the supply chain it can be noticed that these organizations are not only partners of their suppliers and recipients but simultaneously they widen relations on a given stage of the supply chain creating network relations. Flagship enterprises in the network, understood in this manner, have an essential influence on the amplification of the resistance of a supply chain.

The resistance of a supply chain is understood as a property (an attribute) of the organization / system involving rules, procedures, methods and management techniques as well as strategies protecting the organization against the negative results of deviations occurring under the influence of disruptions. Certain papers present recommendations for designing a resistant supply chain (Christopher, Lee, 2001; Rice, Caniato, 2003; Chistopher, 2004; Kleidorfer, Saad, 2005; Sheffi, Rice, 2005; Tang, 2006). However, there is not one and only way of building the resistance of a supply chain. Sheffi (2005) notices that every type of disruptions requires other activities so, depending on key risk factors, the way of building the resistance will be different. Consequently, the first step in the research into the resistance of a supply chain is to identify disruptions and factors amplifying them. Deviations in the anticipated and real level of customer service is the most important measure showing the results of disruptions in material flows.

Sheffi (2005), while investigating ways in which enterprises can respond to strong disruptions and conduct activities reducing threats connected with disruptions, claimed that:

- Reduction of bottlenecks connected with disruptions occurs through monitoring, early-warning systems (an increase in the sensitivity of a supply chain), a quick reaction to the change of needs, collaboration and redundance
- Operating flexibility is increased through standardization of parts, facilitating their replaceability (product modularity, product designing from the logistic perspective), the postponed production strategy or mass customization of products (multi-variantness) in response to changes of needs which are difficult to forecast, management of relations with customers and suppliers.

Tang (2006) perceives the resistance as an essential competitive superiority of a supply chain and suggests strategic development via smoothing effects of disruptions

(deviations). He also stresses the meaning of the postponed production strategy, a flexible base of suppliers, multi-modularity flexible transport. Christopher and Peck (2004) define the resistance of a supply chain as an ability of the supply chain to the return to the original state (flexibility) or transition to a new and more suitable state under the influence of the occurring changes (adaptability).

Therefore, the flagship enterprise, which is supposed to strengthen the resistance of a supply chain, can use three approaches: elimination of disruptions, compensation of disruptions, smoothing of deviations. The research presented in the paper the authors focused on strengthening the resistance through the system reaching the state of the original system (compensation of disruptions).

Fig. 1 shows the relationship between the strategies of strengthening the resistance, mentioned in the literature, indicating that certain strategic activities help to obtain the aims of the superior strategy.

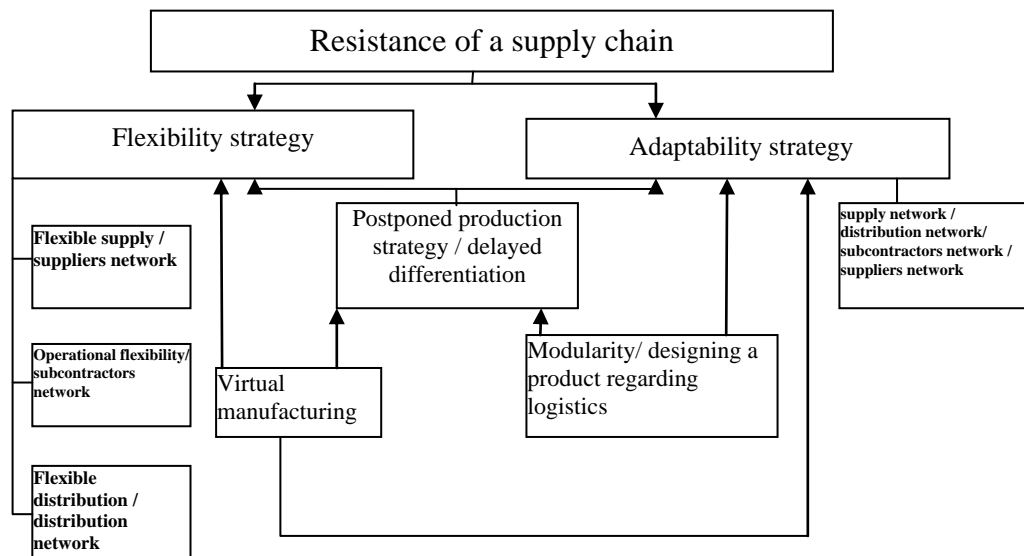

Fig. 1. The resistance strategy

Source: The authors' study

Modularity and designing the product from the logistic perspective is a way for realization of the postponed production strategy and one of possible strategies of product differentiation. Virtual production can help both the flexibility of the organization and its adaptability. Postponed production can be realized via complex network relations between the base enterprise and the subcontractors, and the organization manner can take

into account virtual production. Moreover, the flexibility can be shaped in different phases of the value chain, including on the supply, production or distribution level through network relations. Network relations and the redundancy of resources are shown not only as tools for building the flexibility and the adaptability of the supply chain. The adaptability uses the possibility of reconfiguration of networks constructed in each phase of the supply chain in order to achieve a new level of system equilibrium.

To sum up, the resistance in network supply chains requires describing the structure of a network supply chain, characterizing the enterprises which control the flows as well as defining risk factors and zones of strengthening disruptions. Taking into account these requirements the authors proposed an original methodology of gathering knowledge for the needs of strengthening the resistance of a network supply chain. Two research questions, which became the basis of the put forward hypotheses, were as follows:

Research question 1 What is the influence of risk factors in a network supply chain of metallurgic products on deviations in material flows.

H1. Risk factors affect an increase in the frequency of deviations in material flows

Research question 2 What is the influence of factors strengthening the disruption on risk factors in a network supply chain of metallurgic products

H2. Factors defining the zones of strengthening disruptions intensify disruptions in material flows

3. The concept of gathering knowledge for strengthening the resistance of a network supply chain

The main objective of the research was the construction of the model of strengthening the resistance of the network supply chain from the perspective of the flagship enterprise. This model presents the stage of gathering knowledge and the stage of decision support of the flagship enterprise of a distribution network.

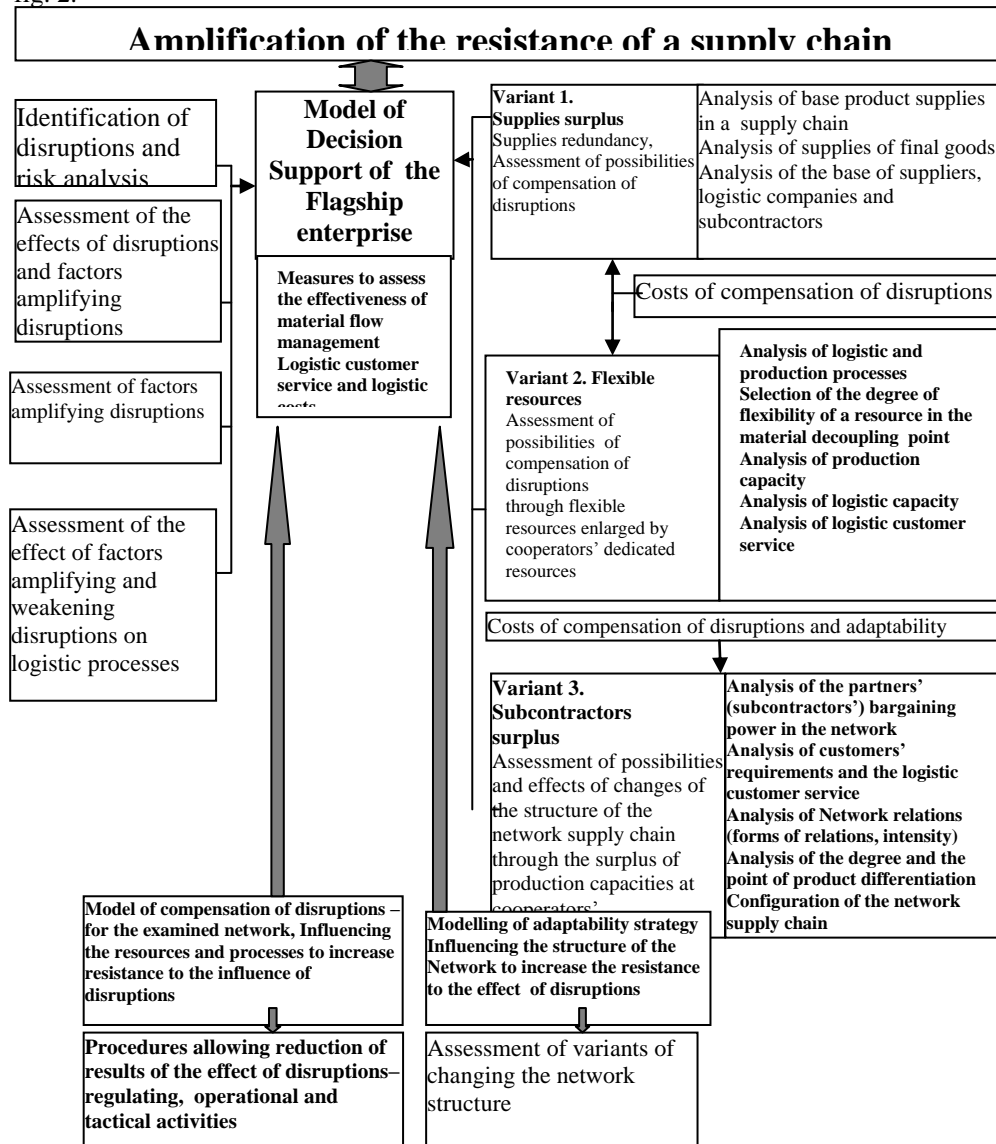

Problems indicated by managers, occurring as a result of including subcontractors into the structure of flows, and the analysis of IT tools in material flow management, induced to channel the research in such a way as to allow working out tools permitting identification and assessment of disruptions as well as an analysis of decision-making variants connected with compensation of disruptions, through considering two options depending on the frequency of the appearing disruptions (Machado et al, 2007; Chopra et

al, 2007):

- flexibility allowing compensation of disruptions via designed mechanisms (e.g. the flexibility of resources, the supplies surplus, the redundance of subcontractors, suppliers, logistic co-operators),
- adaptability involving a change of procedures or network structures

The adopted decision-making range of the material decoupling point was presented in

fig. 2.

Source: The authors' study

Fig. 2 Strategic decision support system of the flagship enterprise

In the research the authors used secondary data gathered for analysing a network supply chain of metallurgic products concerning formation of supplies as well as initial data in the area of the identification of disruptions and assessment of their influence on material flows.

Gathering the initial data was conducted by means of the diary method (Dohn, Gumiński, Matusek, Zoleński, 2013; Di Caprio, Santos-Arteaga, 2009). The measurement tool was a questionnaire called the "the disruption measurement card". The questionnaire contained both closed as open questions. The research conducted by means of disruption measurement card aim at:

- determining which disruptions are not caught by the IT systems supporting material flows in the investigated organizations,
- limitation of potential disrupting factors, selected on the basis of the literature research, to the ones essential for the investigated supply chain.

Disruption measurement cards were made available in three research objects which are different stages of the supply chain of metallurgic products. The cards were filled every day for 6 months by workers of different organizational units. The obtained data were converted in the STATISTICA software.

The process of the analysis of disruptions is a multi-staged one (Blackhurst, Craighead, Elkins, Handfield, 2005). At the first stage the authors suggested using the cause and effect analysis for identifying the relationship between disruptions and deviations. Thanks to this, this stage of research was conducted according to the following steps:

- identifying deviations in material flows,
- indicating the relationship: a deviation in material flows - a result of the disruption (organizational results, e.g.: difficulty in functioning of the process, lack of workers, equipments, lack of materials, lack of information, financial results, including costs connected with extraordinary transport, costs of lost sales),
- identifying the place where the disrupting factor occurs (the base enterprise, the supplier, the subcontractor, transport processes),
- identifying factors strengthening the disruption
- assessment of the total of losses connected with the appearance of the deviation.

The classification of disruptions is based on the system approach which allows

dividing disruptions according to the following phases: entry, inside the system, which involves processes of transformation and exit. The cause and effect analysis allows sorting out the investigated variables in the following sets: deviations in material flows, factors causing disruptions, chain links of the supply chain generating disruptions, factors strengthening disruptions. Thanks to such an approach it is possible to assess the power of their influence on deviations in the realized processes. The set of factors causing disruptions was categorised into endogenous factors connected with the characterization of the order, with the characterization of the base enterprise and with the characterization of the partner, and exogenous actors connected with the environment of the process of order completion.

At this stage research the authors:

- conducted pilot studies which confirmed the thesis that current IT tools were not sufficient for strengthening the resistance of network supply chains
- identified the most frequent deviations in material flows and their results for organizations in a network supply chain of metallurgic products
- defined risks factors distinguished in respect of similar frequencies of the occurrence of disruptions
- defined zones of strengthening of disruptions.

Factors strengthening disruptions as well as risk factors were distinguished by means of the factor analysis.

In the disruption measurement card factors causing disruptions were left in the form of an open question, allowing workers who filled the questionnaire every day to name freely the event which caused deviations in material flows. It was a conscious approach to the manner of measurement which aimed at catching all possible events, and not only those which were known to the author of the questionnaire while creating it. The mentioned disruptions were characterized descriptively in respect of the reasons of occurrence and the results, the subject responsible for the occurrence of a disruption, and they were assessed according to the power of the influence on the organization according to the organizational and financial criterion. The manner of rating the power of the influence of disruptive factors was provided in the table. Factors strengthening disruptions in material flows were also assessed every day. Respondents marked if a given event took place on that day and, if they rated (in the event of a positive response) what power of influence it had on disruptions in material flows.

The obtained results were compared with the knowledge on disruptions, identified through practical IT solutions (ERP class systems), which are used currently.

The integrated ERP system allows simulation of various activities and their analysis, and consequently better planning and management of processes in an enterprise. The ERP system is supplemented by the SCOR reference model. It combines perfectly the business knowledge with the knowledge on possibilities of the implemented IT systems.

All the processes inside the supply chain can be divided into three areas: processes situated above the enterprise, processes connected with the enterprise and processes situated below the enterprise. These areas create the following relationships (Szymanowski 2006, Chopra S., Meindl, 2004):

- Customer Relationship Management - CRM),
- Internal Supply Chain Management - ISCM),
- Supplier Relationship Management - SRM).

Internal Supply Chain Management (ISCM) involves the internal activity of an enterprise, beginning from task planning to completion of customers' orders, and is characterized with a strong integration with CRM and SRM systems.

Supplier Relationship Management (SRM) refers to cooperation between producers and their suppliers, their joint construction of strategic plans, negotiations, monitoring and assessment of the organization of supply processes.

Summing up, it can be stated that present IT technologies involve most of logistic areas, enabling decision support of an enterprise, inventory control, organization of transport routes and any types of tactical and operational logistic activities. The identified gap of the mentioned IT tools is their difficulty in identifying and analysing disruptions at the stage of creating network relations.

In connection with the above, the authors developed an IT tool compatible with the ERP system, aimed at recording disruptions and analysing deviations in material flows. It is a tool from the area of management information systems (MIS). The tool involves a module for gathering knowledge regarding disruptions in a network supply chain (fig. 3).

The proposed procedure is universal and can be applied in different supply chains. However, the tool for gathering knowledge requires adaptation to the specificity of a given industry through conducting research based on disruptions measurement cards, selection of risk factors in respect of frequencies and results, and defining the zones of strengthening disruptions.

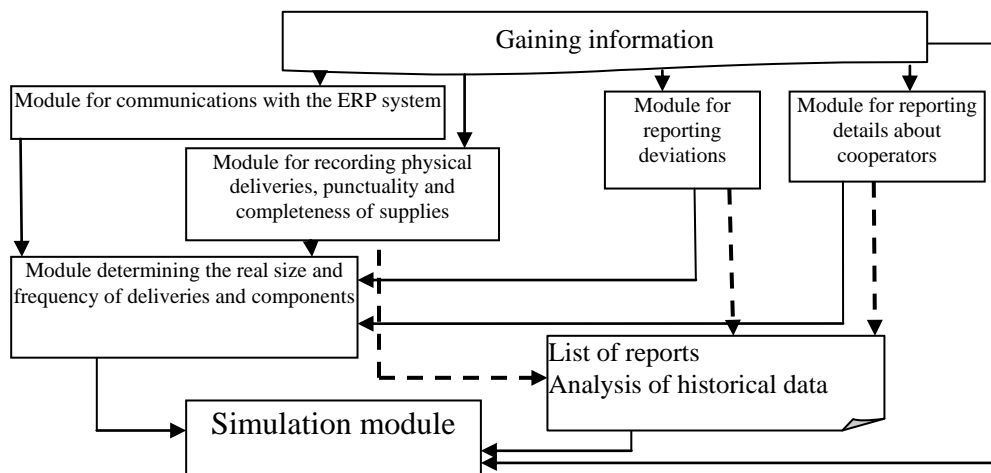

Fig. 3. Modules of the tool Planning supplies of components and controlling the level of material supplies

Source: The authors' study

The developed tool was enriched with a simulation model to support management decisions. The simulation model, in compliance with the adopted assumptions, was developed for all three variants of strengthening the resistance of a network supply chain in the technique of the management systems dynamics.

4. Risk factors and zones of strengthening disruptions in a network supply chain of metallurgic products.

The carried out literature and pilot research allowed selecting 32 factors causing disruptions in material flows in a network supply chain of metallurgic products. The initial analysis of the relevance of the relationship between selected variables, showed correlations between certain variables, therefore the authors decided to carry out the factor analysis in order to connect strongly correlated variables, and consequently reduce the number of variables. Risk factors distinguished in this way were analysed in respect of the factual justification of connecting definite variables in a given risk factor. As a result of the carried out analysis the authors selected 6 risk factors significantly diversified in respect of the frequency of occurrence of disruptions.

- Factor 1 refers to the organization of production and logistic processes,

disruptions are generated by wastage ('muda' according to Lean)

- Factor 2 refers to supplies, disruptions are generated by suppliers
- Factor 3 involves disruptions arisen at the stage of the realization of logistic processes between the base enterprise and the customer
- Factor 4 involves disruptions generated by the subcontractor
- Factor 5 involves disruptions generated by the supplier in the area of the reliability of supplies
- Factor 6 involves disruptions generated by the base enterprise in the area of order realization including monitoring and processing of orders

The distinguished risk factors not only represent significantly the variability of disruptions in respect of the frequency of their occurrence but also have their essential reason. The division of the factors is compatible with the phasic (system) perspective in logistics so it involves suppliers, the base enterprise, logistic enterprises, customers. The authors distinguished two types of risk factors within the base enterprise itself. The first risk factor expresses disruptions resulting from bad organization of work. Variables forming this factor refer to wastage factors in an organization (muda), well-known from the literature. The sixth risk factor referring to the risk generated by the base enterprise refers to events happening as a result of the maladjustment of the supply base of the organization and inspection procedures of the quality inspection to the real requirements of material flows. Similarly, disruptions generated by the supplier in respect of the frequency constituted two risk factors. The second risk factor comprises events connected with completeness, quality or lack of supply, and the fifth risk factor contains events associated with the time of delivery realization.

At the stage of identification of disruptions in material flows in s network supply chain the authors also distinguished key deviations (as a results of disruptions):

- Unpunctual order realization O1
- Incomplete order realization O2
- Unrealized order O3
- Deviations from the determined stock levels O4
- Extraordinary transport O5

The correlation analysis showed that the increase in the frequency of disruptions generated by suppliers is accompanied by an increase in the frequency of unpunctual orders and extraordinary transports. However, the growth of factors from the wastage

group (muda) is accompanied by an increase in the frequency of deviations from the determined stock levels. The growth of disruptions generated by the subcontractor causes an increase in the frequency of deviations from the determined stock levels.

The canonical analysis, where deviations in material flows were the dependent variable and risk factors were the independent variable, confirmed the influence of the frequency of disruptions on deviations (the canonical correlation coefficient $R^2=0,74$ at the relevance level $p=0,0042$). Consequently, hypothesis 1 was confirmed.

Disruption in material flows can become stronger through the influence of other factors which in the literature are defined as factors of amplification of disruptions. The assessment of factors of amplification of disruptions was carried out on a research sample of 54 enterprises of a network supply chain of metallurgic products. Particular zones were selected on the basis of the factor analysis. Taking into account the findings of the literature research (finished with the selection of factors of amplification of disruptions) and also the findings of the empirical research carried out in earlier stages (including especially separating risk factors in respect of frequency) zones of amplification of disruptions were indicated.

The factor analysis was carried out in two steps. At the first step the authors singled out 12 groups of factors which were represented by 20 factors of amplification of disruptions and 97% explained the variability of the examined phenomenon. Not all groups were characterized with a significant representation of factors of amplification of disruptions. At the second step the authors distinguished 5 zones of amplification of disruptions. The description of zones of amplification of disruptions was presented in Table 1. The distinguished 5 zones is represented altogether by 17 factors of amplification of disruptions:

Zone 1 - Zone of amplification of disruptions in the microenvironment of the base enterprise in the suppliers' environment

Zone 2 - Zone of amplification of disruptions in material flows on the line of communication between the nodes of the network supply chain

Zone 3 - Zone of amplification of disruptions in the area of the market

Zone 4 - Zone of amplification of disruptions resulting from limitations of capacity

Zone 5 - Zone of amplification of disruption in the area of the macro-environment of the network supply chain.

The factors mentioned in zones of amplification of disruptions in 93% explain the

variability of factors of amplification of disruptions. The content-related analysis of factors of amplification of disruptions representing particular zones of amplification of disruptions allows acceptance of the division received by means of the factor analysis. The authors indicated a possibility of dividing the factors of amplification of disruptions into homogeneous, in respect of the effect on the frequency of disruptions presented in risk factors, groups defined with zones of amplification of disruptions.

The analysis of the influence of factors strengthening disruptions on the frequency of disruptions expressed in risk factors was effected by means of the canonical analysis, where the components of the independent variable were zones strengthening disruptions, and the dependent variable was represented by risk factors separated in respect of frequency. The obtained configuration of components of the dependent and the independent variable (fig. 4), which significantly explains the influence of zones of amplification of the disruption on risk factors distinguished in respect of frequency, took the canonical correlation coefficient $R=0.699$ at the relevance level $p=0.0054$.

Fig. 4. Results of the canonical analysis concerning the influence of zones of amplification of disruptions on risk factors distinguished in respect of the frequency of occurrence of disruptions

Source: The authors' study

Zones 1,2,4 and 5 strongly and favourably amplify the risk factors distinguished in respect of frequency, whereas they exert the strongest influence on the growth of the frequency of disruptions connected with wastage in the base enterprise and connected with unpunctuality of deliveries generated by the supplier. In the obtained configuration only the second risk factor (disruptions generated by suppliers, including defective or incomplete delivery) has a negative and very low canonical coefficient. Consequently, it can be noticed, first of all, an essential influence of zones strengthening disruptions on the punctuality of processes realized by the supplier and on the organizations of processes in the base enterprise. The findings of this part of the research allow adopting Hypothesis 2. At the same time, the obtained findings in the area of testing both of the research hypotheses became the basis for constructing a simulation model which is a module of an IT tool

5. Variants of strengthening resistance

The stages of creating and analysing risk factors, the zones of amplification of disruptions as well as designing the IT tool and simulation models (Can, Chan, 2006; Celik, Lee, Vasudevan, Son, 2010; Harrison, Lin, Carroll, Carley, 2007), all indicated strategic variants strengthening the resistance to flagship enterprises of the network supply chain of metallurgic products.

The flagship enterprise which is a material decoupling point can strengthen the resistance of the supply chain using one of the options presented in Chapter 3:

- supplies surplus,
- flexible resources,
- network cooperation.

These are alternative strategies of amplification of the resistance of a supply chain, dependent from the level of endogenous and exogenous disruptions. The general model of amplification of the resistance of a network supply chain from the perspective of the material decoupling point consists of three models which provided the basis for simulation models. The assumptions which are common and differentiating the proposed models were shown in the table 1.

Table 1. The characterization of strategic variants of amplification of the resistance of a supply chain

	The supplies model	The flexible resources model	The cooperation model
Common assumptions	Material decoupling point realizing the postponed production tasks differentiating the base product to orders placed by recipients of the automotive industry		
	The transport cycle between MPR and the recipients		
	The supplies of the finished (diversified) products		
	The supplies of the base product (supplies on the entry to the system)		
	The unit costs of supplies		
Assessment criteria:	The unit costs of transport		
	The logistic customer service and logistic costs (it was assumed that the logistic customer service could not be smaller than 0.90 and with such an assumption the authors searched for a solution with the lowest logistic costs)		
The characteristic assumptions for the model			
The characterization of demand	A multivariant product, differentiated on a large scale with a relatively stable demand for each variant	Differentiation of the product dependent from orders for particular variants of the product, large deviations from the forecast demand	Differentiation of the product dependent from orders for particular variants of the product or resulting from the specification presented in the project of the variant of the product, very strong deviations from the forecast demand
The prevailing model of the process	BTF Build to forecast	BTO Build to order	CTO/BTO Configure to order / Build to order
Attributes of resources	Dedicated resources in MPR	Flexible supply in MPR, dedicated substitutional supply at the subcontractor's	Flexible supply in MPR, several subcontractors having at their disposal dedicated substitution and complementary resources
Cooperation	Limited, only refers to substitution resources, irregular relations (loose relations between MPR and the subcontractor)	Limited, refers to the substitution supply, cooperative agreements (strong relations between MPR and the subcontractor)	Strong, refers to substitution and complementary resources, Diversified relations between MPR and the subcontractors

Source: The authors' study

The proposed strategic variants should be investigated in respect of their sensitivity to fluctuations of demand. The proposed simulation models allow determining the thresholds of the efficiency of each variant.

In the assessment of the efficiency of the accepted strategy by the material decoupling point, both the logistic customer service and logistic costs must be taken into account . The determined deviations in material flows correspond to elements of the logistic customer service. Consequently, striving to reduce deviations in material flows, at the same time one strives to improve the level of the customer service. The costs consist of both the costs of transport, storage, non-utilization of production capacities and the costs of lost sale.

Each of the investigated strategic variants of amplification of the resistance has its consequences in the approach to material flow management. The material decoupling point, when choosing a model of flow management, should have data within concerning the frequency of disruptions, the influencing power of zones amplifying disruptions, the required level of individualisation of the product. The key stage of the making-decision process is to identify the value of the zone of amplification of disruptions in the area of the market. It is because this group includes factors characterizing the demand and the attributes of placed orders. It is fluctuations of demand, apart from the power of internal disruptions, that most strongly determine the efficiency of each variant of the strategy of amplification of the resistance of a network supply chain. The results of simulation experiments (Kramarz, 2013) showing the thresholds of the efficiency of each variant of amplification of the resistance by the materials decoupling point of the network supply chain was shown in Table 2.

Table 2. A summary of strategic variants of amplification of the resistance of a supply chain by the material decoupling point

	The supplies model	The flexible resources model	The cooperation model
Assessment criteria:	The logistic customer service and logistic costs are assessment criteria (loc is not smaller than 0.95 and with such an assumption of a solution with the lowest logistic costs)		
Stable demand, slight disruptions inside the system	strongly resistant	unprofitable	unprofitable
Stable demand Considerable disruptions inside the system	not resistant	strongly resistant	low profitability

Unstable demand Slight disruptions inside the system	not resistant	Resistant at average values of demand considerably lower than the maximum outputs of the system. The threshold resulting from the limited production capacity of the flexible and dedicated supply	Strongly resistant; The growth of cooperators is accompanied by an increases in the frequency of disruptions inside the system. The threshold results from the growth of internal disruptions of the system together with the growth of the number of cooperators, these disruptions enter into relations with the zones of amplification of disruptions and are not smoothed by advantages resulting from the large availability of production capacities
Unstable demand, considerable disruptions inside the system	not resistant	not resistant	

Source: Kramarz, 2013

In the first strategic variant the material flow management is based on forecasts of demand for variants of the product. This is the basis for shaping the combination of supplies of the base product and finished products (already diversified base products - fig. 5).

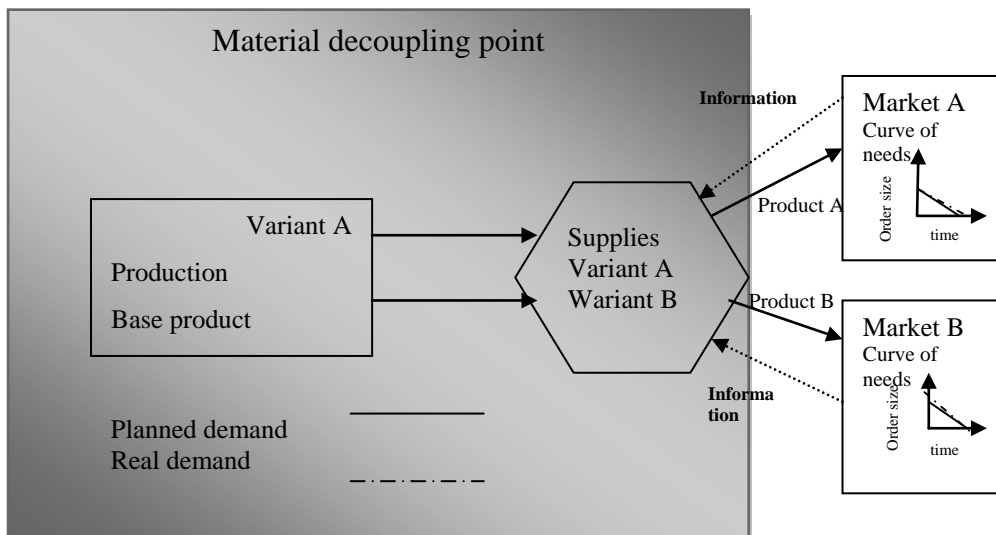

Fig 5. A flow model for the early differentiation strategy (multivariant products)

Source: The authors' study

Slight disruptions of demand and the multivariant product with a comparatively stable demand for each variants allow smoothing of the occurring disruptions with the supplies surplus in the base product stock and in the finished products stock. It is more efficient to build a surplus in the base product stock and form an alarm reserve in the finished products stock on a level close to the average demand for each variants of products. So, the level of the alarm reserve is marked on the basis of demand for variants and on the basis of the norms of supplies. The control system is programmed so as to make up supplies up to the alarm level and consequently to maximize the level of the logistic customer service through limitation of incomplete, unpunctual and unrealized deliveries. The supplies of the base product are created on the basis of a summary demand for variants of products and the norms of the reserve. This model corresponds to the model of production-to-stock, taking into account the postponed production for needs of the differentiation of the product. Variable in the control system are the level of alarm reserve in the base product stock and in the finished products stock (for each variant of the product). The variability of the level of the alarm reserve depends on changes in demand. Controlling involves tracking this variability and compensating the shortage of supplies in each stock. The system performs well in the conditions of a slight variability of demand and slight disruptions. Both the growth of fluctuations of demand and the growth of internal disruptions cause that the system to become not resistant and no configuration of supplies is in a position to ensure the required level of the logistic customer service.

In the second variant of amplification of the resistance (through flexible resources), the process of the flow management involves maintaining comparatively high production powers on the level of the materials decoupling point and supplementing them with dedicated power at the cooperator's.

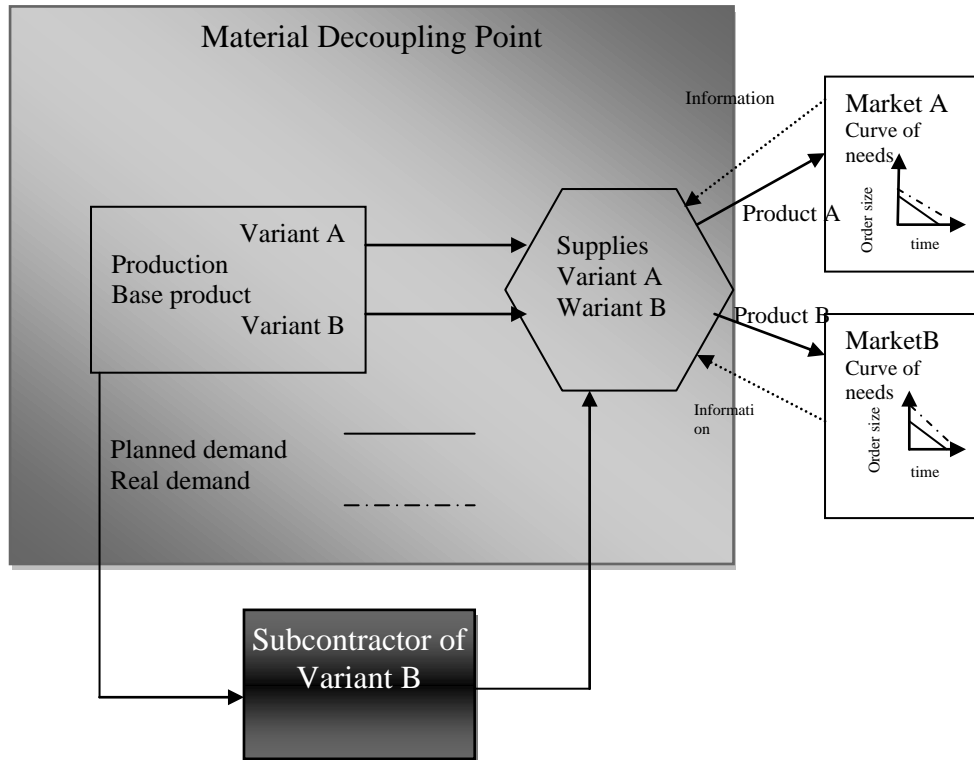

Fig 6. A strategic variant - delayed differentiation - flexible supply

Source: The authors' study

The material decoupling point has a flexible supply allowing differentiation of the base product according to the recipients' diversified needs. In the event of an increase in demand, part of operations connected with production of one variant of the product is directed to the subcontractor, and then the flexible supply realizes orders for the second variant. In this way the designed system is able to react to changes in both the summary demand and the demand for particular variants of the product as well as disruptions in material flows only slightly amplified by cooperation with the subcontractor. Disruptions in this model occur on a lower level than in model 3 because strictly limited numbers of subcontractors allow building strong and formalized relations, based on strictly designed procedures limiting the possibility of generating disruptions. Controlling involves tracking the demand for finished products, shaping the level of the reserve of base products based on summary forecasts, encompassing all variants of the product, and

starting production in the material decoupling point and at the cooperator's depending on real demand for particular variants. It is a management model based on the pull system, in which an impulse for realization of the operation of differentiation of the product (late differentiation) are the recipients' real needs. Any excess of production power and the flexibility of the system cause a possibility of a quick reaction to the variability of the demand. The system shows a high resistance to the average disruption level.

In the last variant of amplification of the resistance (creating a surplus of network relations) the system is controlled by conducting (orchestration) the subcontracting of the operations of the postponed production and building relations in the network. The production and logistic system designed in this way is both flexible and adaptive.

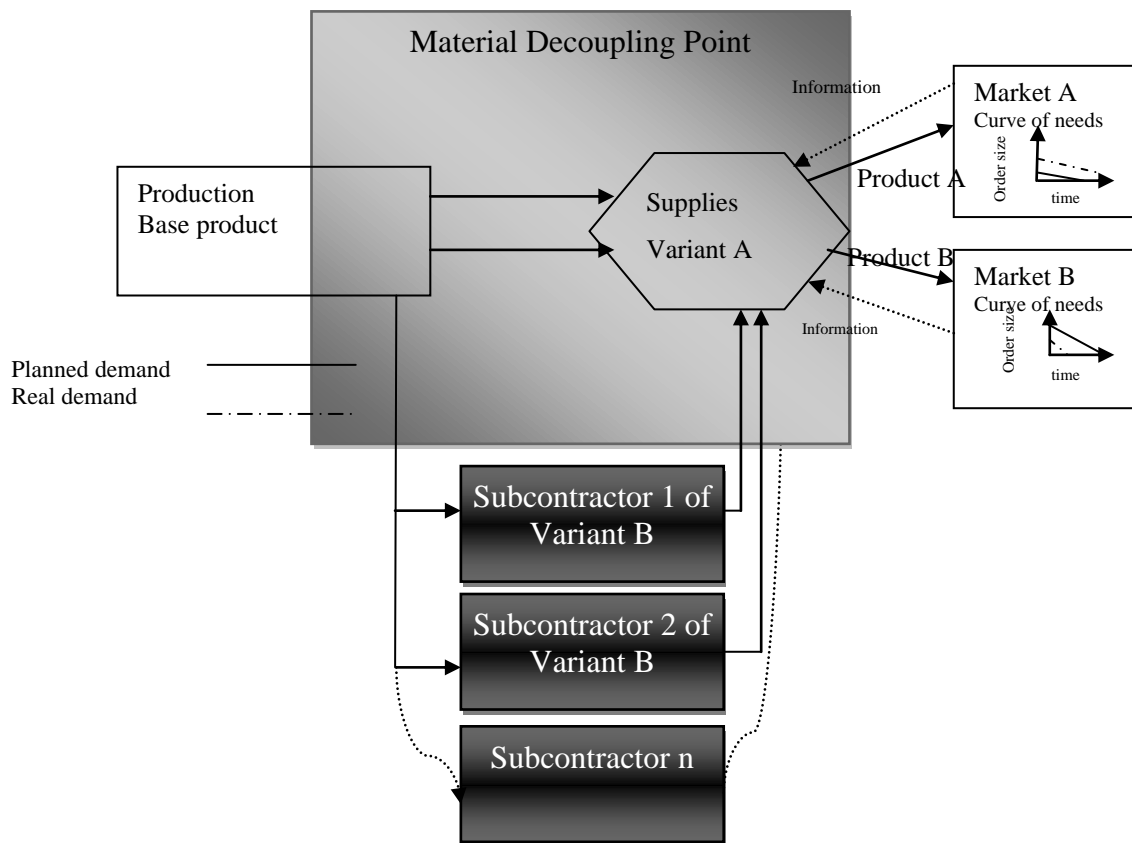

Fig. 7 A strategic variant: delayed differentiation - network relations in the area of subcontracting

Source: The authors' study

The management process involves an estimation of the summary demand for variants of the product, adjusting on this basis the stock level of the base product, receiving orders for variants of the finished product and distributing them between the production powers and partners in the network. The considerable differentiation of a product affects assumptions concerning extensions of the entire time of the production and logistic cycle but simultaneously requires high standards as regards punctuality and plenariness of deliveries. Considerable fluctuations of demand entail establishing additional relations with cooperators. These relations increase production capacities of the entire system. The system is efficient to a certain level of the variability of demand in connection with the fact that building additional relations increases internal disruptions which after exceeding the threshold value reduce the resistance of the entire system. Internal disruptions increase together with the growth of the number of cooperators. Due to the dynamic system of relations between the material decoupling point and subcontractors, relations are weaker, less formalized and more susceptible to the influence of endogenous factors.

Using the relationships between the efficiency of particular strategic variants and the fluctuations of demand as well as including the degree of the differentiation of a product into the decision-making issue, the authors developed a strategic matrix for the flagship enterprise of a distribution network fulfilling the assumption of material decoupling points (fig. 8).

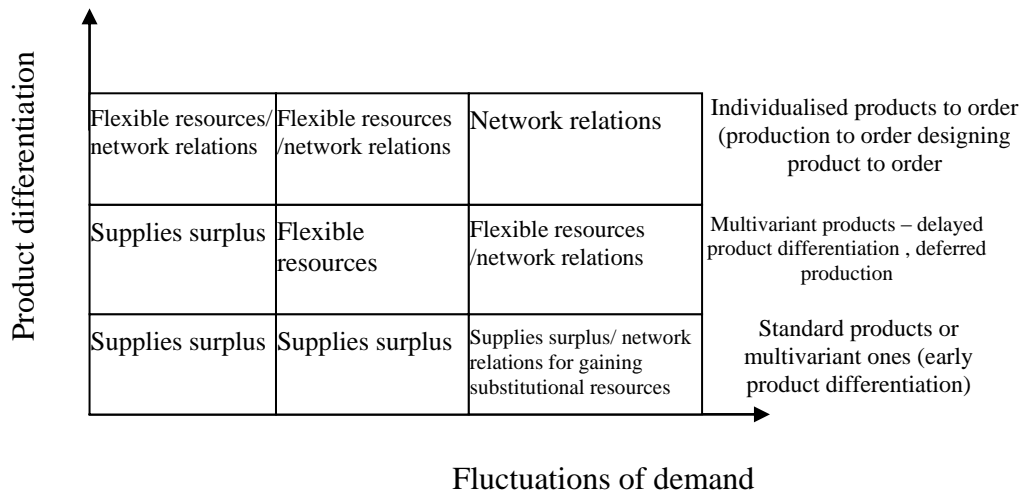

Fig 8. A strategic matrix depending on fluctuations of demand and the degree of the product differentiation

The attributes of the placed orders indicate the degree of individualisation of products. Constant demand for particular variants decides about the possibility of using the so-called mass customization, i.e. production of different variants in compliance with forecasts. Strong fluctuations within particular variants (irrespective of the fact whether the summary demand is characterized also with strong fluctuations or is relatively stable) require making a decision about realization of orders in the pull system and differentiation of base products in compliance with incoming orders. In that case, it is solely supplies of the base product that are becoming essential. The growth of fluctuations of demand causes that it is ineffective to search for amplification of the resistance through a combination of the stock level of the base product and the finished products. Then one ought to search for other ways ensuring flexibility, such as flexible resources or network relations.

Conclusions

The network structure of the supply chain enlarges the flexibility through the redundance of production and logistic resources. Flexibility, however, increases the resistance of the entire supply chain on disruptions

In such structures it is extremely essential to gather knowledge on disruptions. The proposed methodology of measuring disruptions including identification of disruptions, indication of the risk factors and zones of amplification of disruptions aims at adjustment of the designed IT tool which allows knowledge gathering under the specificity of a given industry.

The modules designed in the tool, i.e. the modules for tracking disruptions and for tracking real material flows, compatible with the ERP system, allow undertaking activities to correct the size and the frequency of deliveries and the volume of buffer reserves according to the developed real-time strategies of amplification of the resistance.

The system also allows recording deviations in the past periods and making a list of historic data. These provides the basis for estimating the trends connected with disruptions and referring them to the cooperators' attributes.

The system takes into account the stochastic aspect of cooperation. Through historic analyses it is in a position to assess the variability of demand and deliveries on the part of cooperators as well as the sizes and the reasons of deviations and use this knowledge for

material flow management.

Essential modules of the tool are simulation models which, using the data gathered in the system, permit developing and evaluating variants of amplification by the material decoupling point the resistance of the network supply chain.

The developed simulation models for the network supply chain of metallurgic products allowed carrying out experiments within the sensitivity of each of the three proposed strategies of resistance to disruptions.

Structured Abstract

Purpose – This paper aims to identify the main processes and factors of „knowledge utilization“ (Zhang et al., 2009), especially the role of knowledge management initiatives (Clarke and Rollo, 2001; Wamae, 2009), as a form of generation, distribution, transmission, and usage of knowledge to create sustainable economic value. For this purpose, participating firms, employees, and other individuals are in focus of consideration, which are participating in the transfer knowledge assets of knowledge intensive firms (Abzari et al., 2011) and therefore contribute to the sustainable development of these kind of firms and their commercialization of knowledge intensive products as well as services (Lichtenthaler, 2005; Chen et al., 2010). Finally, further research directions have derived as a result of our literature analysis.

Design/Methodology/Approach – An organizational setting in which knowledge transfer, exchange or utilization should take place is difficult to establish (d'Aspremont and Bhattacharya, 2000). Therefore different main processes and factors are important to recognize. Identification of knowledge assets (Teece, 1998; von Krogh et al., 2001), knowledge governance and coordination (Hicks et al., 2002; Patrucco, 2005; Moon, 2011), relationship building (Antonelli, 2006; Lin and Wu, 2010), knowledge presentation (Desouza and Awazu, 2004; Kafentzis et al., 2004), knowledge protection (Teigland and Wasko, 2003; Mets et al., 2007), and knowledge trade (Jeong et al., 2013) are crucial for the utilization of knowledge. The authors conducted a literature review to knowledge utilization by searching for keywords, like knowledge utilization, transfer or commercialization in different scientific databases. Here the literature review should provide a framework for comparing results of the conducted scientific literature (Creswell, 2009). Therefore only double-blind reviewed articles of different scientific journals were used and the different approaches were analysed in a concept-centric method (Cooper, 1988; Webster and Watson, 2002).

Originality/Value – An overview of different knowledge utilization processes and success factors give firms in knowledge intensive environments the possibility to commercialize their outcomes. The main processes identified were the identification of knowledge assets, the knowledge governance and coordination, relationship building, the knowledge presentation, the knowledge trade, and the knowledge protection. Main

success factors of knowledge utilization, described by the literature are: absorptive capacity, solving customer problems, reputation, rewards and incentives, trust, and reciprocity.

Theoretical Implication – This research paper aims to contribute to knowledge utilization as well as knowledge management literature since the data collected in the literature review showed a focus on these concepts. Further research on knowledge utilization needs to be done to have a clear, homogeneous understanding of knowledge utilization, which is not achieved yet. The state-of-the-art evaluation has also shown a focus on the organizational perspective. The individual perspective needs to be further researched. Finally, a holistic view on knowledge utilization processes and factors could only be found in a few research articles. Therefore a holistic research model on the different knowledge utilization processes and factors, for example as an external knowledge marketing model, needs to be further designed.

Practical Implications – In terms of practical contributions, this literature review may give firms the possibility to enhance their outputs as qualitative services providers by employing the different processes and concentrate on the factors of knowledge utilization. Additionally, in the market for knowledge many uncertainties and risks may occur. Here firms and clients in knowledge intensive industries may enhance their benefits, when the value of knowledge goods is clearer, trusted relationships between the participants are present and systems of quality measurements are implemented. Furthermore, the practical importance of knowledge systems and networks to enhance the firm's knowledge capital is described. Firms should follow an open source strategy to motivate employees, clients and other firms to share their knowledge.

Keywords – Knowledge Utilization, Commercialization, Transfer and Exchange

Paper type – Academic Research Paper

1 Introduction

The globalization of markets, the convergence of previously distinct industries, and the fact that markets become even more unpredictable are challenges for firms (Day and Montgomery, 1999). In these markets consumers have more choices, and they are better informed through expanded media (Day and Montgomery, 1999). Additionally, in the 21st century, the era of communication and information technology, resources are becoming more and more important, which are responsible for the emergence of intangible assets.

One of those important competitive resources in business is knowledge and related knowledge work (Abzari et al., 2011). Entrepreneurs are convinced that knowledge work is important for the innovative power of firms and the key to long-term sustainability and

growth (Davenport et al., 2002). Teece (1998) has already seen knowledge and its application at the very roots of modern economic growth and prosperity. The increasing speed of information transmission, the increasing amount of information that can be transmitted and processed, is leading to the creation of new types or patterns of information firms (Glazer, 1991). In general, these so called knowledge intensive firms are operating in knowledge markets with aims of generating revenues, gaining knowledge access, setting industry standards, profiting from infringements, realizing learning effects, and guaranteeing freedom to operate (Lichtenthaler, 2005). The increasing technological content of products with shorter life cycles and the more intense competition (Lichtenthaler, 2005) is resulting in the need for a precise research on the firm's resource knowledge and how firms can externally commercialize it.

Here the knowledge utilization approach summarizes different ways of effectively use kinds of knowledge resources. The approach contains of a complex process involving political, organizational, socioeconomic, and attitudinal components in addition to the specific information or knowledge (Larsen, 1980). Larsen (1980) proposed that knowledge utilization can be classified as conceptual and instrumental. The conceptual use refers to knowledge that has influenced the way users think about issues. The instrumental use of knowledge refers to knowledge that has influenced action or behavior or changing policy and procedures (Larsen, 1980). Here the authors encompassed knowledge utilization from other approaches, like knowledge management by focusing on the transfer and exchange of knowledge between individuals or organizations. Nevertheless these other approaches still provide different aspects for a general overview on knowledge utilization.

The study on different areas of knowledge utilization showed many lines of research and inquiry. By analyzing scientific reviewed articles of different approaches to knowledge utilization several research questions arose which need to be answered in further research. Especially, which approaches that focus on the utilization/commercialization of knowledge do already exist in the literature? What are processes and factors for effective knowledge utilization?

2 Classification of the Literature Review

The articles which have been considered for the review are organized in a conceptually order to find differences and similarities of considered research issues. The

literature review should provide a framework for comparing results of the conducted scientific literature (Creswell, 2009).

In the first step, a literature review was conducted by keyword search in different scientific databases (EBSCOhost, Web of Science, JSTOR and Elsevier) to summarize the substance of the existing literature and drawing synthesized implications for research and practice from it (Cooper, 1988). Different synonymously terms to utilization were included in the keyword search, like marketing, disclosure, exposure, explication, trade, commercialization, exploitation, selling, commerce, and deploying. The first search was too broad and too many articles were found. Therefore these synonyms were explicitly used in combination with the term knowledge and other terms like know-how or information. The different terms were searched for in the title and abstract of the articles. Here only double-blind reviewed articles of different scientific journals were analyzed with no contextual limitations, but in a limited time period from 1990 to 2013. By doing so the authors tried to follow an evidence-based procedure of searching the literature, described by Tranfield et al. (2003). The overall number of applied literature included sixty-one articles of interest.

In a second step, the overall number of articles was read more carefully and especially references of other articles were carefully studied to find additional related scientific articles. The articles were implemented by backward and forward search in the range of appropriable scientific literature. Here the selection of interests was based on different criteria, which have developed out of the research questions. The interested topics of articles are: any form of knowledge utilization within firms and externally, definitions of knowledge commercialization, knowledge and information disclosure, and factors of knowledge transactions and exchange in general. Hereby additional twelve articles were selected. In this second step of the literature review also articles were excluded from this review, which only describe knowledge or knowledge transfer in general without relating to the specified factors of knowledge utilization, like relationships and networks, the focus on customer problem solutions, or for example the absorptive capacity of firms. In a collateral process of monitoring by the authors, the reliability of the selection process was ensured. The authors have synthesized the following contextual limitations for this research article: best practices/success factors of knowledge utilization, especially the organizational processes and the factors. Because of this specific context of the review and the described limitations, the selection of articles was limited and consequently seven

articles were excluded of the review. Finally, sixty-six articles have been selected for this review.

In the third step of the literature review all selected articles were analyzed more specific. A first general descriptive evaluation of the articles is done in the following paragraph. In **Error! Reference source not found.** the publication years of the relevant articles found by the systematic keyword search in the different databases is shown to emphasize the accelerated focus in this topic.

Figure 1: Overview of Article's Publication Year

In **Error! Reference source not found.** you can find an overview of research methods used in the selected articles found by the systematic keyword search in the different databases. Most of the selected articles have used a theoretical or review method. But the authors also recognized that a majority of articles in this specific topic of scientific research have employed empirical-quantitative data.

Table 1: Overview of the Research Methods in the Selected Articles

Research Methods	No. Articles
Theoretical or Review Method	41
Empirical-Qualitative Method	8
Empirical-Quantitative Method	16
Empirical-Mixed Method	1
Overall No. of Articles	66

In **Error! Reference source not found.** the different research methods used in the literature of knowledge utilization are further analyzed. It can be recognized, that different methods were used over the whole evaluated time frame. Especially theoretical or review articles were often used to handle the focused research topic. One noticing point can be acknowledged, in the first years of the articles' publication in the time frame more theoretical and qualitative research methods were used. In the last years of publication more and more empirical-quantitative research methods were used in the field of interest.

Figure 2: Trend of Research Methods

In the articles different units of analysis are analyzed, but in all articles knowledge is considered as the main resource of firms' sustainable advantage (Nonaka and Takeuchi, 1995; Davenport and Prusak, 1998) and in the considered firms most of the work is of an

intellectual nature, where well-educated, qualified workers produce qualified products or services (Swart and Kinnie, 2003). The scope of review (Cooper, 1988) is defined in processes and factors of knowledge utilization to generate commercializing outcomes for firms in knowledge intensive industries. Here the implicit values of this review are described by supporting knowledge intensive firms to perform and enhance their outputs as a qualitative services provider. In result, this overview of the different processes and success factors in knowledge utilization may contribute to existing theories (Corley and Gioia, 2011). For this reason the different processes and factors are clarified, and their interrelations are more specifically is looked at to further describe the domain of knowledge utilization (Whetten, 1989). These approaches will be analyzed in a concept-centric method (Cooper, 1988; Webster and Watson, 2002), while these concepts are categorized under the definition of different key terms of the interested topic (Creswell, 2009). Additionally, a table of all these approaches will summarize the conducted literature, so key findings and groups of patterns found in the literature will be further explained (Creswell, 2009).

The article is organized as follows: First key variables of knowledge utilization are defined followed by the state-of-the-art of knowledge utilization by presenting existing approaches and important factors of knowledge utilization. The following chapter discusses the state-of-the-art of knowledge utilization and the different success factors which are considered by the selected authors. The last chapter is describing further research and practical implications in the utilization of knowledge.

3 Definition of Key Variables in Knowledge Utilization

The authors included main literature of the firm resource knowledge to clarify different key variables in the topic of knowledge utilization. To have a clear understanding of the resource knowledge, it will be generally defined here. Probst et al. (2003) define knowledge as it refers to all the knowledge and skills individuals use for the solution of problems. In the literature the resource knowledge is summarized as intellectual capital of the firm, which generates value (Zabala et al., 2005). A firm's knowledge asset is based on experiences and expertise of their employees (Spender and Grant, 1996). Tiwana and Bush (2005) describe knowledge as actionable information, which further is an intricate and complex web of heterogeneous and endogenous activities (Antonelli, 2006). The firm provides the physical, social, and resource allocation

structure, so knowledge can be shaped into competences (Teece, 1998). Knowledge involves firm's processes, people, values, culture, intuitions and opinions (Zabala et al., 2005).

Nonaka and Takeuchi (1995) distinguish the tacit and explicit form of knowledge. Both forms are described by different attributes, like intangibility, uniqueness, concurrent usability, value uncertainty and publicity (Nonaka and Takeuchi, 1995; Chen et al., 2010). Knowledge can refer to an object or a capability and it may reside in individuals, groups, documents, processes or repositories (Alavi and Leidner, 2001). Nevertheless or exactly for this reason, Spender and Grant (1996) and Nonaka and Takeuchi (1995) point out, that tacit knowledge is the most useful form of knowledge. The expertise of individuals plays an important role here; it refers to the largely tacit facets of knowledge (Tiwana and Bush, 2005). The conscious and usually reported form of knowledge is the explicit form (Spender and Grant, 1996). Some authors, like Coff et al. (2006) mean, that tacit knowledge has great strategic value, but therefore it must be codified to exploit that value. But also the tacit form of knowledge is a major component of the utilization of knowledge without transferring it into the explicit form, like Chen et al. (2010) or Landry et al. (2012) describe it. Knowledge is characterized by unpredictability about many facets: outcomes, timing or the economic value (Antonelli, 2006). Muller and Pénin (2006) describe that producing knowledge depends on the amount of knowledge available, external or internal.

Today the processing of information in firms is seen as the critical task and the ability to do so as the critical competition requirement (Greenwood et al., 2005). Here firms are in the focus of interests, which clearly distinguish from industrial firms in the type of value creation and level of information asymmetry between the firm and its clients (Sheehan and Stabell, 2010). In general, knowledge intensive firms are defined as organizations within a knowledge economy (Drucker, 1999), that create market value through the application of knowledge to client demands (Swart and Kinnie, 2003). The knowledge intensive firms rely mainly on human and organizational resources, like experts, which are highly educated individuals and the application of expertise to deliver their services, for example banking and financial, legal, accounting, marketing, advertising, human resource management, consulting and medical consulting, architecture, research and high-tech services (Swart and Kinnie, 2003; Greenwood et al., 2005; Sheehan and Stabell, 2010; Leon, 2011; Abecassis-Moedas et al., 2012). The

human resources of knowledge intensive firms are also called knowledge workers which use predominantly cognitive skills (Leon, 2011).

Furthermore, the so called knowledge intensive services are defined as the integration of systematic knowledge and the mechanism of using the knowledge to perform a task (Zhuge and Guo, 2007). It requires the combination of organizational knowledge with skills and experiences, the output is a new process or the way of doing things, new routines, or services (Leiponen, 2006). Knowledge products and services are search, experience, and credence goods (Desouza and Awazu, 2004). These knowledge products and services are mainly subject to the same market and competitive forces that govern any product (Shapiro and Varian, 1998). Uniquely for these products and service is, that they are expensive to create, but cheap to duplicate (Desouza and Awazu, 2004). Further Teece (1998) describes that it is especially difficult, although not impossible, to trade knowledge assets and, more generally, competences. These services are users, carriers and sources of innovation (Leiponen, 2006). They can act globally as innovations in the productive system (Baviera-Puig et al., 2012) and they have a dynamic character during the distribution (Zhuge and Guo, 2007).

A further key term in this article is the knowledge markets, where intangible goods are traded (Kafentzis et al., 2004; Jeong et al., 2013). In general, the market transparency in these knowledge markets is very low and high risks or uncertainties concerning knowledge asset quality and value may occur on both sides (firms and clients) (Desouza and Awazu, 2004). Because of that uncertainty, for example, clients often hesitate to change their knowledge provider (Greenwood et al., 2005). Following activities are described within these markets: comparison of available products and services, acquisition of knowledge of knowledge providers, exchanging of tacit or explicit knowledge forms, competition and cooperation of firms for knowledge resources (Probst et al., 2003; Desouza and Awazu, 2004; Kafentzis et al., 2004; Grover et al., 2009). Two kinds of knowledge markets can be described: internal knowledge markets, where firms actually act as potential markets with buyers, sellers and brokers (Zhuge and Guo, 2007). Firms use these internal knowledge markets as a way to track and manage the flow of knowledge within them (Desouza and Awazu, 2004). On external knowledge markets, knowledge transactions are much more complex than transactions on the markets for most products and services (Lichtenthaler, 2005). These knowledge markets are active markets,

where buyers and sellers participate to trade knowledge, for example in form of intellectual property, copyrights and patents (Kafentzis et al., 2004).

Following participants and factors characterize these knowledge markets: market makers, buyers, sellers, brokers, market rules, and the market space (Desouza and Awazu, 2004). Kafentzis et al. (2004) and Chen et al. (2010) additionally describe different roles in the market for knowledge: the knowledge supplier and requester, third parties, knowledge processor, and the knowledge service provider. A knowledge service provider, which brings buyers and sellers together, provides value-added services (Kafentzis et al., 2004; Bhargava and Choudhary, 2004). They are also called knowledge brokers: brokering knowledge from where it is known to where it is not (Hargadon, 1998).

For the participants with current technologies for distributing information in knowledge markets, it is easy to explore market segments that were not reachable before (Shapiro and Varian, 1998). Here the so called imperfections of the knowledge markets (Teece, 1998) lead to different challenges for participants: the identification of knowledge clients, absorptive capacity, intellectual property rights, adequate compensation for knowledge transfers, assessing the value of intellectual assets, the nature of knowledge (Lichtenthaler, 2005).

In general, human and social factors appear in many areas of trading and exchanging knowledge (Kafentzis et al., 2004). The sharing of knowledge is a social process (Rodger, 2012). Here the “social exchange theory” plays an important role for all participants of the market, which describes that people do share information or knowledge with the expectation of reciprocity (Kankanhalli et al., 2005; Rodger, 2012). Additionally, in these markets for knowledge a high variety of knowledge intensive services and corresponding skill requirements exists (Consoli and Elche-Hortelano, 2010). In other words, the level of education of knowledge employees is quite important, to identify appropriate cooperation partners, to access and assimilate the relevant knowledge (Spithoven and Teirlinck, 2010).

4 The State-of-the-Art of Knowledge Utilization

In this section the authors want to summarize the different approaches of utilizing knowledge and find coherences, relations and similarities between them. Different authors of the analyzed articles use different terms for the utilization of knowledge. In the

following paragraphs different approaches are introduced and main processes as well as factors of knowledge utilization in the existing literature are further explained.

4.1 Existing Approaches of Knowledge Utilization

The analysis of the literature has shown that a lot of different concepts are used by authors to describe in general the utilization of knowledge. Backer (1991) already mentioned, that the knowledge utilization field is fragmented, and needs new synthesis and cross-cutting activities. In the following **Error! Reference source not found.** a summarized overview of the used concepts is illustrated. In the **Error! Reference source not found.** the concepts are listed corresponding to the number of authors applied to these concepts. Different authors also used more than only one concept, so these could several times been counted.

Table 2: Applied Concepts in the Analyzed Literature

Rank	General Concepts	Number of Authors	Rank	General Concepts	Number of Authors
1	Knowledge Management	11	7	Knowledge Intensive Services	2
2	Knowledge Utilization	9	7	Knowledge Outsourcing	2
3	Knowledge Disclosure	8	7	Knowledge Sharing	2
4	Knowledge Exchange	7	8	Knowledge Contribution	1
4	Knowledge Transfer	7	8	Knowledge Exploration	1
5	Knowledge Trading	4	8	Knowledge Governance	1
6	Knowledge Brokerage	3	8	Knowledge Innovation	1
6	Knowledge Exploitation	3	8	Knowledge Marketing	1
6	Knowledge Selling	3	8	Knowledge Methods	1
7	Knowledge Commercialization	2	8	Knowledge Mobilization	1
7	Knowledge Distribution	2	8	Knowledge Production	1

Different approaches for the utilization of knowledge are based on principles of knowledge management. Because main resources used by knowledge intensive firms exist in the form of intangibles, a specialized form of management is needed (Kjaergaard, 2003). Knowledge management is essential to the achievement of the objectives of these firms (Zabala et al., 2005). Like Clarke and Rollo (2001) describe that knowledge management initiatives supporting the generation, distribution, transmission, and usage of knowledge in ways that create economic value. These initiatives for utilization of knowledge are practiced in three main areas: intellectual capital, structural capital and

human capital (Goh, 2005). In general knowledge management is aimed at developing and properly managing an organization's knowledge (Garavelli et al., 2004). Here knowledge management is the process of creating, organizing, storing and using data, knowledge internal policies, and process manuals for organizational performance (Sedaghati, 2012; Zabala et al., 2005). The management of knowledge from the perspective of a producer means, that managing any artefact of the firm, because it embodies considerable knowledge (Cowan et al., 2000). From the perspective of the user, it is how to use these artefacts (Cowan et al., 2000). In the perspective of knowledge utilization, knowledge management is thus the process of creating value from ideas and making it available for the entire firm (Garavelli et al., 2004). The firm's ability to differentiate in the market for knowledge depends on the availability of knowledge-based assets and how these firms employ knowledge management to harness the value of these assets (Goh, 2005). In the management of knowledge, especially from the perspective of knowledge utilization, firms need to realize knowledge-centered principles, like an innovation thinking-value system, a collaborative knowledge strategy, knowledge networks, or human technology solutions (Goh, 2005).

A general basis of knowledge utilization is, that the knowledge transfer and exchange is an interactive process involving the interchange of knowledge (Mitton et al., 2007). One of the main processes of knowledge intensive firms is the transfer of knowledge from one person, or group to another (Abzari et al., 2011). A typical knowledge transfer starts with the identification of knowledge, in which potential benefits of the transfer are signaled to the receiving partner or to the sending partner (von Krogh et al., 2001). In knowledge transfers the process of identifying and transferring the knowledge resources has proven to be trickier and more time-consuming than most firms first imagine (Lucas, 2005). But the ability of firm's members to mix and exchange knowledge determines the rate at which new products and services, in general innovations are developed (Abzari et al., 2011). A next step in the knowledge transfer is packaging and dispatching of knowledge in such a way as to enhance the receiver's potential to act (von Krogh et al., 2001). The last step is the adaption, in which transferred knowledge is integrated with the local knowledge of the recipient (von Krogh et al., 2001).

Different authors, like Muller and Pénin (2006) describe the utilization of knowledge as disclosure of knowledge assets in different networks. In these networks these firms accomplish an open knowledge disclosure strategy, which may help them to generate

partnerships for research and development (Muller and Pénin, 2006). For the same reason, it can improve firms' position on the market and may facilitate to have access to external sources of knowledge more easily (Muller and Pénin, 2006). Senapathi (2011) describes four functions of knowledge dissemination, which are spreading, choosing, exchanging, and implementation of knowledge to accomplish a proper utilization of knowledge. The author describes also that firstly the firms have to determine existing valuable knowledge, experts, communities of practice, and other valuable intellectual assets, that exist within the firm (Senapathi, 2011). Once this is done, the better these assets can be leveraged, disclosed, and utilized (Senapathi, 2011).

Another approach describes knowledge utilization by strategies of knowledge brokerage (Verona et al., 2006; Nair et al., 2012). Knowledge brokerage is made possible by the effective accumulation of external resources in the firm (Nair et al., 2012). The more exposed and open the firm is to ideas generated in the environment, the more it enriches the flow of ideas into the firm (Nair et al., 2012). Verona et al. (2006) describe firms as virtual knowledge brokers, who leverage the internet to support third parties innovation activities. They connect, recombine and transfer knowledge to firms in order to facilitate innovations, hereby they often be close to their customers to provide specific innovation solutions (Verona et al., 2006). For example in markets for creative services, design consultancies have been characterized as knowledge brokers (Abecassis-Moedas et al., 2012). As a result of their access to a broad range of industries, knowledge brokers hold a broader range of ideas than firms working in only one or a few industries (Hargadon, 1998). Additionally, their flexibility in linking past knowledge with the situations of current projects support firms in knowledge utilization (Hargadon, 1998).

Another term is used by Antonelli (2006), Anton and Yao (2004) and Massey et al. (2001). They emphasize the exploitation of knowledge as form of proper utilization of the resource. It can take a variety of forms, from firms using it to produce a new product to firms selling it as a product (Antonelli, 2006). Knowledge exploitation means enhancing the intellectual capital of a firm with existing knowledge (Massey et al., 2001; Anton and Yao, 2004). Main business process, like product development or customer relationship management are highly knowledge intensive and a firm's long term success depends on this exploitation of knowledge across the business processes (Massey et al., 2001). Anton and Yao (2004) describe, that it can be risky for firms exploiting innovation, because it requires some disclosure of knowledge to the public, which makes imitation easier.

Another important approach is made by Lichtenthaler (2005), Wamae (2009) and Chen et al. (2010), which describe the process of knowledge commercialization. Firms commercialize knowledge assets by turn it into sales, licensing, joint ventures, strategic alliances, mergers, new business entities, donations, internal use, divestment of company units or even informal trades and leakages (Lichtenthaler, 2005; Chen et al., 2010). In general these firms trading information products (Chen et al., 2010) and by the ability to translate it into socio-economic solutions, they commercialize knowledge (Wamae, 2009). Thereby a firm's knowledge assets are transmitted to another independent organization involving a contractual obligation for compensation in monetary or non-monetary terms (Lichtenthaler, 2005). Chen et al. (2010) even emphasize that every firm is capable of creating business opportunities from knowledge-commercialized business models. Knowledge commercialization is influenced by the process through which innovative capabilities are produced within firm-based activities (Wamae, 2009). Here research and development specific capabilities and also non-research and development specific capabilities are involved in the commercialization of knowledge (Wamae, 2009). Major challenges in commercializing knowledge are the identification of knowledge customers, their absorptive capacity, intellectual property rights, adequate compensation for the knowledge transfer, assessing the value of intellectual assets, the nature of knowledge and the dynamic nature of demand (Lichtenthaler, 2005; Wamae, 2009).

Often knowledge utilization means to outsource specific knowledge assets. Mudambi and Tallman (2010) define it as outsourcing of firm activities that directly involve the production of knowledge and innovation, and that involve some degree of firm-specific capabilities. The authors outline this process as a make-or-ally decision, which firms have to make for the governance of the protection and leverage of their strategic knowledge assets (Mudambi and Tallman, 2010). Here licensing, franchising and joint ventures are alternatives modes for knowledge utilization (Tarn and Chien-Chih, 2012). These processes are highly tacit business activities with large investments in human capital (Mudambi and Tallman, 2010). They also demand intensive knowledge interactions and the forming of knowledge synergies within networks (Tarn and Chien-Chih, 2012). The outsourcing of knowledge requires the availability of a skilled and motivated talent pool, highly functional technology infrastructure, compatible culture and communication systems (Mudambi and Tallman, 2010). Therefore adaptations, like in corporate culture,

working procedures, and techniques have to be made to outsource knowledge to a perceiving party (Tarn and Chien-Chih, 2012).

Another form of knowledge utilization may be seen as knowledge marketing, which is a good specific form of marketing (Rode, 2001). The marketing of knowledge is clearly distinct to the marketing of industrial goods, because of the specific characteristics of knowledge goods (Rode, 2001). In result, the marketing of these knowledge products and services is a highly challenging task for knowledge intensive firms, especial because of the imperfections of knowledge markets and the disproportionately risk of opportunistic behavior of participants in these markets (Rode, 2001; Lichtenthaler, 2005). For the successful performance of knowledge marketing different resources need to be available in the participating firms: knowledge, experiences, talents, infrastructure, customer, reputation, business relations, alumni, financial capital, and sponsors (Rode, 2001). In knowledge marketing the primary asset is the firm's knowledge base for the commercialization of knowledge (Lichtenthaler, 2005).

Sedaghati (2012) describes knowledge utilization as mobilization, which comprises of specific processes by which knowledge is shared and transferred within organizations. More specific is Landry et al. (2012) describing the utilization as mobile exchange of knowledge of firms with their clients. This exchange consists of tacit and explicit knowledge, even when it is newly created knowledge (Landry et al., 2012).

One possible way of describing knowledge utilization is, that it integrates different knowledge methods, like generation, verification, transformation, reception, organizational learning, culture routines and innovation (Lado and Zhang, 1998). The firm's capability of integrating and transforming knowledge into dynamic core competencies may be an important sustainable competitive advantage (Lado and Zhang, 1998). Also Zhang et al. (2009) describe knowledge utilization in terms of the extent to which a firm uses knowledge from various sources, such as suppliers, customers, competitors, outside research organizations, and consultants, in its product development. They see even knowledge utilization in general as an important predictor of benefits of developing highly and moderately innovative products (Zhang et al., 2009). Here knowledge utilization is described by Zhang et al. (2009) as mediator between product development strategy and product innovation performance.

In general, the knowledge production is a collective process and here knowledge is understood as a collective good, transferred through complex interactions among the

members of communities or networks (Muller and Pénin, 2006). Other authors, like Backer (1993) or Consoli and Elche-Hortelano (2010) define knowledge utilization as possibility to use knowledge to solve human problems. Here Backer (1993) describes different principles for knowledge utilization which require resources for individual and organizational change. The author further mentions different strategically tasks for knowledge utilization, like interpersonal contact, planning and conceptional foresight, outside consultation, user-oriented transformation, individual and organizational championship, and potential user involvement (Backer, 1993).

4.2 *Processes and Success Factors of Knowledge Utilization*

Today in firms the utilization of knowledge and so the transfer of the knowledge often occurs in an ad hoc manner, through advice or daily exchange between collocated employees (Becker and Gassmann, 2006). An organizational setting in which such transfer, exchange or utilization should take place is difficult to establish (d'Aspremont and Bhattacharya, 2000). Therefore different processes and factors are important to recognize. In the following paragraphs these processes and factors for the success of knowledge utilization, emphasized by the literature are summarized.

One of the first processes of the utilization of knowledge is the identification of the knowledge assets a firm possesses or needs, their possible knowledge clients and the knowledge product or service these clients need (Teece, 1998; von Krogh et al., 2001). This identification is also a prerequisite for the implementation of all different other processes of knowledge utilization, like the governance process of knowledge. Furthermore the identification process plays a major role, because of the imperfections of the knowledge markets (Lichtenthaler, 2005). Firms and clients may find adequate partners more easily by the signals of these partners, which are prepared for knowledge transfer (von Krogh et al., 2001).

Some of the main processes for knowledge utilization described by authors are coordination and governance processes of knowledge assets in firms. The heterogeneity of knowledge and participants who possess knowledge require coordination in order for firms to succeed (Antonelli, 2006). Here the governance of knowledge includes coordinated transactions, quasi-hierarchies and constructed interactions (Antonelli, 2006). These governance structures are essential because they influence the disclosure of knowledge (Moon, 2011). In result, firms need to arrange a specific set of economic and

social interactions for the governance of knowledge (Patrucco, 2005). In general the coordination and governance of knowledge is dominated by different factors, like identifying the right knowledge and the intended application (Hicks et al., 2002), finding knowledge providers and recipients, evaluating knowledge assets, trading risks, trading difficulties, low reproduction costs, and determining the knowledge value (Chen et al., 2010). Chen et al. (2010) describe the knowledge value chain as helpful for coordination of different activities in knowledge utilization. Here electronic knowledge repositories are enabling employees to leverage and reuse existing knowledge, share knowledge with others and stimulate the development of new knowledge and ideas (Lin and Fan, 2011).

The approach that relationships are essential for the utilization is described by an external growth by means of takeovers, mergers and acquisitions, which is for internalizing essential knowledge (Antonelli, 2006). A firm by itself seldom has the complete set of resources required to commercialize its knowledge stocks effectively, because new knowledge usually emerges from beyond a firm's boundary (Lin and Wu, 2010). Therefore Lin and Wu (2010) describe that strategic alliances and acquisitions are providing the firms with channels to access externally created knowledge or resources. Partnering with other firms within one industry can provide these important new sources of experiences (von Krogh et al., 2001). Especially industrial firms develop strategies to build stronger networks for knowledge creation and transfer (Mudambi et al., 2009). External and internal knowledge sourcing strategies show different effects on short-term and long-term financial performance (Lin and Wu, 2010). In general, physical proximity encourages the establishment of trustworthy relationships (Mital et al., 2010). Firms need to pay attention to cultural and organizational context, in which their employees and customers are encouraged to develop and share their knowledge (Clarke and Rollo, 2001). Therefore to develop an organizational culture, that reflects the willingness of members to seek out others' disparate knowledge and to share their own is crucial (Hargadon, 1998; Thite, 2004).

An effective knowledge system involves an effective knowledge transfer (Mudambi et al., 2009) and the firm needs to be able to identify experts on recurring problems (Lee and van den Steen, 2010). Lado and Zhang (1998) describe this as experts systems, which facilitate the development and utilization of organizational knowledge. A shared vocabulary and terminology, the initiation of community of practice and the identification of knowledge gaps are crucial prerequisites of these knowledge systems (von Krogh et al.,

2001). In these networks, firms can operate as either knowledge markets or knowledge communities (Garavelli et al., 2004). Garavelli et al. (2004) argument, when firms operate as knowledge markets, the main actors are single specialists, who act as nodes of competencies organized in networks. These nodes of competencies are optimizing knowledge flow processes and avoid unnecessary knowledge flow (Zhuge and Guo, 2007). Hereby the networks can be either collaborative or competitive (Garavelli et al., 2004). Garavelli et al. (2004) additionally explain, when firms are organized as knowledge communities, knowledge emerges through the organization actions. The objective of these communities is to connect people in various forums (Mital et al., 2010). The creation of these knowledge communities support to leveraging existing intellectual capital, to share best practice, for data mining to build customer relationships, and generally to create knowledge networks (Clarke and Rollo, 2001).

The existence of social networks and social ties enhanced by group dynamics, knowledge activists, knowledge sharing culture (Ramanigopal, 2013), environment of mutual respect and trust, a shared purpose, a shared context, and managerial belief (Moitra and Kumar, 2007) are characteristics of knowledge networks. In general, the electronic connectivity today provides a new imperative to manage knowledge better (Clarke and Rollo, 2001). For example these information technologies help firms to leverage scarce expertise (Coff et al., 2006). Here electronic marketplaces as interactive business communities providing a central market space, where multiple buyers and suppliers can engage in e-commerce and commercially exploit their knowledge assets (Kafentzis et al., 2004). This interconnection of relevant knowledge producers can combine internal knowledge of a firm and external pieces of knowledge (Patrucco, 2005). The interconnections need to be socially embedded in an explicit environment, where geographical proximity favors trust, and confidence (Patrucco, 2005). The value of these networks depends on the amount of active participants in them (Clarke and Rollo, 2001). One benefit of this connectivity is the increasing efficiency of the seller, when he interacts and integrates the technological knowledge disclosure of buyers (Bönte and Wiethaus, 2007). But it also bears the risk of benefitting one's rival (Bönte and Wiethaus, 2007).

Different other synonyms are used for knowledge networks, like community of practice, discussion forums, user-populated knowledge bases, or the intranet as virtual workspace (Ramanigopal, 2013). They all have one objective to connect people to reduce capital and operating costs, increasing utilization and improving the firm's market

positioning (Ramanigopal, 2013). Teigland and Wasko (2003) explain that the implementation of intranet-based communication tools, such as electronic discussion networks promoting knowledge sharing. Firms with an interactive communication strategy (Weiss et al., 2008) can enhance their knowledge base.

Knowledge products and services should always be presented in an organized manner, user friendly, easy to navigate, easy to communicate, in a customized and personalized form (Desouza and Awazu, 2004). For the very reason, that the intangibility of knowledge and the imperfections of knowledge markets (Lichtenthaler, 2005) make it difficult for customers to find the appropriate products and services. Additionally, clear policies and rules in the market eliminating associated risks of potential customers (Kafentzis et al., 2004). Today many processes are on-line to accomplish specific tasks and support the knowledge marketplace (Kafentzis et al., 2004). In these virtual knowledge markets hardware and software is necessary to run this market (Kafentzis et al., 2004). A virtual knowledge market enables the participants or virtual roles to effectively capture, publish, share, present and manage knowledge resources (Zhuge and Guo, 2007).

The activation of knowledge providers to transfer their knowledge is based on the trade in knowledge market (Jeong et al., 2013). The trade can be former describe by a person-to-document exchange, a person-to-person exchange or both (Desouza and Awazu, 2004). In general, knowledge based assets can generate economic rents (Lado and Zhang, 1998). Furthermore, firm's willingness to pay for information may result from having information to develop innovative services and products, and to discover cost savings or other advantages in the supply chain (Lumsden and Mirzabeiki, 2008). Rewards, the knowledge sharing culture, and knowledge exchange technologies positively affect the trade in knowledge market (Jeong et al., 2013). In contrast, firms need to make a trade-off decision between realizing monetary and strategic potential of external knowledge exploitation, on one hand, and protecting a firm's knowledge base, on the other hand (Lichtenthaler, 2005). In internal knowledge markets, knowledge can be traded autonomously and the price of knowledge is flexible (Jeong et al., 2013). In external markets the value of knowledge is different for every potential customer (Shapiro and Varian, 1998) and for people providing that (Zhuge and Guo, 2007).

In contrast, knowledge may also provide increasing returns as it is used and shared (Lado and Zhang, 1998; Clarke and Rollo, 2001; Massey et al., 2001). The returns from

knowledge assets are governed by the law of economics like other goods, for example that investments in additional units of knowledge results in a much higher return (Goh, 2005). Additionally, other economic issues of trading knowledge need to be considered by firms, like transaction costs, agency costs, networking, and communication costs (Antonelli, 2006), because knowledge transactions are much more complex than transactions on the markets for most products and services (Lichtenthaler, 2005). Furthermore, extremely high production costs of either form of knowledge exists (Shapiro and Varian, 1998; Chen et al., 2010), but here information products offer vast economies of scale, the more a firm produces, the lower the average cost of production (Shapiro and Varian, 1998). In contrast low replication costs and distribution possibilities, which diminish the value quickly, and the security topics are influencing the knowledge trade (Chen et al., 2010). Especially when knowledge is tacit, transaction costs and agency costs in the knowledge market are very high (Antonelli, 2006).

Knowledge assets are often difficult to copy, but still knowledge leakage through individual's actions participating in information trading has enhanced the importance of intellectual property rights (Teigland and Wasko, 2003). The market for knowledge is distinguished by the extent to which patents and copyrights can be enforced (Antonelli, 2006). In general, the strengthening of intellectual property regimes, more active intellectual property management, has led to a growth of knowledge awareness (Lichtenthaler, 2005). The extent of disclosure and protection chosen by an innovator provides also an important indicator for the quality of their knowledge products (Anton and Yao, 2004). Codified knowledge can be protected by patents, copyrights, trademarks, trade secrets and other intellectual properties (Chen et al., 2010; Senapathi, 2011). It is depending on the value of the intellectual property and the enforceability of protection (Mets et al., 2007), which form should be accomplished. A valuable patent is shared with others by selling licenses, like exclusive, non-exclusive, or semi-exclusive licenses (Mets et al., 2007). Additionally, intellectual property rights to protect commercializable knowledge may act as incentive to produce knowledge (Moon, 2011). The interaction between property rights, disclosure and the imitation decision is the key to managing intellectual property (Anton and Yao, 2004; Kafentzis et al., 2004). Here license fee contracts result in knowledge sharing agreements across firms (d'Aspremont and Bhattacharya, 2000). The choice of an organizational form for protecting knowledge

needs to be aligned with the firm's knowledge assets, not depending on firm size or experiences (Leiponen, 2006).

In **Error! Reference source not found.** a summarized process sequence is illustrated. The different main processes of the utilization of knowledge are closely interconnected and put in an adequate order to implement.

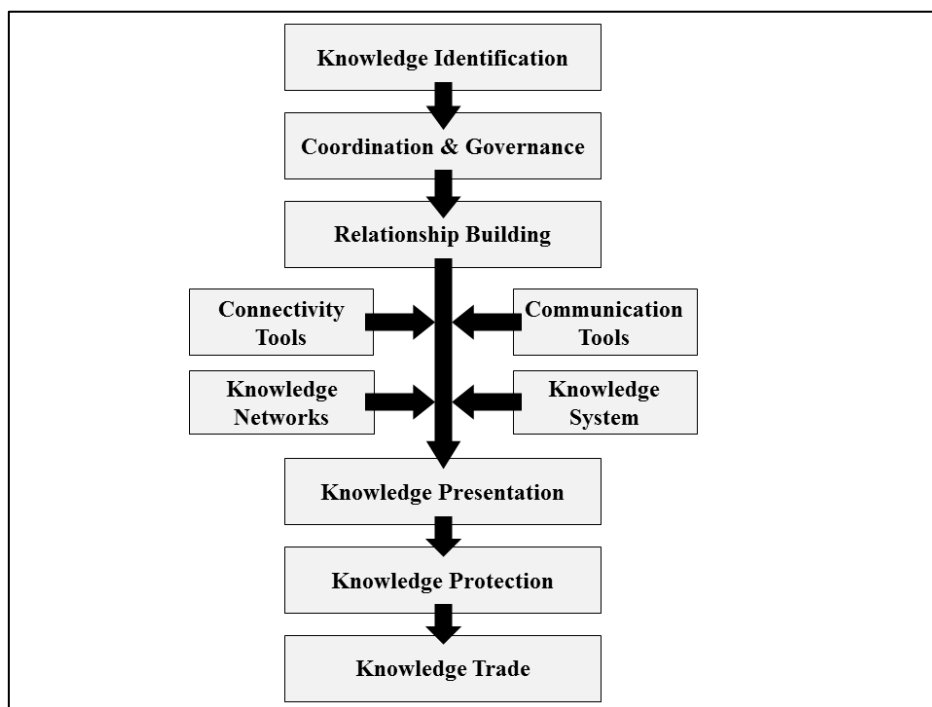

Figure 3: Processes of Knowledge Utilization

In the following paragraphs some of the main factors, highlighted in the selected articles will be described. For example, the knowledge providers' reputation increases the value of knowledge for buyers (Weiss et al., 2008). Therefore often trades in these specialized markets have the goal to change status or reputation of the provider (Zhuge and Guo, 2007). Here the high level of uncertainty regarding quality of knowledge products, allows firms with a brand name and reputation to charge a premium for their confidence (Greenstein and Markovich, 2012). Additionally, firms may increase their reputation by disclosing knowledge, which indicates to other organizations that they are competent (Muller and Pénin, 2006). A good reputation also assists in the development of trust (Rodger, 2012). As a result behaviors of open knowledge disclosure may be

motivated by reputation concerns (Muller and Pénin, 2006). Acquiring a reputation as an innovator may facilitate firms' access to financing, may make it easier to get contracts, grants and subsidies, or hire the best researchers (Muller and Pénin, 2006). Not only reputation, also trust and reciprocity play major roles in knowledge transactions (Antonelli, 2006; Rodger, 2012; Mital et al., 2010). In networks or open sources often the rating of knowledge objects are used by participants to gauge their perception on its quality (Desouza and Awazu, 2003). Additionally, a validating of knowledge providers increases the confidence and trust of buyers (Desouza and Awazu, 2003; Kafentzis et al., 2004). These trust building mechanism, like the rating system will contribute positively to the development of knowledge markets (Desouza and Awazu, 2003). The experience of customers with knowledge provider, their behavioral data, their professional status, and word of mouth determine the judgments of knowledge value by the customer (Weiss et al., 2008).

Within firms employees can be rewarded for what they know (Desouza and Awazu, 2004), the expectation of gaining appreciation, recognition, and reputation are benefits of knowledge disclosure (Zhuge and Guo, 2007). By being rewarded for sharing information and helping others, employees learn to cooperate (Hargadon, 1998). In return, incentives or rewards are important stimuli for information disclosure (Zhao et al., 2012). The organizational rewards are extrinsic motivators (Kankanhalli et al., 2005), which could be redeemed for cash (Moitra and Kumar, 2007). Additionally, knowledge providers can be motivated by intrinsic motivators, like enhancing their knowledge self-efficacy or confidence (Kankanhalli et al., 2005).

A further important factor for the utilization of knowledge is described by different authors as the focus of solving problems of customers. Here firms leveraging their intellectual capital and package it into high value-added knowledge based products and differentiated services which are capable of solving customer problems (Chen et al., 2010). Task specific information, which are collected from the firm's customers are especially relevant for problem-solving services (Verona et al., 2006; Consoli and Elche-Hortelano, 2010). The focus of the problem-solving capability is on the interactions between customers and firms. It is a knowledge based process, which consequently requires flexibly customize services and products to respond to customer feedback (Massey et al., 2001). With technological tools of customer relationship management, like customer interaction systems, integrated channel management, analytical tools (Massey et

al., 2001), the development of customized services and products is supported and the ability of firms to expand their knowledge is maintained (Verona et al., 2006). The key benefits by doing so are described by Massey et al. (2001) and Baviera-Puig et al. (2012) as leveraging organizational knowledge in customer relationship process, improvement in problem-solving processes, individualize interactions with customers, improvements of customer satisfaction through collaborative learning, and facilitation of cross-functional coordination.

One additional factor of right utilization of knowledge is the capability of firms to absorb knowledge or to innovate from their knowledge assets (Chen et al., 2010). The decisions relating to knowledge innovations are ultimately based on three main factors: who (people), what (knowledge assets) and why (business objectives) (Goh, 2005). Innovation is usually perceived as a group of activities involving interaction and knowledge exchanges between people and organizations (Muller and Pénin, 2006). Here the absorptive capacity embodied in people is the key element for the organizational integration of external knowledge (Spithoven and Teirlinck, 2010). Especially the function or skills of the firm's employees become a qualitative aspect of the absorptive capacity (Spithoven and Teirlinck, 2010). Teigland and Wasko (2003) explain the absorptive capacity as combining existing internal knowledge with novel external knowledge to develop creative solutions and improve performance.

In **Error! Reference source not found.** a summarized illustration of the important factor for the utilization of knowledge is shown. The different factors are supporting the knowledge intensive firm by successfully utilize their knowledge assets.

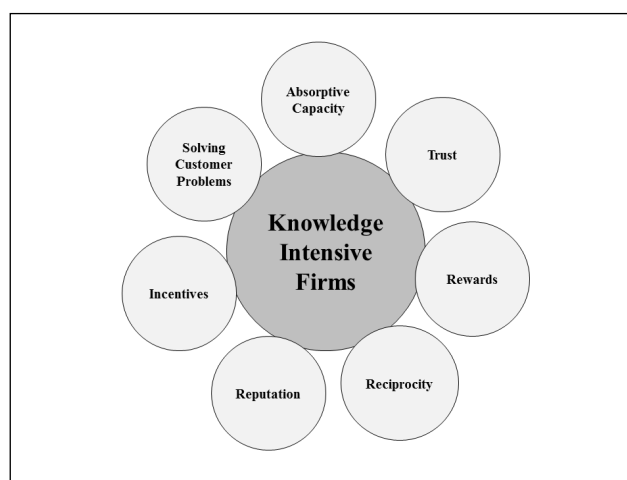

Figure 4: Factors of Knowledge Utilization in Knowledge Intensive Firms

5 Discussion of the State-of-the-Art of Knowledge Utilization

The analysis of the state-of-the-art in knowledge utilization has shown that much research in this interesting topic has been done. Therefore the authors already limited the selection of articles in the beginning by only use double-blind reviewed articles for the state-of-the-art. The number of articles used for the analysis was sixty-six. These articles have shown that a definition of knowledge utilization is difficult to make, because a lot of different concepts were used for this kind of knowledge activity. The authors have counted twenty-two different concepts for knowledge utilization (**Error! Reference source not found.**). One reason for this may have been also the acknowledged positive trend of research in this topic. Furthermore, many different processes and factors for adequate knowledge utilization could be found in the articles. Here a holistic view on these processes and factors could not be found, so the interrelations between different processes and factors and the success of all or just one factor which may be important for knowledge intensive firms could not be analyzed.

In the analysis of the processes researched in the selected literature the focus was on two dimensions, the participants and the knowledge markets. The following **Error! Reference source not found.** shows the allocation of the two different forms of participants in the knowledge utilization process, individuals and organizations. Additionally, the applied form of knowledge market, internal or external is presented in the second dimension of the **Error! Reference source not found.**. It can be recognized, that most of the scientific research is done on both external and internal knowledge markets with the focus on organizations. It can be further identified in the **Error! Reference source not found.** that the external knowledge market with the focus on either organizations or both organizations and individuals is mainly the field of interests of most of the scientists in the research topic of knowledge utilization. On the other hand, until now it is less focused on the individuals as participants in the knowledge utilization process on external, internal or both forms of knowledge.

Table 3: Participants and Place of Knowledge Utilization Processes

Participants \ Knowledge Market	Individual	Organization	Both
	Internal	0	12
External	4	22	2
Both	0	14	4

In **Error! Reference source not found.** the authors integrated a third dimension, the form of knowledge (tacit or explicit), to clarify further the focus of interests in the state-of-the-art in the literature in knowledge utilization. As the authors mentioned before, also in this illustration a focus on organizations can be recognized and the form of knowledge is less acknowledged from an individual perspective.

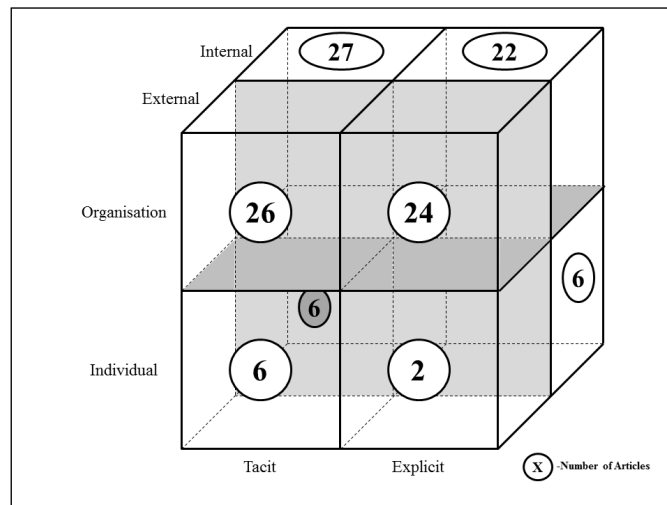

Figure 5: Number of published Articles in different Dimensions (Participants, Knowledge Market & Form of Knowledge)

By considering the success factors of knowledge utilization, Clarke and Rollo (2001) describe that organizations with large customer bases, like bank or insurance companies have possibilities to enhance the use of available knowledge assets. Because of improved data mining and exchange between different functions and managers of the firm, they may develop customer relationships and maintain further business opportunities with

existing customers (Clarke and Rollo, 2001). But furthermore the authors could not find many articles, which described exactly practical implications from the very contingent theoretical research. The analysis on the methods of research used in the articles showed a clear emphasis on theoretical articles. But a trend to more empirical research activities could be recognized in **Error! Reference source not found.**, for example the selected articles of von Krogh et al. (2001), Consoli and Elche-Hortelano (2010), Landry et al. (2012) or Nair et al. (2012).

Different methods are described in the literature of knowledge utilization to overcome the imperfections of knowledge markets. For example, Bakos and Brynjolfsson (1999) describe a method called bundling, where unrelated information goods can be surprisingly profitable (Bakos and Brynjolfsson, 1999). Very similar is another method, which is called versioning. It is described by the provision of quality-differentiated versions of services (Shapiro and Varian, 1998; Bhargava and Choudhary, 2004; Greenstein and Markovich, 2012). A further method is signaling, where firms signal their competences to academic and industrial communities (Antonelli, 2006; Muller and Pénin, 2006; Chen et al., 2010). The knowledge requesters in these communities are enabled to search for the required knowledge, when firms use signaling (Chen et al., 2010). All these methods are focused on the perspective of the clients and their identification of the adequate knowledge service or product. Methods on how organizations can identify the right client or the right knowledge provider for business activities are less mentioned in the literature by now. For example Goh (2005) describes that knowledge innovation in products can be realized by structuring and mapping knowledge, developing knowledge databases, embedding knowledge in new products and services. Here a clear process on how to identify the knowledge a firm needs is still missing.

Furthermore, the internal knowledge markets of firms provide an ideal platform to integrate technological and social aspects of knowledge management (Desouza and Awazu, 2003). The “social exchange theory” describes the motivation of participants in the knowledge market to share their knowledge, for example the expectation of reciprocity (Kankanhalli et al., 2005; Rodger, 2012). But a social dimension in knowledge utilization with the focus on the individual participants is not being researched sufficiently yet.

Only a few authors have focused on the right evaluation of the value of knowledge services and products. Prices of knowledge products across different quality conditions

and different competitive conditions are significantly different (Christen and Sarvary, 2007). The knowledge seller can use multiple methods of pricing: time taken to create it, fixed fees or retainers for their expertise, pricing of bundles, or a commission-based method (Desouza and Awazu, 2004). It is still difficult for firms and clients to evaluate the knowledge products and services, which are presented in knowledge markets. Authors have well described different forms of knowledge networks to build relationships and share knowledge. For example, Senapathi (2011) separates two different groups for dissemination of knowledge: for tacit knowledge, tools are for example communities of practice, chat rooms, online forums, knowledge networks, video conferencing. For the dissemination of explicit knowledge the intranet, knowledge repositories, best practice database, knowledge maps, blogs, or wikis are used (Senapathi, 2011). Additionally, Mudambi et al. (2009) describe three generic structures of communities, the crew, the séance and the guru structures, which give a good idea of how the firm can organize their knowledge systems.

In general, the intention to disclose information is influenced by perceived costs and perceived benefits (Zhao et al., 2012). Different authors describe many different motivational and exhibiting factors of knowledge utilization (Kankanhalli et al., 2005; Rodger, 2012; Jeong et al., 2013). Mitton et al. (2007) additionally describe different barriers of a knowledge transfer, like the lack of experience and capacity, mutual mistrust, negative attitude towards exchange, an unsupportive culture, a poor choice of messenger, information overload, or a limited time for decisions. Furthermore, barriers for knowledge leveraging are physical distances, language barriers, cultural diversity and other social-political factors (Moitra and Kumar, 2007). Here again a social dimension in knowledge management strategies, like in knowledge utilization should be included to manage socialization (Moitra and Kumar, 2007).

6 Conclusion and Future Implications

The state-of-the-art of knowledge utilization is giving a summarized overview how to act as a firm or client in knowledge intensive environments. Here the concept of knowledge management, knowledge disclosure and knowledge utilization by itself, have been widely used by the selected authors of the state-of-the-art. Additionally, the processes and factors of knowledge utilization support firms to commercialize their outcomes in knowledge intensive industries. Main success factors of knowledge

utilization, described by the literature are: absorptive capacity, solving customer problems, reputation, rewards and incentives, trust, and reciprocity. The analysis of the literature has further shown that the knowledge market and its participants are well described and knowledge goods are more and more in the focus of industries today.

For research implications, a further analysis of the knowledge market imperfections and other characteristics need to be done in the future to reduce the uncertainties of participants in these markets. Furthermore, the different concepts of knowledge utilization give the impression, that a clear, homogeneous understanding of knowledge utilization is not achieved in the topic of research yet. The state-of-the-art evaluation has also shown a focus on the organizational perspective. The individual perspective needs to be further researched. Finally, a holistic view on knowledge utilization processes and factors could only be found in a few research articles. Therefore a holistic research model on the different knowledge utilization processes and factors, for example as an external knowledge marketing model, needs to be further designed. This goes in line with Baviera-Puig et al. (2012) saying that the development of more efficient marketing strategies for technology centers is an interesting topic for future research.

For further practical implications, many different interesting contributions can be found in this literature review. For example, the possibility for firms to enhance their outputs as qualitative services providers by employing the different processes and concentrate on the factors of knowledge utilization. Additionally, in the market for knowledge many uncertainties and risks may occur. Here firms and clients in knowledge intensive industries may enhance their benefits, when the value of knowledge goods is clearer, trusted relationships between the participants are present and systems of quality measurements are implemented. Furthermore, the practical importance of knowledge systems and networks to enhance the firm's knowledge capital is described. Firms should follow an open source strategy to motivate employees, clients and other firms to share their knowledge.

Structured Abstract

Purpose – Our study uses insights from theories of creativity and knowledge-intensive firms to conduct analysis on how creativity and innovation emerge in consultancy firms and on which organizational responses are given to the quest for organizational survival in unsettled times. We focus on the essential elements that promote the raise of new organizational areas in which new knowledge is created. A focus on these aspects is particularly interesting since consultancy firms, extreme examples of knowledge intense organization, are in danger of disruption. They are facing a fierce crisis and must focus on some sort of evolution based on creativity.

Design/methodology/approach– We adopt a qualitative research design. We interviewed 60 people inside international consultancy firms, including consultants, managers and partners based in the Italian context. The qualitative adopted approach is particularly suitable for studying socially grounded phenomena such as the one of consultancy firms as organizations made of individuals. Our approach is one of theory-elaboration. For the semi-structured interviews we used personal contacts, snowball sampling and random requests to maximize the variance in the sample. We let the interviewees describe their views about their role, tasks, relationships and approaches to work and change, following a storytelling approach.

Originality/value – There are repeated calls for empirical studies that could improve the body of theoretical work on creativity and innovation. Much prior research focused on the relation between creativity, innovation and organizational knowledge structure. Missing is a focus on the generative elements of creativity and innovation as the basis for creating new forms of knowledge.

We study creativity and innovation in management consultancy firms from an internal perspective seen as consultancy members involved in creating new management

consulting knowledge. In these unsettled times, we demonstrate that the push for creativity and innovation favors management consulting firms being models for an increasingly knowledge-based economy.

Practical implications– Our analysis is particularly needed since knowledge intensive organizations are, now more the before, rethinking their way of doing business in order to remain viable in an environment questing for sophisticated and customized consulting services. Given that “the pace of change being managed by the traditional clients of consulting firms will continue to accelerate, with devastating effects on providers that don’t keep up” (Christensen, Wang, and van Bever, 2013: 4), we focus on members involved in the creation of new knowledge structures, since external relations have already been studied.

Keywords –creativity, innovation, knowledge intensive firm, consultancy, disruption.

Paper type – Academic Research Paper

1 Introduction

Economic globalization, technological advancements, changes in customers’ needs and preferences and the progressive primacy of knowledge as a catalyst for business service industries are some of the elements pushing economy and society to be extreme examples of a Knowledge Economy and Society (Grant, 1996; Dean and Kretschmer, 2007; Martin-de Castro et al., 2011; Martin-de Castro, Lopez-Saez and Delgado-Verde, 2011).

New competitive arenas are raising characterized by new dynamics of competition (Johnson et al., 2002; Diaz-Diaz et al., 2008) where knowledge assets are acquiring increasingly importance when companies face competitors since they recognize that knowledge, new forms of knowledge and business innovation are key factors in sustaining and improving competitive advantages (Galende, 2006).

Moreover, the company’s capability to be innovative and successful depends very closely on the knowledge assets that it holds (Subramanian and Youndt, 2005) and on how it uses them.

Companies must be able to invent new ways to survive in a changing environment, viewing the innovation process as the output of a knowledge intensive business process of management (Nonaka and Takeuchi, 1995).

Our study uses insights from theories of creativity and knowledge-intensive firms to conduct analysis of how innovation and creativity emerges in consultancy firms and

which are the essential elements that promote the raise of new organizational areas (i.e., new knowledge structures or areas of expertise) in which new knowledge is created.

A focus on these aspects is particularly interesting because consultancy firms, described in recent literature as extreme examples of knowledge intense organization, are in danger of disruption.

Since they are facing a fierce crisis that needs to be dealt with, instead of disruption companies must focus on some sort of evolution based on creativity and innovation.

Our paper draws upon a qualitative study of 60 people employed in international consultancy firms based in Italy to elaborate theory on which organizational responses are given to the quest for organizational survival in unsettled times.

Literature recently called for conceptual and empirical research on studies about customized solutions for client firms as a way to maintain viability in such turbulent environment, and our qualitative analysis meets this request.

As a matter of fact our analysis is relevant for a number of reasons.

First, in the literature on creativity there can be found repeated calls for empirical studies that could improve the body of theoretical work.

Second, much prior research has been focused on the relation between creativity and organizational structure. However, missing is a focus on the generative and common elements of creativity as the basis for creating new forms of knowledge. Our analysis provides new and useful insights in the field on management consulting firms and their organizational settings.

Third, prior literature on management consultancy has mainly focused on client-consultant relations and emphasizes analysis and assessment of the external management consultancy function. In fact, as Galende and De la Fuente (2003) pointed out, many authors focused on creativity and innovation from an external perspective while leaving understudied the internal complex dynamic that characterizes the generation of new innovative areas of expertise (i.e., new knowledge structures).

Our approach is to study creativity and innovation in management consultancy firms from an internal perspective seen as consultancy members involved in creating new management consulting knowledge and developing advices to the organization they belong to. This is particularly evident in our analysis of the interviewees' decisions and behavior toward a change in the business model.

Finally, our findings have important implications for understanding the role of creativity in these unsettled times. Our research demonstrates that the “squeeze” of creativity favors management consulting firms being models for an increasingly knowledge-based economy.

2 Research Context: Management Consultancy Firms

Our research context is one where the core product is knowledge: the management consulting industry (Sarvary, 1999).

Management consultancy firms are knowledge intensive firms where “despite their increasing influence little is known about the work of management consultants” (Fincham and Clark, 2002: 1).

“We are understanding that the same forces and processes that destroyed so many businesses are definitely reshaping our consultancy world. We face competitors with new business models almost every day... and also our clients face the same situation...”

In this scenario we must start to rethink our service models and even to experiment new ones... otherwise disruption, also for us, is just a matter of time. We do not want to be too late in the game” (A senior-level manager).

The current unsettled times impose a deep reflection on creativity as a means to cope with various issues associated to the economic crisis.

In the last years consultants and managers rejected the idea of disruption in their industry claiming that their services could never be commoditized and in sourced inside the client firm (Christensen, Wang, and van Bever, 2013).

“We are trying to understand if our business models and therefore the services we provide our clients are changing at the same speed of our demanding clients...”

We must try to find a way to attract new clients...” (A manager).

Clients’ needs are becoming more sophisticated and this process leads them to reduce reliance on consultancy firms as “solution shop providers” firm (Christensen, Wang, and van Bever, 2013). This business model is at risk of being disrupted by others such as value-added process business and facilitated network firm (Christensen, Wang, and van Bever, 2013) and by the fact that the client firm, focusing on service costs and quality, is abandoning the paradigm that high price is a proxy for quality.

In the second quote an interviewed manager explains that it is necessary to find new ways to attract clients and therefore to obtain economic resources to survive. Nowadays clients are exigent and are facing a very strong economic crisis, which imposes them to carefully evaluate whether they really need consultancy services.

There is an increasing academic interest in the management consulting industry (Sarvary, 1999; Fincham and Clark, 2002) and how consulting firms are organized as part of a wider focus on professional services and knowledge intensive firms (Alvesson, 1995; Von Nordenflycht, 2010).

Consulting firms are the embodiment of knowledge-based organizations because their main assets are the expertise and competence of their employees (Engwall and Kipping, 2002).

Creativity in knowledge-based organizations is particularly challenging given the ambiguous nature of knowledge itself. Most recent research views knowledge-based creativity as emerging from ongoing work that is then embodied in organizational structure (Dougherty, 2004).

However, little is still known on creativity in knowledge-intensive firms and its generative elements' relation with organizational structure as a way to generate new forms of knowledge.

Our theoretical interest is to provide a more complete description of how new knowledge-based structures come out, enabling the consulting firm to be creative and to develop innovation.

The above state of the consultancy industry and the literature motivates this inductive study that draws upon interviews with 60 people among consultants, managers and partners in the most important international consulting firms based in Italy and seeks to elaborate theory on how organizations respond to unsettled times.

Because of their ground-breaking role in knowledge management and the widespread industry adoption of knowledge management, the analysis of international consulting industry suits particularly well as a context for our study.

The literature on creativity calls for empirical studies given the lack of verification in the field compared to the wide body of theoretical work (Woodman et al., 1993; George, 2007). Since innovation (as the result of creativity) impact on organizational structure, it is necessary to step back. Many interviewed managers recognized that to be creative an organization should hold some basic common elements in order to be able to create new

areas of knowledge (i.e., new structures or areas of expertise) that could translate in innovation. There is a complex change process governing how nowadays consulting firms try to be creative, building new knowledge-based structures (Langley, 1999; Peterson, 1998; Schulz, 2003). This must be addressed by researchers.

In the last years management consulting constantly transformed due to the fashions of management ideas and techniques. But nowadays change is also driven by other factors. The client companies are increasing their activist role in selecting and managing the resources assigned to their projects. “They have moved more and more work in-house, such as average cost analysis, an exercise that one racked up billable hours” (Christensen, Wang, and van Bever, 2013: 2).

We focus on how creativity and innovation emerge in consultancy firms in terms of internal employees involved in creating new knowledge structures. This analysis is particularly needed since these organizations are, now more the before, rethinking their way of doing business in order to remain viable in an environment questing for sophisticated and customized consulting services.

The management consultancy literature is divided between the external approach which studies the relationship between client and external consultancy functions (Alvesson, Karreman, Sturdy and Handley, 2009; Appelbaum and Steed, 2005; Fincham, 1999; Sturdy et al., 2009) and the internal perspective which studies staff members as designated to share and use new management consultancy knowledge and develop advices to the organization they belong to.

We provide useful contributions on this second approach since it is lacking empirical and theoretical attention from researchers (Sturdy, Wylie and Wright, 2012).

Given that “the pace of change being managed by the traditional clients of consulting firms will continue to accelerate, with devastating effects on providers that don’t keep up” (Christensen, Wang, and van Bever, 2013: 4), we focus on members involved in the creation of new knowledge structures, since external relations have already been studied.

2 Theoretical Background

2.1 Studying the process of new knowledge creation

Knowledge management is the key issue for consultancy companies since their product is knowledge.

“As a firm, and as individuals, we are driven to be the best, to develop unrivaled knowledge and to convey that knowledge to every client, at every time”

(www.mckinsey.com).

Therefore, how are these mission statements practically developed into reality? Is knowledge management embedded in companies? Are companies using the benefits of internal knowledge assets to be creative and innovative in order to survive in unsettled times?

Innovation is an ambiguous term, especially in the case of innovation with the consultancy industry. Different authors use different definitions of innovation.

Researchers have difficulties when defining innovation (Garcia and Callantone, 2002) and this is due to the large variety of meanings available. Following Van den Bosch et al.(2005), inspired by the work of James March, we use the definition of exploration and exploitation as a basis to define innovation.

In fact, “exploration includes activities such as search, experimentation, discovery and innovation, while exploitation involves imitation refining and adapting existing knowledge” (Van den Bosch et al., 2005, p. 26).

Our study explores how creativity and innovation emerges in consulting firms in terms of structures (i.e., areas of expertise) in which new knowledge arises. These structures are “areas”, e.g., sub-units or areas of expertise, within a firm and consultants are given to these units according to some common facets of their proficiency (Kubr, 2002).

In answering the question of how creativity emerges in knowledge intensive firms we further theorize about which are the common generative elements a sub-unit or area of expertise must have to be addressed as a new knowledge-based structure.

By evidencing the basic generative elements of these areas we study how they are combined in sequence and the overall effect of such process on the organization.

This work is embedded in two distinct theoretical traditions.

The first one has viewed organizational creativity and innovation as a multifaceted concept, studied from various perspectives and disciplines. This is due, for example, to the fact that there are many other themes (knowledge management, innovation, learning, etc.) under which similar topics have been studied (Styhre and Sundgren, 2005).

Innovation is considered as compulsory for the company’s survival in dynamic market environments (Nonaka and Kenney, 1991, Forrester, 2000, Cardinal, 2001).

In literature there can be found different definitions of innovation. For example there are some authors that stress the novelty of an idea (e.g. Barnett, 1953; Becker and Whisler, 1967; Aregger,1976). We read in Barnett (1953) that “an innovation is . . . any thought, behavior or thing that is new because it is qualitatively different from existing form” (p. 7). Other authors focus on the subjective recognition of novelty (Rogers, 1983; Zaltman et al., 1984), the first introduction of the novelty (e.g. Schmookler, 1966; Knight, 1967; Kieser, 1969; Vedin,1980), and the new combination of needs and solutions (Pfeiffer and Staudt, 1975; Moore and Tushman, 1982; Rickards, 1985).

The economic world we live in is pushing Partners (e.g., CEOs of the consultancy companies) to guide their organizations with creativity since the importance of innovations has increased dramatically.

Creativity and innovation in knowledge based firms is becoming a real challenge since managerial novelty must come from some kind of combination and integration of different knowledge components. Managers must not only adapt old business schemes (that entail some forms of knowledge) to the existing turbulent environment (Kikoski and Kikoski, 2004), but also need to be creative in defining new knowledge structures (i.e., new business practice areas).

Research on creativity has been booming, yet it is usually defined as the capacity to generate novel ideas, processes, products or solutions (Amabile, 1996).

The study of how creativity emerges is particularly challenging in knowledge-based organizations given that knowledge inheres people, processes and systems (Anand, Gardner and Morris, 2007).

Different approaches challenged these ambiguous knowledge elements. One view stressed the importance of individuals' expertise in creating policies for recruitment and retention of talented people (Starbuck, 1992). Another perspective focused on how social processes determine the degree of usefulness associated to knowledge within organizational contexts (Alvesson, 2004). A third approach studied organizational systems such as codification routines in order to embed innovative forms of expertise (Morris and Empson, 1998; Werr and Stjernberg, 2003; Anand, Gardner and Morris, 2007). Hidden in all these views is that knowledge-based creativity (and innovation) emerges from ongoing work and is then embodied in organizational structure (Dougherty, 2004).

However, far less attention has been paid to the field of creativity in consultancy firms and its relation with organizational structure in the process of generating new forms of knowledge.

In the last years there wasn't a common agreed universal definition of management consultancy, partly because of its essential contestability or its changing over time (Clark and Fincham, 2002).

More recently, Von Nordenflycht (2010) contributed to this line of enquiry attempting to provide a theory and taxonomy of consulting firms as knowledge intensive firms.

Successful innovative outputs come from the managing of internal power relations within the firm. For example, partners are owner-managers that participate in the business as key workers, helped by other employees (lower level managers and junior professionals). They are responsible for the company's overall management and for organizing groups of professionals (who have a specific form of proficiency) into recognizable areas of expertise (Greenwood et al., 1990).

Literature recognizes that partners have a desire for autonomy (Hall, 1968) and for getting control over the client firm and this could lead to dispersion of power and influence within the consultancy firm.

Knowledge based creativity and innovation, in defining new forms of knowledge, could be affected by this careful use of power and influence.

Knowledge intensive firms "commodify" knowledge since they always try to get new clients and expand their scale of activities. In order to remain viable, partners and new promoted partners must develop also reputation through which they could be able to attract new clients and set up junior professionals to perform this work (Gilson and Mnookin, 1989; Maister, 1993; Sherer, 1995). Beyond this, consultancy companies have the need to diversify, in order to prevent possible contraction in their clients' markets, and to invent new ways to exploit the firm's resources (Hitt et al., 2001).

The second theoretical tradition, that of consulting firms as epitomes of knowledge-based organizations, has mainly focused on knowledge related to the expertise and competence of the people employed (Engwall and Kipping, 2002), internal power relations (Greenwood, Hinings and Brown, 1990; Heusinkveld and Benders, 2005) and organic growth and diversification (Suddaby and Greenwood, 2001; Galanter and Palay, 1991; Hitt et al., 2001).

Widespread academic recognition has been given to knowledge as a key source of competitive advantage (Grant, 1997). The increasing importance of knowledge, as a resource to the firm possessing valuable, rare, inimitable and non-substitutable characteristics (Polanyi, 1966; Hall and Sapsed, 2005), in our contemporary society imposes a shift in how consultancy companies think about innovation.

In this context, it is, therefore, imperative to study how consultancy firms create new knowledge and, more importantly, how they transfer new knowledge.

Innovation can be the answer to such a research question in terms of processes in which the organization creates and defines new knowledge structures addressing emerging problems.

Now more than before, and especially in the consulting industry, firms compete on knowledge resources rather than the ownership of lands and capitals (Dunford, 2000).

A large amount of literature, taking the knowledge-based view of the firm (Grant, 1996; Teece et al., 1997; Van den Bosch et al., 2005; Leiponen, 2006), develops the idea that a firm must be capable to learn and to adapt to its changing environment and this is conceived of as an essential condition for its survival.

Kim and Lee (2006) stressed the importance of knowledge in the process of development of a collective knowledge management system that, while generating learning, develops creativity and innovation.

A main difficulty in researching knowledge innovation within the consultancy industry resides in the fact that this kind of innovation is not related to something tangible. New knowledge could come, for example, from a co-production or co-creation process with the client (Van de Aa and Elfring, 2002).

Far more attention is needed to understand how consultancy firms continually create new knowledge-based structures in order to be creative and survive in changing environments.

Therefore the question of how creativity and innovation arise and which are the generative elements of a new knowledge structure is very important in the run for survival.

This dearth of literature on the process of new knowledge creation in consulting firms offers us with a unique opportunity to elaborate theory on how knowledge intensive organizations squeeze creativity in unsettled times.

3 Methodology

3.1 Sample and data collection

This research is explorative because there is limited research on informal knowledge sharing and creation within the consultancy sector.

We adopt a qualitative research design and mainly base our work on semi-structured interviews. In total there were 60 interviews with 60 people inside international consultancy firms, including consultants, managers and partners based in the Italian context.

We define a consultancy firm as a firm that calls itself a consultancy firm, and also a firm which delivers consultancy on the market.

Our initial focus was on studying partners and managers as the leading individuals that drive creativity. Our initial set of interviews, however, revealed that creativity challenges everyone inside the firm.

Following an inductive approach and drawing upon emerging insights from our initial interviews, we refined our questions and started focusing on the concepts of creativity and innovation more narrowly on all the main levels existing in consultancy firms, e.g. partners, managers and junior level consultants.

This narrow focus was also prompted by the dearth of literature on the topic that was raised by the research team during their process of going back and forth between theory and the data (Strauss and Corbin, 1998).

A qualitative research approach was adopted since it is particularly suitable for studying socially grounded phenomena such as the one of consultancy firms as organizations made of individuals, as it allows researchers to elaborate meanings from the actors' perspective.

The approach adopted in this study is one of theory-elaboration. In contrast to a purely deductive approach that tests theory or a purely inductive approach that builds a new theory, a theory-elaboration approach “contrasts pre-existing understandings with observed events in order to understand extant theory” (Greenwood and Suddaby, 2006: 31).

For the semi-structured interviews we used personal contacts, snowball sampling and random requests to maximize the variance in the sample. In all interviews we followed the same semi-structured outline.

People interviewed worked in strategy consultancy, operational consultancy, tax and legal consultancy and financial services consultancy. The information was analyzed and the main quotes regarding knowledge creation and innovation were collected and compared.

Our idea was to let the interviewees describe their views about their role, tasks, relationships and approaches to work and change, following a storytelling approach. Our main concern was to allow them to interpret the questions freely and to deepen the themes they regarded as particularly important.

The interviews were conducted at the interviewees' workplaces and generally lasted between one hour up to three hours and were tape recorded with the approval of the interviewees and transcribed verbatim so as to have 'real time' data, avoiding the recall bias that may occur when participants are asked to comment upon issues retrospectively (Van de Ven and Poole, 1995).

In addition to the interviews that took place with the people inside the companies, meetings have been planned with specialists in the field of consultancy and innovation. Our aim is to get their point of view and practical suggestions.

4 Findings and Discussion. The elements of a new knowledge structure.

In our exploratory analysis we iterated between insights from the existing literature on Knowledge-based innovation and those emerging from our in-depth analysis of interview data.

We found that *four generative elements* are distinctive for a knowledge structure.

4.1 Individual Commitment

"We are a company that develops if people develop and believe in the company"
(A Partner).

Everyone inside consultancy companies tends to align his or her career's progression with the firm's growth. Consultancy companies are organizations in which people develop competencies and knowledge while trying to progress in their career.

During this journey, as long as people's career progresses together with the company's growth and success, people are more driven to develop entrepreneurial skills on behalf of the firm and want to improve their professional socialization, as a way to express initiative towards the company's success.

The individual-personal element leads to the desire to reach the top level of management (for lower level managers and consultants) thanks to professional socialization and entrepreneurial skills' development as a fundamental element constituting a knowledge structure.

The *first dimension* of this individual commitment element relates to people's need to create their *status* as an essential element for gaining access to the better client-projects assignments and for getting more autonomy. People believe it is important to build and show a leadership style in order to be directly related to what they are known for.

The *second dimension* is the person's *determination* to fulfill what is requested by top managers in order to be promoted.

The *third dimension* refers to the partner's role in *supporting and enabling* the building of an area of expertise.

4.2 Differentiation

As long as consultants want to progress in their career, they need to support the building of new organizational knowledge areas. Therefore, it is fundamental that they define their particular expertise and differentiate it in order to define new professional knowledge that can lead the firm into an innovative domain of activity.

The *first dimension* related to this second element is related to the *improvisation* sometime consultants perform when they are asked to solve novel or divergent client's demands. Consultants use existing knowledge but try to improve it modifying processes, methodologies during their work.

The *second dimension* concerns *how the new knowledge is applied* to the client's assignments. One respondent said that "when you are forced to invent something new, than it can happen that also your way of reasoning, thinking and solving problems can change and be re-shaped".

The *third dimension* relates to *uniqueness of knowledge* embedded in the new area of expertise newly created. People that work inside that new knowledge structure should develop their own professional identity different from the one of other areas. It is necessary to point out that they are strongly influenced by the hallmark practice of the company.

4.3 Setting of the boundary

People that created and developed the new knowledge structure must be able to induce others to believe in the relevance of the new area of expertise as a sort of knowledge territory with its own boundaries with the main aim to exploit this new territory to address the client market.

The *first dimension* of this third element is related to the need to *avoid others' "resistance to things which challenge their view of the world"* (A Partner).

The *second dimension* is related to the *power of clients* in helping founders (of the new area) to justify the recognition of the new knowledge structure created. As long as the new area of expertise is successful in terms of client's assignment the founders will be justified in continuing on this knowledge territory.

The *third dimension* is related to the *internal support of client gatekeepers* since it helps the new practice to expand beyond the founders' narrow client base.

4.4 Organizational culture

A new area of knowledge is generate when there is a supportive organizational culture, i.e. everyone inside the company share the idea that creativity and innovation are the basis for long lasting success.

A *first dimension* of the fourth element refers to the *training of people*. In fact is has been noted that is important to work with a variety of partners in the course of a person's career since they face different modes of problem solving.

A *second dimension* is related to the degree of "*sponsorship*" that partners of other areas do in order to introduce and support the new area of knowledge with possible clients.

5 Conclusion and Future Research

"We must be aware that we need to reshape our way of doing business consultancy.

The world is changed. I will never face disruption, as someone may call it, because I will push myself, and the ones that work with me, to have 'the idea' that will boost our portfolio of projects" (A senior-level manager).

Our objective was to define how new knowledge structures rise in consultancy companies (i.e., generative basic elements of a new knowledge area).

A knowledge structure can be defined as an area of expertise (with its own borders - i.e., a separated business area) formed by communities of professionals that contribute to the firm's organizational structure. Project teams, instead, are temporary assemblies of consultants whose main aim is to complete a single assessment for a client and after that the team dissolves.

Our findings on new knowledge structure creation want to shed light on the poorly understood process of knowledge-based creativity and innovation that is very critical to today's firms.

Management consulting firms are extreme examples of knowledge-intensive firms (Alvesson, 2004) in which innovation must be addressed in order to survive in turbulent times.

We have built our work on these literatures to understand the process of knowledge-based creativity and innovation.

We have studied creativity and innovation in management consultancy firms from an internal perspective seen as consultancy members involved in creating new management consulting knowledge and developing advices to the organization they belong to, toward a change in the business model (Engwall and Kipping, 2002).

Our findings have important implications for understanding the role of creativity in these unsettled times (Sturdy et al., 2012).

Our research demonstrates that the "squeeze" of creativity favors management consulting firms being models for an increasingly knowledge-based economy.

We are aware that the insights we draw came from a study set in the context of management consulting firms, but we suggest considering that these findings are interesting opportunities for future research on innovation in the knowledge economy.

We have described which are the four generative elements every firm must possess in order to be able to create a new knowledge structure (new area of expertise). These elements and their dimensions can be seen as means to build opportunities for reacting to turbulent times.

We have focused on individuals as the starting point for innovation within knowledge-based organizations. This could allow us to locate individuals' innovation initiative at the level at which it occurs.

We concentrated on the internal elements that determine creativity and innovation, without discounting exogenous forces entirely, but we believe that at our level of analysis

external forces tend to get filtered through the lens of those who are directly impacted by such forces.

Our work addressed the complexity of creativity and innovation within consultancy firms. We found that complexity resides in the fact that companies, in order to survive to changing environments, need to develop new forms of knowledge thanks to which they could be able to serve new or old clients and to remain viable overtime.

For the full development of innovative knowledge within the consultancy industry, management support is needed. This could be conceived of as the main the reason for the low attention given to innovation by consultancy firms.

Our work, also, addresses the importance of cultural elements as means that could stimulate and encourage creation of new knowledge.

Further research on knowledge-intensive firms could theorize about how such structures emerge (i.e., the dynamic underlying the new knowledge generation) and then get embedded in organizations.

A comparison across industry sectors could be interesting since it could confirm the existence of a typology of knowledge structures that rise in order to react to external negative triggers.

Future research should try to address how cultural aspects could be affected and driven by processes of knowledge sharing. A focus on other business cultures could be interesting as it allows researchers to compare and ultimately generalize the main findings.

More research is also needed regarding the role of the knowledge department in consultancy firms. A creative and innovative culture must be fostered in consultancy companies where people are allowed to get involved and to think about continuous organizational improvement.

Researchers could address leaders and their role in recruiting the appropriate people who will focus on innovation and new knowledge creation is needed. The focal point could be on the leader as a facilitator and as a person that can learn as well from others.

6 Practical Implications

People working inside consultancy companies should have the chance to work out new ideas. Management should support a culture in which creativity and innovation is

fostered. For example, in order to stimulate such process, companies could try to improve informal networking (e.g., lounge rooms or whiteboards in common rooms).

Also, firms should allow more time for people to elaborate new ideas that can generate new knowledge (regardless of the applicability in the field and regardless of the fact that a project might fail). This aspect could stimulate creativity in people working for this kind of companies since they will be paid for their time spent on thinking about how to create new solutions and new knowledge.

The above cited ways to improve new knowledge creation could strengthen the innovative culture of the company and could ensure a long-term competitive advantage.

Structured Abstract

Purpose – The paper studies the impacts of inter-organizational knowledge transfer on performance of a collaborative network. The study focuses on performance information and aims to reveal what motivates organizations to open and share their performance figures to network partners, what impacts they expect to attain and what have they reached with this in practice?

Design/methodology/approach – For the purpose of this study, a total of 16 managers of the partner companies were interviewed. Interviews were carried out in two phases. The first set of interviews was held in autumn 2010. The second interview study was carried out in 2012. The latter interviews focused on the long-term impacts of the provided performance information.

Originality/value – Contribution of the paper relates to two aspects. First, it provides empirical evidence about the impacts of inter-organizational knowledge transfer on network performance. Second, it brings more depth to the analysis of these impacts by combining the research fields of performance management and knowledge management.

Practical implications – The empirical examination revealed that inter-organizational knowledge transfer within the studied network has improved managers' awareness of shared targets and status of networked operations. Thus, the results encourage organizations to engage in network-level performance measurement and sharing of performance information to network partners.

Keywords – knowledge management, inter-organizational knowledge transfer, performance information

Paper type – Academic Research Paper

1 Introduction

The paper studies the impacts of inter-organizational knowledge transfer on performance of a collaborative network. Focus on inter-organizational knowledge transfer is a timely management issue because companies increasingly collaborate and share knowledge with an objective to meet customers' needs more efficiently and effectively (Bititci et al., 2012; van Wijk et al., 2008; Easterby-Smith et al., 2008; Phelps et al., 2012). The study focuses on performance information and aims to reveal what motivates organizations to open and share their performance figures to network partners, what impacts they expect to attain and what have they reached with this in practice?

In addition to inter-organizational knowledge transfer the paper relates closely to a timely issue of networked performance management, which has attained increasing attention especially in the area of service management (Ostrom et al., 2010; Bititci et al., 2012). In order to evaluate performance of service systems (Vargo et al., 2008; Spohrer et al., 2007), information is needed not only on performance of individual organizations but also about the ability of the system members to collaborate and provide value for customers (Grönroos and Helle, 2010; Tucker and Pitt, 2009; Spohrer et al., 2007; Lönnqvist and Laihonen, 2012; Laihonen et al., 2014). Here, empirical examination is conducted in a collaborative network, which is defined as advanced and demanding form of collaboration (Camarinha-Matos et al. 2009). It involves a joint process where the entities share information, resources, and responsibilities to plan, implement, and evaluate activities to achieve a common goal (Camarinha-Matos et al. 2009).

The literature on knowledge transfer has focused on factors impeding and stimulating transfer (e.g. Albino et al., 1999; Kumar and Ganesh, 2009; Laihonen, 2014; Riege, 2007) and the quantitative impacts of transfer (e.g. Boumarafi and Jabnoun, 2008; Tsai, 2001). The paper focuses on the performance impacts and aims to increase understanding also about the qualitative consequences of inter-organizational knowledge transfer (Figure 1). Despite the importance of qualitative understanding about the impacts of inter-organizational knowledge transfer, for example, when pondering whether or not to engage in inter-organizational knowledge sharing, this is a less studied area. The impacts are approached from three perspectives (Franco-Santos et al., 2012): 1) the impacts on people's behavior (e.g. participation and commitment of network partners), 2) the impacts on organizational capabilities (e.g. processes and activities that enable network to perform

better and gain competitive advantage), and 3) the impacts on performance (e.g. effects on financial and non-financial results at all levels of the network).

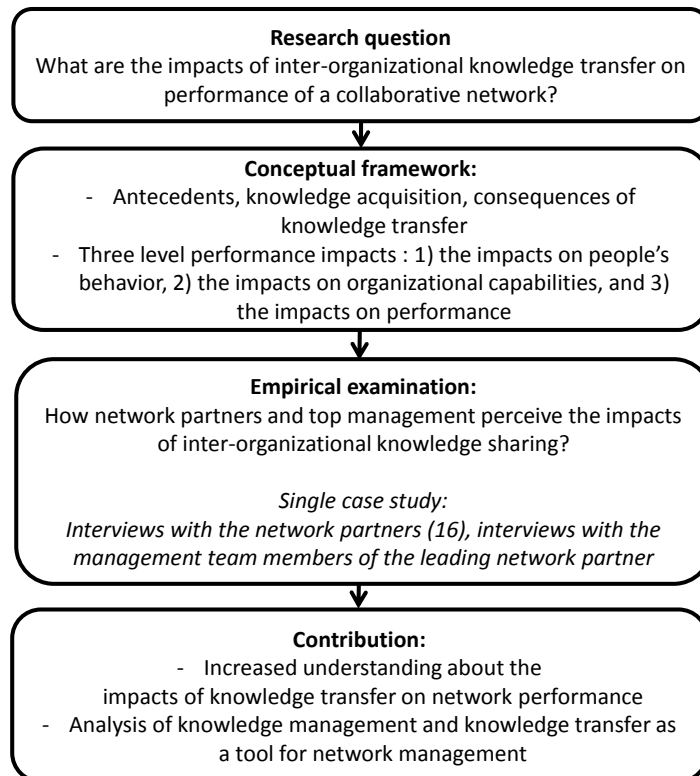

Figure 1. Research design.

The following sections of the paper are organized as follows. The next section reviews the literature on inter-organizational knowledge transfer and performance management. Based on the literature, the critical components of inter-organizational knowledge transfer and the resulting performance impacts are combined into a conceptual framework that forms basis for the empirical analysis. Section 3 describes the empirical research context and methods used. The results section maps the impacts of inter-organizational knowledge transfer at the various levels of the studied network. Analysis follows the empirical section. Finally, the concluding section summarizes the key findings of the paper and suggests directions for further research.

2 Theoretical framework

2.1 Inter-organizational knowledge transfer

Knowledge transfer has been one central research field of knowledge management ever since the early 1990's (e.g. Cohen and Levinthal, 1990; Grant, 1996; Szulanski; 1996). The increased complexity of modern business environments has further increased the importance of and interest in the phenomenon, not only within organizations but also between network partners (e.g. Easterby-Smith, 2008; Hutzschenreuter and Horstkotte, 2010; Inkpen and Tsang, 2005; Khamseh and Jolly, 2008; Martinkenaite, 2011; Phelps et al., 2012; van Wijk, 2008).

Knowledge transfer is defined as the transfer of knowledge from one unit to another (e.g. Cutler, 1989; Albino et al., 1999; Argote and Ingram, 2000; Bender and Fish, 2000; Kalling, 2003; Kumar and Ganesh, 2009). When analyzing knowledge transfer, it is important to understand: 1) who transfers knowledge to whom (actors), 2) what is transferred (content) and 3) in which context (context), and 4) which medium is the most suitable in a given context (media) (Albino et al., 1999; Laihonon, 2014). Inter-organizational knowledge transfer refers to a transmission process where knowledge is transferred across firm boundaries (Collins and Hitt, 2006; Meier, 2011).

Martinkenaite (2011) provides an integrative framework for analysing inter-organizational knowledge transfer. This framework is built on three dimensions: antecedents of transfer, knowledge acquisition and consequences of transfer (Figure 2).

Figure 2. Framework of inter-organizational knowledge transfer (Martinkenaite, 2011).

Martinkenaite (2011) defines antecedents of inter-organizational knowledge transfer as knowledge attributes, organizational attributes and inter-organizational dynamics. The literature has quite extensively studied the attributes of knowledge and considers tacitness, complexity, specificity and institutional embeddedness as key antecedents of

knowledge transfer in inter-organizational setting (Martinkenaite, 2011). It is well-known that tacit knowledge is more challenging to transfer than explicit knowledge (e.g., von Hippel, 1994; Simonin, 1999; Argote and Ingram, 2000). The ambiguousness of knowledge also hampers the transfer (e.g. Zander and Kogut, 1995; Szulanski, 1996, 2000; Simonin, 2004; Coff et al., 2006; van Wijk, 2008). In addition, the value of transferred information matters – the more valuable the information, the more interested the receiver is (Gupta and Govindarajan, 2000).

By organizational attributes Martinkenaite (2011) refers to categories recognized by Easterby-Smith et al. (2008): absorptive capacity, motivation to teach and learn, and intra-organizational transfer capability. Absorptive capacity (Cohen and Levinthal, 1990) of the recipient is defined by its prior knowledge, trust and cultural compatibility among partners, adaptability of the recipient and the amount and quality of communication (Lane et al., 2001). The roles of openness or willingness to share knowledge, trust and previous knowledge correlate positively with knowledge transfer (e.g. Cohen and Levinthal, 1990; Dodgson, 1993; Wathne et al., 1996). Steensma et al. (2005) show that the more willing the donor firm, the greater the opportunity of the receiver to internalize knowledge. A shared context (i.e. similarities in organizational culture, values, and technical skills) expedites the transfer by reducing the ambiguity (Albino et al., 1999). Inter-organizational dynamics concerns also power issues, trust and risk, social ties and structures of inter-organizational relationships (Easterby-Smith et al., 2008).

As the consequences, or performance implications, Martinkenaite (2011) recognizes financial performance, product/market performance, and strategic performance. In this approach learning is seen as a mediator of performance. Author sees knowledge transfer as a two-stage process that involves acquisition of new knowledge and exploitation of that knowledge. Logic behind this is that transfer does not create performance. Instead, knowledge acquisition, that is, “the extent, type and nature of the new knowledge learned” (Martinkenaite, 2011, p. 55), mediates the performance results. Finally, it is important to acknowledge that performance is defined against the strategic objectives of an organization and that any knowledge management initiative, like knowledge transfer, needs to support organization’s business strategy (Hansen et al., 1999; Zack, 1999).

2.2 Three perspectives to performance impacts

From a knowledge-based viewpoint, performance information forms a basis for performance management (cf. Bititci et al., 2007). Management needs up-to-date and accurate information in order to guide organization towards its targets and proactively respond to challenges posed by the environment (Nudurupati et al., 2011). This information enables monitoring performance, identifying weak areas, enhancing employee motivation, improving communications and strengthening accountability (Waggoner et al., 1999; Simons, 2000). Furthermore, an ideal performance management system provides information about strategic uncertainties (Simons, 1994) and external phenomena, such as changes in market situation and customer behavior. It has been noted by several authors that performance measurement combines the views of internal efficiency and external effectiveness (Keegan et al., 1989; Kaydos, 1999; Neely et al., 1995).

Performance measurement system is “a set of indicators used to quantify the efficiency or effectiveness of purposeful actions” (Neely et al., 1995, p. 80). Franco-Santos et al. (2012) emphasize that performance measurement system plays a key role in strategy, communication and management processes and generating organizational capabilities that enable organization to succeed. An important aspect has been noted by de Waal (2004) who stresses the integration of performance measurement information to daily managerial activities. Here, performance information facilitates development, implementation, and review of business strategies by focusing people’s decisions and actions on strategic goals and by encouraging a continuous dialogue about strategy endeavors (Franco-Santos et al., 2012).

Nudurupati et al. (2011) discuss on performance information behavior, which they define as “people’s behavior with performance information”. The literature underlines that in order to foster performance-driven thinking and behavior, management needs to be trained to interpret and analyze measurement results, define action plans and monitor the results of actions (Neely et al., 1995; de Waal, 2004). Specific and clear performance measures and targets are associated with reduced confusion about strategic direction leading to better goal commitment, behavior and performance (Webb, 2004). Franco-Santos et al. (2012) have categorized consequences of performance measurement into three categories: 1) consequences on people’s behaviour, 2) consequences on organisational capabilities, and 3) consequences on performance (Figure 3).

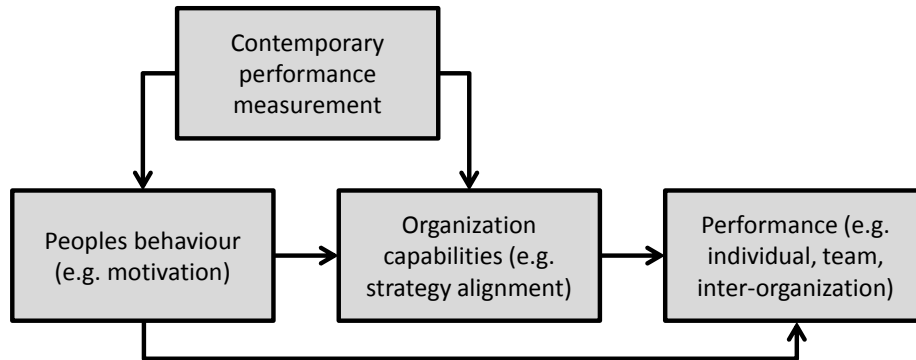

Figure 3. Consequences of performance measurement (modified from Franco-Santos et al., 2012).

According to Franco-Santos et al. (2012) consequences on *people's behaviour* refer to the actions or reactions of employees to measurement (e.g. motivation, participation) and their underlying cognitive mechanism (e.g. perceptions). Authors' results show that performance measurement facilitates development, implementation, and review of business strategies by focusing peoples' decisions and actions on strategic goals and by encouraging a continuous dialogue about strategic endeavours.

Impacts on *organisational capabilities* refer to consequences associated with specific processes, activities, or competences that enable the organisation to perform and gain competitive advantage (e.g. strategic alignment or organisational learning) (Franco-Santos et al., 2012). Franco-Santos et al. (2012) found a strong agreement on the impact of performance information on organizational communication processes, organizational routines and management practices. This is supported by the results of Papalexandris et al. (2004) who highlight the beneficial effects of measurement systems on communication processes at all levels of the organization.

Impacts on *performance* comprise the effects that performance measurement systems have on financial and non-financial results at various levels of the organisation (e.g. firm performance, managerial performance, or team performance). Franco-Santos et al. (2012) classified these performance impacts into two groups: reported performance and perceived performance. Reported performance includes both financial (e.g., accounting performance, market performance) and non-financial performance (e.g., customer satisfaction).

2.2 Conceptual framework

Knowledge management literature considers fairly extensively antecedents of knowledge transfer and issues related to knowledge acquisition. On the other hand, performance management puts a lot emphasis on design, implementation and use of performance measures (Bourne et al., 2000) and gathering performance information (Waggoner et al., 1999) but has left the underlying knowledge processes with fairly modest attention (Nudurupati et al., 2011). By combining the viewpoints of these disciplines it is possible to better understand how performance measurement systems, performance information, learning, and performance relate to each other's.

By combining the frameworks of Martinkenaite (2011) and Franco-Santos et al., (2012) we end up to a conceptual framework presented in Figure 4. In the framework, the performance measurement system is considered as the antecedent of inter-organizational knowledge transfer. The framework recognizes three aspects where performance impacts of inter-organizational knowledge transfer can be detected: peoples' behavior, organizational capabilities, and reported or perceived performance. It also pinpoints that measurement system and provision of performance information do not tell directly what to do and how to improve performance. Instead, those enable learning, which enables performance improvement. If performance improves, it implicitly indicates that the organization has learned and applied the information acquired. Hence, knowledge acquisition and learning are seen as mediators of network performance (cf. Martinkenaite, 2011).

Figure 4. Conceptual framework - impacts of inter-organizational transfer of performance information.

By following the framework presented in Figure 4, the empirical part of the paper studies how network partners and top management perceive the impacts of inter-organizational knowledge sharing in one particular network.

3 Methodology

The aim of the study is to examine what are the impacts of inter-organisational knowledge transfer on performance. The phenomenon was studied in a longitudinal research setting where the data was gathered from a single case network by interviewing network partners. The studied collaborative network (cf. Camarinha-Matos et al., 2009) consists of the main company manufacturing kitchen fitments and reselling firms selling these kitchens to consumers. The resellers are independent firms with a full responsibility for their own businesses. The case network has shared goals and strategies. Firms collaborate in advertising and training as well as provide some support services together. This collaboration is intense and systematic.

The starting point for this research was laid already in 2008, when one of the network partners surprisingly confronted financial problems. Losing a partner would be reflected to the whole network, because finding and educating a new partner would take time and money and is a long-term process. A special aspect of this particular partner related to its role as a trusted partner for its long ranging expertise and experience in the business. This raised a question: why this happened and how the situation could have been detected earlier?

Situation was carefully analyzed and network partners identified that there were two ground reasons for what happened: 1) they had problems in information flow between partners, and 2) they did not have any network-level performance information available, which could have helped in anticipating the situation. In this phase, the second author of this paper stepped in to the process of developing measurement practices. As the result of the analysis, it was considered that the existing measurement information provided only a fragmented picture about the performance of the whole network (e.g. incomes, profit marking and orders). It also focused primarily on the leading network partner and only some fragmented information was available about the other partners. Each partner evaluated their own performance in varying tools and methods.

As a response to the recognized problems, a network-level performance measurement system was designed and implemented in 2009. Purpose was to develop a system that would both provide new information about network-level performance and improve information flow between partners. The new network-level measurement system provides information on financial state of network (e.g. costs, incomes and profit margins), customers (e.g. number of customers and customer satisfaction) and network partners'

satisfaction (e.g. satisfaction with network operations, processes, marketing and products, and welfare and wellbeing). In addition, it offers estimations of future incomes. These key performance indicators (KPI) were derived from the network strategy and partners' competitive strengths. The measurement system was built on a basic idea that all network partners have access to the measurement data and can compare their own results to other partners and the network-level information. During the performance measurement system design process, IT system was developed to support information provision and transfer.

Within the above-described contextual setting, this particular paper studies what impacts have been attained by sharing network-level performance information among network partners. For the purpose of this study, a total of 16 managers of the partner companies were interviewed. Interviews were carried out in two phases. The first set of interviews was held in autumn 2010. At this phase the new measurement system was being used for one year. The interviews were semi-structured and focused on interviewees' perceptions on the measurement system and its utilization. They were also asked about the ability of the system to support network- and partner-level management and to describe both the negative and positive impacts of the use.

The second interview study was carried out in 2012. This time interviews focused on the long-term impacts of the provided performance information. The top management team (CEO, sales director, production directors and financial director), two sales managers and four representatives of reselling network were interviewed. All the interviews were conducted face-to-face except for second interview study four respondents from reselling network were interviewed by telephone. Each interview was audiotaped and transcribed verbatim.

The interview transcripts were carefully analyzed and the recognized impacts were categorized according to the framework of Franco-Santos et al. (2012). Thus, impacts were divided to the following categories: 1) the impacts on people's behavior (e.g. participation and commitment of network partners), 2) the impacts on organizational capabilities (e.g. processes and activities that enable network to perform better and gain competitive advantage), and 3) the impacts on performance (e.g. effects on financial and non-financial results at all levels of the network).

4 Results

4.1. *The impacts on people's behavior*

The findings reveal that the transfer of network-level performance information has increased interviewees' understanding about their own business and its success factors. An important feature of the measurement system is the possibility to compare one's own performance to network-level averages. This provides a baseline for analysing own information and helps to interpret, understand and learn from the results. This also encourages communication between partners and facilitates learning from the experiences of other network partners. The interviewees described the importance of a shared understanding and learning as follows:

“After comparing own company's performance to network performance I understood that my company is performing at the average level.” (Reseller, 2010)

“It is easier for them (network partners) to support and help others, when they have an understanding of the current state of operations in their own reselling unit and network averages.” (Sales manager, 2012)

The top-management interviewees considered in 2012 that network-level information transfer has promoted performance-driven culture and knowledge-based management in general. Performance information has had an important role both in the management of partner organisations as well as decision making at the network-level. The interviewed network partners found performance information useful for self-monitoring, learning and decision support and aligning their operations with the network strategy. Learning from the new performance information had increased their goal commitment. The network partners were more aware and involved with the shared objectives and were better able to evaluate their own performance in relation to network strategy.

The interviewees' perceptions were in 2012 that network-level performance information has increased the openness and transparency between the network partners. Moreover, this has led to an increase in cooperation and participation. In consequence, the

interviewed participants described that trust between the network partners has increased and hence affected positively to a network culture.

4.2. The impacts on organizational capabilities

To ensure the efficient utilization of performance information, some structures and processes are needed, because the new inter-organizational knowledge have to integrated into network routine. Based on the interview results, two enabling structures can be identified that have significantly promoted information use and network-level communication.

First, interviewees emphasized in both interview studies the usefulness of the new meeting practices. In a monthly meeting, managers of network partners gather together to discuss about the new performance information and try to interpret and learn from this information. With the network-level performance information it is possible to make decisions concerning the whole network and define development targets to improve overall performance. Another regular meeting, which has gained added value from the network-level performance information, is a meeting between the main company's sales manager and resellers. In these meetings, the focus is on a single network partner but with the new performance information it is now possible to compare performance of resellers and better evaluate reasons behind certain results as well as recognize the needed development activities. Meeting practices are tools for increasing trust, promoting commitment to network objectives and advancing inter-organizational knowledge transfer. The sales managers described benefits as follows:

“The new meeting practice and especially more in-depth and comparable information has increased trust and openness between the sales manager and resellers. This makes discussion and decision making more structured and open between the network partners.”(Sales manager, 2010)

New measures, more open discussion atmosphere and comparable information have also supported decision making, which is more straightforward when it is based on reliable information. This was emphasized in both interview studies:

“Before the decision making was based on the few informal measures and tacit knowledge, but now we have facts that we can use for managing the network. It is also easier to explain and justify why certain decisions are made.”(Reseller, 2012)

New performance measurement system has also supported and clarified the definition of network roles and responsibilities. The role of the main company has become more consultative. It is increasingly helping network partners with their open questions and challenges. This relates also to a changed role of the measurement system. It is now considered more as a learning and management tool than control mechanism. Management structures have enhanced the spread of knowledge and interaction among the network partners.

4.3. Performance

The empirical evidence shows that reported network-level financial performance (e.g. profit margin, incomes) has not significantly improved after systematical use of new performance measurement system and performance information. According to interviewees, the detected financial improvements were more as a consequence of changes in market environment.

However, network partners reported a notable improvement in financial figures. At the network-level, partners were able to reduce reclamation costs (30%) and marketing costs (15%). These improvements affected directly and positively to network's profit. The interviewees described causes for these changes as follows:

“I compared the reclamation costs to the network-level average and realized that my company suffers from high reclamation costs. After that I started to ask others (network partners) for advice and tips to reduce these costs.” (Reseller, 2010)

“When we (resellers) started actively to follow the reclamation cost, our understanding about the underlying problems increased. Shared discussion and new measurement information enabled a more focused development actions. We learned a lot and were able to reduce them.” (Reseller, 2010)

“I noticed that my firm uses quite a lot of extra for marketing (in addition to chain marketing) compared to other partners and the gained impacts on customer volume were unsubstantial.”(Reseller, 2010)

Furthermore, the results of network’s satisfaction survey in 2011 witnessed that network partners were more satisfied with communication and information transfer between partners than previously. This was further supported by the results of the interview study in 2012, which showed that the new measurement system and shared performance information have increased transparency of operations and enabled more focused development of network processes, like the development of joint service processes and shared marketing campaigns.

5 Analysis

Contribution of the paper relates to two aspects. First, it provides empirical evidence about the impacts of inter-organizational knowledge transfer on network performance. Second, it brings more depth to the analysis of these impacts by combining the research fields of performance management and knowledge management. Whereas the literature on knowledge management has focused predominantly on factors impeding and stimulating transfer (e.g. Kuman and Ganesh, 2009; Laihonon, 2014; Martinkenaite, 2011; Riege, 2007) and the quantitative impacts of transfer (e.g. Yang, 2007; Boumarafi and Jabnoun, 2008; Tsai, 2001) literature of performance measurement and management has mostly ignored the knowledge processes that are needed to transfer performance information between network partners.

The empirical examination revealed that inter-organizational knowledge transfer within the studied network has improved managers’ awareness of shared targets and status of networked operations. This has also led to improvements in both reported and perceived performance. Thus, the results encourage organizations to share their performance information to network partners. This finding cannot be generalized to all knowledge transfer situations but offers support to previous studies arguing that performance needs to be studied as a shared phenomenon, which necessitates and is enabled by inter-organizational knowledge transfer (cf. Bititci et al., 2012; Busi and

Bititci, 2006; Parung and Bititci, 2008; Kulmala and Lönnqvist, 2006; Laihonen et al., 2014; Pekkola and Rantanen, 2014).

The findings contribute to the literatures on inter-organizational knowledge transfer (van Wijk et al., 2008; Easterby-Smith et al., 2008; Phelps et al., 2012) as well as on network-level performance management (Kaplan et al., 2010; Yin et al., 2011; Bititci et al., 2012). The literature indicates that inter-organizational knowledge transfer and learning have firm-level performance impacts in case of strategic alliances (Jiang and Li, 2008; 2009; Meier, 2011). This study provides evidence on the impacts of knowledge transfer in a collaborative network and adds to the literature on strategic alliances (cf. Brouthers et al., 1995; Camarinha-Matos et al., 2009). The results support findings of Cousins et al. (2008) and Mahama (2006), who have found evidence that performance measurement enhances both financial and non-financial performance indirectly by improving cooperation and socialization (i.e., trust and commitment) within the network.

The paper also brings further the idea of systemic performance measurement (cf. Laihonen et al., 2014), which has argued that in a networked business environment, performance is determined by performance of individual organizations, ability of the network partners to co-operate and customer-perceived value or performance (cf. Lönnqvist and Laihonen, 2012). The empirical evidence suggests that transfer of performance information between network partners leads to shared learning and performance improvements at all levels of the system. Thereby, the results indicate that performance measurement system can act as a valuable antecedent for inter-organizational knowledge transfer as the conceptual framework hypothesized. Measurement system defines in a concrete form the joint purpose, objectives and a common language for network partners. Simultaneously, the provided performance information acts as a driver for inter-organizational learning and network performance (Easterby-Smith et al., 2008).

Based on the empirical findings it seems that performance measurement and derived performance information can have valuable roles as knowledge integrators and promoters of learning and thereby, together with users compose a social system that could significantly improve performance (cf. Bititci et al., 2012). This kind of joint learning and inter-organizational knowledge transfer also endorses the maturity of a network. It supports the development of network-level processes, practices and structures by

encouraging partners to share information, resources, and responsibilities to plan, implement, and evaluate activities to achieve a common goal (cf. Pekkola et al., 2013).

A managerial implication of the results seems to encourage organizations to pay more attention on individuals' mental models and attitudes towards performance measurement. Through them it is possible to build a performance driven and knowledge-based management culture, which would yield performance improvements not only on the short run but also in the long-term. It all comes back to a question: what do people do with the performance information? (cf. Nurudupati, 2011). Collaboration is a one way to create and sustain competitive advantage but it necessitates that all partners understand that the focus of network management needs be on the service provided, not on the individual organizations, otherwise the system will not optimize the customer's benefit. Yet, it is important to recognize the factors that will drive success of the network, and finally the network needs to be managed, otherwise, the intended objectives will not be achieved (cf. Yin et al., 2011; Bititci et al., 2012).

6 Conclusions

The paper studied the impacts of inter-organizational knowledge transfer on a performance of a collaborative network. The paper combined ideas from the knowledge management and performance management literatures and composed a conceptual framework that considered performance measurement system as an antecedent of inter-organizational knowledge transfer. The provided performance information was seen as an enabler of knowledge acquisition and learning between network partners. Knowledge acquisition and learning were considered as mediators of network performance.

In the empirical part of the paper, based on the conceptual framework, impacts of inter-organizational knowledge transfer were studied from three perspectives in a collaborative network. The results were encouraging. The empirical examination revealed that inter-organizational knowledge transfer within the studied network has improved managers' awareness of shared targets and status of networked operations. Thus, the results encourage organizations to engage in network-level performance measurement and sharing of performance information to network partners. These drive learning and performance improvement.

The paper provided new insights on the inter-organizational knowledge sharing and increased understanding about the phenomenon of network performance. Interesting themes for the future research would be to examine how the turbulent operating environment or maturity of the network affects inter-organizational knowledge transfer. The main limitation of the paper relates to having only one case network. On the other hand, it is also a key strength of the paper: a deep understanding about the studied network and access to previously untouched information provided a much-needed possibility to examine the research question in a unique case environment (cf. Yin, 2009).

Despite of its weaknesses, the paper lays a foundation for developing a knowledge-based and performance-oriented management culture in networks. Simultaneously it puts in evidence the central role of knowledge management in fostering the vitality of the network. Without proper information and understanding about the effectiveness of operations, efficiency of various partners and ways of organizing it is not possible to make informed decisions.

Structured Abstract

Purpose – Global economic integration, technological change, the rise of digital opportunities and a new and sophisticated demand for products and services are creating a multitude of new opportunities and business options for firms and organizations. Accordingly, they are increasingly challenged to develop more and more renewed strategic, management and knowledge models, approaches, tools and techniques to satisfy effectively customers and to improve performance and sustainability. Although these scenarios characterize all the economic activities, this is particularly true for some industries more involved to face these transformations: it is the case of the banking sector. In fact, in the last decade, in a regulatory framework changing and under an high competitive pressure, banking organizations are revisiting and expanding their traditional borders and modalities to do business, trying to re-think their internal structures and to integrate more effectively places and channels, new services, new technologies, customers' wants and cost-reduction needs.

The aim of the paper is then to examine the new strategic, management and knowledge models elaborated and adopted in the banking sector in the Italian context. The relationships among these models and the business performance of the main banking organizations are identified and analyzed. Five successful experiences related to the adoption of new strategic, management and knowledge models are introduced and discussed.

Design/methodology/approach - To support our arguments we adopt a multiple-case studies methodologies. We provide the case examples of Banca Fineco, Azimut, Banca Fideuram, Banca Mediolanum and Banca Generali which recently have effectively planned and implemented innovative strategies and models aimed to activate and support a sustainable growth of their business.

Originality/value - This paper contributes to further develop our comprehension about the importance to elaborate and implement new strategic, management and knowledge models in a very relevant business sector such as the banking one. The analysis of the case-examples shows in particular how some Italian banking organizations – often considered too small to compete in the capitals global competition – have been able to elaborate and successfully implement new mechanisms to guarantee performance and sustainable growth.

Practical implications – The paper provides implications for future research and useful insights for management. However, further and detailed case studies are called to improve understanding of the phenomena and the capacity to generalize insights and best practices.

Keywords – Strategic, management and knowledge models; Banking; Services; Italy

Paper type – Academic Research Paper

1. Introduction

Global economic integration, technological change, the rise of digital opportunities and a new and sophisticated demand for products and services are creating a multitude of new opportunities and business options for firms and organizations. Accordingly, they are increasingly challenged to develop more and more renewed strategic, management and knowledge models, approaches, tools and techniques to satisfy effectively customers and to improve performance and sustainability. Although these scenarios characterize all the economic activities, this is particularly true for some industries more involved to face these transformations: it is the case of the banking sector.

In the last decade, in a regulatory framework changing and under an high competitive pressure, banking organizations are revisiting and expanding their traditional borders and modalities to do business, trying to re-think their internal structures and to integrate more effectively places and channels, new services, new technologies, customers' wants and cost-reduction needs. In particular, great relevance is playing the technological innovation, and specifically the evolution and the adoption of the ICT as basic pre-condition for the banking operations. In fact, ICT do not involve only the administrative and control activities, but all the productive processes characterizing the banking players. In fact, ICT deeply changed from a passive tool aimed to reduce costs and deliver internal procedures to key innovative factor able to improve practices, generate new financial products and services till to create new markets.

The aim of the paper is then to examine the new strategic, management and knowledge models elaborated and adopted in the banking sector in the Italian context. The relationships among these models and the business performance of the main banking organizations are identified and analyzed. Finally, five successful experiences related to the adoption of new strategic, management and knowledge models are introduced and deeply discussed. Specifically, we provide the case examples of Banca Fineco, Azimut, Banca Fideuram, Banca Mediolanum and Banca Generali which recently have effectively planned and implemented innovative strategies and models aimed to activate and support a sustainable growth of their business. The analysis of the case-examples show in particular how some Italian banking organizations – often considered too small to compete in the capitals global competition – have been able to elaborate and successfully implement new mechanisms to guarantee performance and sustainable growth.

2. The banking sector in Italy: state-of-the-art and evolution

2.1 From traditional banks to innovative banking

In the last decades, in Italy, the traditional banks have been often unable to defend their market shares, remaining linked, also in a period of crisis, to passive and reactive attitudes and to strategic and operative behaviors not customer-centric. Accordingly, in the last years, a great debate at political and industrial level is emerging about the closing of banks' agencies and the cutting to the employees (Bracchi and Masciandaro, 2013; Forestieri and Mottura, 2009).

However, it is possible to state that the ways to answers to the new challenges and the level of performance and growth of the players of the banking sector have not been common (Bracchi and Masciandaro, 2013): in fact, different banks have understood on time the need to change radically their strategic value propositions and consequently their business models according to new knowledge and management practices. In particular, great relevance plays the capacity not only to read the market dynamics but mainly to understand the life, the wants and needs of the final customers and then to provide them solutions more and more tailor-made and thought and proposed according to a consultancy-driven approach, from wealth management to wealth planning and wealth advisory; from consultancy platforms and customer financial processes analysis to portfolio management, and so on.

In order to better analyze these macro-dynamics, an empirical research aimed to test the assumption that the achievement of good business performance is related to the elaboration and the adoption of new strategic, management and knowledge models has been designed and developed. In the next section, data and methods and the main insights are introduced and discussed.

2.2 The empirical research: data and methods

A detailed research on the economic and financial performance of the most important Italian banks has been designed. However, for sake of simplicity, the details of the empirical research are not reported in this paper. A research protocol has been elaborated and balance sheet data from 2008 to 2012 have been collected and elaborated. In particular, the collection and the analysis of synthetic but relevant indicators such as the Core Tier as proxy of the solidity of the bank, and the Return on Equity (ROE) and Net Incomes as proxies of the revenues capacity of the bank have been developed and used. The indicators referred to year 2012 are reported in Table 1. The insights of this empirical research determined the chance to identify clearly the banking players that better could face the challenges of the new competitive scenarios and were able to run successfully change management programs. In the following sections of the papers, on the base of a desk analysis, a detailed presentation of the best real cases, their value propositions and their new knowledge and management models adopted to guarantee sustainable growth of their business is introduced and analyzed.

Table 1. Performance indicators of the selected Italian banks

Companies	Performance Indicators (2012)		
	CORE TIER 1 %	UTILE NETTO (mln euro)	ROE %
Unicredit	10,84	865,0	1,84
Banca Intesa	11,2	1.654,0	3,29
Banca Popolare di Vicenza	8,23	64,0	1,9
UBI Banca	10,29	83,0	0,87
Banca Popolare di Milano	8,38	-430,0	-10,48
MPS	8,5	-2.000,0	-33,56
BNL	7,7	51,0	13,8
Credem	9,4	121,4	6,11
BCC di Roma	13,31	20,1	3,1
Unipol Banca	8,4	13,4	1,46
Banca Profilo	22,7	2,1	1,49
Banca Intermobiliare	9,04	-64,9	-18,11
Banca Finnat	33,6	6,2	3,49
Banca Mediolanum	19,25	351,0	24,71
Banca Generali	12,5	133,1	33,68
Banca Fideuram	18,9	205,3	27
Banca Finco	9,23	125,0	38,72
Azimut	10,29	160,3	27,25

3. Cases of excellence in the banking sector in Italy

3.1 Banca Fineco: technologies and operational excellence as levers of innovation and value creation

Banca Fineco is the direct bank belonging to the Unicredit Group in which plays the importance role of central point of the asset gathering. Since 1999, it is synonymous of innovation in the financial services. It is focalized almost exclusively on segments of the retail customers. Its core value is the trading online, i.e. the creation of a lot of banking, investment and trading tools accessible via web, phone and smartphone or through the consultancy of over 2.000 personal financial advisers organized in a network of over 250 financial shops, called Fineco Centers.

On 2008, from the integration of Unicredit Xelion Banca and Banca Fineco, a new banking organization able to combine the professionalism and the capillarity of the network of the financial consultants with the strength of an outstanding technological platform of financial services was created.

In fact, it is widely recognized that the success of Banca Fineco is grounded on the technological advantage of its platforms about the online banking and trading: it has been able to exploit effectively the potential of the technological tools to increase revenues, to reduce costs and to improve the quality of its product and services: for example, through the easiness of the trading-on-line Power Desk platform, the efficiency of Logos platform to follow the financial markets in real time directly through the smart phone, the utility of the mobile applications on iOS, Android e Windows Phone, letting a complete management of the financial services of the bank in distance way.

Moreover, in order to maximize these investments in structural intellectual capital, Banca Fineco has paid attention also to the human resources dimensions of intellectual capital, organizing specific training activities on technology and engineering fields as well as assessment activities and competences plans for all the Group Managers and recruitment plans for talents.

The innovation strategy of Banca Fineco has been systematically integrated by the regular activities about the identification and the analysis of the customers' needs and questions as well as by monitoring the international best practices and by the attention paid to the input and information provided by the commercial network and the customer care.

More recently, great attention has been dedicated to improve the easiness to use Fineco platforms, managing technological aspects, contents and graphical interfaces; for example, on 2011, the releases of Fineco App for iPhone, the new Fineco App for the operative system Android, the Chart Trading, and other innovative services have been launched and the results achieved till now confirm the goodness of a business model strongly oriented to provide innovative services, easy-to-use and with competitive costs, able to involve and satisfy all the investors and traders that gradually use the finance online.

Also within the banking area, in order to create segmentation of the customers' base and to premium the best customers, a set of 113 services and exclusive conditions – called Apex – has been created and launched. Finally, relevant investments in marketing and communication to promote and support customer attraction and to create brand recognition have been developed continuously till now.

Summarizing these evidences, it is possible to state that Banca Fineco is applying a strategic model based on the differentiation, elaborating value propositions (Tracy and Wiersema, 1997) mainly referred to operational excellence and price leadership. Operational excellence is achieved through the use of the virtual platforms that let to offer products and services minimizing costs and reducing wastes, without traditional agencies on the territories, i.e. not employing front-office collaborators. All this determines the attempt to become also a price leader. Being an online bank, Banca Fineco can exploit successfully the chance to provide homogeneous and standard products and services without time and place constraints.

3.2 Banca FIDEURAM and Azimut: customer intimacy as lever of innovation and value creation

Banca Fideuram is a company of the Intesa Sanpaolo Group traditionally specialized in producing, managing and selling financial products and services addressed to high-profile and upper affluent customers. It is one of the leaders of the private banking in Italy; in fact, through its private bankers, it offers a complete specialized financial consultancy and a wide portfolio of solutions able to satisfy the asset management and the financial and insurance needs of very asking customers.

The financial consultancy provided by Banca Fideuram is based on dialogue, trust and personal relationships between customer and private banker as well as on structured approaches supporting the identification and the definition of the profile and states of the

customer. Accordingly, the attention about all the specificities and details of the customer' profile as well as about strictly confidential aspects is a core value of the consultancy provided by Banca Fideuram.

Also *Azimut* can be considered one of the leaders of the private banking in Italy. *Azimut* is a relevant financial consultancy company not belonging to any banking Group. It is structured in five networks - Apogeo, Az, *Azimut* consultancy *Azimut* Global Advisory and *Azimut* Wealth Management – aimed to provide outstanding services of consultancy on asset management directed to high-profile and upper affluent customers. Its core values are efficiency, rapidity and strong customer-orientation and its business model is based on an open architecture in which is possible to find products and services both developed within the *Azimut* networks and developed by other relevant international players of the financial world. All this in order to effectively capture the better opportunities on the markets, coherently with the *desiderata* of each customer.

Moreover, in order to maximize operational systems and to reach integration with the territorial systems in which operates or wishes to operate, *Azimut* often defines agreements and partnership with the local banks

Summarizing these evidences, it is possible to state that both Banca Fideuram and *Azimut* are applying a strategic model based on the differentiation, elaborating value propositions (Tracy and Wiersema, 1997) mainly referred to customer intimacy and niche.

3.3 Banca Mediolanum and Banca Generali: integration as lever of innovation and value creation

The strategic and business model of Banca Mediolanum - since its foundation on 1982 - is based on the model of integration, i.e. to emerge as provider of a wide portfolio of products and services, from banking services to savings management to insurance.

It is a winning model in which the main customer is not the single investor but often the family with its diversified wants and needs. It exploits a multichannel approach to the market and a smart use of the technologies as tool of customer relationships management, in particular referred to the back-office activities.

Also Banca Generali adopts with success the strategic and business model based on the integration of various product and services at financial, banking and insurance level directed to affluent and private customers, mainly through a network of financial

consultants. The adoption and the success of this strategic model are also linked to the internationalization processes that have traditionally characterized Banca Generali.

4. Conclusions

This paper has examined the new strategic, management and knowledge models elaborated and adopted in the banking sector in the Italian context. The relationships among these models and the business performance of the main banking organizations have been identified and analyzed and five successful experiences have been introduced and discussed. In particular, the case examples of Banca Fineco, Azimut, Banca Fideuram, Banca Mediolanum and Banca Generali which recently have effectively planned and implemented innovative strategies and models aimed to activate and support a sustainable growth of their business have been presented. This paper contributes to further develop our comprehension about the importance to elaborate and implement new strategic, management and knowledge models in a very relevant business sector such as the banking one. The analysis of the case-examples shows in particular how some Italian banking organizations – often considered too small to compete in the capitals global competition – have been able to elaborate and successfully implement new mechanisms to guarantee performance and sustainable growth. The paper provides implications for future research and useful insights for management. However, further and detailed case studies are called to improve understanding of the phenomena and the capacity to generalize insights and best practices.

Structured Abstract

Purpose – Quantifying managerial ability is central to management literature. Prior research indicates that manager specific features (ability, talent, reputation, or style) affect economic outcomes and are therefore important to economics, finance, accounting, management and IC research as well as to practice. Most of the measures used in archival research, also reflect significant aspects of the firm that are outside of management's control. The paper, coherently with Demerijan et al. (2012), is directed to exploit the possibility to measure the managerial ability assessing managers based on the efficiency with which they generate revenues.

Design/methodology/approach – The paper addresses his aims applying a more sophisticated approach to the three stage estimation (Fried *et al.*, 2002), in which both Data Envelopment Analysis (DEA) and Stochastic Frontier Approach (SFA) are used to estimate the efficiency scores firms to derive a measure of manager ability (MA). The method used could be named “two-stage SFA DEA” approach. Our idea is to obtain a measure of MA as residue of the inefficiency equation of SFA and to use it as a new input to insert in the “second/third” DEA stage. The Italian banks have been chosen as the sample to investigate and implement our model.

Originality/value – The originality of the paper consists in the proposition of a new model to measure managerial ability, able to outperform the alternative measures of managerial ability, simple to use as it is based on easily obtainable financial data and available for a broad cross section of firms. Moreover, our paper is original also from a technical point of view, by employing not just the SFA or DEA methodology, but a “two stage DEA SFA” approach, in which the frontier and the inefficiency equation are estimated simultaneously.

Practical implications – We believe that our managerial ability score exhibits an economically significant manager-specific component and contains less noise than

existing proxies of managerial ability. This more precise measure of ability opens the door to a wide array of studies that previously were difficult to conduct.

Keywords – Managerial ability, Data Envelopment analysis (DEA), Stochastic Frontier Approach (SFA), “two-stage SFA DEA” approach

Paper type –Practical Paper

Acknowledgments - Though this work is the fruit of joint reflection and collaboration, for academic reasons sections 1 and 2 are to be attributed to Stefania Veltri, sections 3 and 4 are to be attributed to Graziella Bonanno, who also contributed to section 5, which together with section 6 are to be attributed to Giovanni D’Orio

1 Introduction

Quantifying managerial ability is a central theme for management literature. Prior research indicates that manager specific features (ability, talent, reputation, or style) affect economic outcomes and are therefore important to economics, finance, accounting, management and intellectual capital (IC) research as well as to practice.

Prior research is limited to measures such as media coverage and historical returns, which are difficult to attribute solely to the manager versus the firm (Rajgopal 2006), or manager fixed effects, where there is evidence of a manager-specific effect, but the quantifiable effect is limited to managers who switch firms (e.g., Bertrand and Schoar 2003; Bamber et al. 2010; Ge et al. 2011).

The main aim of the paper instead, coherently with Demerijan et al. (2012), is to provide a measure the managerial ability more precise of the existing measures (i.e. more able to exhibits an economically significant manager-specific component) but at the same time containing less noise than existing proxies of managerial ability, a measure that allows to better distinguish the effect of the manager from the effect of the firm.

The paper addresses his aims applying an approach stemming from the three stage estimation (Fried et al., 2002) but more sophisticated than this, hereafter “two-stage DEA SFA” approach. Applying “two-stage DEA SFA” approach, both Data Envelopment Analysis (DEA) and Stochastic Frontier Approach (SFA) are used to estimate the efficiency scores firms first, then to derive a measure of the manager ability. This method consists of estimating the frontier and the inefficiency equation simultaneously. In this way the first and the second stages are incorporated in a single one and the efficiency

scores are estimated through a parametric method which takes into account also a random error and not only the inefficiency taking away from the frontier.

The idea behind the paper is to obtain a manager ability measure as residue of the inefficiency equation and to use it as a new input to insert in the “second/third” DEA stage. The Italian listed banks have been chosen as the sample to investigate and implement the model, as banking industry has been object of several studies employing DEA methodology (Battese et al., 2000; Casu et al., 2004; Seiford and Zhu, 1999).

The originality of the paper consists in the proposition of a new model to measure managerial ability, able to outperform the alternative measures of managerial ability, simple to use as it is based on easily obtainable financial data and available for a broad cross section of firms. Moreover, our paper is original also from a technical point of view, as it employs not just the SFA or DEA methodology, but a “two stage SFA DEA” approach, in which the frontier and the inefficiency equation are estimated simultaneously.

We believe that our managerial ability score exhibits an economically significant manager-specific component and contains less noise than existing proxies of managerial ability. This more precise measure of ability opens the door to a wide array of studies that previously were difficult to conduct.

2 Literature Review

The impact of management on firm performance is a topic of everlasting interest in the managerial literature. Several are the proxy used in literature to measure managerial ability. Some studies refer to broader measures to proxy the managerial ability, such as the prior industry-adjusted stock returns (Fee and Handlock, 2003), the CEO’s financial press visibility and the firm’s prior industry-adjusted return (Rajgopal et al., 2006) and a combination of CEO tenure, prior media mentions, appointment from outside of the firm, and prior industry-adjusted stock returns (Milbourne, 2003). Other studies (Tervio 2008, Carter et al. 2010) used executive pay to infer managerial ability. A number of studies proxy managerial ability looking at the market reactions, such as Hayes and Schaefer (199), that identify able managers as those who were hired away by another firm, and Bennedsen et al. (2010), that examine firm profitability following deaths affecting the CEO. Several studies, finally, rely on manager fixed effects as measure of CEO’s ability,

such as Bertand and Schoar (2003), Bamber et al. (2010), Ge et al. (2011). Anyway, all of the measures above examined lack of precision and often rely on infrequent events.

Studies using DEA characterize themselves to provide a more precise measure of managerial ability. Among these, Murthi et al. (1996, 1997) measure managerial ability in the industry sector, Barr and Siems (1997) and Leverty and Grace (2012) within the bank and insurance sectors. In each of these studies, the inputs and outputs to the DEA vectors are industry specific. For example, in Murthi et al. (1996) the inputs include product quality and product price, and the outputs include market share. In the Leverty and Grace (2012) insurance study, the inputs include administrative and agent labor, and the outputs include the present value of real losses incurred for personal and commercial short-tail lines. The study of Demerjian et al. (2012), instead, measure efficiency for a large cross section of firms, spanning most industries. In detail they use as DEA input five stock variables (net purchased fixed assets, net operating leases, net Research & Development, purchased goodwill and other intangible assets and two flow variables (cost of inventory and selling & administrative expenses) to capture the choices managers make in generating revenues (output). Demerjian et al.'s (2012) study also differ from the others because the authors modify the DEA generated firm efficiency measure by excluding from it key firm-specific characteristics that the authors expect to aid (firm size, market share, positive free cash flow, and firm age) or hinder management's efforts (complex multi-segment and international operations), attributing the unexplained portion of firm efficiency to management.

The paper propose a measure of managerial ability that, coherently with Demerjian et al. (2012) allow to better distinguish the effect of the manager from the effect of the firm and to obtain an ordinal ranking of quality for the sampled firms using a "two-stage SFA DEA" approach described in the following section. The model will be applied to the Italian banking sector, on which focused several studies employing DEA methodology (Battese et al., 2000; Casu et al., 2004; Seiford and Zhu, 1999).

3 The "Two-stage SFA-DEA" approach

The methodology used in this work is an alternative of the tree stage DEA SFA approach proposed by Fried *et al.* (2002) and perhaps it would be appropriate to call it "two-stage SFA DEA" approach. The traditional version of this approach consists of three steps. In the first one the authors use DEA in order to estimate the initial measure of

firm performance. In the second stage, the first stage performance measures are regressed against a set of variables. In this way, a decomposition of the variation in the performance is obtained, which is formed by a part attributable to environmental effects, a part due to managerial inefficiency and a part attributable to random errors. Finally, in the third step, DEA is used in order to re-evaluate the firm performance with adjusted inputs (or outputs, depending on the orientation of first stage DEA).

We introduce an alternative approach to the just described one using SFA at the first stage in order to implement the specification proposed by Battese and Coelli (1995). This method consists of estimating the frontier and the inefficiency equation simultaneously. In this way the first and the second stages are incorporated in a single one and we estimate the efficiency scores through a parametric method which among other things takes into account also a random error and not only the inefficiency taking away from the frontier. Our idea is to obtain a manager ability measure as residue of the inefficiency equation and to use it as a new input to insert in the “second/third” DEA stage.

SFA is a parametric method which allows to make inference on the estimated parameters by assigning a distribution error. Further classification distinguishes the stochastic methods from the deterministic ones. The first take into account that a bank may stray from the efficient frontier also for reasons of random nature and not only for the inefficiency. The wide application of SFA is due to the possibility to decompose the error in two parts, the inefficiency and the random errors. Under this profile, SFA is preferable to the DEA (Data Envelopment Analysis), that is a non-parametric methods. The DEA supposes that the distance from the frontier is explained entirely by the inefficiency and it does not consider random errors as may be, for example, the errors of measurement of the variables or those due to unexpected events. A further advantage of the method SFA is the ability to insert in the model a set of variables that explain the inefficient component. In particular, the specification proposed by Battese and Coelli (1995) estimated the frontier model and the inefficiency equation in a simultaneous way. This method therefore offers a guarantee to consider in the estimation of the frontier an exogenous component of inefficiency.

In particular, the methodology used in this work can be described as follows:

1. The first stage involves estimating simultaneously the cost frontier and the inefficiency equation defined in the system (1):

$$\left\{ \begin{array}{l} \log Cost_{it} = \sum_{j=1}^J \beta_j \log y_{ij} + \sum_{n=1}^N \gamma_n \log w_{in} + u_{it} + v_{it} \\ u_{it} = \sum_{k=1}^K \eta_k z_{itk} + e_{it} \end{array} \right. \quad (1)$$

where $Cost_{it}$ is the total cost incurred by the i -th bank at time t ; y_{ij} represents the value of the j -th output obtained from the bank i in year t ; w_{in} is the cost of the n th input used by the bank i in the year t ; β_j and γ_n are the respective parameters to be estimated; u_{it} is an erratic component that measures the inefficiency. This is a no-negative variable; v_{it} is, instead, the random error; with $j = 1, \dots, J$ and $n = 1, \dots, N$. And, moreover, z_{itk} represents the k -th variable at time t that influence the i -th bank; with $k = 1, \dots, K$. Our interest is to obtain manager ability measure as residues of the inefficiency equation and to introduce it in the DEA second stage estimation.

2. The second stage consists in implementing DEA approach with another input, the manager ability estimated in the previous step. DEA is the most used method in the literature of manager ability (Demerjian et al., 2012; Hajiha and Ghilavi, 2012; Leverty and Grace, 2012).

Let x_i and q_i be, respectively, the column vectors of inputs and outputs, X and Q the input matrix and the output matrix, the variable returns to scale (VRS) linear programming problem can be written as follows (Afriat, 1972; Banker, Charnes and Cooper, 1984; Battese *et al.*, 2005):

$$\begin{array}{ll} \min_{\theta, \lambda} & \theta, \\ \text{st} & -q_i + Q\bar{\lambda} \geq 0, \\ & \theta x_i - X\bar{\lambda} \geq 0, \\ & I'\bar{\lambda} = 1 \\ & \bar{\lambda} \geq 0 \end{array} \quad (2)$$

where θ is a scalar, $\bar{\lambda}$ is a $I \times 1$ vector of constants and the third expression of (2) is the convexity constraint.

4 The sample: data and variables

Data are from the ABI Banking Data, which provides the balance sheets of Italian banks from 1993 to the present. Moreover, some variables (for example, bad loans calculated by geographical location of customers) are taken from the BIP (“Base Informativa Pubblica” online) released by the Bank of Italy. The period covered by this analysis is 2006-2011. There were 686 banks in 2006, 692 in 2007, 689 in 2008, 686 in 2009, 648 in 2010 and 631 in the last year. The sample consists of CCBs (on average 63%), Ltd (on average 32%) and Popolari banks (on average 6%). As can be seen, most of the banks are small and minor (92% of the sample in 2006 and 94% in 2011). In addition, the proportion of banks that have their main office in the North is 60% of the sample. This is a much higher value than that for banks that have their main office in the South (20%). In order to highlight some information about the Italian Banking System, Table 1 reports the distribution of Total Assets for geographical areas and legal categories. As can be seen, this industry is characterized by a breakdown and, for each macro-area or legal class, banks have specific and different characteristics.

Table 1. Average values of Total Assets by geographic area and legal category (constant values in mln of euros - NIC Index Istat, base year = 1995)

With regard to the variables used in the econometric analysis, in the extensive review proposed by Berger and Humphrey (1997), it is argued that the intermediation approach

proposed by Sealey and Lindley (1977) is the most appropriate to evaluate financial institutions. For these reasons, the variables we include in the model are selected according to this approach.

Although there is a heated debate about which specifications of inputs and outputs to choose in the study of bank performance, there is a certain consensus in considering loans to customers (y_1) as the main banking output. We introduce another output into the model, namely the non-interest income (y_2). This choice is justified by the fact that today's banks offer a range of non-traditional "collateral" services for which they obtain positive gains. The third output used in this work is that of securities (y_3), composed of loans to other banks, equities and bonds (Barra et al., 2011). With regards to inputs, we use labour, capital and deposits. In the SFA stage we use the input prices in order to estimate the cost frontier, while in the DEA stage, we apply a production frontier introducing a fourth input given by the Manager Ability' measure calculated in the first stage. The traditional inputs are three. Labour (x_1) is measured as the number of employees of individual banks. The cost of labour (w_1) is calculated as the ratio of personnel expenses to the number of employees. The cost of capital (w_2) is measured in this work as the ratio of expenses that are not considered in the other input variables in the frontier model and the banking product (x_2). Therefore, the numerator includes administrative expenses (excluding personnel expenses), operating expenses, the interest expense net of interest on amounts due to customers, depreciation of fixed assets and commission expenses. The administrative expenses include cost items, such as those relating to electricity, rent and maintenance of various types. Finally, the third input considered is given by the deposits from customers (x_3) whose cost (w_3) is given by the ratio of interest paid to customers and the total amount of deposits. The dependent variable in the cost function, $\text{Cost}(y,w)$, is the total cost of individual banks and this is calculated as the sum of administrative expenses, interest expense, operating expenses, commission expenses and depreciation of fixed assets.

As already mentioned, the specification made by Battese and Coelli (1995), which allows the simultaneous estimation of equations of system (1), implies a need to define the determinants of inefficiency. One environmental variable that explains bank performance is credit quality (z_1), which we calculate as the ratio of non-performing loans to total loans to customers. Both these variables are defined by customers' geographical location and are taken from the BIP of the Bank of Italy. The values of the loans quality

(z_1) are linked to each observation through the definition of four geographical macro-areas. In order to take into account the bank's risk position and the effect that this may have on efficiency scores, an indicator of bank solvency (z_2) is introduced. This is calculated as the ratio between regulatory capital and risk weighted assets and is a measure of banks' capital adequacy in relation to the credit risk. Furthermore, this is calculated on a territorial level by considering the same four macro-areas used for z_1 . It is also useful to consider the weight of each bank within the industry and, in this sense, the Herfindahl index (z_3), has been adopted. It is calculated for each geographical macro-area as the sum of the squared market share of each bank in the sample. This is an issue which has been addressed in many works (Casu and Girardone, 2009; Dongili et al., 2008; Fontani and Vitali, 2007) which have aimed at verifying whether a higher concentration in the industry, such as has occurred in the Italian banking sector since the '90s, may influence bank efficiency. In general, the outcome is uncertain, since the operations of consolidation have resulted in an increase in size with an eye to probable and expected increases in efficiency levels. On the other hand, this may cause an increase in banks market power. Turati (2008) proposes a model that captures the relationship between profitability and efficiency. The results support the idea of a competitive banking sector and, according to the author, the consolidation operations lead to an increase in banks' bargaining power, which is bad for customers. The *ftse* index (z_4) is introduced into the model in order to capture the relationship between the effects of the current crisis, reflected in Stock Exchange transactions, and bank efficiency. Moreover, a dummy for each year of the analysed period is introduced in order to consider a time effect on the efficiency scores. This dummy is meant to capture what happened in the years before and after the crisis, which reflects phenomena which are different from those gauged by the other z -variables. Finally, we have included some dummy variables in order to take into account the fact that any difference in the levels of cost efficiency may be determined by legal category, geographical location and/or size of banks.

5 Main findings

We report the results of both the stages.

5.1 First stage: results from SFA

The translog cost function for the banking sector is estimated as a system of equations. The aspects of the firm's behavior that we observe are total cost, the allocation of total cost across the various inputs (i.e., input expenditure shares), the firm's output level, and the input prices that the firm faces. The translog function allows for both positive and negative scale effects, that is, average cost can both decrease and increase across the range of the cost function. In this sense, the translog function can represent a production function that is not homogeneous. The elasticity of cost with respect to output is the ratio of marginal to average cost.

Essentially, this allows the observable information about the behaviour of the firm such as total resources expenditures, the distribution of these expenditures across inputs, the output yielded by these expenditures and the resources prices faced by the firm all to be used in the estimation of the parameters of the model. In addition to the restrictions on the estimated parameters, there is the restriction that the error terms in the share equations sum to zero.

In Table 2 there is the estimation of the cost frontier for the Italian banking system for the period 2006-2011. All the coefficients of our model for the translog cost function are significant.

Table 3 shows the cost inefficiency equation for the Italian Banking system (2006-2011). All the coefficients are significant. The coefficient for "Bad Loans" has a positive sign. This means that the higher is the incidence of suffering (or, in other words the lower is the credit quality of the territorial area where the bank has its main office), the higher is the values for estimated inefficiency.

The coefficient of the "Solvency Ratio" has a negative sign. If banks have high solvency ratio, the lower is the risk to which they are subject, than the lower is the level of inefficiency that they register.

Table 3. Inefficiency equation estimates for Italian banks (2006-2011)

	Coefficients	SE	z-value	p-value

The coefficient of Herfindhal's index has a negative sign. This means that Banks in which the concentration of Total Assets (relatively to their main office) is higher reached the highest levels of efficiency.

The coefficient of FTSE index has a negative sign. This signals a pro-cyclical trend in efficiency.

The highest cost efficiency values are achieved by CCBs and by Banks with the main office in North-Est. The efficiency levels are higher in small Banks than in major ones, but minor, medium and large Banks achieve cost efficiency levels higher than the small ones.³

These results are quite interesting and sometimes surprising (such the one that smaller banks are more efficient than bigger banks) but for our aim, the most important issue is the following one. We obtain that the erratic component u_{it} , the share of the composite error that measures inefficiency, has been "clean up" from some sources of inefficiency (bad loans, solvency, etc.), then we can use the residual of the inefficiency equation as an acceptable proxy to signal managerial ability.

5.2 Second stage: results from DEA

In the second stage, we apply DEA under the hypotheses of both Constant Return to Scale (CRS) and Variable Return to Scale (VRS). The assumption of VRS seems to explain

³ In this estimation, BCCs are the group of control for the legal category, Banks that have the main office in North-Eastern Italy are the group of control for the geographical side.

better some features of the organisation studied but it is useful to conduct a CRS and a VRS DEA upon the same data since that doing this way it allows us to decompose the technical efficiency (TE) scores obtained into two components, one due to scale inefficiency and one due to “pure” technical inefficiency (i.e. wrong input mix or managerial inefficiency). If we have a difference between the two TE scores for a specific observation (or Decision Making Unit) this indicates that the Decision Making Unit has scale inefficiency. When this happens we can calculate this inefficiency using the difference between the VRS TE score and the CRS TE score.

In Table 4 there are the efficiency scores estimated with DEA without and with Manager Ability’s measure as new input of the production function. The standard errors are in italics. We performed a test on the differences between means and we widely reject the null hypotheses of equality.⁴ This result allows us to consider the Manager Ability as a significant variable to be introduced in the estimate of a production function with the DEA approach.

Table 4. Estimated DEA for the Full Sample with and without Manager Ability’s measure as new input of the production function.

⁴ The result of the two tests (one for CRS, one for VRS) is available on request (in the case of CRS, the t-statistic is equal to 29.10, while in the case of VRS, it is equal to 25.58).

The average efficiency scores of Table 4 show that when we consider the additional input of Managerial Ability the results of efficiency improve. This happens for all the years and for all the observations. The magnitude of improvement is different in different years. Figure 1 shows the trend in the estimated average Efficiency Score. It is clear from the Figure that including Managerial ability as a input gives us better scores. It means that Managerial ability has a positive impact on the efficiency of the sample. The trend is increasing from 2006 until 2008, it decreases 2009 and 2010 and slightly improves for 2011.

In Figure 2 we can observe the magnitude of improvement given by Managerial Ability. This value is calculated as the differences between the efficiency score obtained without this input and the efficiency score obtained including in the estimation the proxy of Managerial ability.

The highest value is observed in 2008; years 2007, 2009 and 2010 show a similar value of the impact of Managerial ability on efficiency while the minimum is observed in year 2011.

Figure 1 Trend in the average Estimated DEA - Full sample with and without Managerial Ability's measure.

Figure 2 Impact of Manager Ability. Full Sample.

Table 5 reports the estimated efficiency when we introduce MA's measure as input. We show the results disaggregated for legal category and size. Also in this table, the standard errors are in italics.⁵

As can be seen, in the case of VRS we obtain an increase of estimated efficiencies, but trends remain substantially unchanged. When we disaggregate for legal category, we find that Popolari Banks perform better than Ltds and CCBs and that the latter register the worst results. As regard the size, it easy to realise that the largest Banks achieve the higher levels and that with decreasing size also the estimated values decrease. These results confirm the existence of a strong heterogeneity in Italian Banking System.

⁵ In this stage, we exclude banks that register SFA-efficiency scores with a standard deviation greater than 0.10 between 2006 and 2011 (27 observations). Moreover, DEA requests a full matrix of values, therefore the final number of observations, for this step, is 2948.

We are able to reproduce the table 5 when estimating a stochastic cost frontier in the first stage. We chose not to include it because does not the focus of the paper. However, from the SF cost side, CCBs perform better than the others one, while Ltds are placed in the same intermediate position with respect to what happens when estimating the production function through DEA. For what concerns the size, we find a conflicting result because in this case we obtain that the minor banks are positioned in first place with the highest levels of cost efficiency, while the major banks are in last place. The ranking remains unchanged with respect to the other banks (small, medium and large).

6 Conclusions and future research directions

Quantifying managerial ability is central to management literature. Most of the measures used in literature reflect significant aspects of the firm that are outside of management's control. The originality of the paper consists in the proposition of a new model to measure managerial ability, able to outperform the alternative measures of managerial ability, simple to use and based on easily obtainable financial data and available for a broad cross section of firms. The paper aims to exploit the possibility to measure the impact of managerial ability on technical efficiency.

To do this we use a sophisticated approach to the classical three stage estimation, in which both Data Envelopment Analysis and Stochastic Frontier Approach are used to estimate the efficiency scores firms. This allows us to derive a measure of Managerial Ability. The method used is a "two-stage SFA DEA" approach. Our measure of Managerial Ability is the "clean" part of the residue of the inefficiency equation of Stochastic Frontier Approach and we use it as a new input in the "second/third" Data Envelopment Analysis stage. We observed an improvement in efficiency scores calculated with this new input for all years and for all the average samples. This can be seen as a proxy of positive impact of Managerial Ability on technical efficiency. We believe that our proxy of managerial ability score exhibits an economically significant manager-specific component and contains less noise than existing proxies of managerial ability. This more precise measure of ability allows a wide array of studies that previously were difficult to conduct.

An interesting topic for further research can be to develop a "behaviour" model for inefficient firms. Since we estimate a technical efficiency frontier, the Observations (Decision Making Units - DMU) on the Frontier can be seen as "fashionable" DMU for all the DMU that are not fully efficient (not on the Frontier). In this way, all the frontier DMU can be treated as "peer". "Peers" define the relevant part of the production frontier for a DMU. If a DMU is not fully efficient, given the previous and following estimation we can calculate which is the target (i.e. produced output given the used inputs) that the DMU could aim at if efficient. An example will make it clear. (see Figure 3). Output Z can be produced using two inputs y and x. The points on the iso-product curve (A,C,E and F – let us not consider D yet) are DMUs producing the quantity Z of output in an efficient way, using different technologies (the vectors departing from the origin indicates the input combinations). DMU B produces the quantity Z using a sub-optimal technology.

If DMUs on the frontier have a Technical Efficiency score of 1, B will have a smaller Technical Efficiency score, i.e. 0.8. This means that for that DMU could be possible to reduce the consumption of all inputs by 20% without reducing output. If we draw a vector between the origin of the axis and B, the vector will cross the production frontier at the point D. D can be seen as an ideal firm that uses the same technology of B but efficiently (it uses less inputs for the same quantity of output). D could be firm B using its technology efficiently. Point D can be obtained as a linear combination of point A and C. A and C will be the “peers” firms of B.

Figure 3 Frontier and Peers

Since we can have a proxy of Managerial Ability as an input (and for all inputs), we can calculate a "weight" for each peer and for each input, including Managerial Ability. The weight obtained for each input, in each estimate and for each “peer” is “the importance” of that firm as a peer in the linear combination (i.e. in the example D is at the same distance between A and C so the weight of these two peers will be i.e. 0.5 and 0.5. If D was very close to A, the weight would be 0.90 for A and 0.10 for C).

This approach can give some useful direction to non-efficient DMU in the changes needed in each input (including Managerial Ability) to achieve full efficiency, and this can be an interesting starting point for a new work.

Structured Abstract

Purpose – Today's socio-economic crisis ongoing in many countries, is strongly challenging the value creation approaches and the sustainability of traditional for-profit enterprises' model, mainly focused, if not exclusively, on the satisfaction of the shareholders or the owners. In this context, that sees even more companies reducing or shutting down, the Social Enterprise (SE) is increasing the production and the opening of new units, distinguishing for its competitive capability and sustainability. The paper investigates the reasons at the basis of such SE's performance, identifying in the management model setting the peculiar reason: multistakeholder structure, balanced value creation among stakeholders, integrated management of three key dimensions: compliance, process performance, knowledge and learning.

Design/methodology/approach – The research has been designed on the basis of case study methodology. In particular an Italian Social Enterprise theoretically significant and relevant for the investigation of the research topic has been sampled. The qualitative data collected have been carried out from interviews to the Director, observation of day to day management practices, participation to enterprise's internal meetings, access to organization's repositories.

Originality/value – The paper analyses one of the oldest Italian social enterprises, and discloses key elements of its management model, providing useful insights for a sustainable value creation model setting.

Practical implications – Identifying social enterprise management model's settings, enable to compare traditional for-profit enterprises' model with SE's ones. For-profits may benchmark useful settings in order to create value and be sustainable in today's turbulent competitive context.

Keywords – Social Enterprise, Value creation, Management settings, Integrated governance.

Paper type – Research Paper

1 Introduction

Today's socio-economic crisis ongoing in many countries, is strongly challenging the value creation approaches and the sustainability of traditional for-profit enterprises' model, mainly focused, if not exclusively, to the satisfaction of the shareholders or the owners.

In this context, that sees even more companies reducing or shutting down, the Social Enterprise (SE) is rising, distinguishing for its competitive capability and sustainability. The paper investigates the reasons at the basis of such successful SE's model, identifying in the management model dimensions and settings the peculiar features.

As a counter altar of the for-profit company, the SE is a type of enterprise characterized by the absence of profits, the moderate role of shareholders, and the aim of providing services or products of a collective and common interest. These characteristics of the SE's model distinguishes it in terms of value creation and sustainability.

SEs adopt a peculiar management model that identifies some basic drivers and combines them effectively, in order to fulfil requests and expectations of a wide range of stakeholders.

The management model of a SE is then a model in which the management dimensions and their settings are effective in terms of sustainable value creation, the distribution of value creation involves various internal and external stakeholders, as well as the contribution to enterprise's achievements comes from a variety of complementary stakeholders. The SE's value creation model appears to be more sustainable, and more fitted against specific stakeholder's interests.

The paper analyses the case of an Italian SE, of about 2 centuries of life. It highlights how the management model is multi-stakeholder, support and distributes value among equally important stakeholders, is set on three main interacting dimensions: compliance, performance, knowledge.

The paper explores the management foundations (dimensions and settings) underlying the SE, identifying its peculiar characteristics. The paper address, besides, implications to for-profit companies in order to enhance value creation and sustainability dynamics.

Although the growing economic importance of SE, few attention is paid by management literature in order to disclose its management foundations, to reveal its value creation dynamics. An higher attention should be paid by the management research community in order to analyze this emerging model of doing business, more robust and sustainable in today's turbulent environment.

The paper is organized as follows. Section 2 provides the background of the research, section 3 presents the research project, the case study's data and methods, section 4 reports the results, and section 5 outlines conclusions and implications.

2 Background

2.1 Social Enterprise and value creation

In the last years the deep changes of the economic, political and socio-cultural contexts are stressing the foundations of business and enterprises, mainly or exclusively based on the goal of profits.

This have determined new reflections about companies management, entrepreneurship and models of development in advanced countries. In fact, the emerging dynamics have accelerated the search of new models of doing business able to reconsider the paradigm of the free market and to re-think the roles assigned to the different forms of enterprises (Linzalone and Lerro, 2014).

In order to build a sustainable economic system, it is crucial to ground the enterprise on more-extended key actors and to find a new balance among them. Particularly effective is the non-profit, social services providers' 'business' model (Stiglitz, 2009), and the role they have. It can provide a new company's management setting, able to balance financial capital, workforce and collective interests to support the emerging deep changes in the economic and social structures of the advanced countries (Dasgupta P., 1998; Sen A., 1998).

Social enterprise has no universally agreed definition (Leadbeater, 1997; Prabhu, 1999) since it is mainly characterized by its diversity and heterogeneity. Accordingly there is no universally accepted definition of social entrepreneurs (Shaw and Carter, 2007). Social entrepreneurs have been variously described as "those people who bring to social problems the same entrepreneurship and imagination that business entrepreneurs bring to wealth creation (Blair, 1997). They initiate social innovation and change

(Drucker, 1999; Leadbeater, 1997), motivated by the opportunity to adopt an innovative approach and creative use of resources and relations to satisfy needs which the state welfare system cannot or will not meet (Thompson et al., 2000). Other scholars have sought to identify common characteristics to social entrepreneurs (Leadbeater, 1997; Leadbeater and Goss, 1998; Prabhu, 1999; Thake and Zadek, 1997; Thompson et al., 2000).

What really matters about SEs is how the profit earned is reinvested and who benefits from it.

Indeed, what distinguishes social enterprises from traditional businesses is the fact that the social impact is considered more important than profit maximization. In particular, it is important to understand the impact that a social enterprise has on society and who benefits from its business.

The definition of SE can vary according to different countries and contexts (Spear et al., 2009). In the UK, the SE is “a business with primarily social objectives whose surpluses are principally reinvested for that purpose or the community, rather than being driven by the need to maximize profit for shareholders and owners” (UK Cabinet Office, 2006).

In Italy the Social Enterprise is a “a qualification, not a form of company; it can be acquired by all those private organizations, no-profit, that operate in a stable and principal way, an economic and organized activity, in order to produce and/or deliver goods and/or services of a social utility, aimed to serve a general interest (D.Lgs. 155/2006).

According to OECD (1999) SE is a “private activity conducted in the public interest, organized with an entrepreneurial strategy but whose main purpose is not the maximization of profit but the attainment of certain economic and social goals”.

Yunus argues that “SE is a cause-driven business and the social business investors/owners can gradually recoup the money in-vested, but cannot take any dividend beyond that point [...]. The purpose of the investment must be merely to achieve one or more social objectives through the operation of the company, no personal gain is desired by the investors. The company must cover all costs and make profit, at the same time achieve the social objective, such as, healthcare for the poor, housing for the poor, financial services for the poor, nutrition for malnourished children, providing safe drinking water, introducing renewable energy, etc. in a business way” (Yunus M. , 2007).

Social enterprise has a peculiarity in comparison with other subjects operating in the third sector: the continuous search of a synthesis between the social service/assistance to deprived persons, and the capability to produce revenues with respect to explicit and implicit rules of the Third sector's market frame (Fiorentini, 2006).

From the different definitions the literature provide, it is possible to point out some agreed features of the SE's business model:

- the aim of creating and delivering social values, opposed to the business aim of profit maximization for the owners;
- the need to adopt a multi-stakeholder approach, and consider a wide range of target stakeholders, both internal and external;
- the basic importance of monitoring and evaluating impacts on the society, not just the results on the user;
- the need of a synergic and integrated management approach, able to balance different value creation target needs;
- the need of generate sales - as of a for-profit enterprise - and manage to cover costs, in particular the cost of work;
- the strategic importance of generating a surplus, over the cost covering, in order to reinvest in innovation of: technologies, knowledge, physical infrastructures;
- the explicit and recognised importance of stakeholders' contribution to the SE's performance; they influences each other according to a reinforcing loop: the more the SE increases performances, the more the stakeholders contribute and facilitate it.

2.2 The Business nature of the Social Enterprise and its Management model

The SE's management model can be defined as hybrid. This definition is well represented by Dawans et al. (2012), that define a social enterprise as “a business venture created for a social purpose, mitigating or reducing a social problem or a market failure, and to generate social value while operating with financial discipline, innovation and determination of a private sector business”.

SE differs from traditional for profit oriented, because, even in the variety of legal formats determined by the different national laws, they keep in common the principles of pursuing business strategies and solutions in order to achieve social aims, and to reinvest the surplus for community benefit (Haugh, 2006).

Fig. 1 - The hybrid nature of Social Enterprise (ISE, 2011)

Social entrepreneur has been defined as who “builds strong and sustainable organizations, which are either set up as not-for-profits or companies” (Schwab Foundation, 2009).

The debate about different SEs typologies is even large, but can be effectively summarized according to Stalder's '*SE's Business models typologies*'.

Source	SE Business models
Alter, 2006	Mission centric, Mission related, Unrelated to mission
Elkington and Hartigan, 2008	Leveraged non-profit business model, Hybrid non-profit business model, Social business model
Dees et al., 2001	Purely philanthropic, Mixed, Purely commercial
Global Entrepreneurship Monitor, 2009	Traditional NGO, Not-for-profit, Hybrid, For-profit

Tab.1 - SE's Business models typologies (Stalder, 2010)

According to Dees an important prospectus comes from Alter (2006) that synthesizes in the 'Hybrid Spectrum of enterprises' the differences among enterprises and their management model structure an settings, distinguishing: pure non-profit with social value creation commitment, non-profit with income generating activities, Social enterprises, socially responsible business, corporation practicing social responsibility, for profit with no commitment to social value creation.

Dees et al. 2001, propose an interesting comparison of SE's business models identifying dimensions and settings.

	Purely Philanthropic	Hybrids	Purely Commercial
Organization	Nonprofit organization (e.g. foundation, NGO)	Social Business (e.g. social venture)	For-profit Corporation (e.g. corporate philanthropy)
Methods, Goals and General Motives	Mission-driven	Balance of mission and market	Market-driven
	Appeal to goodwill	Mixed motive	Appeal to self-interest
	Social value creation	Social and economic value	Economic value creation
Destination of income/profit	Directed toward mission activities of nonprofit organization	Reinvested in mission activities or operational expenses and/or business growth	Distributed to shareholders and owners
Key Stakeholders			
Beneficiaries	Pay nothing	Subsidized rates and/or mix of full payers and those who pay nothing	Pay full market rates
Capital	Donations and grants	Below-market capital and/or mix of full payers and those who pay nothing	Market rate capital
Workforce	Volunteers	Below-market wages and/or mix of full payers and fully paid staff	Market rate compensation
Suppliers	Make in-kind donations	Special discounts and/or mix of in-kind and full price	Charge market prices

Tab. 2 - SEs' Business models: a comparison (Dees et al., 2001)

As first important dimension of SE's business model it is important to highlight the multi-stakeholder nature. It is very important to consider the role and the stakeholder target, since it is a group or an individual that can influence, or be influenced from, the achievement of enterprise's goals (Freeman 1963). The tight and circular interaction between stakeholder's interests and enterprise's business performance becomes even more clear in a turbulent and global environment, where stakeholders can joint in groups and increase their power, can use the information technologies and its communication pervasiveness to support or obstacle enterprises' goal achievement. Enterprises should then consider stakeholders as strategic factors of companies competitiveness, and operate a stakeholder based management model.

Stakeholders, indeed, driven by their personal goals participate to the enterprise, so they depend from it, and the enterprise's health depends from them (Ahlstedt e Jahnukainen, 1971; Freeman, 1984; Cornell e Shapiro, 1987; Hill e Jones, 1992, Brenner, 1993).

Different classifications of stakeholders can be found in the literature. Freeman and Reed (1983) grouped the stakeholders into primary and secondary. Primary stakeholders are those necessary for the survival of the enterprise: shareholders and investors, employees, customers, suppliers. Secondary stakeholders are instead those not involved in transactions and not necessary for the survival enterprise, but anyway able to move the public opinion in support or against enterprise's performance: media, communities, administrations.

Another shared classification proposed by the literature is the one that recognizes internal and external stakeholder, depending on the involvement in the enterprise's activities.

Preston supports the thesis that "the four key stakeholders of any enterprise sorted by importance are: customers, employees, community, shareholders" (Preston, 1990), that is arguing that if the right needs and interests of the first three groups are satisfied with efficacy, the shareholders take a great advantage. Profit is a byproduct of the ability in satisfying with responsibility the right needs and expectations of primary stakeholders.

A multi-stakeholder approach to the management of any enterprise is a key element in order to plan and control enterprise's goal achievement; it allows to manage the enterprise taking the higher contributions from stakeholders, or reducing their opposition, to a company's goal. It is then important the role they have in the management model and the set of dimensions, in order to consider even more stakeholders as "participants to a process of sustainable and shared value creation" (Freeman, 1984).

3 The Case study

An enterprise's management model needs to consider different stakeholders, needs to render explicit the cause-effect dynamics of value creation indicators, and finally needs to stress the setting enabling value creation sustainability. A group of scholars argue that enterprises embodying those principles in the management model are more performing in conventional performance (profits, sustainability, growth) than others.

3.1 Methodology and research design

In order to explore how the management model structure and setting can enable a sustainable value creation a case study research has been designed.

The SE has been identified as a holder of the business and management characteristics more stressful for the study. SE competes like a business company on the market but needs to comply with non-profit economic constraints and the collective interest. Given the multi-stakeholder nature, and its dependency with SE's operative performances and sustainability, the research population has been pointed to the SEs.

On the basis of the identified population, a list of potential SEs has been defined according to theoretical motivations (Glaser e Strauss, 1967). The SEs we listed represented a polar type, that is an extreme situations in which the phenomenon of interest is transparently observable (Pettigrew, 1988).

A letter of invitation to contribute to the research has been sent to listed SEs, and then the most significant one 'Istituto dei Ciechi di Milano', among three respondents, has been chosen. A plan of open and semi-structured interviews with the Director took place, and the results organized in tables.

3.2 L'Istituto dei Ciechi di Milano

The Istituto dei Ciechi di Milano (hereinafter reported as 'Istituto') provides training, supporting services, work opportunities for blinds and visually impaired people.

The Istituto was founded in Milan by Michele Barozzi in 1840. Along almost 2 centuries the Istituto renovated physical structures, services, technologies and knowledge, making of sustainable value creation for users and communities its distinguishing factor.

Significant milestones of the Istituto's life are:

- 1868 - Istituto gains the title of Moral Authority with Italian Royal Decree as 3rd oldest italian institute for the blinds;
- 1869 - A kindergarten is built for the accommodation of blind students and a laboratory were established.
- 1925 - A 'Home for blind women' was set up with the purpose of facilitating job opportunities;
- 1926 -Istituto is recognized as a collective-society service provider, and a Royal Decree subsidies it, over the charity donations.
- 1950s - Public subsidies are cancelled; the Istituto's board starts up entrepreneurial initiatives to collect financial returns. A consulting service and a “Tiflopedagogica”

(pedagogy for visual impairment) research centre are set; in few years the Istituto becomes a European leader in consultancy and research.

- 1993 - A radical innovations plan involving information technologies, research in pedagogy for visually impaired, location and spaces logistics, teachers training, start;
- 2006 - Istituto starts developing and organizing social events, exhibits and shows, related to the 'world of blindness', making the event organization and the fundraising fundamental source of incomes. An Historical Museum "Luis Braille" is set, and the cultural and artistic heritage belonging to the Istituto (paintings, sculptures, musical instruments) is installed as a permanent exhibit; a library, an historical archive, and a photographic one are also set and available for the community;
- 2007 - The Istituto's building, located in the Milan city centre, is renovated and provided with areas dedicated to concerts. A new stream of business services starts up: location for events. Besides, a grant for journalists and the magazines that better promote the cause of blinds and visually impaired is launched.

4. Management dimensions and settings enabling sustainable value creation.

The Istituto's model.

The data collection has been organized in a double round interview. The first round, according to the administration of an open interview to the Istituto's Director, has addressed the structural dimensions and the purposes of the management model.

The second round of interviews, still administered to the Director, has addressed the settings of the management dimensions, according to Istituto's value creation targets.

The Istituto's management model. The management model is not explicit. It is encrypted in the director's management routines; it also doesn't conform to explicit models known in the management literature, like Balanced Scorecard, or Performance Prism. The purpose of the model is to support a multi-stakeholder management approach, and secure planning and control of activities addressing value creation. A rationalization of the Istituto's management model allowed to identify the following structural dimensions:

- value creation targets,
- value creation drivers,
- management dimensions.

The Istituto's management settings. After having defined the structural dimensions of Istituto's management model, a second round of interviews took place. According to the management structure the list of key stakeholders representing targets for the Istituto has been set under Value creation targets. A value driver depending on the target stakeholders is the dimension to be set in order to plan proper management targets.

Finally three management variables have been set out by the Istituto's Director in order to plan and control process/activities: compliance to social and ethical values, service and process performance, knowledge and growth of persons. A qualitative assessment of impact correlation between management dimensions and value creation has been drawn through a qualitative scale grading: strongly, moderately, weakly. Istituto's Director evaluated how impacting have been, on the basis of recent decades enterprise's observations, the management dimensions on the value creation; in this way it is captured and exploited the setting of management model dimensions, enabling Istituto's value creation dynamics.

Value creation		Management dimensions		
Targets	Drivers	Compliance	Performance	Knowledge
Blinds and visually impaired (users)	Service effectiveness	●	●	○
User's families	Support	○	●	○
Employees	Salary and satisfaction	●	○	●
Community	Reputation	●	○	○
Suppliers	Quality/Price	○	●	○
Milan's Public Admin. (City house, etc.)	Service efficiency	●	●	○
Media	Public awareness	○	○	●

● strongly ○ moderately ○ weakly

Tab.3 - Istituto's Management model: structure and settings.

4. Final remarks and Conclusions.

Sustainable value creation becomes even more important for enterprises, as the competitiveness becomes turbulent and higher.

The SE represents a model of enterprise characterized by the absence of profits and the aim of providing services or products of a collective and common interest. These

characteristics of the SE's model distinguishes it in terms of value creation and sustainability. Its management model structure and settings appear to be particularly enabling the value creation, due to a cyclical support between stakeholders' value and stakeholders' contribution; the last results in a support to the enterprise's performances. The case study reveals useful insight to for-profit companies management, addressing some issue about the management model: reconsider the value creation targets and the stakeholders, review the impact they have on the value creation and on its sustainability, set the management dimensions and proper indicators.

Particularly important is also the cross dimensional interaction among management model's dimensions, and the advantage coming from an integrated management across them. According to Monks and Minow (1995) "the relationship among various participants in determining the direction and the performances of corporations" is crucial in the management of an enterprise. This highlights that the factors impacting on enterprise's performances are not based in the company but even more outside. The Management model needs then to be enlarged and approached to a governance model.

Governance has, intact, elements of stakeholder management (Kooiman, 1993) because it involves multiple stakeholders that are interested in specific tasks (Kooiman, 1993; Beritelli et al., 2007; Kjaer, 2004).

Governance does not involve a given hierarchy and a self-evident leadership so it involves less predictability and government control (Breda, Costa and Costa, 2006) compared to the government that often may oversee tasks that have to be completed (Mhone and Edigheji, 2003; Newman, 2001; Kjaer, 2004).

Abstract

The proposed article aims to show which aspects of organizational skills contribute to successfully maintaining an open innovation model. Open innovation is a global approach to innovation management analysed from different angles, such as the strategic, technological, human, and market aspects. Although various research trends have contributed to understanding open innovation, a key element is missing from the debate: the role-played by organizational arrangements and skills in implementing open innovation. The purpose of this paper is therefore to fill this blank area in research on open innovation by addressing the following research question: What organizational framework should be put in place to develop organizational skills for open innovation? Our approach is based on a case of inbound open innovation concerning the improvement of an urban transport system, led by a French high-tech group with an active open innovation policy.

Key words: open innovation, organizational arrangements, organizational skills

Paper type: Academic research paper

1 Introduction

In an environment of global competition based on new ideas, shorter product life cycles and market uncertainty, a company's capacity to innovate is viewed as a source of sustainable competitive advantage. In this context, the innovation model is evolving so as to adapt to the rapid diffusion of knowledge. Rothwell (1994) identifies five generations of innovation since Schumpeter's linear process, from the chains that link markets and inventions (Kline and Rosenberg, 1986) to extensive networking. In 2003, Chesbrough (2003) introduced the concept of open innovation – which offers an alternative to the closed innovation model centred on in-house research results that are very expensive and long to obtain – in the form of an open model based on both internal and external knowledge sources. Unlike the closed model, which assumes in-house Research and Development (R&D) and targets traditional markets, open innovation puts the emphasis on outside relationships to acquire and/or develop inventions. Academic work done on open innovation denotes on the one hand, the use of external and internal knowledge sources to accelerate internal innovation, and on the other hand, the use of external paths to markets for internal knowledge (Chesbrough, 2003, 2006a). In other words, this open model puts forward two complementary aspects (Chiaroni *et al.*, 2010). The first of these is inbound open innovation, which is based on establishing relationships with external organizations or individuals with the purpose of accessing their technical and scientific skills for improving internal innovation performance. Specifically, inbound open innovation involves inward technological transfer, including the practice of leveraging other people's ideas and actively collaborating in research activity organizations with the purpose of commercially exploiting technological knowledge. The second aspect is outbound open innovation, which is the practice of establishing relationships with external organizations because firms rely on other sources in addition to their internal R&D (Chesbrough and Crowther, 2006).

Opening up the innovation process towards the outside involves intensive collaboration between people with skills and experience in different institutions, departments and technological domains. Numerous interactions provide an opportunity to acquire new technologies, establish rewarding partnerships and react faster to the market. To adapt to this opening up, firms focus on their core skills and on attaining complementary capabilities (Hagel and Brown, 2005). Recent work by Wallin and von

Krogh (2010) puts the accent on integrating knowledge into the organization of open innovation. This approach also involves analyzing the individual skills and knowledge of open team members (Leiponen, 2005). The issue of how to organize knowledge and skills as a driving force in open innovation management has rarely been tackled in published research. Yet the identification of these skills, their integration into organizational structures and their development are key to implementing an open innovation model. We therefore analyze the organizational skills shaped by long-term organizational structures necessary for integrating external sources into open innovation processes.

For companies, the transition towards an open model involves identifying its organizational skills supported by specific organizational structures (Charoni *et al.*, 2010; Chesbrough, 2003; Deck, 2008). Christensen (2006) points out that, “open innovation can be considered an organizational innovation”. Recent studies have shown the importance of organizational support in creating new partnerships, routines and skills matrices to move towards a process of open innovation (Marshak, 1993; Chesbrough, 2006b). They offer a general overview of the organizational structures for open innovation without a deeper understanding of organizational mechanisms for implementing open innovation. Despite the attention it has attracted, there are still unanswered questions regarding the ideal organizational set-ups for an open process, in particular in the case of inbound activities. This article takes up this recognition of the role of organizational methods in structuring new organizational skills for successfully managing inbound open innovation. Concretely, this involves illustrating to what extent the development of organizational skills is based on establishing a specific organizational framework in order to make inward collaborations and transfers. This research focuses on the case of a major French group with intense R&D activity *in the sustainable urban transport* based on an inbound open innovation model.

The first part presents the framework of our analysis on organizational arrangements and the issues of organizational skills in an open innovation model. The second part focuses respectively on the methodology and the results of this research.

2 Open innovation: analysis of organizational arrangements and skills

The objectives of this part are to analyze studies of organizational arrangements specifically aimed at open innovation (2.1) and then define the characteristics of

organizational skills for this model (2.2). This will enable us to highlight the connections between these notions and build up our theoretical framework for analysis.

2.1 Organizational arrangements to manage open innovation

The relationship between organizational arrangements and innovation has been the focus of numerous studies. The outcome of an innovation process is defined by the characteristics of the organizational set-ups, which have been recognized as crucial (Drucker, 2007). According to Menguc and Auh (2009) the organizational arrangements adopted by firms influence the development and carrying out of innovation. Christensen (2006, p. 35) remarks that, “open innovation can be considered an organizational innovation”. However, apart from the work done by Chesbrough (2003), little research has been undertaken to understand organizational structures for open innovation. Nevertheless, changes in organizational arrangements are crucial to opening up the innovation process (Naqshbandi and Kaur 2011). In particular, the organizational structure lever is considered as the starting point for the process of implementing open innovation (Chiaroni *et al.* 2010). Establishing new organizational set-ups also makes it easier to collaborate on research and integrate external knowledge and technologies, which are more complex than for products and services (Lichtenthaler and Ernst 2006). In the same vein, Hansen and Nohria (2004), emphasize that effectively managing externally acquired knowledge requires the development of complementary internal organizational systems focused on accessing knowledge and integrating it into the firm’s innovation processes. In this section, we describe the reference framework that was used as a guide to gather and interpret the empirical data collected through the case study. This framework was developed by looking into organizational set-ups, in particular those that combine exploration and exploitation in the innovation process (Ferrary, 2011; Verona and Ravasi, 2003), and into the rare research dedicated to the organizational characteristics of the open innovation model.

Ambidextrousness and open innovation

Studies on innovation look at the structures that make it possible to combine two complementary approaches: exploitation innovation, which mobilizes existing knowledge in the company to rapidly respond to the market, and exploration innovation, which involves significant renewal of knowledge (Raisch and Birkinshaw, 2008; March, 1991).

In practice, the firm is supposed to gain a sustainable competitive advantage through striking an efficient balance between exploration and exploitation (Andriopoulos and Lewis, 2009) and efficiently exploiting the disruptive innovations generated by exploration (Benner and Tushman, 2003; McNamara and Baden-Fuller, 1999; O'Reilly and Tushman, 2004). Published studies propose different configurations for ambidextrous organization, which is defined as an organization's ability to reconcile explorative and exploitative activities simultaneously (Tushman et al. 2002). While Benner and Tushman (2003) promote ambidextrous organizations with separate structures (usually a central research laboratory for exploration innovation and operational departments working on exploitation innovation), other studies propose more complex organizational forms that favour the transfer and reconfiguration of skills (Verona and Ravasi, 2003; Foss, 2003). These outfits have been qualified as "hybrid" (Foss, 2003), "flexible forms" (Volderba, 1996), "semi-structures" (Brown and Eisenhardt, 1997) and "dynamic communities" (Galunic and Eisenhardt, 2001). Research done by Ferrary (2011) shows that in open innovation, companies combine exploitation and exploration in ambidextrous structures with highly specific characteristics (Chanal and Mothe, 2005):

- Organizational flexibility, which is the capacity to modify structures, decision-making circuits and communication in the face of change;
- Extensive communication, which offers stakeholders a great deal of freedom to improvise within innovating projects;
- Creation of a scientific expertise network within the research centre targeting external cooperation to acquire and commercialize knowledge.

However, these ambidextrous structures do not explicitly correspond to an open model, which puts the accent on interactions with the external environment and collaboration between external and internal stakeholders. Recent management studies have thus looked at the specific features of organizational set-ups that make these connections feasible.

Organizational characteristics of open innovation

Beyond the issue of organizational ambidexterity, studies done by Chesbrough (2003) underline how modifications in organizational support allow the process to be opened towards the outside. In fact, in open innovation processes, organizational boundaries become porous as a result of the firm's close interaction with different actors

in their environment (universities, research labs, customers, exhibitions, venture capital firms, etc.) (Chesbrough, 2003, van de Vrande, 2010). This opening out of the innovation process thus requires setting up organizational arrangements that encourage external collaboration and the construction of new internal skills. Specific organizational characteristics for this model can be identified in academic work:

- Top management plays a significant role in setting up organizational changes (Chiaroni *et al.*, 2010); in the same vein, the cohesion and strategic alignment of the firm's various functions play a key role in establishing successful open innovation (Naqshbandi and Kaur, 2011);
- Specific structures and measures are created to promote the opening-up of the innovation model (Chesbrough and Crowther, 2006);
- Independent "open innovation" business units are set up (Kirschbaum, 2005) with dedicated cross-functional teams (Huston and Sakkab, 2006) or independent R&D units devoted to open projects (Chiaroni *et al.* 2010). The cross-functional interface is important with "non-routine and reciprocal information processing systems";
- Organizational roles are defined, e.g. gatekeepers who manage the interface between the firm and its external environment (Tushman, 1997);
- A network of partners is put in place during the initial phases of the innovation process, encouraging the acquisition of external knowledge (Perkmann and Walsh, 2007);
- A firm-level inter-organizational network is established by leveraging R&D managers' personal social networks. These networks are mainly explorative to probe new areas of knowledge that are different from those that they traditionally master (Chiaroni *et al.* 2010);
- Formalized processes for evaluating external knowledge are put in place to complement the existing explorative network. In this evaluation process, an important role is played by the IP Office, which defines mechanisms for facilitating knowledge transfer and protecting companies from opportunistic behaviour (Chesbrough 2006b).

Coordinating and centralizing activities are also crucial to operating an open model. Mortara and Minshall (2011) point out that multiple options exist to coordinate the two extreme approaches, centralized and decentralized. According to Tripak *et al.* (2006)

the major strong point of centralized R&D is that it encourages risk-taking and long-term thinking, while decentralized R&D primarily encourages aligning projects, business needs and shortening the time to market. An alternative is a hybrid structure, which gives business units the capacity to handle incremental innovation for current products and may exceed the resources of a central R&D department, but with less efficiency than other structures. Research does not clearly show whether an autonomous structure or a centralized structure is best suited to open innovation (Linton, 2002).

Along the same lines, Charoni *et al.* (2010) highlight the importance of routines and procedures in the adoption and success of open innovation. This involves the formalization of structures, defined as a form of control employed by bureaucratic organizations, or in other words, the degree to which a codified body of rules, procedures or behaviour prescriptions is developed to handle decisions and work processing (Naqshbandi and Kaur, 2011). Formally structured organizations are characterized by institutionalized rules, policies and routines, difficult cross-function integration, and reduced spontaneity and flexibility in operations, leading to behaviour programming and strict rule enforcement (Chen and Huang, 2007). In contrast, an informal organizational structure is characterized by openness in the system, which is a necessary precondition for initiating ideas in the innovation process (Naqshbandi and Kaur, 2011). According to Damanpour (1987), high formalization makes administrative innovation easier, while low formalization facilitates the adoption of technical innovations. Firms employ both formal and informal coordination. Nevertheless, Naqshbandi and Kaur (2011) show that published studies imply that open innovation tends to be favoured by informal, rather than formal, organizational structures.

These characteristics relate to the strategic and operational levels of open model management. Our research aims to identify the organizational arrangements that promote dynamic connections between these two levels and help the construction of organizational skills.

2.2 Open innovation: identifying organizational skills

The previous section highlighted the characteristics of organizational arrangements that foster the operation of an open model. To open up the black box of open innovation, in this section we analyze the issues of organizational skills that enable this model to take shape in the long term. In this sense, open innovation is not a one-off

event between closed innovations, but rather a continuous, complex process in the organization. We therefore consider a continuous trajectory of innovation, whereby strategy and structure exist before individuals commence an innovation activity, so that they can take on the firm's strategic orientations as their operational activities progress (Drucker, 1993, Reich, 1991). This leads us to consider that an analysis of the open innovation process is based on strategic orientations supported by a specific structure and operational activities taken on by stakeholders who may or may not be from the organization. Structure, strategy and organizational activities thus contribute to building up organizational skills. Therefore, in order to understand organizational skills in the case of open innovation, we analyze them taking three approaches. Firstly, this involves looking at the issues of management through skills (in human resources management) in which the analysis of organizational skills is based on individual and collective skills borne by individuals or teams possessing knowledge. Secondly, the strategic approach shows us how the structure encourages the creation and integration of knowledge, formalized into organizational and collective skills. Lastly, we take a third approach to show how we can use the analysis of organizational arrangements and knowledge to shed light on another facet of organizational skills, i.e. the connections between on the one hand strategy and organizational structure, and on the other hand between the different levels of skills, including collective, individual and environmental skills.

The HRM approach: skills-based management

Research on Human Resources Management (HRM) analyzes the connections between four levels of skills: individual, collective, organizational and environmental skills¹. The notion of skill is understood here as “the capacity of an individual, a working group or a company to mobilize resources (knowledge, know-how and behaviour” (Aldebert and Loufrani-Fedida, 2013, p. 57). In the innovation domain, this definition is aimed at mapping skills and explaining their dynamics. HRM therefore assumes that human resources and skills are key factors in innovation (Purcell, 1999; Lepak and Snell, 1999). Nevertheless, this approach is focused on managing individuals, e.g. knowledge workers (Drucker, 1993, 1999) and their skills, perceived as human capital (Aliouat and Nekka, 2000). In other words, these workers' individual skills lend them a strategic

¹ *The notion of environmental competence has rarely been studied in HRM; it mainly concerns external knowledge outside the company's control.*

power. On an operational level, management developed on the basis of skills and its strategic target are thus centred on the specific management of individuals in order to keep them in the organization (Blackler, 1995; Reed, 1996; Scarbrough, 1999).

Beyond these different issues, HRM studies put forward two approaches for skills-based management, one of which is bottom-up and the other top-down. The first bottom-up approach is based on analyzing the aggregation of individual skills: from the work situation (individual or professional skills) to the combination of these individual skills in a work collective (collective skill) (Bataille, 2001; Retour and Krohmer, 2006). The challenge comes at operational level, and relates to the capacity of a collective to resolve common and/or pooled operational problems. This analysis is necessarily limited by the fact that collective skills are presented as the sum of individual skills, whereas an analysis should look at the outcome of cooperation between stakeholders in order to build up knowledge. However, the human dimension of collective skills is difficult to apprehend because it is made up of knowledge that individuals and the group does not totally master. In fact, it is not possible to ascertain how much knowledge a group has invented. In our research, we therefore consider that collective skills are fuelled by knowledge possessed by an individual and a group of individuals, by knowledge and know-how aimed at building up shared representations, and knowledge-understanding resulting from exchanges between individuals using a shared and formalized language (Retour, 2005).

The second, top-down, approach centres on identifying the operational organizational set-ups (e.g. project teams) through which collective knowledge develops; these are thus formalized into collective skills (Attias-Delattre, 2011). The latter result from a combination of internal and external individual skills gathering into organizational coordination modalities those create formal and informal interactions. It is at this point that we make our analysis of organizational skills, based on coordination, routine and shared language.

Thus, HRM approaches emphasize collective skills. In the bottom-up approach, the managerial challenge centres on individuals possessing key or rare skills, and in the top-down approach it involves teams possessing resources that are mapped. Despite the dearth of studies on organizational and environmental skills in HRM, it is worth noting that in both approaches the characteristics of these skills partially overlap those of knowledge. Indeed, if the extent of knowledge is broader than skills, then managing skills

will involve optimizing resources (Dietrich *et al.*, 2010; Aldebert and Loufrani-Fedida, 2013).

The strategic approach of organizational skills

The strategic approach, the resource-based model, aims to identify what “a company can do” (Barney, 1991; Grant, 1991) in order to create value by drawing on skills, knowledge and organizational structures. This approach allows us to analyze how an organization creates and integrates internal or external knowledge and implements (applies) them within a formal and informal organizational framework (Rindova and Kotha, 2001, Montealegre, 2002). In this sense, organizational skills (although neither visible nor observable) are common practice and part of formal coordination modalities (like structure) and informal ones (like interpersonal exchanges). Organizational skills emerge from processes to develop collective skills and organizational set-ups: the capacity of a collective of individuals at work to constantly invent innovations beyond the organizational supports that structure it.

With this approach, organizational skills can also integrate environmental skills, which correspond to an organization’s capacity to mobilize knowledge in its environment (stakeholders outside the company like research laboratories, suppliers and clients) that *are beyond its control*. Thus, this collective expertise and knowledge is implemented and developed by organizational structures in order to be formalized into organizational skills.

This approach takes us back to the connection between skills and knowledge. Although skills and knowledge are often linked, the two notions do not involve the same challenges. Knowledge is the result of a managerial action that aims to produce skills that can be identified and evaluated. When the aim is mapping (e.g. skills inventory) and evaluating, it is thus a team’s skills and incompetencies that are described. Yet in an innovation process, the major focus is on existing knowledge and knowledge gaps. Even if an analysis of skill characteristics does not aim to evaluate a research team’s lack of competencies, it should nevertheless point to the evaluation of a lack of knowledge in its members. It is this last challenge that an open innovation skills analysis should take into account.

The approach of organizational skills through knowledge

This organizational skills approach in open innovation connects a strategy,

developed in an outfit, with operational activities, formalized into collective skills². Concerning the second aspect, it is the analysis of knowledge that allows us to understand the dynamics of skills in this linear logic made up of key skills, organizational skills, collective and individual skills.

In order to characterize organizational skills, Blacker (1995) puts forward a typology of organizational knowledge according to where it occurs: in individuals and routines (which he calls *embodied* and *embedded*) and in brains, dialogue and symbols (*embrained*, *encultured* and *encoded*). The main contribution of this analysis is to shed light on the dynamics of knowledge. This is not only individual, collective or structural: it takes the form of “communication-intensive organizations” (Attias-Delattre, 2011b), i.e. based on communication and collaboration in the key process. These elements are present in research done by Grant (1996) and Wallin & von Krogh (2010) on knowledge analysis. Their studies help us to understand the dynamics of organizational skills at different levels (organizational, collective and operational) using the following:

- Rules and directives: the capacity to regenerate

“Rules may be viewed as standards which regulate the interactions between individuals” (Grant, 1996, p. 114). In this approach, knowledge analysis is rooted in both the accumulation of knowledge and in the organizational capacity to formalize coordination processes. In an open innovation situation, formalizing these processes is not enough. This is because in an open model, it is not so much the knowledge mobilized that is essential, as the direction given to its mobilization. The rules and directives here represent a communicational meditation that makes innovation possible by furnishing it with organizational logistics. Thus, collective knowledge and skills are rooted in the organizational capacity to formalize common representations of a solution, i.e. whether or not to pursue an innovation project, whether to integrate different stakeholders in the process. The rules and directives mainly have a communications objective: “low cost method communicating”.

² *Organizational skills are analyzed for their capacity to overcome the limits of its members' way of thinking (Teece et al., 1994) through its organizational set-ups in order to integrate fragmented and individual knowledge (Grant, 1996). This integration leads to conceive the organization as a set of capabilities organized into a structure or architecture (Grant, 1996). However, the notions of structure and architecture do not only cover formal structure, they also encompass routines (forms, rules, norms, conventions [March, 1991]).*

- Sequencing

This involves emphasizing the stages of the innovation process. In an open innovation situation, we are as interested in the innovation as a result as we are in the action of innovating. Multidisciplinary teams with more or less defined objectives work together at every stage of the project. A representation of the innovation stages is functional by nature: it is broken down into the professions and implemented resources that allow skills to be produced with a view to performance. By placing ourselves in a temporal dimension, the gates of passage from one stage to another constitute the key elements of these stages for the teams.

- Informal routines

The construction of organizational skills is done within a decision-making group that “allows both a community of targets and a matching of action” (Savoyant, 1999). However, decision-making “is the result of a confrontation” (De Terssac and Chabaud, 1990) “of representations from the group’s members” (Troussier, 1990). Thus, informal routines are analyzed in the action of the decision-making process at collective and individual level; informal routines structure tacit knowledge while creating the group’s memory (Walsh and Ungson, 1991; Anand *et al.*, 1998; Ackerman and Halverson, 2004; Cardin, 1995; Weick, 2001; Chedotel and Pujol, 2009) through a “repertoire of responses” and a “grammar of action” (Habermas, 1986). Informal routines thus contribute to building a collective memory that is an essential lever to ensure the long life of an open model.

- Group problem-solving and decision-making

We have shown that in an open innovation situation, collective skills manifest themselves in the development of decision-making processes. At individual level, activating collective decision-making processes presupposes one condition: that group members acquire social skills (Cannon-Bowers *et al.*, 1995; du Chatenier *et al.*, 2010). These are the capacities for communication and negotiation implemented during interactions; they are specific to each situation encountered. These social skills are both inter-personal (e.g. being able to speak in public, able to listen, notice other people’s reactions) and organizational (e.g. draw up a road map, cooperate) (Stevens and Campion, 1994). In this sense, collective skills acquired during the decision-making process is an inter-communicational skill on the problem rather than a skill of a communicational character. Thus, a group discussion should not only serve to find a recognized technical

solution, it should also guarantee inter-communicational rules of communication (rules and directives, coordination modes, routines) in order *that everyone has an opportunity to contribute to finding* a legitimate solution.

In conclusion, our theoretical analysis of organizational skills has shown that previous research has mainly centred on mapping or photographing organizational skills (Danneels, 2002; Belderbos *et al.*, 2004; Trott, 2005; Adebart and Loufrani-Fedida, 2010). Yet in an open innovation process, organizational structures and skills are two facets of the same open innovation activity. In an open innovation situation, the outcome of these interactions is of a strategic, organizational and operational nature. This means that organizational skills only really make sense when analyzing the emergence and validation of new knowledge resulting from a strategy supported by the organizational structure. Consequently, our perspective on analyzing organizational skills considers innovative activities (individual and collective), their formal and informal structuring, their validation, and their integration.

In this first part, we have highlighted the contribution that published studies have made regarding organizational structures and organizational skills for an open innovation model. Despite the interest of these studies, some issues remain unanswered and have directly guided our research:

- Literature on organizing open innovation is centred on highlighting organizational characteristics in general. It gives little information on actual organizational support, which, at a more aggregated level, takes into account internal and external stakeholders' effective involvement in managing open innovation;
- Despite their variety, these organizational characteristics are never connected with developing organizational skills.

Thus, in our research, organizational structures and organizational skills are analyzed at each phase of the inbound open innovation process.

3 Empirical case study

3.1 Methodological approach

As we have just shown, existing studies have done very little to develop issues regarding organizational set-ups linked to building organizational skills in an open

innovation model, calling for a qualitative research based on a single case study. This research method seems particularly well suited to fully understanding a specific issue. The choice of a single case can be justified provided that it is “representative” or “typical” (Yin, 2003). This research uses the “qualitative case study” of a major French international group in the high-tech sector, over a period of four years. The goal was to analyze specific phenomena which have been little studied to date and which correspond to particularly innovative situations (David and Hatchuel, 2007). The case was selected for its very dynamic R&D strategy based exclusively on an inbound open innovation model for *sustainable urban transport*, as well as its activity in the highly innovative and competitive high-tech sector. The results draw from an analysis of data collected since 2008. Semi-formal interviews were regularly held with a technical department manager, the head of an R&D laboratory, the technical department’s external projects manager, and the group’s IP managers. The interview guidelines were produced by analyzing structural characteristics put forward in published works. The results of the interviews were validated by the interviewees. Secondary data (internal and external documentation) also corroborated the information obtained through the interviews.

Last but not least is the group’s ambition to set up multiple open innovation projects, in particular with an inbound approach. These open projects aim to develop technological solutions rather than final products; these solutions in fact take the form of fairly developed technological demonstrations that could be used by different partners in their programmes for developing totally distinct products. Inbound open projects rarely concern the development phases of a concrete product.

3.2. Results

This research points to two types of result. The first of these underlines the organizational arrangements established in a perspective of managing open innovation projects (3.2.1.). The second identifies the organizational skills implemented throughout the different stages of an inbound open innovation process (3.2.2).

3.2.1. Overview of organizational arrangements

The group studied builds up networks of external partnerships with different stakeholders depending on the type of project. This network can be used to choose a partner in line with a project’s strategic importance:

- “strategic” projects are established with special partners with long-standing relationships (3-4 years). The established trust makes it possible to set up a common laboratory within the project, make joint investments and physically exchange researchers between sites;

- “multi-stakeholder” projects result from European calls for tender. Their main objective is to develop collaboration with several stakeholders of different natures, i.e. research institutes, suppliers, clients and competitors. These relationships can then evolve to become a strategic project;

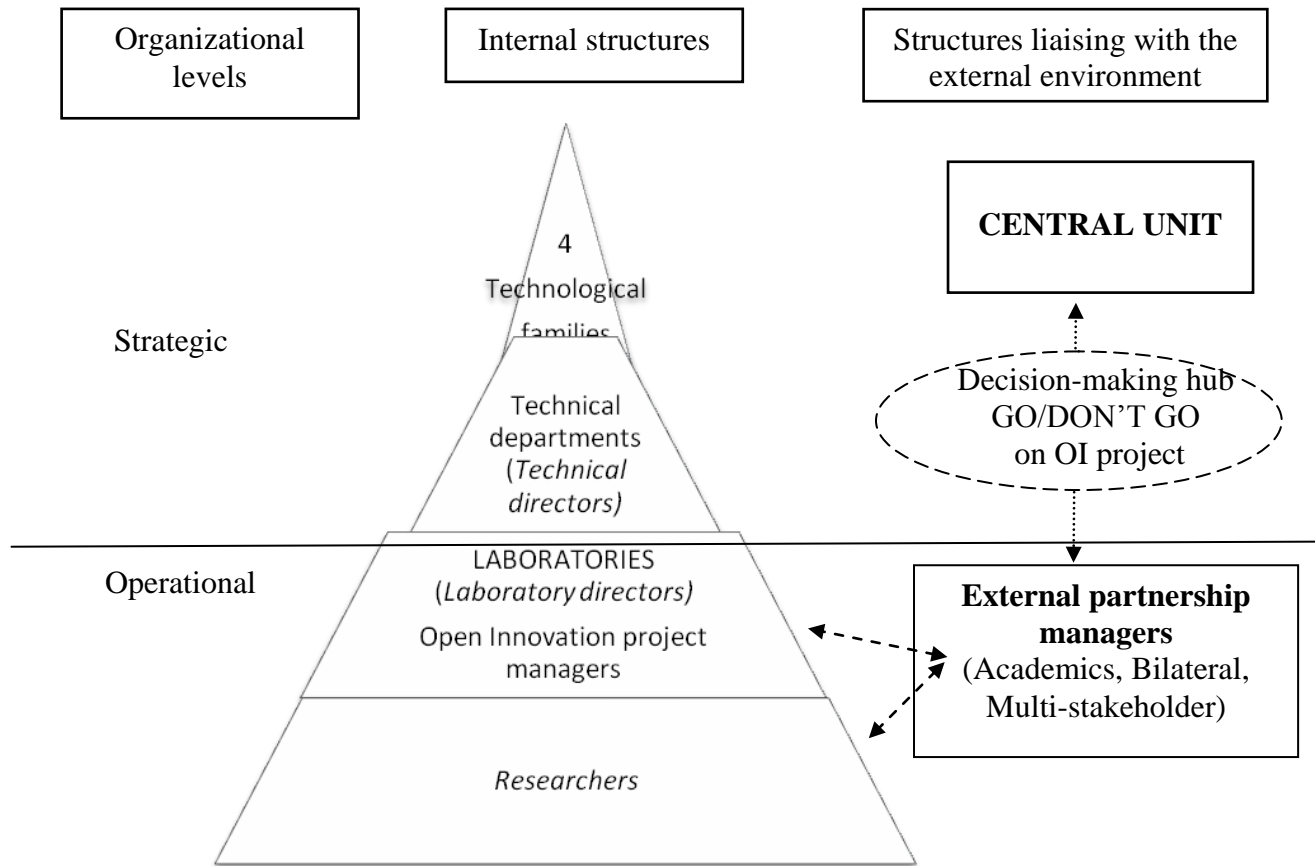

- “bilateral” projects are put together with external partners that possess specific technological skills. These partners can become special partners on a strategic project, depending on the quality of knowledge produced and the exchanges.

Thus, these different open projects can evolve in different directions: from a bilateral framework agreement into a strategic framework agreement, or a European call for tender into a bilateral project with a special partner. The creation of the network is supported by a specific organizational design applied at two levels: strategic and operational (Figure 1). For each of these levels, we will study the overall structure and the special organizational arrangements used for managing open projects.

- *Overall strategic structure*

On a strategic level, R&D management is organized by technological families that correspond to families of products. Currently, four technological families exist, each of which is managed by an R&D vice president who establishes the strategic priorities in terms of innovation. To support these families, technical divisions supervise research activities by the group’s main technical domains. Their mission is to coordinate the associated laboratory activities, mainly inbound and outbound open projects. This cross-cutting organization aims to coordinate strategic decisions between product families and technical divisions. On one side, annually, the board of directors and family vice-presidents define the axes and research objectives. On the other side, on an everyday level, they support projects put forward by the technical departments and ensure that their results are used in several families of products.

Figure 1 – Organizational design: strategic and operational level

- Specific strategic structures, centred on managing the interface with the external environment

Within the technical departments, a specific structure called the “central unit” is created solely to manage external relations. This unit coordinates all of the group’s open innovation projects with clearly defined missions. This starts with selecting propositions for open projects, studying how they connect with the general strategy, and validating the project’s content before it is put into operation by the research laboratory. Then, when the research activities take place in the laboratories, the unit monitors their progress and finally, checks whether the targets are achieved. To carry out these missions, the director of the unit works with several external partner managers (e.g. laboratory directors, project

managers and researchers). The latter are split into type of partnership, i.e. those with academic stakeholders, bilateral partnerships with companies (suppliers, clients or other external organizations), or multi-stakeholders involved in European calls for tender. These managers also handle all interactions with the external environment: from mapping out stakeholders to making external and internal contacts, and negotiating the signature of contracts. Once the framework agreement has been signed, the research laboratory is responsible for the operational implementation of open projects.

To sum up, the unit coordinates the strategic aspect of open innovation projects and does so following steps and procedures that are clearly defined for all families and technical departments, by:

- studying the benefits of the project in strategic, technological and financial terms;
- establishing consortiums with multiple partners (major companies, SMEs, universities and research centres, public organizations, etc.);
- signing standard framework agreements for calls for tender or specific framework agreements for bilateral projects.
- checking that results match the targets of open projects.

In addition, this central unit submits the projects to a cross-cutting decision-making committee comprising heads of technical departments, project and laboratory managers, and the unit manager. This committee positions the central unit's innovation proposition and validates the "open/or not" decision for the innovation project. Its objective is to decide whether the innovation project will be open or not, define the type of collaboration, the partners and the clauses of the contract. This decision is formalized by a specific procedure called the "*initial gate of passage*".

- *Overall operational structures*

Research laboratories manage the operational implementation of research projects. From an organizational point of view, the laboratory director works with the technical director of the department at a strategic level and with the person responsible for the product line at operational level. This open innovation process is supervised by a "project manager" who coordinates the activities of both internal researchers and external project participants. Each researcher is associated with a single laboratory. However, the cross-cutting structure means that she or he can also be part of open projects supervised by other technical departments. Thus, the group's cross-cutting approach, both strategic

and operational, encourages the development of researchers' individual skills as well as the creation of new collective skills within research teams.

- Specific operational structures for open projects

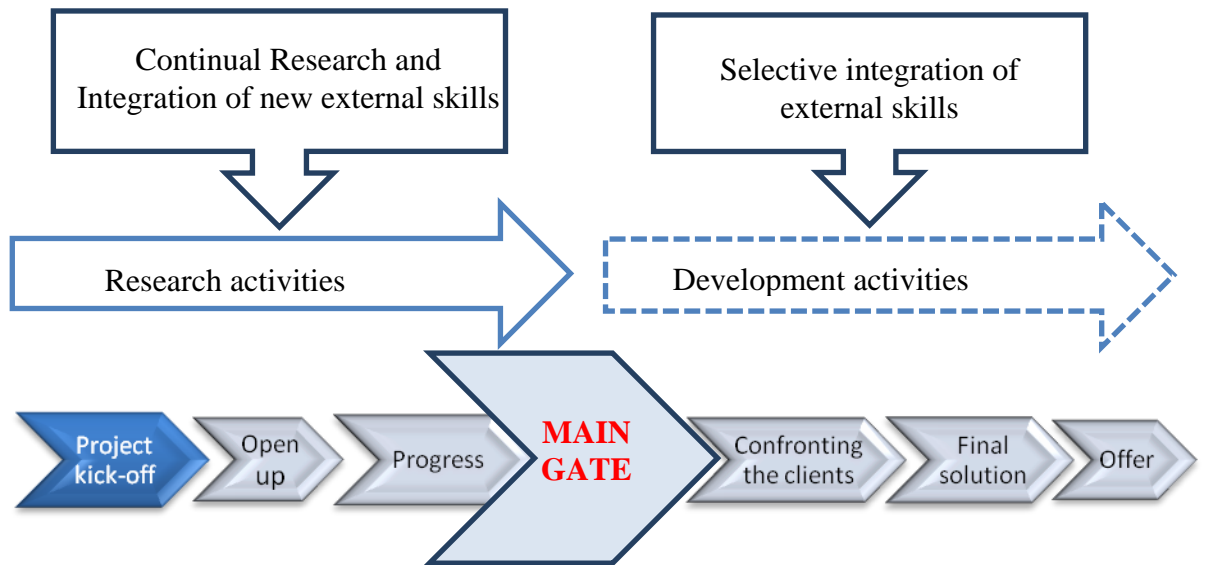

The most active research laboratories in terms of open projects delegate the supervision of these projects to an “external partnership manager” named within the laboratory. He or she acts as a middleman between the central unit and the open project manager. The project manager is responsible for the project's operational management, in particular exchanges with the outside and the progress of stages. However, the group's cross-cutting structure is not restricted to this activity: like the researchers, they can be associated with several types of project carried out in their laboratory and other technical departments. This cross-cutting nature consolidates the integration of specific skills and the creation of collective skills “tailored” to each project.

The analysis of general open innovation structures broken down to the strategic and operational levels needs to be completed by a detailed analysis of the steps of an open innovation project. This approach will give us a better understanding of the dynamics of the organizational skills used in a concrete research project.

3.2.2. *Open innovation process: sequential presentation*

Our research centres on analyzing organizational skills throughout the various stages of an open innovation project as they occur in the laboratory studied. Described sequentially (Figure 2), the process is structured into six steps around a “main gate” that marks the point between research activities mostly carried out in collaboration with external actors (upstream), and the development activities of these results, which mostly involve internal stakeholders (downstream).

Figure 2 - Phases of the innovation process

Phase 1: Project kick-off

The aim of this step is to validate whether or not to kick-off of a research project by answering a key question: “go or don’t go?” Individual projects can either be proposed by the laboratory director or the technical department director in a “technology push” approach, or by the product line manager in a “market pull” approach. The decision-making process is thus a joint one, and the people involved come from within the group, i.e. the technical department director, the laboratory directors, the project manager and the researchers. These different stakeholders bring the required expertise to accomplish the main activities of this step, which relate to technological monitoring, the definition of technological priorities, the study of the freedom to operate and legal protection. These operational activities are carried out drawing from internal knowledge and informal procedures. On the other hand, the final decision to go or not to go with the research project is a formal procedure and depends on the group’s strategic R&D objectives or future clients’ identified requirements. However, although coordination procedures during this step have been recently put in place in order to save communication costs, they are identical and standardized for both open innovation and closed projects.

Phase 2: Decision to open up a project to the outside

This is the open model's actual departure point, since this phase involves a decision on whether the research project will only be set up internally or whether it will open out to external stakeholders. The "open or close innovation process" decision involves the vice-presidents of the technological families, the laboratory director and the technical department director. Open innovation mainly involves high-tech projects for the future, which require pooling complex and varied knowledge. The decision depends on strategic and technological criteria as much as the market. In fact, the final decision is influenced upstream by specific operational activities, including finding and evaluating partners, how wide to open (i.e. national or international), the establishment of industrial property and the final framework agreement. These activities therefore depend on the knowledge of all internal stakeholders, on comparisons, and on communication-based mediation that makes it possible to decide to open up. As for the first step, the decision is formalized thanks to pre-defined rules for all technical departments. Thus, the process that leads to this choice depends on both pre-established rules and the creation of new organizational knowledge.

Phase 3: Establishment and progress of the open project

This stage involves the operational progress of the project, which can last 12 to 24 months. Collaboration with external stakeholders mainly takes place during this stage and follows few specific rules and procedures. This joint work between internal and external stakeholders calls for social skills, which are both inter-personal (e.g. ability to explain, be patient, understand, negotiate, work together, speak and understand different languages) and organizational (e.g. collaborate, draw up plans). These skills allow stakeholders to build up a common language together with a technological aim. However, throughout this stage, their activities are guided by targets set out in the framework agreement and by the production of formalized results that feed into the following stage.

Phase 4: "Main Gate" to development

The crucial point of an open innovation project is the "main gate", which opens out towards developing the technical solution. The decision-making procedure is collective, initiated by the research project manager. The final decision is made by the department's technical manager and the product line manager, who possess the technical,

industrial and commercial skills to validate the development of the project's future applications. The decision-making process is thus based on their individual and collective skills accumulated throughout the preceding steps of the project, and on the confrontation of their strategic and operational representations of the project.

They ultimately deliver a formal document setting out the technical parameters and possible applications as well as the industrial impact of the technological solution. This framework document is common to all of the technical departments, and sets out the essential criteria for making the decision. Thus, the passage through the "main gate", as for step 2, involves formal procedures, formalized documents, and clearly defined decision criteria. This is one of the two major decisions in an open innovation project. The first relates to the actual existence of the research project, the second finalizes the external collaboration.

In fact the first four phases, lasting three years on average, take place in an open model. They are followed by the industrial development phases, which are mainly carried out by the group's internal stakeholders. External stakeholders occasionally intervene in the following phases (e.g. phase 5) involving a final client or a special R&D partner.

Phase 5: Confronting the clients

The industrial development of each technological solution cannot be envisaged without adapting to the client's requirements. This stage therefore involves studying the concrete applications of the technological solution in connection with the external client so as to draw up a prototype. Frequently, the client is involved right from the second stage of the project as an external partner via its R&D department. At this stage, its engineering department is involved in defining the industrial applications. For the internal stakeholders, the decision is taken by the laboratory director, the technical department director and the product line manager. This decision-making process is based on "*the accumulation of past capabilities and common know-how in the collective memory*" (inside source) of internal and external stakeholders. This also helps reduce the communication costs in the development of the project. Although the writing of the call for tender and response to clients are both standardized, the preparatory work remains informal.

Phase 6: Final solution

This decision making involves improving the prototype using complementary technology so as to finalize the product for the client. This final solution is demonstrated to the external client as well as to different internal technological families in order to optimize the profitability of the open project. The product line manager and marketing manager decide on the final solution. In house, this involves organizing and structuring knowledge in order to adapt the solution to the demands of internal and external clients. During the negotiation with clients, the comparison of representations helps build up a common, specific language by using technological, commercial, inter-personal and negotiating skills.

Phase 7: Putting together the final product

The marketing manager and product manager supervise the final product’s actual specifications and its introduction into the group’s catalogue. The offer will be different depending on individual clients’ specific demands. This therefore requires a single connection between stakeholders possessing highly varied skills of a technical, commercial and legal nature. Although the framework of the final offer is standardized, it does allow some liberty in finalizing the content of the offer. This is a decision made entirely by the internal stakeholders.

The organizational arrangements established during the different phases of the project continue to exist independently of the individuals that comprise it. They have an in-house stability and the capacity to evolve in order to accompany the opening up of the innovation process. This means that internal and external knowledge can be organized and structured in a specific way when an individual open project is set up. The various aspects, shown in table 1 below, are taken up in the next part of our discussion.

Table 1: Organizational skills and stages of the open innovation process

Sequences	1 Initial Gate	2 Open up	3 Progress	4 Main gate
Stake -holders	- Technical department director - Laboratory director - Research OI Project	- Vice-presidents of technological families - Technical department director	- Laboratory director - Researchers - External	- Technical department director - Laboratory director - Research OI project

	manager -Researchers	- Laboratory director	stakeholders	manager - Product line manager - Researchers
Activities	- Technological monitoring - Definition of technological priorities - Definition of object of the project - Industrial property	- Search for partners - Decision on type of open innovation (national/ European) - Decision on industrial property - Draft framework agreement	- Research activities on the open innovation project's technical aspect	- Technological demonstration of projects - Definition of applications of technological solution and functional uses
Rules and directives	General framework of project	Framework agreement with external partners	Main gate preparatory documents	Form for transferring results towards development
Informal routines	In-house comparison of representations and integration	In-house comparison of representations and integration	Comparison of representations in-house and with external partners. Integration	
Group problem solving	GO/DON'T GO?	Open / Not open	Solve operational problems	GO/DON'T GO to industrial development

Sequences	5 Confronting clients	6 Final solution<	7 Offer
Stakeholders	- Technical department director - Laboratory director - Product line manager	- Product line manager - Researchers	- Marketing manager - Product line manager
Activities	- Drawing up of bids for tender (80%)	Demonstration: - to clients	Final solution

	- Decision on the product - Response to clients (20%)	- to external collaborators Definition of final product	
Group problem solving	Customer decision	Industrial solution	End/Not end
Rules and directives	Prototype specifications	Framework document defining the final product	Framework of final offer
Informal routines	Comparison of representations with external client and integration	Comparison of representations with each internal and external client and integration	In-house comparison of representations and integration

3 Discussion

The objective of this article is to shed light on organizational skills by looking at the organizational set-ups that foster their construction in the case of an inbound open innovation process. To make things simpler, the main lessons learned from this study are summed up in a table (Table 1). The structure and construction of organizational skills are closely linked in open model management. Several points are worth underlining.

By taking into account the role of organizational arrangements in building up organizational skills (Chesbrough 2003, Charoni *et al.*, 2010) this study proposes a detailed analysis of the specific structures put together at every stage of an open innovation process. As mentioned in the first part of this research, few studies have specifically centred on the actual organization of the stages in an open process. This research therefore provides a rare study context by emphasizing the main characteristics of organizational arrangements throughout a real-life open innovation project. More precisely, an analysis of our case study highlight the following:

- Firstly, our analysis sheds new light on research done by Naqshbandi and Kaur (2011), which claims that coordination between top management and the various research stakeholders plays a key role in the cohesion and success of open innovation. In the case studied, this connection between strategy and operations is

present in the subordination of each laboratory's project to the group's strategic priorities. This subordination emerges in two strategic plans drawn up at strategic level for each technical department and for the group's four technological families: the Strategic Business Plan, which defines the development focus of all of the products, and the Technical Strategic Plan, which sets out the technological objectives. These plans constitute an essential guide for choosing laboratories' open projects.

Our analysis also brings insight into the actual modalities of this coordination. In fact, coordination between deciders at strategic level (vice-presidents, technical department) and operational level (laboratory) is constant rather than just at the launch of an open project. This cooperation aims to optimize results for the whole group and create a network of partners of trust. Thus, coordination ensures that the results of open projects in several product families, as well as the different skills of laboratory researchers (internal and external), are all used on the same project.

- Secondly, our study adds to discussions on decentralization in an open innovation process. We observe a fairly "hybrid" model that hinges on the centralization of decisions when moving from one step to the next, and a decentralization in operational activities within each step. We consider that this result comes close to the concept put forward by Mortara and Minshall (2011) on the open innovation model's evolution towards a more flexible approach. The group studied guarantees flexible coordination through informal exchanges between family vice-presidents, technology department managers, and laboratory managers. Thanks to this flexible coordination, the group's strategy can be adequately implemented and continually fuelled by the department's creative momentum. Indeed, laboratories' open project propositions are supported by top management in terms of skills (external or internal from the other laboratory) and additional funds.
- Thirdly, our study highlights the crucial importance of an interface with the industrial property department when implementing inbound open innovation. According to Lhuillery and Pfister (2009), strong patent protection affects a firm's opportunities to access technologies. Nevertheless, our study shows that in inbound open innovation, patent protection makes it easier to share project results and guarantees their successful implementation in the firm's product. Moreover, IP rights help to harness a firm's benefits (Grindley and Teece 1997). IP is an important tool that creates a

platform for technology transfer and collaboration within an open innovation model (Veugelers and Cassiman, 1999). Hence, companies' involvement in open innovation may depend on the strength of IRP protection and early collaboration with the IP department. In our case, protecting all technological results is a vital criterion in the decision to open up.

- Finally, this case study contributes to earlier research, bringing new insight into specific structures set up to manage links with the external environment. According to literature, these specific structures are devised to implement and promote openness (Chesbrough and Crowther, 2006), as well as to manage relations with external partners and monitor the acquisition of the results targeted (Chiaroni *et al.* 2010). Our research therefore puts the emphasis on a specific structure, the "central units" at strategic level and the "external partnership managers" at operational level, which create new organizational skills involving different internal stakeholders, new roles (e.g. gate keepers) and different partners.

In this organizational context, our research brings insight into understanding organizational skills:

- Firstly, our results help us understand the way that organizational skills are built up at each stage of an open innovation process. The key contribution is that we can go further than the photographic approaches that appear in literature, both in terms of mapping skills and knowledge and in terms of functional structures. We propose, on the contrary, a sequential approach. This perspective is fundamentally new. For each phase of an open innovation process, organizational skills are analyzed through the organizational arrangements that structure them and the knowledge implemented. This rationale gives us a much more detailed understanding of organizational skills. It reveals the complexity of interactions between the knowledge possessed by the different internal and external stakeholders, and the formal rules and informal routines that make it easier to work together and achieve the targets of an open project. Existing studies have not taken this kind of approach, even in an embryonic manner.
- Secondly, our research qualifies results by Trott and Hartmann (2009) on the major role that strategic decision collectives, in particular "gate keepers", play in the success of an open innovation process. Our results show that these gate keepers only occur at decisive stages in order to guarantee a project's strategic coherence. However, other

decision-making collectives are established to ensure projects' operational continuity. These are obviously formal and visible, but their role is to structure the dynamic of organizational skills between the strategic and operational levels.

- Thirdly, we shed new light on the formal logic in open innovation. In this sense, our research refines the results of Damanpour (1987), who considers that low formalization facilitates the adoption of technical innovations and knowledge exchanges. In our case, we observe existing rules and directives for stakeholders right from the first stage of their project. However, our sequential approach reveals two types of formalization: intense formalization during the passage from one stage to the next, and low formalization within each stage. These intense and low formal procedures are established for three essential activities: administrative (follow-up on delivery of results at each stage and operational progress), technical (control of technical parameters with external partners), and commercial (study of whether in line with customer expectations).

- Fourthly, our study adds to works on the conception processes by skills and knowledge, analyzed as a whole (Encaoua *et al.*, 2001, Hatchuel *et al.*, 2001, Le Masson *et al.*, 2006). In our case, this not only involves case-by-case coordination of individual, collective or functional skills (e.g. R&D, marketing) during the different stages, but also the long-term structuring of organizational skills to optimize the (internal and external) coordination and communication costs of the entire innovation process. Thus, taken as a whole, this process represents a totally separate open innovation function. According to Le Masson *et al.* (2006), this can be characterized by inputs such as organizational skills (rules, directives, sequencing and available knowledge), collective, individual and environmental skills, and by outputs in the form of the new knowledge produced.

Taking inputs in their final state, our analysis helps make the link between the two approaches to skills: bottom-up and top-down. By identifying inputs for each open project through what the company knows *how to do* (Barney, 1991, Grant, 1991) and especially by *what it does not know how to do*, we illustrate the major importance of taking a strategic approach to skills to implement the progress of an open project. However, at operational level, an HRM approach guarantees the optimization of the necessary resources (Dietrich *et al.*, 2010, Aldebert and Loufrani-Fedida, 2013) by managing the individual, collective and organizational skills useful for producing new knowledge. It is this connection between a strategic approach and HRM that guarantees the objectives of the project's internal and external collaborations.

Lastly, our research slightly opens up the black box of skills in open innovation at operational level. Many studies have pointed out that, for stakeholders, the dynamics of organizational skills can only produce knowledge if they are based on two complementary elements: informal routines between stakeholders in order to conceive innovative solutions, and group problem-solving, which gives individual stakeholders an opportunity to participate in the decision-making process (Grant, 2006, Wallin and von Krogh, 2010). Our case study confirms the role of informal routines in building a common representation of problems to allow the production of new knowledge (Grant, 1996). Our results refine the author's perspective, by highlighting the construction of common representations to solutions (and not problems) as the outcome of informal routines. This is because the internal and external knowledge mobilized by the project team aims not only to attain a common vision of the problem, but in particular to build a common representation of the solution. Among these informal routines, we stress the major role of the collective memory of judgement (Walsh and Ungson, 1991; Anand *et al.*, 1998; Ackerman et Halverson, 2004; Cardin, 1995; Weick, 2001, Chedotel and Pujol, 2009) as a vital lever in building up a solution. This collective memory provides stakeholders with a grammar of action (Habermas, 1986) that allows them to combine their individual and collective skills in finding a solution. Because informal routines do not twirl around the organization without an operational outcome, this collective memory is also partly formalized in the visible organizational set-ups. Thus, in our case study, informal routines, and in particular the collective memory of judgement, are a key factor in building up the organizational skills required for future open innovation projects. In addition, as shown by Grant (1996), we also observe that these informal routines guide interpersonal communication in the decision-making collective. In our case of open innovation, it is the organizational skills already built up through projects that create inter-communicational communication rules. These guarantee that each internal and external stakeholder has the opportunity to contribute to group decision-making.

5. Conclusion

The objective of this research was to elucidate the organizational skills employed for inbound open innovation by analyzing how they are structured within organizational arrangements. This exploratory analysis of organizational skills adds a

complementary perspective to those on the arrangements and skills required for inbound open innovation. Despite the representative character of the selected case, more specifically, this article extends previous research on several levels:

- Firstly, it sheds light on the organizational arrangements of open innovation by precisely describing the organizational support, stakeholders and decisions at each phase of the open model in its inbound dimension. This research includes both organizational issues and skills-based issues by showing how they effectively interweave at the most aggregated level of links between external and internal stakeholders;
- Secondly, this research adds to analysis on open innovation in terms of organizational skills, which are not just a combination of the individual or collective skills of external and internal stakeholders. We show that they result from a specific organizational framework that built the dynamic of skills.

The managerial implications involve organizational issues, aiming to:

- Reinforce and stabilize open innovation processes by creating specific organizational means for building up organizational skills. We point out that open innovation management currently depends not just on implementing structures, but more importantly, on building up organizational skills. The challenge is to involve external actors with diverse and specific skills that enhance internal skills. The focus should therefore be on developing multi-skills collaboration, in all its complexity, which requires systemic organizational set-ups. The main difficulty is thus to devise organizational arrangement and skills and establish them in the long term.
- Build up and develop organizational skills by creating multiple, open project structures. These skills require an open innovation function encouraging cooperation in a long-term between external and internal stakeholders.

This exploratory research lays the foundations to discuss the role played by organizational arrangements in building up organizational skills in an open innovation model. This discussion is all the more urgent since current studies have made little contribution to the subject, while companies are starting to put greater emphasis on managing skills in their open model and have changed the way they organize themselves to reflect this.

Structured Abstract

Purpose – Still little is known about the determinants of the openness degree. Examples of investigated determinants are firm-specific or environmental/external factors. However, the role exerted by some of them remains unclear. In particular, it is still debated the influence by the so-called “technology aggressiveness”. As a matter of fact, evidences on the relationships between the technology aggressiveness and openness are in fact conflicting. The aim of this study is thus to shed further light on the relationship between technology aggressiveness and openness degree in order to give a more conclusive evidence to the debate.

Design/methodology/approach – We elaborate a structural equation model which enriches the state-of-the-art by explicitly testing the interplay among technology aggressiveness, openness (innovatively measured in terms of partner intensity, phases intensity, and variety) and innovative performance. Our study relies on data from more than 400 firms by a survey research developed in Finland, Italy and Sweden.

Originality/value – Findings shows that openness, if measured as partner intensity and phase intensity, fully mediates the relationship between technology aggressiveness and innovative performance, by suggesting that the effectiveness of a firm’s technology aggressive behaviour is strongly related to the intensification of collaboration with the partners along the innovation funnel. Conversely, openness variety seems to play an opposite role and is differently influenced by partner and phase intensity. This result likely emphasises the cost-side of an open behaviour becoming harder to manage, and thus costly, when involving too many different partners, phases and contents.

Practical implications – If one hand firms, which adopt a technology aggressive strategy, are recommended to deeply open their innovation process in order to foster innovation performance. However, due to the fact that a high openness variety could generate some downside, managers should be very careful in the management of different phases, sources and contents. So that a call to find adequate strategies for effectively

managing the collaboration process in order to avoid waste of resources and efforts clearly emerges.

Keywords – Open Innovation, Partner Intensity, Phase Intensity, Openness Variety, SEM.

Paper type – Academic Research Paper

1 Introduction

It is largely recognized by scholars, belonging to several theoretical perspectives (strategic resource-based perspective: von Hippel, 1986; Katila and Ahuja, 2002; innovation management literature: Chesbrough, 2003; Dahlander and Gann, 2010), that cooperative agreements and partnerships aim at creating value and enhancing firm innovativeness. It is also recognized that open innovation resides on a continuum ranging from closed to thoroughly open” approaches and it is usually measured as openness degree through collaboration breadth (i.e. number of external knowledge sources used in innovation activities: Laursen and Salter, 2006) and depth (i.e. intensity of collaboration with each external partner, ranging from surface to deep collaboration as collaborative interactions intensify: Laursen and Salter, 2006; Lazzarotti et al., 2011).

Despite relevant exceptions (Sofka and Grimpe, 2010; Drechsler and Natter, 2012), still little is known about the determinants of the openness degree. Examples of investigated determinants are firm-specific (e.g. innovation-strategy approach and goals pursued with collaborations) or environmental/external factors (e.g. technological and market dynamics). However, the role exerted by some of them remains unclear. In particular, it is still debated the influence by the so-called “technology aggressiveness” construct, intended as the firm technology strategy and its orientation toward high specialization and radical innovation (Miles and Snow, 1978; Brockhoff and Pearson 1992). As a matter of fact, evidences on the relationships between the technology aggressiveness and openness are conflicting. On one hand, literature argues that technological aggressive firms, just because of their specialization and emphasis on radical innovation, are focalized on research activities inside the firm and are reluctant to rely on technologies that are available from external sources (Brockhoff and Pearson 1992; Lichtenthaler and Ernst, 2009). On the other hand, Colarelli O’ Connor (2005) and Lichtenthaler (2008) find that a strong emphasis on radical innovations pushes firms to

adopt approaches based on a higher degree of external technology acquisition because they may not be able to internally develop all the relevant knowledge.

The aim of this study is thus to shed further light on the relationship between technology aggressiveness and openness degree in order to give a more conclusive evidence to the debate. To this purpose, we elaborate a rigorous structural model which enriches the state-of-the-art by explicitly testing the interplay among technology aggressiveness, openness and innovation performance.

2 Research framework and questions

The research framework is depicted in figure 1: it shows the influence of technological aggressiveness on OI choices and the impact of OI choices on innovative performance. In the following we will discuss the state-of-the-art of the literature regarding the relationship between technological aggressiveness and OI choices and soon after we will discuss main results of the literature analyzing the impact of OI choices on innovation performance.

Figure 1 - The research framework

Technological aggressiveness and OI choices

As previously stated, evidences on the relationship between technology aggressiveness and openness are rather scant and conflicting and thus require further extensive investigation. Partly, as shown below, this is due to the different operationalisations of both OI choices and technological aggressiveness.

For example, Lichtenthaler and Ernst (2009) measure technology aggressiveness through three items (*i.* ‘The firm’s emphasis is on radical rather than on incremental innovations’, *ii.* ‘The company’s R&D activities are highly specialised,’ and *iii.* ‘The importance of development activities relative to the firm’s overall R&D activities is high’) and find that technology aggressiveness has a strong influence on a firm’s approach to OI, constituting a major determinant of the degree of opening up the innovation process. More precisely, when these two authors analyse the impact exerted by aggressiveness on technology acquisition (operationalized by asking firms if “a

considerable part of the company's technologies is acquired from external sources"), their results confirm the research hypothesis they formulated, i.e. technology aggressiveness is negatively related to the extent of external technology acquisition. The aspect that differentiates Lichtenthaler and Ernst's (2009) results respect to prior research – they explicitly refer to Brockhoff and Pearson (1992) – is that this relation is not as strong as some findings in prior research indicate. The explanation of the limited strength they found can be retrieved in the fact that firms are forced to increasingly acquiring external technology, with technological exploration to be interpreted as a must rather than an option. In other words, with the trend toward OI, firms may have to choose to acquire external technology relatively independent on their degree of technology aggressiveness. Surprisingly, when Lichtenthaler and Ernst (2009) analyse the impact exerted by an aggressive technology strategy on technology commercialization (operationalised by asking firms if they 'used external technology commercialisation a lot over the past years') their results contradict the research hypothesis they formulated (i.e. technology aggressiveness is negatively related to the extent of external technology commercialisation). Indeed, contrarily to research expectations, they find the opposite results: firms with an aggressive technology strategy do not rely less but more on external technology exploitation. This result can be explained through the fact that external technology commercialisation nurtures important strategic benefits in terms of the possibility of setting industry standards, entering into new markets, and realising learning effects. All in all, first results indicate that an aggressive technology strategy is negatively related to the degree of external technology acquisition and positively related to the degree of external technology commercialisation.

While focusing the attention on only one of the three items which operationalise the construct 'technology aggressiveness' (see above) – i.e. only on the firm's emphasis on radical rather than on incremental innovations – Lichtenthaler himself (2008) finds that the degree of openness seems to rise with the emphasis on radical innovation, especially concerning the degree of external technology commercialisation. Two reasons can explain this fact: on the one side, the opportunity to commercialise knowledge which, not applied in the organisation, reveals to be residual; on the other side, the possibility to facilitate the acceptance on the market, as well as the creation of a standard. But also when analysing technology acquisition, radical innovation exerts a strong positive impact in that firms

which emphasise radical innovation are not able to develop all knowledge internally, but rather have to strongly rely on complementary external sources (Lichtenthaler, 2008).

This result, in particular, deserves further analysis because the impact of the emphasis on radical innovation is controversial. Indeed, when analysed as an item within the technology aggressiveness construct, it seems to have a negative impact on the degree of external technology acquisition, but, if analysed individually it shows the opposite influence, i.e. a positive influence on openness, interpreted as an inbound process. The inconclusiveness of the debate in the literature is even stronger if we include in the analysis the contribution of Laursen and Salter (2006) who indeed find that only one dimension of openness - search depth (but not breadth) - is associated with radical innovation: *“[i]n early stages of the product life cycle when the state of technology is in flux, innovative firms need to draw deeply from a small number of key sources of innovation, such as lead users, component suppliers, or universities. In these early stages, only a few actors may have knowledge of the key technologies underlying the evolution of the product. Innovators need to cling to these sources, drawing deeply from their knowledge and experience. As the technology and market mature and the network supporting innovation expands, more and more actors inside the innovation system retain specialist knowledge. In order to access the variety of knowledge sources in these networks, innovative firms need to scan across a wide number of search channels. In doing so, they seek to find new combinations of existing technologies to enable them to make significant improvements in their existing products”* (p. 146).

OI choices and performance

The impact of OI models on performance has been investigated in terms of company's competence base, development costs and time to market of new products/processes, the level of innovativeness of new products/processes and sales volume/market acceptance of new products.

Literature is unidirectional in showing the impact of the outside-in process on the access and integration of internal company capabilities with new and complementary knowledge of external firms (Gassmann and Enkel, 2004). Instead, literature results are not unidirectional as far as the reduction of development time is considered: for instance, if on the one side Gassmann and Enkel (2004) state that the benefits of co-operation are seen in an improvement in the competitive position and in a risk minimisation, but not in

a reduction of development time, on the other side, according to Kolk and Puümann (2008) firms not concentrating on Open Innovation strategies fail, as rising development costs and shorter product life cycles make it increasingly difficult to justify investments in innovation.

Many contributions in the literature support the impact of open innovation on the level of innovativeness (Lichtenthaler, 2008; Dahlander and Gann, 2007). Laursen and Salter (2006) quote many studies the point to the importance of open behavior by firms in their search for innovative opportunities and they suggest that performance differences between organizations can be ascribed to this behavior.

Lichtenthaler (2008) underpins the effect of open innovation on firms' innovativeness and hence competitive position; similarly, Dahlander and Gann (2007) show that the relationships with other actors help firms to increase innovativeness. Also, Laursen and Salter (2006), while investigating the role of external search strategies in shaping innovative performance, suppose that those organizations that invest in broader (breadth) and deeper (depth) search of external partners may have a greater ability to adapt to change and therefore to innovate: searching widely and deeply across a variety of search channels can provide ideas and resources that help firms gain and exploit innovative opportunities. However, their results put in evidence that the over-search may produce negative consequences on innovation performance itself because of the search costs it implies. Results show that the relationship between innovative performance and the search breadth/depth presents tipping points after which openness—in terms of breadth and depth—can negatively affect innovative performance.

Research hypotheses

The discussion above puts in evidence the existence of an important gap in the extant literature, which concerns the lack of a framework that, while considering concurrently technological aggressiveness, OI choices and innovation performance, helps the readership to understand if openness (intended as outside-in process) performs a mediation role in the relationship between technological aggressiveness and innovation performance. Indeed, with the exception of Laursen and Salter (2006), to our best knowledge no work has been carried out on the relationship between the technology aggressiveness, the OI choices and performance. Building on the only contribution

which considers the above relationship (between technological aggressiveness, OI choices and innovation performance) - i.e. Laursen and Salter (2006) - we go a step further operationalising OI choices not only in terms of partner from which ideas and technological opportunities can be drawn, but also in terms of contents they provide and phases of the innovation funnel which are porous to knowledge flows from the outside toward the inside. According to this operationalisation of OI, we expect that the aggressive firms that intensely focus on radical innovation not only are likely to draw more deeply from few external sources of innovation than firms that are not aggressive (Laursen and Salter, 2006), but also that they intensely open their innovation funnel in very few phases of the innovation funnel, specifically the early phases of the innovation process, to absorb external knowledge. This is underpinned by those contributions that show that in the early phase of the product life-cycle innovations, come from a narrow range of sources (De Backer, López-Bassols and Martinez, 2008; Perkmann and Walsh, 2007), in many cases from universities and research centers. Indeed, De Backer, López-Bassols and Martinez (2008) find out that universities and government research institutes are generally considered to be an important source of knowledge transfer for the innovation activities of companies, especially in more upstream/research activities. Perkmann and Walsh (2007) confirm, at least for universities, De Backer, López-Bassols and Martinez (2008)'s results: "*The concepts of open, networked and interactive innovation, however, would suggest that actual relationships between universities and industry [...] – play a stronger role in generating innovations*".

Differently, if the nature of the innovation is incremental, many different sources of innovation are involved and firms need to be able to work all along the innovation funnel with many different actors in the innovation system (Laursen and Salter, 2006), that bring in the collaboration very different contents. According to Tushman and O'Really (1996) and Abernathy and Utterback (1975), firms may focus on 'fine-tuning' the product by means of incremental improvements which are inspired by many different sources of innovation, in terms of both partners (Laursen and Salter, 2006) and contents (Huizingh, 2011; Bengtsson et al., 2013), and which involve almost all the phases of the innovation funnel. Indeed, along the different phases of the funnel, different partners may bring in the collaboration many contributions in terms of access to cutting-edge technologies, new products and markets (Azadegan and Dooley, 2010), technological and production

capabilities (Oh and Rhee, 2010) and supply chain management capability as well (Wu et al., 2006).

Therefore the following hypotheses can be put forward:

HP 1: The more technologically aggressive are the firms, the less effective partner, phase and content variety will be in influencing innovative performance.

HP 2: The more technologically aggressive are the firms, the more effective partner and phase intensity will be in influencing innovative performance.

3 Methodology

3.1 Sample and data collection

We relied on a survey research developed in 2012 by a group of researchers from three different countries: Finland, Italy and UK. In order to ensure comparable results across nations, before each country began conducting the survey within their respective countries, guidelines regarding the design phase were distributed. We followed different steps for the survey development (Forza, 2002); the following describes the details of each of these steps.

Sample

Concerning sample, three main concerns were considered: target and frame population, sample design and sample size, as follows:

- Target and frame population: To draw the population frame, it was recommended that each country refer to widely available sources to promote study replicability. Hence, for the selection of the firms the use of the NACE Rev. 2 codes was suggested. In addition, it was recommended concentrating the analysis on the manufacturing industry (though CI also takes place in service industries or public administration), because theory-testing research requires a well-developed body of knowledge, and manufacturing is no doubt the most investigated field in the literature regarding open innovation; hence, the codes 10-32 and 98 in NACE Rev. 2 were chosen.

Finally, in order to best represent open innovation activities, the recommendation was to include all statistical units with no less than 10 employees.

- Sample design: The choice was to conduct probabilistic sampling in order to ensure representativeness of the sample and, hence, the generalisability of results (Babbie, 1990).
- Sample size: Each country was urged to reach a minimum sample of 70 firms.

Data collection method

The data were collected by means of questionnaires distributed by email to participants. The advantages of such method include low cost, completion at the respondent's convenience, absence of time constraints, guarantee of anonymity and reduction of interviewer bias (Forza, 2002). Its shortcomings, on the other hand, are represented by lower response rate as compared to other methods, longer completion times and greater effects due to the lack of both interviewer involvement and open-ended questions.

Measurement instrument

The survey was conducted as a questionnaire whose items regarded company characteristics (in particular size and industry), the OI choices in terms of partners, phases and content, and the effects of OI on performance.

Answers are measured by perceptible 7 point Likert scales, ranging from 1 = "not at all"/"strongly disagree" to 7 = "to a very high extent" /"strongly agree". In addition, respondents could choose "I do not know".

The measurement instrument was developed with specific guidelines for: (i) wording (the way questions are posed to collect specific information), (ii) respondent identification (identification of the appropriate respondents for the questionnaire) and (iii) rules of questionnaire design (following rules of courtesy, presentability and readability to help and motivate respondents to answer).

With regard to wording, closed questions were used (except for those regarding the company's name, number of employees, and the previous fiscal year's turnover), and to avoid double-barrelled questions (i.e. questions with different subparts with different possible answers).

Regarding respondent identification, participating countries were urged to identify people who were knowledgeable about OI, in particular R&D managers or similar.

The questionnaire was drafted in conformity with the design rules and supplemented with a clear, but concise introduction providing an explanation of the aims of the survey, instructions for filling it out and the guarantee of confidentiality.

Pilot testing the questionnaire

A test of the resulting questionnaire was conducted on two groups of subjects: colleagues and target respondents.

As for colleagues, the questionnaire was distributed to a group of colleagues to check whether the questionnaire accomplished its objectives. For target respondents, after the questionnaire was translated into the native language, each country had to involve a number of firms in order to gather feedback on anything that might affect the answers. These two tests were conducted independently.

Data sample

We could rely on a database of 415 firms spread across the three countries (87 firms in Finland, 152 firms in Italy and 176 firms in Sweden). Such firms can be taken as representative of manufacturing firms in their respective countries.

3.2 Constructs

The main variables investigated in the paper are reported in table 1. Beyond the technology aggressiveness, our model includes a multi-faceted measure of openness, through the variables partner intensity (i.e. to what extent firm interacts with the different players of the innovation process); phase intensity (i.e. the firm's level of collaboration with partners at the different phases of the innovation process); and openness variety (i.e. the overall variety of the innovation process measuring the number of different external players, phases and contents here included). Finally, the measure of innovation performance is well grounded in the open innovation literature coherently with Lazzarotti et al. (2011). More exactly:

- Openness Strategic Orientation: this construct, whose items are reported in table 1, measures the level of technological aggressiveness. Although the operationalisation of this construct is newly created, some measures are underpinned by the literature:
 - i.* We focus on radical rather than incremental innovation is adopted from Lichtenthaler and Ernst (2009);
 - ii.* We have a broad product/market portfolio:

adapted from Lichtenthaler (2008) and *iii*. We have a broad technology portfolio: adapted from Lichtenthaler (2008);

- Openness innovation performance: The operationalisation of this construct, which is built on Chiang and Hung (2010), has been published in Lazzarotti et al. (2011). Its items are shown in table 1;
- Openness Intensity (Partner): the operationalization has been published in Lazzarotti et al. (2011), which builds on Laursen and Salter (2006). Seven external sources of knowledge and technology for innovation were considered (universities and research centres, innovation intermediaries, government agencies, customers, suppliers, competitors, companies operating in other industries). To compute Openness Intensity (Partner), firms were asked to indicate on a 7-point Likert scale the intensity of collaboration with each external source;
- Openness Intensity (Phase): firms were asked to indicate to what extent they collaborated in the last five years with external sources along the five phases of the innovation process, from idea generation to commercialisation (idea generation, experimentation, engineering, manufacturing, commercialisation). This construct, which is adopted from Lazzarotti et al., 2011 and Lazzarotti and Manzini, 2009, has an explorative nature: it aims to deepen the state of the art literature that, mainly focused on the 'who' question (i.e. the partners to be involved), not rarely has overlooked the 'where' question, i.e. the number and type of phases of the innovation process to be opened to external partners in order to collaborate and, hopefully, co-create along the innovation funnel (Lazzarotti and Manzini, 2009; Ferrero et al., 2013);
- Openness Variety aims to measure heterogeneity of sources during the openness innovation process. Specifically, the proposed construct accounts for diversity in partner enrollment, related phases of the innovation process and, finally, contents exchanged. Items which characterize this construct are built in order to measure (1) the number of different partners actively involved in the innovation processes, (2) the number of different phases interested by external collaboration and (3) the number of different contents concerning for example access to new technology, process and product innovations, or more broadly capabilities and/or competences (reference items are reported in appendix).

3.3 SEM

The research model has been evaluated using a Structural Equation Modelling (SEM) approach since it is widely recognized as having substantial advantages over the first-generation techniques such as principal components analysis, factor analysis or multiple regression (Anderson et al., 1988; Chin, 1998; Shah et al., 2006). The SEM method in fact allows researchers to model, simultaneously estimate and test complex theories with empirical data.

After the theoretical specification of the research model and the sub-sequent definition of the structural model and the related constructs (see previous sections where hypotheses elicitation and construct operationalization are discussed), the main steps for model testing are reported here following:

- a1) Collect data for model testing;
- a2) Test reliability of constructs;
- a3) Test the structural model;
- a4) Evaluate the model fit, and
- a5) Interpret the results and eventually refine the model.

4 Analysis and results

As anticipated, we have first tested constructs' reliability; after that, causal relationships were introduced and evaluated by testing the full structural equation model.

4.1 Construct reliability

CFA was assessed to validate reliability of adopted constructs and measures. We have assumed Content Validity to be maintained, since the constructs are mostly well-grounded in the literature. Reliability of constructs was then tested using the internal consistency method that is estimated using Cronbach's alpha (Cronbach, 1951; Nunnally, 1978; Hull and Nie, 1981). Typically, reliability coefficients of 0.70 or higher are considered adequate (Cronbach, 1951; Nunnally, 1978). Nunnally (1978) further states that permissible alpha values can be slightly lower (0.60) for newer scales. As an addition, loadings and their statistical significance (Dunn et al., 1994) for constructs' items were examined as preliminary evidence of convergent validity.

Outputs from the analysis are reported in table 1 and show that all the theoretical constructs exhibited quite acceptable levels of reliability. Results show that all the factor

loadings are above the .60 and that the alfa-cronbach indexes respect the selected threshold in order to allow confirming reliability of the constructs. Just a critical point has been evidenced and it is about the Openness Variety construct which present a Cronbach's alpha Index of .55. At the same time, the novelty of the construct proposal support us in maintain Openness Variety into the investigated model with an exploratory connotation.

Table 1 - Measures

Measures	Factor loadings
<i>Openness Strategic Orientation (Alfa-Cronbach .82)</i>	
We prioritise new product and service development and innovation to meet new and changing consumer demands	.67
We aspire to be the technological leader	.74
We focus on radical rather than incremental innovation	.70
We try to hire the best scientists and experts in the market	.66
R&D and marketing are our core competencies	.71
We normally use innovative, flexible and non-routine technologies	.73
We have a broad product/market portfolio	.61
We have a broad technology portfolio	.72
<i>Openness Innovation Performance (Alfa-Cronbach .82)</i>	
Reduce innovation risks	.78
Reduce new product/process development cost	.83
Reduce time to market	.77
Introduce new or significantly improved products or services	.74
Introduce new or significantly improved process of producing our products or services	.68
<i>Openness Intensity (Partner) (Alfa-Cronbach .67)</i>	
Universities and research centres	.60
Innovation intermediaries	.63
Government agencies	.66
Customers	.61
Suppliers	.60
Consumers	.61
<i>Openness Intensity (Phase) (Alfa-Cronbach .70)</i>	
Idea generation	.80
Experimentation	.84
Engineering	.73
<i>Openness Variety (Alfa-Cronbach .55)</i>	
Partner Variety	.72
Phase Variety	.77
Content Variety	.72

4.2 Structural model

The structural model was finally tested. Main results are summarized in figure 2 neglecting for sake of clarity and simplicity the other model parameters (e.g. construct covariance, factor loadings and errors) which can be found in the appendix.

The hypothesized relationships between Openness Strategic Orientation and Innovation Performance constructs, as mediated by the Openness Intensity (here measured both in term of Partner and Phase Collaboration) are supported by the data. Standard regression weights are .59 (significant at the .001 level) between Openness Strategic Orientation and Openness Intensity (Partner) constructs and .47 (significant at the .001 level) between Openness Intensity (Partner) and Innovation Performance. In the case of Openness Intensity (Phases) their measures are .41 (significant at the 0.001 level) and .19 (significant at the 0.01 level) respectively.

As concerning the construct Openness Variety, instead, it is evident the central role on the final impact on Innovation Performance. Regression weight is negative -.27 (significant at the 0.01 level). The negative impact is in its turn influenced by the constructs Openness Intensity (Partner) and (Phase). The first positively impacts on Openness Variety: measured regression weight is .40 (significant at the 0.001 level). The second pattern, on the contrary, reveals a negative impact: regression weight is -.29 (significant at the 0.001 level).

Figure 2 and Appendix report details about the estimated impact of Openness factors on the Innovation Performance construct.

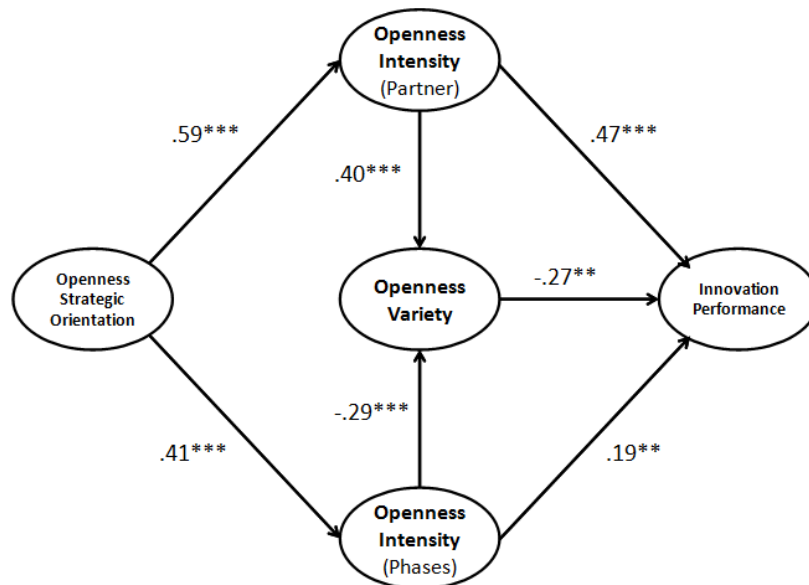

Figure 2 - The structural model

4.3 Model fit

As recommended, a set of multiple fit indexes (see table 2) was used to check the goodness-of-fit of the measurement scale with data. Goodness-of-fit criteria evaluate how well the data fits the proposed model and are generally categorised into three groups representing (absolute) model fit, (incremental) model comparison, and model parsimony (Schumacker and Lomax, 1996). Concluding, these evidences provide an overall good support for the results to be deemed an acceptable representation of the hypothesized constructs.

Table 3 - Multiple fit indexes

Index	Value for RI	Recommended values For a good fit	Recommended values for very good fit	Sources
χ^2	607.6	-	-	-
RMSEA	0.06	< .08	< .05	Byrne, 1998
NFI	0.82	>.8	> .9	Byrne, 1998; Zhang et al., 2002
N-NFI or TLI	0.87	>.8	> .9	Byrne, 1998; Zhang et al., 2002
CFI	0.88	>.8	> .9	Byrne, 1998; Zhang et al., 2002
IFI	0.89	>.8	> .9	Byrne, 1998; Zhang et al., 2002
PNFI	0.71	-	> .5	Byrne (1998), Mulaik et al. (1989).
PCFI	0.77	-	> .5	Byrne (1998), Mulaik et al. (1989).
χ^2/df	2.34	>1 and <5	>1 and <3	Bollen (1989); Carmines and McIver (1981); Hair et al. (1998); Jöreskog, 1969

5 Discussion

Findings show that strategic orientation construct is positively related with openness if measured as both openness intensity (partner) and (phase) (relationship with openness variety instead is not significant), which in their turns, are positively related with innovation performance. As an addition, preliminary evidence from the model also seems to suggest full mediation of these two constructs between technology aggressiveness and innovation performance since the direct relation becomes not significant if analysed concurrently.

Thus effectiveness of a firm's technology aggressive behaviour obtaining higher innovation performance seems strongly related to the intensification of collaboration with the partners along the innovation funnel. Conversely, openness variety seems to play an

opposite role which is differently affected by openness intensity (partner) and intensity (phase). Particularly, when interpreted in terms of openness intensity (partner) and variety, the relationship between openness construct and innovation performance confirms the pattern evidenced by Laursen and Salter (2006). Increasing collaboration with partners is positively related with higher innovation performance but this is also related with a major variety of the collaboration exchange which has in its turn a negative relation with final innovation performance so limiting the previous positive effect.

This result clearly emphasises the cost-side of an open behaviour becoming harder to be managed, and thus costly, when involving too many different partners, phases and contents; and, it also alerts about the need to find adequate strategies for effectively managing the collaboration process in order to avoid waste of resources and efforts. Possible routes obviously spread from reducing the system complexity e.g. limiting partner, phase and content variety, to trying to manage the increased process complexity e.g. through the identification of adequate managerial levers, and also the definition of criteria for optimal allocation of resources supporting/driving the focalization of efforts depending on context specific factors/needs.

On the contrary, if openness is interpreted as phase intensity, i.e. the intensity of external collaboration during the different phases of the innovation process, the model shows an interesting effect of openness Intensity (phase) on openness variety. If it is still true that Openness Intensity (Phase) construct is positively related to Innovation Performance, Openness Intensity (Phase) has a negative relationship with Openness Variety (which in its turn is negatively related with Innovation Performance) so that suggesting a restrictive effect on Openness Variety. Thus, the higher the collaboration intensity during the different stages of the innovation process the lower is likely to be the overall Openness Variety in term of Partners, Phases and Contents. This condition could also limiting the negative effect of Openness Variety on Innovation Performance.

A first interpretation of this evidence may also suggest that phase focalization is a possible candidate (or strategy) in order to manage complexity of the collaboration process and thus a way to deal with the costs and potential inefficiencies of Open Innovation. Keeping collaboration efforts high and focused on specific process phases, avoiding marginal/superficial involvement of resources potentially leading to misuse and dispersion, might help firms in limiting, selecting or managing Openness Variety more effectively and finally obtaining better innovation results.

6 Conclusions

This study contributes on the debate about the type of relationship linking technology aggressiveness and openness. Results show that openness, if measured as partner intensity and phase intensity, mediates the relationship between technology aggressiveness and innovation performance. In other words, the direct relation between technology aggressiveness and innovation performance is not significant, by suggesting that the effectiveness of a firm's technology aggressive behaviour is strongly related to the intensification of collaboration with the partners along the innovation funnel. Conversely, although openness variety is positively related to partner intensity, variety seems to play an opposite role. This result likely emphasises the cost-side of an open behaviour becoming harder to manage, and thus costly, when involving too many different partners, phases and contents (Laursen and Salter, 2006; Praest Knudsen and Bøtker Mortensen, 2011).

Beyond the emerged results as concerns the interplay among the investigated variables, the originality and the value of our paper reside also in two methodological connotations:

- A more fine-grained definition of the openness concept, which takes into consideration other facets of openness with respect to those usually analysed in the literature;
- A powerful statistical model, as SEM, offering great advantages and flexibility in order to match the theoretical model with the data, and especially to model complex relations amongst multiple variables, consider unobservable latent variables, evaluate measurement errors for observed variables and constructs. This usually leads to more valid conclusions on the construct level.

Practical implications – Firms, which adopt a technology aggressive strategy, are recommended to deeply open their innovation process in order to foster innovation performance. However, due to the fact that a high openness variety could generate some downside, managers should be very careful in the management of different sources and contents.

Structures Abstract

Purpose: The article presents a study about knowledge mobilization for sustainable growth. Thus, the present study aims to advance the understanding of how crowdsourcing and open innovation can mobilize knowledge to generate actions in a company that will stimulate its sustainable growth.

Design/methodology/approach – We propose a theoretical and descriptive approach based on literature review about crowdsourcing, open innovation and sustainable growth of the company. A single case study, using qualitative interview and data content analysis, was carried out in a large Brazilian building and developing company in order to analyze how crowdsourcing and open innovation actions can provoke sustainable ideas and organizational growth.

Originality/value – The construction sector is a relevant participant in the Brazil's economy. It was responsible for over 5% of the country's gross domestic product (GDP) in 2012 (IBGE, 2012). The companies in this sector in Brazil have been going through a continuous growth process. The study pursues providing evidence of the positive effects of the use of crowdsourcing via a web based platform through which information and innovative ideas are shared within this competitive sector in a sustainable way.

Practical implications – The strategic management between non-monetary social and environmental activities and economic success is necessary for a sustainable business company (Schaltegger et al. 2011). Sustainable company growth is a challenge for companies facing a tough competitive scenario in the business environment they operate. The case study used shows a large Brazilian company that has been dedicating time to acquire crowd-source knowledge and combining that with their expertise and ideas. This has resulted as the case study will show in a tool that has contributed to improving its internal processes as well as the application of an overall more sustainable business model. The implementation of ideas resulting from the knowledge acquired through crowdsourcing also improved the company's relationship with its customers and other stakeholders.

Keywords – Crowdsourcing, Open Innovation, Sustainable Growth, Knowledge Mobilization

Paper type – Academic Research Paper / Practical Paper

Introduction

Besides being a challenge for companies, knowledge mobilization is an important issue in terms of research since many studies have indicated that knowledge is the basis for innovation (Bennet and Bennet, 2007) and specially open innovation (Abouzeedan and Hedner, 2012). Companies have been using the open innovation channels, to mobilize outsiders' knowledge. External knowledge, applied in internal company issues, can develop innovative business to the company and result in a new way of managing the interaction between company and community. These acts have shown positive results in the companies' operational practices and communities' welfare (Chesbrough, 2003). Within open innovation scenario new tools can grow such as crowdsourcing, a phenomenon which also relies in the constant interaction between company and community. Nevertheless communities are human knowledge exchange cooperatives and Crowdsourcing use the crowd's cooperation to problem-solve company's issues. Most crowd-source communities are formed out of self-interest and the mutual economic benefit for the participants. Outsiders' participation is considerably higher when actions result in mutual benefits (Howe, 2008). Innovation become easier when companies are able to align the open and shared knowledge with action for sustainable growth, ensuring the company's profitability and social and environmental well-being of the community and stakeholders (Savitz, 2007; Sanford 2011).

This study aims to understand how the articulation between open innovation and crowdsourcing platforms can generate ideas that mobilize external and internal knowledge. Furthermore this articulation can result in development of processes, products and services and improvements in the economic, environmental, and social perspective. A case study was carried out in a large Brazilian construction and developing company, to illustrate how the articulation of knowledge mobilization and open innovation tools can help ensure the company's sustainable growth.

1. Open Innovation and Crowdsourcing

Open innovation concepts are not new in the practices of organizations, however the term was popularized in academic research environment by Chesbrough (2003), aiming to explain the changes in innovation processes of companies. It expands the capacity for innovation across organizational boundaries and combines internal and external ideas into architectures and systems whose requirements are defined by a business model. The

business model utilizes both external and internal ideas to create value, while defining internal mechanisms to claim some portion of that value (Chesbrough; 2006). A permeable environment between the company and the environment encourages constant interaction between the parties, increasing knowledge spread. Abouzeedan and Hedner (2012) note that open innovation requires the sharing of knowledge and resources to carry out innovation activity within and among organizations. Open innovation is powerful (Loren, 2011). It can demonstrate skill, mitigate risks for the company, increase revenues, and even transform company's model of business, launching a company ahead of its competitors. A well planned and executed open innovation program can release value restrained in unrealized ideas. The open innovation is a multifaceted concept applied in different contexts. Questions related to intellectual property or even other phenomenon as with open source, crowdsourcing, innovation distributed and other terminologies are still in discussion, so the major differences or equalities are not clear yet.

Specifically about Crowdsourcing, some studies indicate that the term has been increasingly associate to open innovation (Bücheler, Fuchslin and Sieg, 2011; Chanal et AL. 2008, Sloane; 2011). Hossain (2013) highlights that crowdsourcing is showing great growth strategies for organizations, for good practical performance, in the other hand the "rigorous research" still extremely scarce. Sloane (2011) defines crowdsourcing an extrapolation of open innovation when the company throws a complex challenge to a specific group in order to solve technical or scientific problems. Several authors use the concept of crowdsourcing to describe a problem-solving tool, which uses individuals connected to the internet, through an open call to seek solutions (Howe, 2008; Brabham, 2008; Vukovic, 2009; Ribiere & Tuggle, 2010; Doan et al., 2011; Kazai, 2011). Some publications report crowdsourcing beyond the problem-solving. It can be a source able to generate many new ideas (Heyes et. Al. 2012; Ribiere and Tuggle 2010, Poetz and Schreier, 2009). Brabham (2008) also enlarge the Crowdsourcing concept as problem-solving. According to the author, it's a phenomenon which groups of people, in certain circumstances, can overcome specialists. Outsiders may provide new perspectives to internal problems. And work interconnecting internal and external ideas in an environment of cooperation, aggregation, consensus and teamwork is transforming innovation scenario (Chesbrough, 2011). O job previously limited to organization boundaries, in a shared information environment can be done by anyone with common interests (Howe, 2006; Whitla, 2009). The constant interaction and exchange of

knowledge creates a constant flow of information shared between the parties characterizing moments of knowledge mobilization.

2. Knowledge Mobilization

Knowledge Mobilization is defined as the process of creation, assimilation, leveraging, sharing and application of knowledge in a certain community. In human and social sciences Knowledge Mobilization involves the movement of the effective creation and adaptation from the source (researcher or specialist) up to application (practitioners, community leader, community) by effective and sustainable actions (Bennet and Bennet, 2007). Considering that knowledge is constantly changed when transferred between people, findings and hypotheses from experts when mixed communities can result in a very different direction of the expected result. According to Bennet and Bennet (2007) once knowledge emerges through research, it can create a strong bond with the community and may be the link to integrate the researcher community and the practitioner community, using older experiences and moreover represent a new social configuration.

It may seem that crowdsourcing and open innovation follow different paths of knowledge mobilization in relation to the origin point of new knowledge. The suggestions from the communities of open innovation and crowdsourcing arise from various sources, usually not experts (Lebraty and Lebraty, 2013). Even though Knowledge Mobilization and open innovation tools present different knowledge sources, they are both connecting to similar principles. According to Levin (2008) the relationship between knowledge and its use runs in both directions; practice affects research just as research affects practice. The stemming population ideas are suggestions for improvement that subsequently will be use by companies' experts to find creative and sustainable solutions. The concepts are interconnected by a common goal: the use of knowledge to create value for the community and organization. The Bennet and Bennet (2007) adds the importance of the strategically mobilized networks, such as the open innovation and crowdsourcing platforms, to consider important issues. With this information development tools, technological orientated, is possible share knowledge and information among stakeholders, and further develop sustainable actions.

3. Company sustainable growth

In academic research the term sustainable related to economic performance of the companies is still quite wide. Many authors consider that sustainability can interfere positivity in communities' welfare (Pätäri AL. 2013; Fosfuri et. Al., 2013; McAdam and Leonard, 2003; Stundivant e Ginter 1977). In the other hand, some authors (Dely 1990; Bromiley and Marcus, 1989) believe that economic and sustainable involvement of the company and that of a community are paradoxes and impossible to be a successful combination.

Even given the diversity of views on this relationship, it is undeniable that sustainability has become a mainstream policy to business,

Companies are operating in scenery of open communication with customers and stakeholders in general, which exert a charge for sustainable actions, far beyond the charges demanded by governments (Esty and Winton, 2006). However the concern about the environment (social e ecological) can be for some companies a leap frog to a competitive advantage in business (Bellia and Pilato, 2013; Schrettle et. AL. 2013; Takala Et. AL, 2013; Porter and Van der Linden,1995; Garriga and Melé, 2004). Companies that focus on costs and environmental risks and corporate social responsibility realize, in the course of time, more opportunities for growth and profit will be created through sustainability (Esty and Winston, 2006).

At this point it is important to highlight that it is the sustainable growth of organizations that makes a difference, not just development. According to Bartelmus (2012) sustainable development can be applied to everything: business, people, governments, but can get lost in vague goals and not consistent metric, often directly associated with the human and emotional needs, making a generic concept and poor of indicators. The sustainability in economic activity has a greater chance of success than the holistic vision of development. According to Penrose (1959) growth of the firm means not only the increase in the volume of products, but a gradual change in the economy. It is a natural condition that will occur when the internal and external environment provide favorable conditions.

Savitz (2007) utilize the concept of "Triple Bottom Line" to defend the involvement of sustainability in the corporate environment for business growth. According to the author sustainable company conducts its business to generate naturally a flow of benefits to all stakeholders, employees, customers, business partners, the communities within it

operates and obviously shareholders. It might seem a utopian vision, that of a community that benefits directly as it enriches shareholders, but through strategies and routine actions this can indeed happen. Companies that grow sustainably have to focus on the business, but also on social and environmental issues. The company's sustainable growth needs the management of tangible and intangible resources to find the "sweet spot," In other words, a situation or place that a combination the best conditions for the achievement of a goal / profit mingle inseparably with the search common good of the stakeholders (Savitz, 2007). Sanford (2011 p.) also highlights the importance of the relationship with stakeholders. "Responsible companies "do the right thing" when it involves all stakeholders". Right action with customers, employees, local communities, investors, planet or any other stakeholder can not only transform the economic performance (increased sales / profits and market share), but also play a central role in curing social and environmental problems. To managers it is undoubtedly a great challenge to maintain the perfect balance between profitability, economic performance and social performance. But the effort for the development of sustainable actions ends up generating value in consumer perception. Sustainability in company stock can add business value by reducing risks and the strategic management between non-monetary social and environmental activities and economic success is necessary for a sustainable business company (Schaltegger et al. 2011). And further whether the aim is to generate value, the role of the intangible becomes increasingly important for the economic growth of the company and its impact on social and environmental relations.

Many times the intangibles are not directly related, however, it is an important background for actions. Some authors depict knowledge as an important factor for sustainable growth of the organization. Yusof and Bakar (2012) discuss knowledge as a valuable resource to increase the company performance in a turbulent environment. However, when poorly managed, knowledge becomes irrelevant and useless in companies. Hence the mobilization of knowledge can be an element that contributes significantly for high and sustainable performance, especially if it is built on sustainable relationships (Bennet and Bennet, 2007).

Method

Case studies enrich the theory through practical applications in the real world. They are rich in data and can become inspirations for others in future studies (Eisenhardt and

Graebner, 2007). A case embedded in theory, serves as illustration for future cases, and might become a base-case to develop new ideas around the subject (Siggelkow, 2007). According to Schaltegger et al. (2011) to select a business case for sustainability the interviewer needs to discover a situation where economic performance increases while the corresponding company takes in consideration, not only its success but also environmental and social issues important for the stakeholders and the community. But often what appear to be such a case is in fact not. Cases can give a distorted image because the results stated as examples of sustainability are not the product of strategically created conditions. In those cases the alleged sustainability may not sustain the test of time. In the area, of sustainability cases do not just happen. They have to be created, and strategically thought. A business case for sustainability is characterised by three requirements that have to be applied. First, the company has to voluntarily commit to an activity with the intention to contribute to the solution of societal or environmental problems and not only be motivated by legal requirements or stick profit driven motives, but must exhibit a real concern about the environment. Secondly, the activity must also help create a positive business effect contributing to the company's success. These effects must be measurable in a convincing and tangible way (reducing costs, increasing sales, competitiveness, customer retention, reputation, etc.) The cause and effect relationship can be direct or indirect, but may not be speculative. And finally in the company's strategic planning in the case the matter of sustainability needs to be a clear goal imbedded in its corporate culture as a mean to success.

Crossing Schaltegger et. AL (2011) considerations for sustainable cases with open innovation and crowdsourcing cases, grounded in knowledge mobilization, become easy to realize the singularity of the case. Similar cases were not identified in other studies of synergistic integration of concepts; therefore this case study may serve as an illustration for future studies in that field. To characterize the case study documentation was created based on reports, publications and other disclosed data in the company's media channels. With the media published data associated with theoretical background a semi-structured questionnaire was developed consisting of two in-depth interviews with qualitative character. A social media manager and the technician responsible for the web open innovation platform answered the surveys in order to investigate the disclosed information as well as add more information about the company, guidelines, policies, actions and practical applications. After the data was collected from the surveys, content

analysis technique was used to describe the content of the messages. Content analysis was chosen to allow the researcher understand and capture the perspective of the answers, and to know the environment within where the event took place (Roesch, 2005).

To analyze were the first twenty ideas already adopted by the company in their business originated the online platform was used. The period for the analysis of the case study was between august 2nd and September 27th 2010. The categories of analysis used were the “Triple Bottom Line” for sustainability, so the original ideas of the users were analyzed from the web; the use of the idea in the projects of the organization and the economic, environmental and social benefits generated by each idea.

The case study

The real estate sector in Brazil has been expanded to record levels since the 2000s, driven by the country’s economic development, credit expansion, and the strengthening of capital markets. According to the trade union of sale, rental and property management in São Paulo in the first half of 2013 only in the São Paulo’s metropolitan region sales had an increase of 46% compared with the same period of 2012. This data have focus only in São Paulo. In the national scene the construction industry is responsible for more than 5% of the country's GDP, employing over 3.6 million people (CBIC, 2013). Some government programs to stimulate sector are responsible for the increase of sales. The largest government housing initiative is called “Minha Casa, Minha Vida”. In Brazil traditionally interest rates are relatively high and owning one’s own home is out of reach for a substantial part of the population if commercial banking is the only source available for a mortgage loan. This program offers low interest financing assistance to the population to buy their own home. By doing so it also increases the demand for a specific type of home. It was responsible for almost two million homes sold between 2011 and 2013. In 2013 31% of the homes sold in Brazil where through this program. In the same period the government invested R\$ 193 billion, and held about 1.3 million jobs in 2013 which represents 2.6% of the formal labor force of the country’s economy who were involved in building these homes (CBIC, 2013).

Even in a favorable economic and financial scenario the construction industry has a poor knowledge management, causing a huge loss of resources of all kinds (Abdul-Rahman and Wang, 2010). The company, object of this study has operated in construction, development, purchase, and sale of real estate for over thirty-six years and

serves more than ten thousand customers along the country. Beside the factor of being a traditional company, the singularity of the case comes from new uses of knowledge. The company promotes the best use of resources and knowledge management in their business policy, and is keen to demonstrate in its guidelines the environmental responsibility, through interaction in the development of sustainable actions. In 2011, the company formalized through its annual sustainability project a “Sustainability Policy”. The goal is generate financial returns to investors and also help society to develop, focusing on the social and environmental perspectives, in order to minimize impacts and operational risks in the medium and long term.

This business policy pursues a healthy work environment, encouraging innovation in business with focus on financial returns, and also the reducing of the impacts on the environment and communities. To reach these goals the company encourages rational use of resources through new technologies and processes and the reuse of waste. To encourage and adopt sustainable practices beyond company’s boundaries, a program of action was developed called “Collaborative Consumption”, defined by the company as the sharing, exchanging, loaning, renting and donating goods and services without need to purchase them, allowing the economy of resources and avoiding waste. The Collaborative Consumption gained force due to the growth of on-line relationships and networks, allowing the information exchange and valuing sustainable habits. As a stimulus the company conducts research and invites partners to apply and promote that practice. The company also utilizes different platforms in order to develop spaces that encourage collective intelligence, where new ideas are welcome and the community feels comfortable to share new solutions.

The concept of Collaborative Consumption consists of three elements: Collective and Collaborative Knowledge; Open innovation combined with Crowdsourcing and Co-creation, and Collaborative Use of the products. **The Collective and Collaborative Knowledge** is an internal portal where knowledge is shared through meetings, discussions, forums and where employees can discuss ideas and propose solutions. The program has a collaborative database of studies and academic papers, articles, and cases of students from different areas that help spread relevant knowledge and information. In order to facilitate the participants access and use of this medium a number of adult training courses have been developed about construction programs as well as about digital literacy. The teachers are professionals, highly familiar with the subject matter,

that on a volunteer basis provide training to all workers of the company with the aim of including them in this project.

Open innovation, crowdsourcing and co-creation are actions developed through an online platform with open access and meant to be used as well by company workers as members of the general public. On this platform any comment aimed at suggesting an idea, or even the initial thought of an idea without limiting any subject matter may be posted. The intent of this platform is that any idea, no matter how simple or complex, that could lead to improving production, output, or to the improvement of the welfare of the community, from whomever in the company and disregarding the hierarchical internal structure can be evaluated. While on the other hand the public. People can talk on the website about their dreams houses, relationship between the Company and the community. The website has collected a significant amount of relevant information. From 2010 to 2012 the portal reached 224.762 visitors and 2.270 of these submitted their ideas and comments by participating in a bonus score program. The majority of participants were men (75%). These participants helped create a database of 1.949 ideas about issues such as safety, accessibility, leisure, convenience, welfare, finance, information technology, sustainability, marketing, sales and customer relationships, pets, infrastructure, and design. The ideas came from different parts of the country, with most coming from São Paulo, but many were also from Rio de Janeiro, Minas Gerais, Paraná, Brasília, Rio Grande do Sul, Bahia, Pernambuco, and Ceará. In social networks like *Twitter* and *Facebook*, the scope of the program hit 21.917 occurrences, the majority (92%) were neutral and only 0.1% were negative. The company, after testing many of the ideas generated through the portal has applied 35 ideas of these, which have contributed to the company's innovation and the improvement of processes and products. The incoming ideas from the platform are tested by a multidisciplinary team and if approved, adapted to a compatible format and then applied. The categories used in the analysis phase were based on the "Triple Bottom Line" theory, dealing with responsibility for sustainable business growth and the environmental relationship. Elements that were considered in the evaluation phase were the application that the company used in the processes and the economic, social and environmental benefits of each action (table 1). In the analysis it is possible see that even the simplest actions arising from clients' common problems when analyzed and expanded by internal teams, can develop innovation in products, improve the involved processes and achieve sustainable solutions. Cost

reduction, reuse of resources, better use of space, security and convenience to customers are the kind of improvement goals of the actions resulting from this process. The ideas provide a base for development of specific solutions to deal with specific problems. In the cases that, after the internal process within the company to evaluate the idea and decides to implement it, a significant product/process improvement occurred and consequentially a social or sustainable improvement was also registered. Sometime an idea can generate benefit for the three foundations of the “Triple Bottom Line” in the same action, i.e. Bake sharing, the digital panel energy consumption.

Specifically about crowdsourcing as a problem-solving tool, the company developed some projects which positive results. Since 2009 the company uses the network to find solutions, i.e. the announcement of a new institutional collaborative consumption. The company would like to see how the market expert could solve this specific challenge. They recurred to the crowd looking for an advertisement to encourage the practice of collaborative consumption, to highlight the differences and actions already promoted by the company. With the challenge the company was able to see how the crowd was facing collaborative consumption and realign the guideline of the company policy. The winner won seven thousand reads. Another challenge in crowdsourcing area in the platform was to create hoardings which could transmit company values by visual project that agree with the company's enterprises. The winner of that contest had his idea printed on the enterprises' hoardings and also received as prize four thousand reads.

About **Products Collaborative Consumption** the company believes that attitudes, ideas and sustainable practices are habits. Reeducation for conscious consumption, through modern developments may offer conditions for making more sustainable houses and apartments. Technology offers numerous conveniences and facilities, and it allows products to be made causing less impact to the environment. Collaborative Consumption is a change of habits, and so the company encourages customers to use sustainable practices in their day life. Following the initiative was developed action like “Bikes sharing”. The company provides common bicycle stations to condominium members, so people use their cars less and thus less pollution for the planet attaching the concepts of sustainability to urban mobility. Other initiative is the “Car Sharing” this one offers to the condominium members a company's car to mobility inside neighborhood. Thus people do not need to use their own vehicles to get around within the condominium and even favors interaction between community members when the rides

are shared. The company is investing resources in order to pursue new environment friendly sources of energy. Internal researchers have been testing clean energies like: photovoltaic and wind energy. In order to reduce the impact of garbage in the environment the company is investing in the use of composting plants. A collaborative consumption application was developed to help exchange and share objects with the network. Following the Triple Bottom Line it is important to highlight the economic performance of the company. In the third quarter of 2013 profits of R\$ 62 million were reported. At that moment in time the Year To Date profits had already reached the R\$ 178 million. The third quarter 2013 company reported a net income of R\$ 436 million (47% increases over the previous year) and the markup was 14%. The financial results of 2013 show a positive development contributing to the company economic growth.

Conclusion

The study on the knowledge mobilization to leverage sustainable growth reveals that open innovation and crowdsourcing still represent a challenge for companies, mainly when they intend to use these concepts in order to gain competitive advantage as state Bücheler, Füchslin and Sieg (2010). To manage these concepts the company needs flexibility, cooperation, teamwork (Howe, 2008; Chesbrough, 2011). Of these platforms arise ideas, solutions and knowledge originating from different sources as customers, experts, stakeholders in order to improve products, services, and consequently the communities and individual welfare (Esty and Winton, 2006; Savitz, 2007; Sanford, 2011). The analysis of the case also shows the presence in Companies in the USA of the entrepreneurial awareness about reducing activities that generate a negative environmental impact and that a "collaborative consumption" programs, can be successful where the company is able to interconnect financial benefits to social and environmental benefit.

Emphasizing the strength of a sustainable organization policy is important. As cited by Schaltegger et. AL (2011) the business case for sustainability should be created, it does not just happens. The company studied offered through its policies and guidelines the necessary elements to create a unique case involving synergistically tools open innovation and crowdsourcing in order to create, promote and encourage sustainable actions. Another singular fact to be considered in the study is that the organization is inserting in an overheated economy sector which culturally does not invest its resources

in intangibles. From the actions' analysis it is possible to notice that, even in this complex market, the company has the willingness to innovate in the way it constructs its building, respects the environment, facilitates and launches new ventures, anticipates trends and relates with customers. This company's environment of concern and open expression created by the web platform encourages ideas and values the intangibles. It has generated positive results for the organization. Even the simplest idea related to the needs of customers and the community, explained in a crowdsourcing/open innovation platform and connected with company's internal experts, can develop innovative actions in relation to products, processes and services.

During the process of exchange and interaction between the company and the community the knowledge mobilization is reinforced (Bennet and Bennet, 2007). In different moments in the report the perception of how important relationships are in this process can be detected. It is clear that platform allows many ideas to develop because it stimulates the value adding element of knowledge mobilization and that this results in innovation at product and services level and in sustainable growth of the company.

Table 1

PLATFORM SUGESTION	USER DESCRIPTION ACTION ¹	AVAILABLE AT:	IMPROVED ACTION PERFORMED BY THE COMPANY	ECONOMIC BENEFIT	ENVIRONMENTAL BENEFIT	SOCIAL BENEFIT
CLEAN ENERGY GENERATION	Enjoy the water fall by gravity pipes to a construction, through an internal system accumulate energy to illuminate hallways and livings with LED systems	http://tecnisaideias.com.br/web/ideias/geracao-de-energia-limpa	The LED lighting, the air-conditioned in the ballrooms are fueled by renewable energy. And besides, at the construction sites of projects is used solar energy (all showers are heated by this system). The company has been using solar energy and wind energy.	Reduction of energy cost, water reuse and better use of resources.	Reuse of water and resources, without requiring the production of energy.	
USE OF NON-SKID FLOOR AS STANDARD TO AVOID ACCIDENTS	The use of non-slip flooring throughout the building as a safety standard would be something important to the welfare of the resident and his family. Should be a standard in all houses.	http://tecnisaideias.com.br/web/ideias/utilizacao-de-piso-antiderrapante-como-norma-para-evitar-acidentes	The company created the gerontology awareness, which besides anti-skid flooring, added a number of safeguards to ensure the safety of people at all ages. This project have been deployed more handrails on stairs / pools and bars support. In bathrooms, doors with larger spans more ramps and wider sidewalks, among other actions to make the safest and most democratic of all ages areas.	Organizational innovation in the company, and value creation to brand and enterprises.		Safety and comfort in buildings. Prevention against the risk of accidents.
STRUCTURE TO STIMULATE THE USE OF	Incorporation of an efficient structure of bicycle racks, with	http://tecnisaideias.com.br/web/ideias/estrutura-que-	The bicycle racks have some basic equipment for maintenance of bicycles.	Organizational innovation in the company,	The bike may be the best alternative to the	Encourages physical exercise,

BICYCLES AT HOME AND AT WORK	space for small repairs and maintenance. The idea can be applied in residential and commercial projects as well, creating better conditions for the user who wants to go to work by bike. In residential bike racks could be restricted to an air pump, some basic tools and a tripod to suspend the bike during maintenance. It would be interesting locker rooms with showers and bins to store personal items cyclist. With this stimulus, more people would use the bike to go to work.	estimule-o-uso-das-bicicletas-em-casa-e-no-trabalho	And besides the new enterprises in São Paulo and Curitiba already have the "Bike Sharing" program, where common use of bicycles are offered to residents of the developments.	and value creation to brand and enterprises.	chaotic road traffic of large cities to reduce the emission of damaging gases to health and the planet.	and strengthen ties with neighbors.
DIGITAL PANEL SHOWING THE SPENT OF EACH ELECTRIC DEVICE	More important than a sustainable home is to explain to the customer why sustainable is important, and a great way to make it happen is showing the economy done by right environmental actions. A digital panel can show the expense of each home product. It can reduce energy cost by demonstrate clearly the spending.	http://tecnisaideias.com.br/web/ideias/painel-digital-mostrando-o-gasto-de-cada-item-eletrico-da-casa	Residents of São Bernardo do Campo projects were the first to receive a digital monitor coupled to the light box that allows the resident to check the consumption of appliances in real time. The electrical system will be grouped into five circuits that will record separately the consumption of the refrigerator, the washing machine, the microwave, the sockets and the general lighting environments. On the LCD screen it can check the snapshot and cumulative energy consumption of each item and estimate of the value of the account at the end of the month. Consumption can be followed by internet. ²	Process innovation. Customers reduced up 20% of monthly spending on energy.	Avoid excessive expenditure of energy, ie, better use of resources.	Consumer awareness of appliances which use the most energy, promoting ecological awareness.
GARAGE SHELVES	Imagine the following situation: You are a surfer, skater, cyclist, practitioner of any other sport / activity that requires a great outfit, but unfortunately you live in urban centers. All weekend you grab your board in your room, go down 13 flights of stairs because your board does not fit in the elevator and go to the coast. On the back is the same thing, only you're even more tired. Current garages should be about 3 or 4 feet tall, are generally tight horizontally, but there is a big gap in the ceiling. The proposal is	http://tecnisaideias.com.br/web/ideias/garagem-com-prateleiras	For the enterprises already delivered, shelves were provided in the spaces available. The company is seeking to take advantage of the space garages increasingly. In São Paulo was released the first garage with infrastructure for hybrid cars.	Best use of the spaces of customers as a way of innovation in the company. Customer generates less effort and more practicality. Creates value for the company's relationship with the customer.	Better use of space.	More convenience.

	to create guards suspended volumes in the garage to store objects.					
EXCLUSIVE DISCOUNTS	The company could offer some advantages to exclusive discounts, i.e. on telephone operator, cable television, gyms, furniture and electronics store, cinemas and parks.	http://tecnisaideias.com.br/web/ideias/descontos-exclusivos-technisa	Besides finding partners for services such as on cue, the company also sought partners to develop more sustainable products.	Partner companies to provide better services and products to customers. These partnerships also encourage innovation in the company.		
FOLDING WALLS	The apartments have to use all the spaces. It would be great if the company did hinged walls so that we can move the walls so he could make more spaces.	http://tecnisaideias.com.br/web/ideias/parades-articuladas	In enterprises with Gerontology Consciousness several areas have articulated walls. In other enterprises hinged walls can be used as needed by the client. It was not implemented in all works because of rise costs.	Value creation in enterprises and branding	Better use of space.	More convenience and comfort
PRECISION SWITCHES (AND REGULATION)	Combine switches to control intensity (analog or digital) would be of great value to assist in saving energy. For example, imagine that in addition to a switch on and off may have a control bar, or a button that makes you vary the intensity of energy that pass through it, do that during the day, or even overnight, the desired brightness can be achieved. It is an example of the usefulness in addition to potential savings with this control.	http://tecnisaideias.com.br/web/ideias/interruptores-de-precisao-e-regulagem	Some enterprises already have this service of progressive enlightenment. Launches planned in most environments already has this device.	Organizational innovation in the company, and value creation to brand and enterprises.	Energy resources save	More comfortable
ROOFS AND REFLECTORS HEATERS	The roofs of the houses could be formed by reflective materials that soft heat absorption by the housing.	http://tecnisaideias.com.br/web/ideias/telhados-refletores-e-aquecedores	The experts inside the company analyzed, developed a system of roofs that absorb solar energy, saving electrical energy. In a new development we used the green roof system, enabling the absorption of sunlight.	Cost reduction in electricity and better use of resources	Green areas in the roofs	
QR CODE	This idea is based on Qr Code, a new bar code which can be used as a marketing tool. The Qrcode can be used on company announcements in the media, billboard, booklets, folders, and others. Qrcode may provide property information, photos, videos. All this in "customer's hand."	http://tecnisaideias.com.br/web/ideias/qrcode-um-novo-jeito-de-se-comunicar-com-seu-cliente	In 2012 the company invested in the creation of QR Code application technology "augmented reality" that allows customers to view the facade and around a building before it is ready.	Organizational innovation in the company, and value creation to brand and enterprises.	Using the technology, thus reducing the expense of paper and therefore lower deforestation.	Convenience, safety shopping.
CUSTOMIZATION OF	Buy an apartment in	http://tecnisaideias.com.br/web/ideias	An application called "Digital Survey" was	Innovation in process	With the use of internet is not	Increased reliability

APARTMENT IN VIRTUAL PLANT	labor is complicated. My idea would be an application to the company that, when buying an apartment in the plant, the customer can choose the options of flooring, wall color, crockery, etc site. The client can also be used for models of decorative objects and furniture for your apartment already imagine the way he is. This application will also serve to monitor the progress of the work, in which stage is so. I believe so, the customer would keep your dream closer to reality until the completion of the works.	s/personalizacao-virtual-dos-apartamentos-na-planta	developed. The customer can make the process of inspection before delivery of the keys, more agile and secure. Also works for videos accompaniments are available within social channels.	improvement. Possibility for the client to follow the company promises. Value creation and brand reliability.	necessary to travel to the works, saving resources.	and security.
FAUCET ON BALCONIES FLATS'	The apartments without barbecue do not have faucets in the balcony. The idea is to include the balconies faucets for easy cleaning with water for watering plants and other needs.	http://tecnisaideias.com.br/web/ideias/torneira-em-sacadas-de-apartamentos	Besides the implementation of faucets on the balconies of the apartments, was developed in partnership with two other companies ecological, a grip done by 100% renewable and ethanol produced from sugar cane	Answer a perceived need by the customer. Increasing degree of customer relationship.	Ecological grid is produced with renewable source material, not generating consequences to the environment	More convenience.
CRUSHERS INSTALLATION	Support the creation of waste grinders in the sinks of the enterprises, with a particular pipeline that takes it to an appropriate location for trash	http://tecnisaideias.com.br/web/ideias/instalacao-de-trituradores	The idea of installing crushers in each habitation unit would considerably raise the cost of the project. But from this idea developed composting plants in the neighborhoods of the company, reusing waste. ³	Eliminates high costs of waste disposal in the projects and ensure proper disposal of waste.	Reuse of residues, proper waste disposal and processing of waste into fertilizer.	Awareness of the importance of separation and recycling. Recyclable residues are used by cooperatives.
CONDOMINIUM STORAGE	Rresidents complain about lack of space to store objects and obsolete files other belongings end up cluttering your space in the apartment. The company could make room in storage boxes for old object, safely and necessary care. These boxes could be on garage floors to facilitate the logistics, getting more accessible transportation.	http://tecnisaideias.com.br/web/ideias/self-storage-no-condominio-1	From the suggestion the garages spaces were readapted to meet customer needs.	Value creation to the company's brand and enterprises.	Better use of space.	More convenience.
INCREASE SAFETY IN BUILDINGS WITH BIOMETRIC LOCKS	All external locks in buildings and homes, external doors should have biometric locks, probably with digital identification, and the possibility of using a common key as backup.	http://tecnisaideias.com.br/web/ideias/aumentar-a-seguranca-nos-predios-fechaduras-biometricas	Some new enterprises are already receiving biometric locks. The company also analyzes a solution to increase the security locks on all the developments, so as not to raise costs.	Differential security, creating value for the company enterprises.		More safety to inhabitants

CONTEST BUILDING CONCEPT	Contest promoted by the company for architectural design of Building Concepts. The winner would receive a prize, beyond professional disclosure. Could be a way to prospect for professionals in architecture and graphic design. All rights in the designs would be sent to the company.	http://tecnisaideias.com.br/web/ideias/concurso-predio-conceito	Was released in the crowdsourcing platform within the portal open innovation challenge: "Brazilian Challenge competition creative decoration services, interior design and architecture." The platform received solutions to the challenge and the best solution has been awarded seven thousand dollars.	Open Innovation to create and develop new ideas.	New technologies that enable better use of resources and ecologically correct materials.	Team work and cooperation
GAS LEAK DETECTOR	Equip apartments with leak detector gas sensor that monitors and gas central kitchen, reducing the risk of fire / explosion. As people stay less and less time at home during the day, it is necessary that the alert is displayed in the lobby of the building, which can be done using the installation of intercom.	http://tecnisaideias.com.br/web/ideias/detector-de-vazamento-de-gas	At first leak detectors were deployed in the central gas ventures of units. The company still studying the implementation of individual detectors.	Ensures greater safety of the customers and the enterprises become safer.	Prevents gas leak disaster or other substances	More safety to inhabitants
GAMER SALOONS	Usually "Gamers" are introverted, even anti-social, prefer to live in virtual worlds. To make this group of people to meet and socialize better, the idea of a Gamer Hall in condominiums where people in this group could have video-game, interacting with another "gamers" and letting that anti-social life, which is one of the reasons of depression in many people.	http://tecnisaideias.com.br/web/ideias/salao-gamer-em-condominios	All new enterprises already have play areas that promote interaction among residents. Some areas counts with utilities so that the public can best use them free. Also the developments with Consciousness Gerontological prioritize socializing and leisure facilities offer integrated so that the elderly do not become isolated. A games room next to the playground, encouraging interaction.	Creates company value by answering the need of clients.		Social inclusion of condominium members of all ages. Sharing of information and knowledge.
EXCLUSIVE SHOPPING COLLECTIVE	Could be a electronic billboard in the condo with an application for the use of collective purchasing. The idea consists of a particular company offering only intended for audience development.	http://tecnisaideias.com.br/web/ideias/compras-coletivas-exclusiva-tecnisa	Partnerships have been developed with several companies to offer discounts to customers. These discounts are sent via e-mail.	Customer value. Establishment of partnerships.		
<ol style="list-style-type: none"> 1. By ethical reasons was chose not to disclose the names of the authors of ideas. The platform the company discloses the surnames of authors and commentators according to the registration done. 2. The company deployed individual consumption meters for each residence. In 2010 an estimated 33,059 cubic meters of water have been saved. In 2012 the estimated water save rate was 122,796 m³ (Relatorio de Sustentabilidade Tecnisa, 2012). 3. A company recycled more than 32 tons of used material in the enterprises in 2012, an increase of over 20% over the previous year (Relatorio de Sustentabilidade Tecnisa, 2012)

Structured Abstract

Purpose - The diffusion of the open innovation paradigm has been changing the ways in which firms acquire, manage and exploit their intangible assets. It is widely recognized that intangible assets play a relevant role for companies in creating and developing their core competences, thus yielding competitive advantage and leading to innovativeness. This paper aims at analysing the composition of intangibles portfolio of R&D intense companies and relating it to the degree of openness of their innovation processes. Further, the linkage between portfolio composition, structural features and performances of companies is investigated.

Design/methodology/approach - To analyse companies' stock of intangibles, we recorded them in different categories and calculated composition ratios. In order to quantify the degree of openness of companies we considered revenues and costs from open innovation activities and investments and divestments of innovation-related intangibles, occurring in either separate acquisitions or within business combinations. Finally, different variables are used to describe structural features and performances of companies. The analysis is performed on a sample of 243 world top research and development (R&D) spending companies, according to *The 2012 EU Industrial R&D Investment Scoreboard*, for which the 2012 annual reports were analysed. Results are discussed from cluster, one-way ANOVA and correlation analyses.

Originality/value - The paper contributes to the existing literature on the measurement of open innovation from two perspectives. First, it focuses on the pecuniary dimension of the phenomenon, using quantitative, objective data. Second, while most literature is focused on inbound metrics, our paper suggests a set of metrics which can be used for both inbound and outbound processes, allowing to define the ways in which companies can capture value from the exploitation of their technology, i.e. the business models of

companies. Moreover, the paper contributes to the understanding of the relevance of intangible assets in open activities.

Practical implications - The paper addresses the need for operative, practical instruments, which can help managers to monitor the impact of the investment in intangibles on companies' innovation processes after an open-oriented approach. It proposes a set of metrics enabling to evaluate their core competences and relate them to the propensity to open up innovation processes. Further, given the availability and objectivity of annual report figures, this accounting framework can also be used by decision-makers for comparisons over time and space, also allowing the benchmarking with competitors.

Keywords - Open innovation, Intangible assets, Innovation metrics, Bio-pharmaceutical, Technology hardware & equipment.

Paper type - Academic Research Paper

1 Introduction

Open innovation (OI) has been one of the most debated topics in innovation management research in the last decade and can be defined as *“the use of purposive inflows and outflows of knowledge to accelerate internal innovation, and expand the markets for external use of innovation, respectively”* (Chesbrough et al., 2006). The adoption of the OI paradigm has been changing the ways in which firms acquire, manage and exploit their intangible assets. As a matter of fact, after an open perspective, the firm becomes an active participant in the innovation market, acquiring knowledge assets from outside and selling or licensing the intangibles which are internally unexploited.

Firms may open up their innovation processes on two dimensions, namely inbound and outbound (Gassmann and Enkel, 2004), the former referring to enriching the company own knowledge base through the integration of suppliers, customers and external knowledge sourcing; the latter to earning profits by bringing ideas to market, selling intellectual property (IP) and multiplying technology by transferring ideas to the outside environment.

Despite the large attention OI has raised in literature, innovation measurement is still looking for an appropriate metrics system that monitors the investments and the effects of open vs. closed innovation approaches, in order to help companies to find their right balance. The measurement of the value of OI activities is increasingly important and metrics systems are not yet adapted to monitor and measure the value of such activities (Enkel and Lenz, 2009). Moreover, while a large number of studies focuses on the inbound dimension of openness by analysing the acquisition of external knowledge (e.g.,

Laursen and Salter, 2006), less attention has been paid to outbound processes: Poot et al. (2009) encourage scholars to explicitly measure outflows of knowledge in future studies.

Therefore, the purpose of this paper is to contribute to the existing research on OI, by analysing the companies' intangibles portfolio composition and relating it to the degree of openness in their innovation processes. The research questions we aim at answering are how the openness of a firm can be measured after an accounting perspective, which are the categories of intangibles that mostly characterize open companies and which is the linkage between portfolio composition, structural features and performances of companies. In doing so, we use secondary data gathered from annual reports of companies in order to define both the intangibles portfolio composition and all the costs, revenues, new investments and divestments linked to open innovation.

Our paper is organised as follows. In the next section, a literature review on the approaches to the measurement of openness is reported, with a particular focus on intangibles. Section 3 provides a detailed description of our framework. In Section 4 the application of the framework to a sample of 243 world top R&D spending companies is reported. The companies, belonging to bio-pharmaceutical and technology hardware & equipment industries, were selected from *The 2012 EU Industrial R&D Investment Scoreboard* (JRC, 2012) and their 2012 annual reports were analysed: results from cluster, one-way ANOVA and correlation analyses are outlined. Discussions and conclusions, including limitations and suggestions for further research, close the work.

2 Literature review

In what follows, literature contributions concerning the measurement of open innovation will be briefly presented, with a particular focus on intangible assets, in order to underline the relevant role of intangibles in innovative activities.

Since the definition of the open paradigm in 2003, Chesbrough underlines the *pecuniary* dimension of the phenomenon: one of the six principles of the OI concept states "*we should profit from others' use of our IP, and we should buy others' IP whenever it advances our own business model*". Literature contributions using pecuniary variables to measure the openness degree of companies include the percentage of sales in products and services from external technologies and the percentage of net income generated from own technology licensed to other firms (Chesbrough, 2004), the new revenues opportunities deriving from licenses, spin-off and sales divestiture and the cost

savings from leveraging external development (Chesbrough, 2006), as well as the investment per year in collaborative R&D (Al-Ashaab et al., 2011). Actually, the pecuniary features are innate in the definition of the OI paradigm itself, through in- and out-licensing, minority equity investments, acquisitions, R&D contracts, spin-outs and sale of innovation projects (Chesbrough and Crowther, 2006).

Yet, even if a number of studies underlines the economic issues of OI (Enkel et al., 2009), most contributions do not use pecuniary variables to measure the degree of openness of companies, rather adopting different perspectives.

As to inbound processes, there is a strong body of literature based on the Community Innovation Surveys which measures OI through the external *sources of knowledge* (Ebersberger et al., 2012; Köhler et al., 2012; Laursen and Salter, 2006; Poot et al., 2009; Salge et al., 2012; Sofka and Grimpe, 2010; Tether and Tajar, 2008). Moreover, Chesbrough himself defines a number of variables that do not refer to the pecuniary issues of OI: for example, OI effects can be measured in terms of *time* savings from both inbound and outbound practices (Chesbrough, 2004; 2006).

A further set of OI metrics can be traced back to *industrial property rights*: protection breadth, i.e. the wideness of IP rights such as patents, trademarks and copyrights (Ebersberger et al., 2012) and the number of patents per year as a result of collaborative projects (Al-Ashaab et al., 2011) can be both considered as proxies of OI.

Moreover, some studies suggest operational measurements for OI related to the *collaborative projects* in which the companies are involved (Al-Ashaab et al., 2011; Chesbrough, 2004) and the *human resources* within the companies that take part to such collaborations (du Chatenier et al., 2010) together with the new models for managing scientific personnel (Petroni et al., 2012). Finally, OI can be considered as a set of *practices* for profiting and also a cognitive model for creating and researching those practices (Chesbrough et al., 2006), with the usage of different openness practices in the stages of concept, development and commercialization (van der Meer, 2007).

From this brief overview of the literature it is clear that a number of different approaches are used to measure the degree of openness of companies, consistently with the multidimensional nature of the phenomenon. Yet, if for some non-pecuniary approaches the operationalization of the OI concept is widely recognized, after a pecuniary perspective a comprehensive measurement system is still lacking. Further, no link is found in literature between the accounting measurement of OI with intangibles,

even if the role of intangible assets is of great interest for innovation (Kaplan and Norton, 2004). As a matter of fact, intangibles provide shelter for innovators, since they are difficult to imitate, and may bring competitive advantage and lead to innovativeness (Cho and Pucik, 2005; Cohen and Levinthal, 1990; Nonaka, 1991). In theoretical and empirical studies, most researchers have used intangible assets as proxies for innovative activities (Lev, 2001; Milbergs and Vonortas, 2004), and treat expenditures on intangibles as investments in innovation capacity (Arundel, 2007; Corrado et al., 2006; Nakamura, 2001): the variation in intangible assets between two periods can be considered as a proxy for current innovation effort (Rogers, 1998). Cañibano et al. (2000) point out that financial statements could provide a sound basis for the measurement of innovation if they included more relevant information on the intangible determinants of the companies value. In fact, in industries in which knowledge is the main source of future benefits, the information provided by financial statements may have little or no relevance at all, as investments in R&D and other innovative activities are not appropriately reflected in them: as a matter of fact, they are either fully expensed as incurred, or amortized over short periods of time.

Thus, from all the previous considerations, two gaps emerge as to the measurement of open innovation: first, the lack of operationalization of OI after an accounting perspective and, second, the lack of linkages between the accounting measurement of OI and intangibles. This paper aims at filling these gaps complementing the existing measures of openness with a systematic framework based on the quantification of the pecuniary flows in OI transactions. Also, it provides a set of accounting indicators for analysing companies' intangibles portfolio in order to relate its composition to the degree of openness of their innovation processes.

3 Framework: definition of the indicators

The methodology we suggest is intended to evaluate how the companies' intangibles portfolio composition is related to (1) the degree of openness, (2) the structural features and (3) the performances of companies (Figure 1).

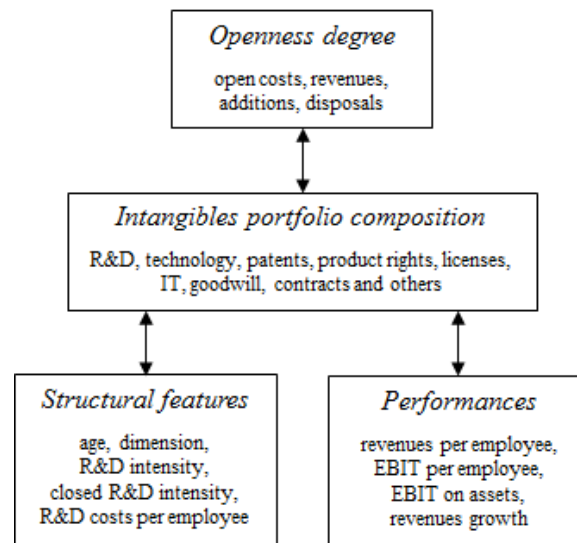

Figure 1 Relationships under investigation

In what follows, a detailed description of our methodology is reported, with the definition of intangibles shares, open innovation metrics and structural variables.

3.1 Intangibles shares

In order to analyse companies' intangibles portfolio, we grouped all the different intangibles reported in annual reports in 10 categories¹:

- *R&D*, e.g. development projects, in-process R&D;
- *technology*, e.g. core technology, product and process technology;
- *patents*, e.g. patent rights, acquired patent portfolio;
- *product rights*, e.g. trademarks, brands;
- *licenses*, e.g. license payment, license fees;
- *IT*, e.g. computer programs, software development costs;
- *other IPRs*, e.g. intellectual property, intangible rights;
- *goodwill*;
- *contracts, agreements & relationships*, e.g. customer base, non-compete agreements;
- *other intangibles*, e.g. intangible assets under construction, internally developed intangible assets.

¹ See Appendix A for the list of terms we grouped in each category of intangibles.

Note that we have included the general categories ‘other IPRs’ and ‘other intangibles’ because, in different cases, in the notes to the financial statements it is not better specified the kind of intangible.

In order to determine the intangibles portfolio composition, some ratios can be calculated, as the net value of the specific category of intangible disclosed in the notes to the financial statements divided by the total net value of intangibles reported on the balance sheet. Thus, 10 shares can be defined, e.g.:

$$R\&D\ share = \frac{R\&D}{total\ intangibles}$$

All the shares range from zero to one, respectively corresponding to the case in which the portfolio does not contain the specific category of intangible and to the case in which it contains exclusively this category.

3.2 Open innovation metrics

A comprehensive measure of OI after an accounting perspective can be obtained through the quantification of the economic and financial flows characterizing the transactions in the innovation market.

OI transactions can be divided into inbound and outbound ones, the former characterized by innovation-related costs and intangible investments, the latter by innovation-related revenues and intangible divestments. Costs and revenues affect the income statement of the company and will be defined economic measures of OI, additions and disposals regard the balance sheet and will be termed financial measures.

As to open costs, we have to include all the costs carried by the company for the internal use of external R&D and IP resources, as well as all the R&D and IP costs internally developed for external use. On the contrary, all the costs internally generated for internal use have to be excluded (e.g., R&D staff costs incurred for internal activities or costs carried to internally develop IP that will be used by the company itself).

Within open revenues, we have to consider all the revenues deriving from the external use of internally developed R&D and IP. On the contrary, all the revenues deriving from product sales have to be excluded.

Thus, open costs and revenues comprise collaborative costs and revenues, referring to joint development projects with third parties under long-term agreements; costs deriving from the outsourcing of R&D services and revenues resulting from R&D services

performed on behalf of third parties, including grants received from the government for R&D activities; in-licensing costs, out-licensing revenues and royalty fees paid or received. The first two categories concern R&D, while the third regards IP; further, three different underlying logics can be defined, from an increase of knowledge for both the parties, through the delivery of a black box, to the concession of a right without the transfer of ownership.

As to additions and disposals we have to include all the new investments and divestments of innovation-related intangibles, such as acquisitions of in-process R&D, development projects, licenses, patents, trademarks and other intellectual property rights, technology rights and goodwill, occurring either in separate acquisitions or within business combinations, mergers and acquisitions (BCMAs). Thus, two different logics can be defined as well. When a separate acquisition occurs, a focalized interest on an intangible, e.g. a specific patent, can be outlined. On the contrary, within BCMAs, the acquiring company can be interested not only on the recognized intangibles, but also in the knowledge and the expertise of people working in the acquired firm. Such a distinction makes it important to consider the goodwill arising from BCMAs as a proxy for intellectual capital, consistently with literature (Boekestein, 2009; Brännström et al., 2009).

Note that not all the increases and decreases of intangibles can be considered as open, since we have capitalization of development costs or internally developed intellectual property rights, amortization, impairment charges, reclassifications and currency translations, which are all linked to internal accounting operations and adjustments, rather than to exchanges with third parties.

According to the proposed framework, OI is a four-dimensional phenomenon, represented by costs, revenues, additions and disposals. In order to quantify the degree and define the nature of OI, four basic indicators can be calculated by comparing, for each of the four components, the items deriving from OI to the related items which define the total business of the company:

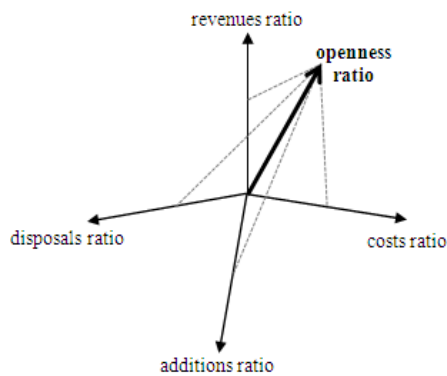

$$\text{Costs ratio} = \frac{\text{costs from OI}}{\text{total R\&D and IP costs}}$$

$$\text{Additions ratio} = \frac{\text{additions from OI}}{\text{total intangibles}}$$

$$\text{Revenues ratio} = \frac{\text{revenues from OI}}{\text{total revenues}}$$

$$\text{Disposals ratio} = \frac{\text{disposals from OI}}{\text{total intangibles}}$$

Thus, OI can be represented in the space R^4 (Figure 2), where each of the basic ratios is a Cartesian coordinate and each company can be represented as a point, whose distance from the origin is proportional to its total degree of openness.

$$Openness\ ratio = \sqrt{\frac{Costs\ ratio^2 + Revenues\ ratio^2 + Additions\ ratio^2 + Disposals\ ratio^2}{4}}$$

Figure 2 Open innovation four-dimensional space

All the ratios range from zero to one, respectively corresponding to a totally closed and a totally open behaviour.

3.3 Structural features and performances

In order to describe structural features and performances of companies we considered a number of variables. As to structural features we used:

- *age*, measured in number of years from the date of establishment;
- *number of employees*, as a proxy of firms' dimension;
- *R&D intensity*, defined by R&D expenditure on total revenues;
- *closed R&D intensity*, measured as R&D expenditure net of open costs on total revenues, as a proxy of absorptive capacity (Cohen and Levinthal, 1990);
- *R&D costs per employee*, as a proxy of the focalization on R&D of human resources.

Further, the following performance indicators were considered:

- *revenues per employee* and *EBIT per employee*, as measures of company efficiency;
- *EBIT on assets*, as a proxy of company profitability;
- *growth*, measured in terms of annual increases of revenues.

4 Application of the framework

4.1 Sample

The suggested framework was applied to a sample of 243 world top R&D spending companies, according to *The 2012 EU Industrial R&D Investment Scoreboard*, for which the 2012 annual reports were analysed². Two industries were selected: bio-pharmaceutical and technology hardware & equipment; according to ICB codes, the former is divided into biotechnology (BIO) and pharmaceutical (PH) segments, the latter in computer hardware & office equipment (HW), semiconductors (SC) and telecommunications equipment (TLC) segments. We excluded all the companies for which (1) their annual reports, available on the internet, were either incomplete, with no notes to the consolidated balance sheet and income statement, or not filling IFRS or US GAAP standards; (2) no intangibles are disclosed in the balance sheet; (3) only the gross carrying amounts of the different types of intangibles are disclosed in the notes.

Data collected from the annual reports were used to define, for each company, the intangibles shares, the total openness ratio and its components (i.e. costs, revenues, additions and disposals ratios), the structural features and the performances.

4.2 Cluster analysis

In order to group together the companies having similar compositions in their intangibles portfolio, a Ward hierarchical clustering with squared Euclidean distances was performed using the intangibles shares as clustering variables. Different solutions with different numbers of clusters have been compared and five clusters have been chosen, trying to balance different criteria, such as statistical significance, easiness of interpretation, and consistence of each cluster.

² When the annual report refers to the year ended before 30th June, the 2012-2013 report was considered, otherwise the 2011-2012 one. All data were converted in euro by using the exchange rates as of 31st December.

The five clusters³ obtained were named after the intangibles prevailing in the portfolio (Table 1):

- *R&D owners* (12,8% of the sample) - the intangibles portfolio of the companies in this cluster is mainly characterized by R&D;
- *technology owners* (25,5% of the sample) - the intangibles portfolio of the companies in this cluster is represented by the prevalence of technology and goodwill;
- *patents owners* (4,9% of the sample): the intangibles portfolio of the companies in this cluster is mainly characterized by patents;
- *product rights owners* (7,0% of the sample): the intangibles portfolio of the companies in this cluster is represented by the prevalence of product rights;
- *goodwill owners* (49,8% of the sample): the intangibles portfolio of the companies in this cluster is mainly characterized by goodwill.

As we can see from our results, *goodwill owners* represent the largest cluster with about half of firms in the sample pursuing acquisition strategies since goodwill can be registered only when a BCMA occurs.

Table 1 Clusters definition: mean values of intangibles shares

Shares	R&D owners	Technology owners	Patents owners	Product rights owners	Goodwill owners	Total sample
R&D share	77,8%	3,0%	0,6%	2,9%	2,7%	12,2%
Technology share	1,1%	22,2%	2,3%	1,7%	7,1%	9,6%
Patents share	1,6%	3,6%	76,1%	0,1%	3,0%	6,4%
Product rights share	3,3%	1,1%	0,2%	60,1%	3,8%	6,8%
Licenses share	2,6%	5,3%	2,2%	0,2%	0,5%	2,1%
IT share	1,9%	11,5%	2,5%	0,8%	0,8%	3,8%
Other IPRs share	0,3%	9,7%	0,0%	0,0%	0,5%	2,8%
Goodwill share	10,2%	24,9%	15,2%	32,3%	74,0%	47,5%
Contracts share	0,9%	8,5%	0,3%	0,0%	6,0%	5,3%
Other intang. share	0,4%	10,1%	0,6%	1,9%	1,7%	3,7%
Total	100,0%	100,0%	100,0%	100,0%	100,0%	100,0%

Further, one-way ANOVA was performed to determine whether the belongingness to the clusters is a discriminating factor for the variables under study (Table 2): most of them resulted to have statistically different mean values among the five clusters.

³ See Appendix B for the list of companies and clusters.

Therefore, Tables 3 to 6 provide the description of the clusters in terms of segment, openness, structural features and performances.

Table 2 One-way ANOVA - discriminating factor: clusters belongingness

Table 3 Cluster description by segments

Segment	R&D owners	Technology owners	Patents owners	Product rights owners	Goodwill owners	Total sample
BIO	13 41,9%	10 16,1%	4 33,3%	4 23,5%	14 11,6%	45 18,5%
PH	7 22,6%	17 27,4%	2 16,7%	13 76,5%	20 16,5%	59 24,3%
HW	3 9,7%	3 4,8%	2 16,7%	0 0,0%	19 15,7%	27 11,1%
SC	1 3,2%	24 38,7%	3 25,0%	0 0,0%	40 33,1%	68 28,0%
TLC	7 22,6%	8 12,9%	1 8,3%	0 0,0%	28 23,1%	44 18,1%
Total	31 100,0%	62 100,0%	12 100,0%	17 100,0%	121 100,0%	243 100,0%

As to the segments, the following results are observed (Tables 2 and 3):

- *R&D owners* are mainly represented by biotech companies, followed by pharmaceutical and telecommunications equipment ones;

- *technology owners* are primarily characterized by semiconductors companies, followed by pharmaceutical and biotech ones;
- *patents owners* are mainly represented by biotech and semiconductors companies;
- *product rights owners* are only characterized by bio-pharmaceutical companies;
- *goodwill owners* are mainly represented by semiconductors companies.

Table 4 Clusters description: mean values of openness ratios

Openness ratios	R&D owners	Technology owners	Patents owners	Product rights owners	Goodwill owners	Total sample
Revenues ratio	29,8%	18,6%	39,8%	7,7%	8,6%	15,3%
Costs ratio	18,4%	10,7%	11,0%	1,4%	4,2%	7,8%
Disposals ratio	0,3%	1,4%	2,7%	0,0%	0,7%	0,9%
Additions ratio	12,8%	12,4%	8,7%	15,5%	13,3%	12,9%
Openness ratio	24,6%	17,5%	26,4%	11,2%	11,7%	15,5%

As regards openness degree (Tables 2 and 4):

- *patents* and *R&D owners* are more open than the companies belonging to the other three clusters, particularly as to revenues and costs;
- no significant differences among clusters are found as to both additions and disposals ratios.

Table 5 Clusters description: mean values of structural features

Structural features	R&D owners	Technology owners	Patents owners	Product rights owners	Goodwill owners	Total sample
Age	22	37	54	51	45	41
No. of employees	1.056	17.059	12.827	12.638	21.071	16.497
R&D intensity	23,3%	14,6%	3,8%	18,2%	12,0%	12,3%
Closed R&D intensity	19,1%	13,4%	3,6%	17,7%	11,3%	11,5%
R&D costs per employee (k€)	188	83	162	87	61	90

As to the structural features, the following results are obtained (Tables 2 and 5):

- *R&D owners* are represented by the youngest firms in the sample. They also have higher R&D intensity, absorptive capacity and R&D focalization of the human resources;
- *patents owners* are characterized by the oldest companies in the sample. They also have lower R&D intensity and absorptive capacity;
- *goodwill owners* are the companies with the lowest R&D focalization;

- no significant difference among clusters is found as to dimension.

Table 6 Clusters description: mean values of performances

Performances	R&D owners	Technology owners	Patents owners	Product rights owners	Goodwill owners	Total sample
Revenues per employees (k€)	456	304	445	483	301	341
EBIT per employee (k€)	-25	4	-7	108	12	11
EBIT on assets	-8,8%	-2,3%	2,1%	16,4%	1,7%	0,4%
Revenues growth	43,8%	11,7%	83,3%	17,1%	2,3%	15,0%

As to performances (Tables 2 and 6):

- *product rights owners* show the highest levels of revenues per employee ratio, followed by *R&D* and *patents owners*;
- *patents owners* have the highest revenues growth rate, while *goodwill owners* the lowest;
- no significant differences among clusters are found as to both EBIT per employee ratio and profitability.

4.3 Correlation analysis

Correlation analysis was performed to examine the relationships under investigation (Figure 1). Table 7 shows only an extract of the correlation matrix since we are interested in investigating how openness, structural features and performances are related to the intangibles shares and not in the links between the variables themselves. As we can see from our results, no significant correlations are found as to IT and other IPRs shares.

As to the propensity to open up innovation processes, we found that the prevalence of R&D in the portfolio exhibits a weak positive correlation with openness, particularly as to its economic dimension. Similarly, an high share of patents shows a weak positive correlation with openness, especially as to outbound transactions, while the prevalence of technology is only directed related to open additions. On the contrary, an high share of goodwill in the portfolio is negatively correlated to openness, particularly as to revenues and costs.

As to the linkage with structural variables, our results show that only R&D share is statistically related to all features. In particular, an high share of R&D exhibits a weak negative correlation with age and dimension, a weak positive correlation with R&D

intensity and absorptive capacity, and a moderate positive correlation with R&D focalization of human resources. Further, the prevalence of products rights shows a weak positive correlation with age, and that of patents exhibits a weak positive correlation with R&D costs per employee ratio. Conversely, both an high share of goodwill and of contracts in the portfolio is negatively related to R&D focalization.

Finally, as to performances we found that both the prevalence of R&D and of product rights is directly related to company efficiency; on the contrary, an high share of goodwill is negatively correlated to it. The prevalence of product rights is also directly correlated with profitability, whilst both that of R&D and licenses is inversely related to it. A final remark regards growth; in fact, R&D and patents shares are directly correlated with annual increases of revenues, while the prevalence of goodwill is inversely related to growth.

Table 7 Pearson's correlation coefficients

Variable	R&D share	Technology share	Patents share	Product rights share	Licenses share	IT share	Other IPRs share	Goodwill share	Contracts share	Other int. share

5 Discussions

Some discussions can be pointed out as to both the methodology and the results deriving from the application to bio-pharmaceutical and technology hardware & equipment industries.

Despite accounting standards, annual reports can be quite different one from the other in their form. As to revenues, in some cases those deriving from OI are directly disclosed in the income statement exhibited separately from net sales as other income, but in most cases revenues composition has to be detected in the notes. R&D cost composition is never disclosed directly in the income statement and the relative note has to be looked up. Further, some innovation-related costs - such as collaboration profit-sharing or acquired in-process R&D - can be recorded separately from R&D costs in the income statement. In particular, royalties and license fees are disclosed as operating expenses and can be reported as a separate item or included in cost of sales or in R&D costs. Obviously, the denominator of the costs ratio was built by considering all the costs related to the innovation process, even if they were not included in the R&D costs.

As regards disposals and additions of intangibles, two different approaches are used by IFRS and US GAAP. While the former explicitly discloses all additions and disposals - internal, in separate acquisitions and within BCMAs - in the note to intangibles, the latter only discloses additions from BCMAs in the notes regarding business combinations. Thus, in order to obtain the additions and disposals of separately acquired intangibles, the difference between the gross value at the end of the year, the gross value at the beginning of the year, the value of BCMA additions and any impairment charge or reclassification has to be performed. However, this assessment is approximate, because if the difference is positive, we record a separate addition but some separate disposals of lower value might have occurred and vice versa.

As to the analysis of intangible assets, the first evidence from the application is the variety of terminology used to define the same conceptual item within the different annual reports of companies. For this reason we grouped them in different categories⁴ to examine the composition of companies' portfolio.

Further, as mentioned above, we excluded from our sample all the companies for which only the gross carrying amounts of intangibles were disclosed in the notes to the

⁴ See Appendix A for the list of terms we identified for each category of intangibles.

consolidated balance sheet with a single depreciation rate not attributable to the specific categories of intangibles.

As to the application of the framework to R&D intense companies, some results can be pointed out.

First, we found that an high share of R&D or patents in companies' portfolio has a positive and significant effect on the degree of openness of their innovation processes. This is consistent with the results of cluster analysis, since *R&D* and *patents owners* are more open than the companies belonging to the other three clusters. On the contrary, the prevalence of goodwill in the portfolio is inversely related to openness, thus, companies pursuing acquisition strategies, i.e. *goodwill owners*, are less open in their innovation processes. Once again this is consistent with the results of cluster analysis, but also with the observation that BCMA's can be considered as hierarchy mechanisms. Further, as to the components of openness, we found a significant positive relationship between the R&D share with revenues and costs ratio. Thus, *R&D owners* are mainly characterized by inbound and outbound economic transactions. Differently, *patents owners* are mainly represented by open revenues and disposals; therefore, an high share of patents enables those companies to licensing or divesting the intangibles which are internally unexploited. Conversely, we found a negative relationship between the goodwill share with revenues and costs ratio. Thus, the OI processes of *goodwill owners* have a financial nature. Another consideration regards the companies having an high share of technology in their portfolio; their openness is mainly related to the acquisition of intangibles from outside.

Second, as to the structural variables, our results show that only the prevalence of R&D is statistically related to all features. In particular, an high share of R&D is inversely related to age and dimension and directly related to R&D intensity, absorptive capacity, and R&D focalization. These results are consistent with those of cluster analysis. Moreover, the prevalence of products rights is directly related with company age, and that of patents with R&D costs per employee ratio. On the contrary, both an high share of goodwill and of contracts in the portfolio is negatively related to R&D focalization.

Third, as regards performances, we found that both R&D and products shares are directly related to company efficiency; on the contrary, goodwill share is negatively correlated to it. As to profitability, the prevalence of product rights is directly correlated to it, whilst both that of R&D and licenses is inversely related to it. A final remark regards growth; in

fact, high shares of R&D and patents are directly correlated with annual increases of revenues, while the prevalence of goodwill is inversely related to them.

6 Conclusions

Despite the huge interest OI has raised in literature, it is still unclear how to quantify it and what is the relevance of intangible assets in open activities. The aim of this paper is to fill such gaps by providing an accounting framework for both analysing the composition of companies' intangibles portfolio and relating it to the degree of openness of their innovation processes.

The work is based on the analysis of annual reports, defining both the pecuniary flows related to OI transactions - costs and revenues from joint development projects, outsourcing of R&D services or intellectual property licensing and additions and disposals of innovation-related intangibles - and the composition of the internal stock of intangibles. The framework was then applied to a sample of 243 world top R&D spending companies in bio-pharmaceutical and technology hardware & equipment industries, whose annual reports for the fiscal year 2012 were analysed. Both the framework applicability and its explicative power and usefulness were validated.

The paper contributes to the existing literature on the measurement of open innovation from two perspectives. First, it focuses on the pecuniary dimension of the phenomenon by outlining all the economic and financial flows linked to open innovation activities and, after this perspective, it follows Chesbrough's suggestion. Second, it proposes a set of metrics which can be used not only for inbound processes but also for outbound ones, allowing to define the ways in which companies can capture value from the exploitation of their technology, i.e. the business models of companies. Further, the paper contributes to the understanding of the importance of intangible assets in open activities, by investigating which categories of intangibles mostly characterize open companies.

The paper addresses the need for operative, practical instruments, which can help managers to monitor the impact of the investment in intangibles on companies' innovation processes after an open-oriented approach. As a matter of fact, it proposes a set of metrics enabling to evaluate companies' core competences and relate them to the propensity to open up their innovation processes. Further, given the availability and objectivity of annual report figures, this accounting framework can also be used by

decision-makers for comparisons over time and space, also allowing the benchmarking with competitors.

Three limits can be outlined for the work. First, the disharmony of accounting standards over countries limited our analysis only to the companies which adopted either IFRS or US GAAP, resulting in an under-coverage of the sample. Second, being focused on accounting indicators, our framework can be used to analyse only the pecuniary dimension of open innovation (Dahlander and Gann, 2010) and thus it cannot be generalized to such industries as software, where sourcing and revealing are widespread. Third, the analysis is based only on one fiscal year, limiting the generalization of results. At the moment we are collecting data for a longitudinal analysis in order to highlight the trends in open innovation strategies pursued by companies.

Appendix A. List of intangibles by category

R&D

Acquired R&D
Acquired research and development projects
Advance payments and projects under development
Capitalised expenditure for research and development work
Capitalized development costs
Capitalized development projects
Cleviprex milestones
Completed development works costs
Construction in progress
Deferred development costs
Development costs
Development expenditure
Development projects
Development projects, developed in-house
Development rights
Development services
Development works under construction
In-process R&D
Internally generated development costs
Payments made and capitalized development costs for current projects
Product development costs
R&D
Upfront milestone paid to third parties for development of products

Technology

Acquired and developed technology and software development cost
Acquired product technology
Acquired special technology
Acquired technology rights
Completed technology
Core and developed technology
Core developed technology
Core technology
Core technology and patents
Current technology
Developed and core technology and patents
Developed product technology
Developed technology
Developed technology and other
Developed technology rights
Existing and core technology-product
Existing technology
In-process technology
Patented and completed technology
Product and process technology
Purchased technology
Purchased technology and other intangible assets
System technology
Technology
Technology and patents
Technology intangibles
Technology know-how
Technology licenses
Technology-based

Patents

Acquired patent portfolio
Acquired patents, trademarks, licenses and know-how
Out-licensed patents
Patent licensing
Patent rights
Patented technology
Patents
Patents and acquired R&D
Patents and industrial property
Patents, licenses and similar rights, brands, trademarks and other
Patents, trademarks and tradenames

Product rights

Brand license
Brands
Currently marketed products
Developed product rights
Product intangibles
Product licenses
Product related intangibles
Product rights
Product marketing & distribution rights
Products and product rights
Products, trademarks and other rights
Trade names
Trademarks
Trademarks and brands
Trademarks and tradenames
Trademarks, patents and licences

Licenses

Acquired manufacturing facility production licenses
Licences and software
Licences, patents
License agreements
License agreements and other
License fees
License payment
Licenses
Production licenses

IT

Capitalized development costs for ERP
Capitalized software
Capitalized software licenses
Completed IT development projects
Computer programs
Computer programs and other
Computer software
Internal use software
Internally developed software
IT development projects in progress
IT system projects
IT-software in progress
Purchased computer software
Purchased internal use software, backlog and in-process R&D
Purchased software
Rights/web domains
Software
Software & databases
Software and patents
Software cost
Software development costs
Software licences
Software license and technology

Software licenses and other licenses

Wireless spectrum

Other IPRs

Industrial rights and similar rights and assets

In-licensed rights and patents

Intangible rights

Intellectual property

Intellectual property rights

Intellectual property rights acquired for currently marketed products

Intellectual property rights acquired for in-process R&D

Intellectual property rights, brands and other intangibles

Rights

Goodwill

Goodwill

Knowledge Transfer in Regional Industry Clusters for Organizational Resilience

Peter Schmiedgen*, Jörg Rainer Noennig

Junior Professorship for Knowledge Architecture
Department of Architecture
TU Dresden (Dresden University of Technology)
01062 Dresden, Germany

* *Corresponding author*

Structured Abstract

Purpose – The aim of the current study was to identify and analyse success factors of knowledge transfer in innovation processes of regional industry clusters that increase organizations' and, in turn, clusters' resilience.

Design & Methodology – The research process consists of three parts: literature review looking at success factors for inter-organizational knowledge transfer in innovation processes, empirical study on the identified factors, and statistical as well as analytical evaluation of the results. Object of the study was Silicon Saxony, Germany – a regional high-tech cluster of producing and developing companies, research and education institutions, suppliers, service providers, and consultancies. After combining the identified factors, derived hypotheses concerning the dependency and correlation were analysed using a standardized online survey: knowledge- and innovation managers of all member organizations of the Silicon Saxony Association were contacted. A total of 55 representatives completed the questionnaire.

Originality & Value – Up to now, research in this field is little and studies are mostly theoretical or qualitative. The current quantitative-empirical study puts dependencies and correlations of factors in evidence that support inter-organizational knowledge transfer in innovation processes building up resilience. Innovation culture was identified as the central factor. Furthermore, with the results four types of organizations were identified and characterized by indicating their participation in the regional industry cluster and their understanding of knowledge transfer.

Practical implications – The results of the study offer a cross-disciplinary argumentation for managers to improve innovation culture and their participation in clusters, which in turn, increases their organizational resilience. Managers are equipped with instruments measuring success factors for knowledge transfer. With the results they can identify weak points in their organization and improve them.

Keywords – Innovation Management, Knowledge Management, Cluster Management, Resilience Management, Communication Management

Paper type – Academic Research Paper

1 Introduction

Regional industry clusters (RICs) are known as essential drivers of innovation and build strong networks that can support organizations in turbulent times. These two advantages of RICs are based on knowledge transfer between the organizations increasing their resilience to global competition (i.e. Langford, 2010; Mattsson, 2009; Porter, 1998, 2000; Wei, 2012). Because of these regional synergies, they are often part of national and international funding-programs developing sector-specific industry.

Often the exchange of knowledge does not happen in the expected amount because the success factors for the transfer are not exactly known (Blomkvist, 2012; Pinho, Rego, & Cunha, 2012). Up to now, research in this field is very little and most analyzes are theoretical or qualitative. Filling this gap, the aim of the current study was to identify and analyze success factors of knowledge transfer in innovation processes of RIC that increase also organizations' and, in turn, clusters' resilience.

Upon this introduction, the paper starts with a theoretical framework of the topic and an introduction of the key terms in chapter two. Chapter three explains the research design of the current study, introduces the identified success factors of inter-organizational knowledge transfer in innovation processes in RIC connected to resilience approaches, and describes the derived hypothesis. Chapter four gives an overview to the used methods and in chapter five the findings of the statistical analysis are presented.

2 Theoretical framework

Innovation management: In literature "innovation" has a huge range of different definitions. This study is based on a wide understanding of this term. Innovations are in seen in different levels – innovation in...

- products / services
- processes / methods
- strategies / business models
- organisational structures
- social systems

Besides the multi-level understanding of innovation, innovation management has a diverse functional spectrum, too: On the one hand, innovations can't be managed but, on

the other hand, innovations can also not be taken for granted. Therefore, the task of innovation management is not only planning, organizing, leading, evaluating, and deploying personnel in innovation processes but also improving a holistic creative environment and indicating important impact ranges (Richardson, 2010; Tidd & Bessant, 2009). Consequently, innovation management has the main task to support a wide understanding of its' broader potentials and is not only responsible for inventions in research and development departments (Müller-Prothmann, 2006). With the increasing adoption of open innovations strategies the borders of innovation management disappeared and made it even more complex to meet all stakes of involved internals and externals. One of the main factors in these processes is knowledge transfer.

Inter-organizational knowledge transfer in innovation management: Sharing knowledge is an essential part of innovation processes and thus, a main challenge for employees that are responsible for organizational innovation management (Billington & Davidson, 2013; Hayes & Fitzgerald, 2009; Love & Roper, 2009). In literature a lot of models and approaches can be found for intra-organizational knowledge sharing (Fang, Yang, & Hsu, 2013; Pinho et al., 2012). But knowledge transfer triggered by open innovation strategies is still mainly unexplored field. Thus, the current study focuses the exchange of knowledge between organizations in innovation processes.

Resilience in regional industry clusters: RICs are concentrations of legally independent organizations in a region that are operating in the same, similar, or complementary industrial sectors. Clusters are geographic concentrations of interconnected companies, specialized suppliers and service providers, firms in related industries, and associated institutions (e.g. universities, standards agencies, and trade associations) in particular fields that compete but also cooperate (Porter, 1998). An association membership connects them and builds an additional brand. The aim of the cluster is to increase competitive advantages over organizations that are not part of the cluster. For that, the organizations indirectly and directly support each other (Porter, 1987, 1991, 2000):

- Indirect support: For example, other successful companies in the cluster attract new customers (B2B and B2C), highly educated employees (high potentials), and new company locations.

- Direct support: For example, other organizations cooperate, collaborate, share resources, and build long-term business links with the own organization.

These are in short the advantages of RICs. Of course, there are also disadvantages that the current study does not focus.

The question is: how do these factors support organizational resilience? For a long time in context of organizations, the term resilience was understood as the capability to react fast to crises, to learn from them, and to be “immune” in future. Newer approaches added the competence to start an innovation loop while counteracting disturbances and discussed the role of regional clusters building a strong network in dynamic markets (Giroux, 2012; Giroux & Prior, 2012; Malone, 2002; Nielsen, 2006; Norris, Stevens, Pfefferbaum, Wyche, & Pfefferbaum, 2008; Seville, 2008). The symbiotic of RIC-relationships and their co-evolutionary orientation makes organizations, and in turn the cluster resistant against disturbances. Especially in times of increasing unforeseeable crisis or disasters this empowers organizations resilience by building up strong and flexible networks of knowledge (Brandenburger & Nalebuff, 1996; J. Wang, 2007; W.-T. Wang & Belardo, 2009). Additionally, innovation loops can be structured and established together. Thus, learnings can be shared and costs as well as resources of these innovation processes can be split to build up resilience (Brandenburger & Nalebuff, 1996).

In conclusion to the theoretical background and the current state of research, this study focuses the exchange of knowledge in innovation processes between organizations that are located in the same region and operate in a similar sector as an essential part for creating resilience.

3 Research design

3.1 Research process

The research process consists of three parts: literature review investigating success factors for inter-organizational knowledge transfer in innovation processes in RIC connected to resilience approaches, empirical study on the identified factors, and statistical as well as analytical evaluation of the results.

In the first step, relevant literature was sighted focussing on factors increasing and supporting inter-organizational knowledge transfer processes that are connected to resilience approaches in the research fields of innovation management, communication management, and knowledge management. Then, hypotheses were formulated based on assumed dependencies. Finally, a study was carried out analysing these hypotheses. Object of the empirical study was Silicon Saxony – a regional high-tech cluster of producing and developing companies, research and education institutions, suppliers, service providers as well as consultancies. All of these organizations are located in Saxony/Germany and are operating in the following branches: micro- and nano-technologies, software, applications, smart-systems, and energy-systems.

3.2 Research focus: success factors for knowledge transfer

The following success factors improving the inter-organizational knowledge transfer were identified:

Awareness: Organizations that are not aware of the meaning of inter-organizational knowledge transfer do not set up structures, cultures, and strategies supporting internal as well as external innovation management. As a result the network-support in crisis gets more improbable. This, in turn, affects the whole cluster cause its resilience is also based on a high number of connected members (McAslan, 2010; Pinho et al., 2012; Szulanski, 1996, 2000).

Face-to-face communication: Inter-organizational knowledge transfer consists of complex communication processes. Different mind-sets, educational backgrounds, and even specialist-languages of all involved parties hinder an efficient exchange of know-how. Consequently, all senses must be used and instant check-backs should be possible (synchronicity). Up to know only face-to-face communication can support these needs. Especially, complex, unforeseen situations require barrier-free communication channels (Daft & Lengel, 1984, 1986; Daft, Lengel, & Trevino, 1987; Klitmoller & Lauring, 2013).

Involvement: Knowledge transfer is an act of communication and it is widely spread that managers think that good communication is always naturally given. But knowledge transfer is complex and with the support of professional communication management it can be improved (Chua, 2004). Furthermore, the characteristic of innovation culture is shaped by the involvement of all departments in the organization.

Time: One of the most recurring factors in literature is time. If the management does not concern time for workshops, meetings, or events in schedules of knowledge carrying employees the bidirectional transfer won't happen. But also the person him or herself has to reserve available time to interact with representatives of other organisations (Pinho et al., 2012; Szulanski, 1996, 2000).

Innovation culture: Every organization evolves an individual culture that is part of the corporate identity and includes shared rituals, beliefs, opinions, norms, values, behaviours, etc. The innovation culture represents the attitude towards innovative processes and their impacts to the organization. A high innovation culture is seen as an essential factor to increase the intra- and inter-organizational knowledge transfer. In these environments all employees are called upon to actively share their knowledge in innovation processes regardless of their position or hierarchical level (Hall & Goody, 2007; Jones, Cline, & Ryan, 2006; Whitman & Panetto, 2006). There are regulated incentive systems that support idea creation and it is known that the success of the organization depends on on-going innovations - even in times of crisis.

Understanding of knowledge transfer: For an efficient knowledge transfer the advantages of this process and its long-terms effects must be known. A wide understanding means that employees not only reduce the exchange of know-how on items focusing a direct connection to financial aspects (i.e. acquisition of new customers, applications for funding, or increasing sales) (Earl, 2001; Faucher, Everett, & Lawson, 2008; Paulin, 2011; Shaw, Hall, Edwards, & Baker, 2007; Wei-Tsong & Belardo, 2005). If they understand the broader potentials they can actively attract transfer partners that help also to overcome disturbances.

Open innovation: If an organization shuts down its gates it may not lose important IP. But on the other hand, it is isolated from the rest and "innovation doesn't take place in isolation [...]" (Tidd & Bessant, 2009, p. 62). The same principle works for unsteady market developments: nowadays organizations have a better chance to survive with a strong (knowledge-) network (Billington & Davidson, 2013; Chesbrough, 2003).

Cluster participation: Just to be a formal part of a RIC is not all. Most of the potentials and advantages of a RIC can only be used by an active participation. Thus, organizations must actively interact and share their knowledge to be recognized and build up strong and save relationships (Porter, 2000).

State of development: The state of development of knowledge transfer is a self-assessment and a benchmark between organizations. If an organization is critical with its performance it has recognized its backlog-demand to other members of the cluster and sees possible starting points for improvement (see also Pallier et al., 2002).

3.3 Hypotheses and research model

Hypothesis 1: Knowledge transfer in RICs is seen as an important issue in future.

H1: μ Importance will increase $>$ μ Importance will remain the same or will decrease

H0: μ Importance will increase \leq μ Importance will remain the same or will decrease

Hypothesis 2: Knowledge transfer in innovation processes via face-to-face is still the preferred form of communication within a RIC.

H1: μ Face-to-face communication $>$ μ Any other forms of communication

H0: μ Face-to-face communication \leq μ Any other forms of communication

Hypothesis 3: The more the department of communication management is involved, the higher is the innovation culture.

H1: μ Innovation culture with high involvement of communication management $>$ μ Innovation culture with low involvement of communication management

H0: μ Innovation culture with high involvement of communication management \leq μ Innovation culture with low involvement of communication management

Hypothesis 4: The more the responsible employee spends time on innovation management, the higher is the innovation culture.

H1: μ Innovation culture with high work-share on innovation management $>$ μ Innovation culture with low work-share on innovation management

H0: μ Innovation culture with high work-share on innovation management \leq μ Innovation culture with low work-share on innovation management

Hypothesis 5: The higher the innovation culture, the higher is the participation in the RIC.

H1: μ Participation in RIC with high innovation culture $>$ μ Participation in RIC with low innovation culture

H0: μ Participation in RIC with high innovation culture \leq μ Participation in RIC with low innovation culture

Hypothesis 6: The higher the innovation culture, the wider is the understanding of knowledge transfer in innovation management.

H1: μ Understanding of knowledge transfer in innovation management with high innovation culture $>$ μ Understanding of knowledge transfer in innovation management with low innovation culture

H0: μ Understanding of knowledge transfer in innovation management with high innovation culture \leq μ Understanding of knowledge transfer in innovation management with low innovation culture

Hypothesis 7: The higher the innovation culture, the higher is the state of development of knowledge transfer in innovation management.

H1: μ State of development of knowledge transfer in innovation management with high innovation culture $>$ μ State of development of knowledge transfer in innovation management with low innovation culture

H0: μ State of development of knowledge transfer in innovation management with high innovation culture \leq μ State of development of knowledge transfer in innovation management with low innovation culture

Hypothesis 8: Organizations with an open innovation strategy have a higher state of development of knowledge transfer in innovation management than organization with a closed innovation strategy.

H1: μ State of development of knowledge transfer in innovation management with open innovation strategy $>$ μ State of development of knowledge transfer in innovation management with closed innovation strategy

H0: μ State of development of knowledge transfer in innovation management with open innovation strategy \leq μ State of development of knowledge transfer in innovation management with closed innovation strategy

Figure 1 shows the presumed connections between the identified success factors of knowledge transfer and assigns the described hypotheses. Based on this theoretical background a questionnaire was created including all operationalized success factors (see appendix) and some further questions to characterize the persons and their organizations in the sample.

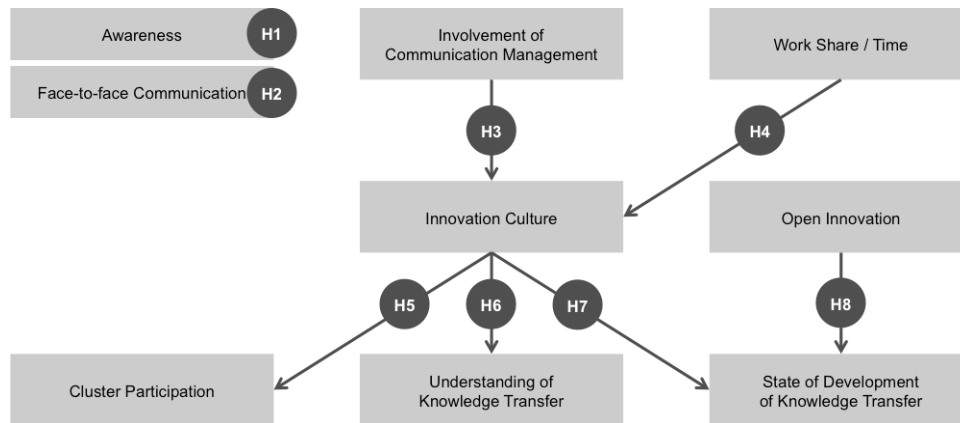

Figure 1: Research model

4 Methods

4.1 Sample, data collection and analysis

An invitation was sent via email distribution lists to the member-organizations of Silicon Saxony. It included the request to forward the email to the person in the organizations who is responsible for innovation management. Furthermore, the email consisted of a short explanation of the research interests, a statement of support for the research of the Silicon Saxony Association, and a link to the online questionnaire. All collected data was anonymous.

The questionnaire was online from December 7th 2010 to January 16th 2011. Two reminder emails were sent in this period within an interval of two weeks. A total of 55 organizations (24% response rate) completed the questionnaire. In a few cases of the following statistical analysis the sample is a bit lower because only 42 of 55 answered all questions. The rest filled out 75% of the questions or more – datasets with less response were filtered out.

The data was statistically analysed following the hypothesis and using SPSS-Software. The following statistical tests were used: univariate Anova for analysis with mean values and Spearman's rank correlation coefficient (r_s) for analysis of correlations of metrical data or recoded ordinal data.

4.2 Indices and recoding

For the analysis of the hypothesis several indices were created out of a set of appropriate questions:

Innovation strategy: The respondents had to evaluate eight statements in question 3 (Q3 see appendix). These statements were randomized in their order and consisted of four characteristics of open innovation and four of closed innovation following Chesbrough 2003. In the first step, all values of closed innovation were multiplied with (-1) and then the mean values of all answers were calculated. The index “Innovation Strategy” provides information if the organization has an open or closed innovation strategy – the higher the value, the more open (scale: -6 to 6). Organizations with negative values were grouped in category “Closed Innovation” and organizations with a value of 0 or higher were grouped in category “Open Innovation”.

Innovation culture: This index is based on Q4 (see appendix). The mean value of the answers to three statements focussing the innovation culture was calculated (scale: 1 to 6). The higher the index value, the higher is the innovation culture. For some analysis and figures a dichotomous variable of the index “Innovation Culture” was used: organizations with a value 4 or lower have a low innovation culture and respondents with a value above 4 have a high innovation culture.

Understanding of knowledge transfer: The index is based on Q5 (see appendix). The items focusing a direct connection to financial aspects were filtered out to evaluate a wide understanding of knowledge transfer in innovation management: “acquisition of new customers”, “application for funding”, and “increasing sales”. In the second step, the mean value was calculated of the remaining six items (scale: 1 to 6). The higher the index, the wider is the understanding of knowledge transfer in innovation management.

Cluster participation: The index is based on Q6 and Q7 (see appendix). In the first step, Q6 was recorded: If the organization was active in a working group and in a sub-cluster it got value 2. If it was only active in one of both it got value 1. Members of Silicon Saxony that were neither active in a working group nor in a sub-cluster got value 0. As a second step, the mean value of interests in activities in the cluster (Q7) was calculated and added to the values of Q6. The sum builds the index “Cluster Participation” (scale: 0 to 8). The higher the index value, the higher is the participation in the regional cluster.

5 Findings

5.1 Sample characteristics

The asked innovation managers had an average professional experience in the field of innovation management of 10.9 years. They spend 22.0% of their work time in innovation management. 59.5% have a degree in engineering, 23.8% in natural sciences, and 11.9% in economics. The organizations they work for focus mostly on innovations in products & services (\bar{O} rank: 1.59), processes & methods (\bar{O} rank: 2.27), and strategies & business models (\bar{O} rank: 2.61). Their fields of competence are mainly the manufacturing industry (45.5%) and service & consulting (34.5%). More than a half of the organizations have 50 or more employees. The following table 1 shows all recorded data of the organizational characteristics.

Table 1: Organisational Characteristics

Field of competence	%	Types of innovation	\bar{O} Rank
Manufacturing Industry	45.5	Products / Services	1.59
Service / Consulting	34.5	Processes / Methods	2.27
Non-University Research and Education	9.1	Strategies / Business Models	2.61
University Research and Education	5.5	Organisational Structures	3.85
Supplier	3.6	Social Innovations	4.42
Other	1.8		
Sector	%	Employees	%
Semiconductor	58.2	1 to 10	25.5
Equipment	25.5	11 to 50	21.8
Electronic	25.5	51 to 100	16.4
Computer	21.8	101 to 500	23.6
ICT	18.2	501 to 1,000	5.5
Automotive	14.5	1,001 to 5,000	5.5
Photovoltaics	10.8	5,001 to 10,000	0.0
Medical Technology	9.1	More than 10,000	1.8
Environmental Technology	7.2		
Aerospace Technology	3.6		

5.2 Analysis of hypotheses

Hypothesis 1 - Knowledge transfer in RICs is seen as an important issue in future: More than two thirds of the responsible persons for innovation management see an

increasing importance of knowledge transfer between organizations in RICs (see fig. 2). Hypothesis 1 is confirmed.

Figure 2: Q11 - What is your prediction of the future role of knowledge sharing in innovation management between organizations in regional industry clusters? (n = 42)

Hypothesis 2 - Knowledge transfer in innovation processes via face-to-face is still the preferred form of communication within a RIC: Figure 3 shows that knowledge transfer via face-to-face with 47.6% is the most used communication form in RICs. It is followed by internet-platforms (38.1%) and email (28.9%). New media channels like video-chats (42.9%) or wikis (40.5%) are often used for internal knowledge transfer but not in the innovation management within the RIC. Hypothesis 2 is confirmed.

Figure 3: Q10 - When you think of the internal and external communication: how are the following channels used for knowledge sharing in innovation management. Please specify if these channels are used "internal" or "external within the regional industry cluster". (n = 42)

Hypothesis 3 - The more the department of communication management is involved, the higher is the innovation culture: By comparing the mean values of the involvement of the communication management departments in organizations with a high innovation culture ($\bar{x} = 4.00$) and a low innovation culture ($\bar{x} = 2.92$) a significant difference ($p = .027$) can be confirmed. A significant correlation ($r_s = 0.348$; $p = .038$) can also be identified between innovation culture and involvement of the communication management department (see also fig. 4). Hypothesis 3 is confirmed.

Figure 4: Q2 - Please think of all innovation processes in your organization: how much are representatives of the following departments involved in innovation processes? Please use a scale from 1 "not involved" to 6 "high involved". & Index Innovation Culture (n = 36)

Hypothesis 4 - The more the responsible employee spends time on innovation management, the higher is the innovation culture: In organizations with a low innovation culture the mean value of the work-share for innovation management is 14.2% and 26.8% in organizations with a high innovation culture. There is also a significant correlation between both variables ($r_s = 0.427$; $p = .005$). Hypothesis 4 is confirmed.

Hypothesis 5 - The higher the innovation culture, the higher is the participation in the RIC: A not significant trend ($p = .063$) could be identified between innovation culture and cluster participation. Hypothesis 5 is not statistically confirmed but a trend could be observed.

Hypothesis 6 - The higher the innovation culture, the wider is the understanding of knowledge transfer in innovation management: There is a significant correlation between

innovation culture and the understanding of knowledge transfer in innovation management ($r_s = 0.419$; $p = .005$). Hypothesis 6 is confirmed.

Hypothesis 7 - The higher the innovation culture the higher is the state of development of knowledge transfer in innovation management: No significant correlation could be measured ($r_s = 0.212$; $p = .177$) but a visible trend was identified in figure 5. Hypothesis 7 is not statistically confirmed.

Hypothesis 8 - Organizations with an open innovation strategy have a higher state of development of knowledge transfer in innovation management than organizations with a closed innovation strategy: Figure 6 shows a visible trend between innovation strategy and development of knowledge transfer but it could not be proved statistically ($r_s = 0.209$; $p = .196$). Hypothesis 8 is not statistically confirmed.

Figure 5: Index Innovation Culture & Q5 - How would you evaluate the following aim of internal and external knowledge sharing? Please use a scale from 1 “unimportant” to 6 “very important”. (n = 44 to 45)

Figure 6: Index Innovation Strategy (Q3) & Q8 - How would you evaluate the state of development of your organizations knowledge sharing in innovation management in comparison to other organizations of the regional cluster Silicon Saxony?

5.3 Typology of organizational knowledge transfer in RIC

With the results of the indices “cluster participation” and “understanding of knowledge transfer” four different types of organizations were identified: Champions, Single Player, Potentials and Traditionalists (see fig. 7)

Champions: Champions have high cluster participation and a wide understanding of knowledge transfer. These organizations relatively tend to an open innovation strategy (41.7%) and have a high innovation culture (75.0%). The state of development of their own knowledge transfer is evaluated critically (“average or worse” = 70.0%).

Single Player: The second type has a wide understanding of knowledge transfer but its participation within the cluster is low. These organizations have a closed innovation strategy (77.8%) and a high innovation culture (77.8%). The state of development of their own knowledge transfer is seen critically.

Potentials: Organizations with limited understanding of knowledge transfer and high cluster participation belong to the third type. They have a closed innovation strategy (75.0%) and a high innovation culture (62.5%). The state of development of their own knowledge transfer is seen positive (“above-average or better” = 71.4%).

Traditionalists: The last group of identified organization types have a limited understanding of knowledge transfer and the participation in the cluster is low. These

organizations have a closed innovation strategy (71.7%) and a low innovation culture (53.3%). The state of development of their own knowledge transfer is seen critically (“average or worse” = 86.6%).

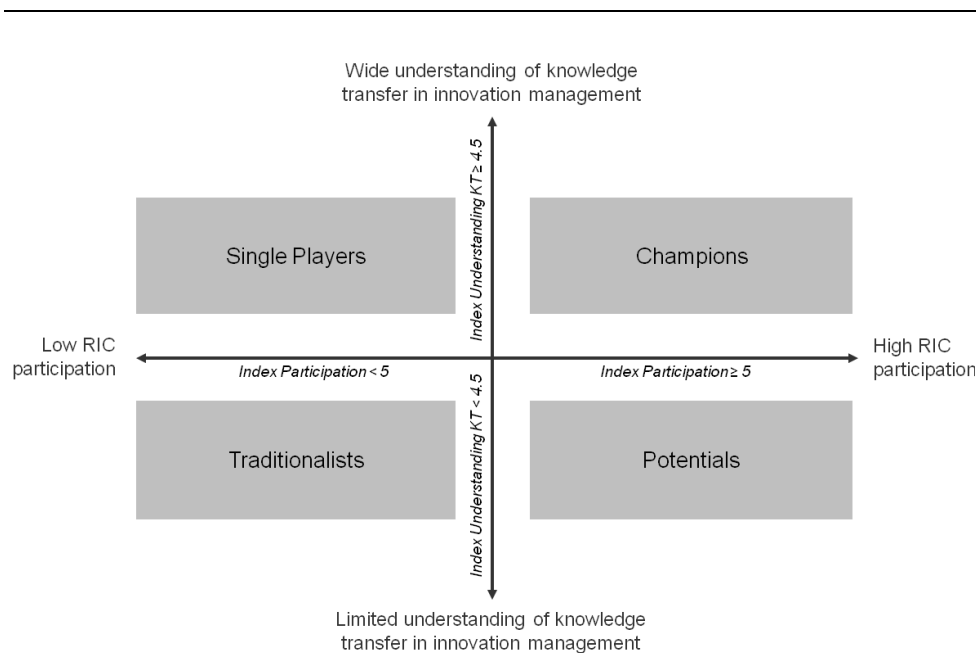

Figure 7: Types of organizations in RIC

6 Discussion

6.1 Implications

The results show that innovation managers expect an increasing importance of knowledge transfer in RICs. It is expected that the capability to support and actively design knowledge transfer is getting part of the future roles of innovation managers. In addition, personal communication will still be the most used channel to exchange knowledge. New media will although be used but more as additional channels. Thus, innovations managers in RICs have to keep their rhetorical skills and should also animate employees to prefer face-to-face communication instead of the most time saving, comfortable, but in these cases inefficient channels.

The current study has proved that innovation culture is one of the central factors for successful knowledge transfer in RICs. With the results of hypothesis 1 and 2 it was shown that the involvement of professional communication management in innovation processes increases the innovation culture. Thus, innovation managers should consult communication professionals from time to time checking if the internal and external knowledge transfer processes are efficient, because this, in turn, affects the environment for knowledge transfer. The second factor that influences innovation culture is the spent time for innovation management. Managers should keep in mind that the more time on innovation management is spent the more the innovation culture grows. At least a small work-share for appointments connected to knowledge sharing should be implemented in the schedules of every employee.

The findings of hypothesis 3 and 4 show that with time and the integration of departments the innovation culture increases. A high innovation culture in turn causes a higher participation in the RIC and a wider understanding of the potentials of knowledge transfer. In the light of the results of hypothesis 5 and 6, innovation culture should not only be seen as an internal strength but also as an enabler for external bidirectional knowledge transfer in RICs that offers possibilities far beyond financial aspects. As mentioned above this is the basement for building up organizational and cluster resilience. Organizations management should be aware of that in future.

Four different organization-types considering the knowledge transfer in clusters could be identified with the data:

- The *Single Players* are organizations that have a highly developed innovation culture but seem to have prejudices to share their knowledge. Further investigations should identify the reasons of their reservation (i.e. protection of IP, missing trust, perceived superiority) so that these barriers can be removed.
- The *Traditionalists* have a to learn the possibilities of knowledge transfer first. They are stuck in old structures. It is the task of other organizations and the cluster association to explain the advantages of being part of a RIC.
- The *Potentials* are very active in the cluster but they still not have developed a wide understanding for knowledge transfer. Consequently, they are not using they full potential.

- The *Champions* have understood the advantages of knowledge transfer in RIC and make actively use of it.

6.2 Limitations and future research

The current study has an explorative character, which in turn offers many starting points for future research. In the following the central limitations are explained in short:

The small sample limits the statistical analysis and also decreases statistical power. Nevertheless some statistically correlations and differences were observed. This argues in favour of the quality of the used instruments and the strength of effects between the identified factors. Because of the few quantitative studies in this research field the questions in the survey had partly no proven background and were transformed from statements in literature. For example in the analysis of hypothesis 7 and 8 a visible trend could be observed but was not statistically confirmed. This could be an indicator for a non-valid instrument.

In general the object of interest is a very complex one and even in literature there are many different perceptions of the understanding of e.g. knowledge transfer or innovation culture. In addition to that, the respondents had no possibility for check-backs. Personal interviews were not possible because of personnel and financial restrictions. These circumstance effect the quality of answers.

Another limitation is that the respondents selected themselves. This has the effect that probably mostly innovation managers completed the survey that were familiar with the topic. Furthermore, it could not be checked if the target persons actually filled out the online questionnaire. Furthermore, the answers provide only the view on the organization of the representative.

The current study was analysing only one RIC. Future research should identify possible differences in correlations between different clusters, add an isolated control group of organizations, and use greater samples to increase the statistical power of the results. Before that, the instruments measuring the factors should be improved. In additional studies the different cluster types should be analysed more in detail. Also a long-term investigation on their business performance could be tracked to strengthen the identified roles.

7 Conclusions

The paper analysis the central factors for inter-organizational knowledge transfer in RICs connected to resilience approaches. It could be shown that the importance of this topic will increase in future and that face-to-face communication is the central channel for transferring knowledge in RIC. Innovation culture was identified as an important success factor for knowledge transfer. It is depending on the work-share of innovation managers that is spent on supporting innovation processes and the involvement of other departments - especially professional communication managers. The analyses prove that innovation culture has, in turn, a positive effect on the participation in RICs and creates a wide understanding of the aim and potentials of knowledge transfer. It can be concluded that organizations should support employees to actively share their knowledge in innovation processes, that the management should offer attractive incentive systems, and that innovations should be seen as a central part of the organizations' mission. All these factors increase the benefits from being part of a cluster. This improves not only the resilience of the organization but also of the whole cluster.

The paper includes instruments measuring the success factors for inter-organizational knowledge transfer and provides an argumentation to let employees spend more time in knowledge sharing. With the typology of organizations in RIC the specific roles of organizations can be identified. By knowing the type of organization and its' characteristics the starting point for improvement is identified. Future research should reproduce these results with additional factors, bigger samples, and different clusters. Investigations on the used instruments could also improve the quality of data.

Appendix - Questionnaire

Q1 Types of innovations

“Innovation” is a broad term: what kinds of innovations are mainly focused in your organization. Please sort the following types of innovation. Start with the most important.

Items (randomized)	Mean value (n = 45 to 51)
01 Products / Services	1.59
02 Processes / Methods	2.27
03 Strategies / Business Models	2.61
04 Organizational Structures	3.85
05 Social Innovations	4.42

Q2 Innovation structure

Please think of all innovation processes in your organization: how much are representatives of the following departments involved in innovation processes? Please use a scale from 1 “not involved” to 6 “highly involved”.

Items (randomized)	Mean value (n = 21 to 47)
01 Research & Development	5,55
02 Production	4,21
03 Human Resources	3,37
04 Marketing	4,64
05 Communication Management	3,62
06 Legal	2,52
07 Finance	3,83

Q3 Innovation strategy

When you think of your organization strategic view in innovation management: how strong would you agree to the following statements? Please use a scale from 1 “totally disagree” to 6 “totally agree”.

Items (randomized)	Mean value (n = 44 to 46)
01 The company that gets an innovation to the market first will win.	4.76
02 We should control our IP, so that our competitors don't profit from our ideas.	4.87
03 To profit from R&D, we must discover it, develop it, and ship it ourselves.	4.22
04 The smart people in the field work for us.	4.62
05 Not all the smart people in the field work for us. We need to work with smart people inside and outside the company.	4.61

06 Building a better business model is better than getting to the market first.	4.55
07 We should profit from others' use of our IP, and we should buy others' IP whenever it advances our business model.	2.62
08 External R&D can create significant value: internal R&D is needed to claim some portion of that value.	3.38

Q4 Innovation culture

The importance of innovation differs from organization to organization: how about your organization? Please evaluate the following statements. Please use a scale from 1 "totally disagree" to 6 "totally agree".

Items	Mean value (n = 48)
01 All employees are called upon to actively share their knowledge in innovation processes regardless of their position or hierarchical level.	5.04
02 There are regulated incentive systems for all employees that support idea creation.	3.04
03 The success of the organization depends on on-going innovations	5.10

Q5 Understanding of knowledge transfer

How would you evaluate the following aim of internal and external knowledge sharing? Please use a scale from 1 "unimportant" to 6 "very important".

Items (randomized)	Mean value (n = 44 to 45)
01 Overcoming barriers against change processes	3.50
02 Activating other employees to share knowledge	4.53
03 Acquisition of new customers	5.45
04 Positioning as an innovative organization	5.16
05 Building trust and confidence in crisis	4.23
06 Building networks / find new cooperation partners	4.71
07 Application for funding	3.70
08 Attraction of new employees	3.89
09 Increasing sales	5.05

Q6 Participation I

Is your organization next to the membership in Silicon Saxony an active member of a working group (i.e. equipment, software, photonics) or of a sub-cluster (i.e. Cool Silicon)?

Items	% (n = 55)
01 Yes, working group and sub-cluster	32.7
02 Yes, only working group	36.4

03 Yes, only sub-cluster	5.5
04 Neither nor	21.8
05 I don't know	3.6
99 No answer	0.0

Q7 Participation II

Please think of activities in the cluster Silicon Saxony. How strong is the interest of your organisation to participate in the following activities? Please use the scale from 1 "no interest" to 6 "very high interest".

Items	Mean value (n = 53 to 54)
01 Fairs / exhibitions	3.81
02 Information events	3.08
03 Presentation of products or processes	3.19
04 Campus events	3.34
05 Reports / Documentaries	3.47
06 Congresses / Meetings / Presentations	4.43
07 Shared Online-Platform	3.72

Q8 State of Development in Knowledge Transfer

How would you evaluate the state of development of your organizations knowledge sharing in innovation management in comparison to other organizations of the regional cluster Silicon Saxony?

Items	% (n = 42)
01 We are one of the leading organizations in Germany.	2.4
02 We are one of the leading organizations in the cluster.	2.4
03 We are above average.	26.2
04 We are the average.	42.9
05 We still have weak points.	26.2
99 No answer	0.0

Q9 Average work-share

When you think of a normal week: what is your average work-share (circa) for innovation management?

Items	Mean value % (n = 42)
01 --_%	21.98

Q10 Knowledge transfer channel

When you think of the internal and external communication: how are the following channels used for knowledge sharing in innovation management. Please specify if these channels are used "internal" or "external within Silicon Saxony".

Items	In % (n = 42)	
	Internal	External within the RIC
01 Print-Media (i.e. mails, info-sheets)	40.5	23.8
02 Face-to-Face (i.e. meetings, workshops)	59.5	47.6
03 Email (i.e. personal email, newsletter)	59.5	28.6
04 Internet-Platforms	45.2	38.1
05 Blogs	21.4	7.1
06 Wikis	40.5	4.8
07 Social Media	11.9	9.5
08 Instant-Messaging / Video-Chats	42.9	9.5

Q11 Future prediction

What is your prediction of the future role of knowledge sharing in innovation management between organizations in regional industry clusters? Knowledge sharing ...

Items	% (n = 42)
01 ... gains in importance.	76.2
02 ... remains the same.	19.0
03 ... becomes less important.	4.8
99 No answer	0.0

Why Innovative Entrepreneurs Love Art 1)

Han van der Meer

Technical University Delft, Faculty of Industrial Design Engineering,
Department Product Innovation Management
Saxion University for Applied science, Knowledge Centre for Innovation and
Entrepreneurship.M.H. Tromplaan 28, 7513 AB Enschede, the Netherlands

Structured Abstract

Purpose: As is commonly known the bond between the wealthy powerful elite and artists is having long lasting roots. Although it seems to be a very old phenomenon it is still rather actual. Once aware of it an unavoidable observation seems to be: entrepreneurs love art. But why? And if we can find an answer to this first question will this answer help us understand the act of business creation in entrepreneurship? The paper will address these questions.

Design/methodology/approach The starting point of the paper is an overview of the major literature on the phenomenon of art appreciation in business. In literature we found 5 major motives. With the use of the 5 motives as sensitizing concepts, a rather open interview protocol was developed. In long interviews with 10 CEO/owners of innovative Dutch companies these concepts were explored. Based on the first results of the study a field experiment was carved out to provide a rich source of data.

Originality/value The experiment provided the data presented in the paper. Based on a quantitative analyses of the profile of the participants versus non participants the paper will address the question of the relation between innovativeness and art appreciation. This is a first step in unravelling our major research question.

Practical implications The results of the study so far indicate there is much more in harnessing the bond between the Arts and Entrepreneurship than an occasional visit to the concert hall or a museum. Organizing a fruitful dialogue between Arts and Entrepreneurs needs further research and designs based on the outcome of our research.

Keywords Arts-based initiatives, innovation, entrepreneurship

Paper type. The author wished it could have been a Practical Paper but it is still a rather Academic Research Paper.

1 Introduction

It is believed Plato was the first to define the three basic questions in philosophy (Störig 1979):

1. is it true? (logica)
2. is it just? (ethica)
3. is it beautiful? (aesthetica)

Like the path of the debate and development of philosophy administrative sciences seem to follow a sequence of a first and heavy debate on the first question (for instance Taylor 1856-1915 or in our days Osterwalder 2010) followed by some input from the side of (business) ethics (for instance Braungart 2002). Neither in philosophy nor in business much scholarly attention is given to the last question. Nevertheless it seems of high importance for the development of humanity in general and particularly the development of business.

So why not ignite the debate on the nature of aesthetics in business and start an inquiry in beauty and the role of beauty in business creation?

2 Starting the journey: A first inquiry

Looking at the connection of art appreciation and innovative entrepreneurs the author has been fascinated by this phenomenon for years. As is commonly known the bond between the wealthy powerful elite and artists is having long lasting roots. For example the word meceanas (in Dutch a well known word for the benefactor of arts) stems from the Roman knight Gaius Cilnius Maecenas (65 till 8 bC). So it is a very old phenomenon but still rather actual. Once aware of it, it seems an unavoidable observation: innovative entrepreneurs love art. But why?

In the rather scarce literature on the subject (Antal 2009; Buswick, Craemer and Pinard 2004; Taylor, Hansen and Hansen 2005; Styre & Eriksson 2007; Barry and Meisiek 2010; Darsø 2004 and Schiuma 2011) several possible motives for the appreciation of art by business are given. Although Richard Greene (Greene 2004) claims there are “64 Purposes of All Arts” in the uor research in 1995 we limited ourselves to 5 major motives found in literature:

1. Investment
2. Borrowed plumage
3. Nice forms

4. Resemblance of the process
5. Pivot to the future

Some 15 years later these 5 motives show a remarkable overlap with the reasoning of Schiuma (2011) when he puts the relation between arts and business in the following matrix.

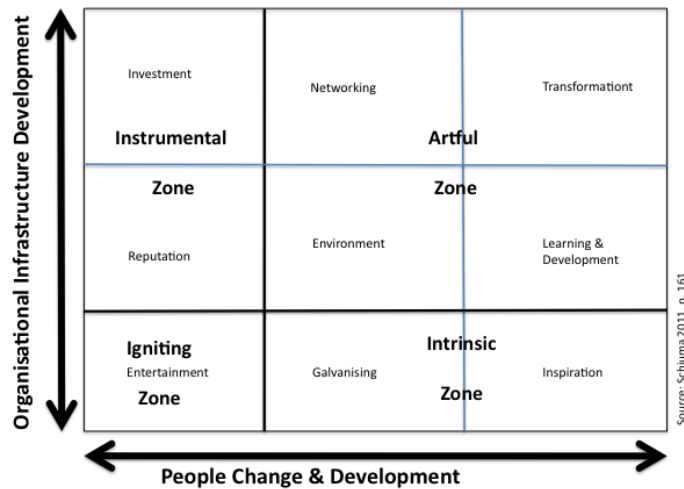

Figure 1 The Arts Value Matrix (Schiuma, 2011)

With the use of the 5 motives as sensitizing concepts, a rather open interview protocol was developed. In long interviews with 10 CEO/owners of innovative Dutch companies these concepts were explored. The interviews lasted from 1,5 hour till 4 hours and were held in the period August 1995 till April 1996. The transcriptions of the interviews are the basis of further detailed analyses leading to the following preliminary results.

The motive *Investment* means the possession of works of art as a good way of investing one's money and with the purpose of making profit on the longer term. Two CEO's gave this motive as their main reason of their interest in art "Aah, in old days I used to sell knickers now I sell Art".

To strut in Borrowed Plumage is a Dutch expression for the fact to be near someone with success others will find you successful as well. In our case will the beauty and prestige of a piece of art reflect on the perceived beauty, good taste and prestige of the owner of that piece. This reason shows an overlap with the term "Cultural Capital" as

introduced by the French sociologist Bourdieu (Bourdieu, 1986). For 3 of the CEO's in the research this seemed a very prominent reason behind their buying of art.

Nice forms is the motive of a CEO for hiring an artist in to better shape his product and make it thus more profitable. In two of the companies in the research this motive was a dominant factor why the arts were used. *"Each year we ask an artist to make a piece of work with the theme Sleep (the company is a pillow producer). It is attractive on the walls of our offices and it makes a nice new year's gift for our resellers. They really appreciate this and ask every year for it"*.

Resemblance of the process reflects the resemblance of the innovation process of an entrepreneur with the creative process of an artist. This motive is in literature also referred to as "workarts" (Barry and Meisiek, 2010). For 3 of the interviewed CEO's it was an important motive to enlarge their thinking with the world of artists. One of the interviewed CEO's did put it like this *"Whether you paint or model your company it is almost the same. It is never finished, it is never what you really meant it to be. Sometimes it goes well and sometimes you are drawn back for years, things simply did not work and you have to try again and again and again."*

Finally the last motive *"Pivot (or lookout) to the future"*. In this motive the artist is someone who is working on the border of what is and what will be. The artist gives form to "Zeitgeist" (spirit of the age) and is supposed to be years ahead of other more average people. Observing (contemporary) art can be helpful to understand "Zeitgeist" and by doing so providing inspiration or new paradigms (Barry and Meisiek, 2010) for the companies' translation of vision into form. Verganti (2010) tossed the term *Interpreter* for this mechanism. It is probably no coincidence Verganti devotes over 3 full pages text to Artist as being a key source for *Interpreters* followed by only a little more than one page for the second source *Participants in Pioneering Projects*. This motive is expected to be a very important one for our entrepreneurs, a real key motive. But our first inquiry showed differently: only one out of our 10 CEO's pointed out this was a major result of his love for art. *"Every time I visit a museum my notebook is filled with ideas. Last time in Groningen I wrote 12 down"*.

So we can conclude the motives we know from literature indeed can be observed in the cases and the interviews but none of them in a very convincing or prominent way.

However in the interviews a sixth motive came forward that was important for almost all the interviewed CEO's (9 out of 10) namely *"Arts give me energy"*. For many the arts

are a form or a source of energy and this seems the major motive why entrepreneurship and arts join forces and lead to new developments. In a conversation the author had with a Pakistan cricket coach on the subject of this state of energy who put it in this way “*We have the same phenomenon in sports. We call it “being in the zone”.* Energy is also one of the prominent topics in the work of Antal (2009) when she discusses the reasons why individuals in her study like or use art. Barry and Meisiek (2010) refer to a specific form of energetic state that art provokes. For this form the term mindfulness was introduced earlier by Langer (1989).

3 Digging a bit deeper in the first results

It can be argued that this type of research brings us eventually to the topic of consciously looking for inspiration in a consciously created state of astonishment. The state of astonishment that occurs when we are actively aware of what we know and what we do not know. In the words of Laozi “To know you don't know is best” (Henricks 1989). It is this state of astonishment that will provide both the employee as well as the entrepreneur the ability to give form to what not yet (completely) is there. Art can bring us in this state of astonishment. Or as one of our CEO's did put it “an almost limitless state of energy”.

But what does this bring us? Is this useful? Probably it is. Consciously nurturing the relation between entrepreneurship, companies and art means looking for times and places where we can exploit the combination of arts with entrepreneurship and see whether this helps entrepreneurs in creating new business.

4 Implications for further research

However, the contact between artists and companies is not at all obvious and further research is needed. Based on the research so far at least three major research topics can be distinguished :

1. Need for review and operationalization
2. What separates arts from other energizing interventions
3. Not all arts are the same

5 Need for review and operationalisation

Looking at the literature until now we see a seemingly repetition of arguments and hardly any reference to earlier work . Although Antal (Antal 2009) starts with some overview of literature but she is missing rather important work too (for instant Darsø, 2004) and although Schiuma did publish a good study on the value of arts his literature base is more business orientated than arts (Schiuma 2011). We seem in need for some thorough review of all literature to provide a solid starting point for further scientific research in the field of the relation between art (appreciation, interventions) and business.

Since the topic is one that provokes romantic pondering the need for scientific rigidity is even more needed and we should try to find good instruments to measure what we hypothesize. So far the field is lacking any form of validated instruments for research (see also Barry and Meisiek 2010).

6 What separates arts from other energizing events

One of the basic questions in our research is Why do you want to use art/do you like art? Why not simply go to football match if you want to find energy. Has this to do with the specific nature of Beauty? Is this Esthetical like the third basic question of Plato? Although one can hypothesize arts is a deep personal experience that provokes all different kind of responses from one and the same stimulus whereas sports are far more one-dimensional in experience it is indeed a hypothesis. Can we define Beauty? To find academic evidence still a lot of work has to be done.

7 Not all arts are the same

In the work so far we treated all arts and all art interventions alike. This “one size fits all” approach is a not to be accepted oversimplification of the nature of art and the use of arts in business. We should see what type will contribute to the ‘almost limitless state of energy’ and in what ways.

So before we can answer the obvious question “in what ways can we organize the Bussiness Creation prospering from Art?” a lot of work still has to be done. The research so far proofs to us that there is more to it than the occasional visit to the museum, cinema or concert hall.

8 A first step in the evidence based research

Our inquiry gave us some theory, some literature but hardly any evidence based research so far.

Based on the first results of our inquiry an experiment was carved out to provide us a rich source of data. In the period 2012/2013 Saxion University of Applied Sciences performed a rather unique project named De Kunst van/en Ondernemen (loosely translated in *The Art of/and Entrepreneurship*). 9 Saxion student entrepreneurs were paired with 9 student artist of Artez (the Eastern Dutch Art School). Based on the dialogue of the entrepreneur with the artists the latter produced a work of art reflecting his findings during the dialogue. A third student in Communication Studies filmed the process and made a short video clip of it. The artworks were exhibited one per month over a period of 9 months in the Central Entrance Hall of the main building of the Saxion Enschede Campus. At the end of the cycle the works of art were exhibited at the Twentse Welle, the local Historical Museum. The works were then auctioned in a public auction open to all entrepreneurs in the region.

This experiment provided several possibilities for evidence based research. At least three experiments will be performed. The first when the 9 entrepreneurs were selected (are the applicants different from the non/applicants ?), the second is the in-depth analyses of the process with the entrepreneurs and artists and the last when the auction is held (are the visitors different from the non visitors?).

In the first experiment we selected the participating entrepreneurs from our database of Saxion entrepreneurs (n=368) by means of a non attractive simply fact stating letter. Eleven entrepreneurs showed interest in participation out of which the nine participants were selected by the organisers of the project. After the selection a small inventory was send the entrepreneurs that showed no interest (n=368-11=357) asking for the reason why they did not participate (categories of answer 1. I did not notice the letter; 2. I do not have the time for such a project; 3.I have no commitment to art: 4. Other reasons). The response to the small inventory was 123 being slightly more than 34%. We now compared the profile of the companies of the entrepreneurs as we have them in our database on the aspect of innovativeness over the group of our participants and the group "I have no commitment to art". In the table below the very first results are given.

Table 1 Participants and non-participants with no commitment to art divided in categories of innovativeness (N=123; N=16)

Innovativeness	Participation	No participation No commitment to art
Below average	0	2
Average	3	3
Above average	8	0
Market leader	0	0
Unique in the world	1	0

Looking at the first data the results seem promising. Although numbers are quite low significant differences between the answers of participants and non-participants feeling no commitment to art can be found ($\chi^2=9.8$; $df=3$; $p=0.02$). Thus providing us with a first hint to answer the question “Do *innovative* Entrepreneurs like Arts better than *non-innovative* Entrepreneurs? “. And the answer found in this small study is: Yes. But we are still left with the question Why? Further research in this matter is on its way.

9 To conclude

The field of Business Aesthetics seems to be on l’heure bleue, the French expression of the time of night between Dark and Dawn (04.00-till sunset). We should try to move onto the lighter zones and get some data.

Let us start the dialogue on how we can get a more evidence based type research. The Saxion experiment is one of these attempts. Let us join forces to mine and harness the relation between Business Creation and the Beauty of Art.

Northampton Square, London EC1V 0HB

Structured Abstract

This paper explores theoretical frameworks, drawn primarily from learning theory, which might inform future research into arts-based initiatives (ABIs) in organisations and HE, and both the analysis and dissemination of outcomes. The theoretical insights considered here include pedagogical and philosophical models (eg Buber 1937/2002; Heron 1992; and Gardner 2006, 2011); psychological and management frameworks in self-efficacy, social cognition, socio-constructive approaches and complexity theory (eg Bandura 1997; Hutchins 1995; Kolb and Kolb 2010; Mowles *et al.* 2008); and models applied to research in the creative arts, including metaphor, aesthetic distancing, embodiment, and threshold concepts (eg McGilchrist 2009; Pässilä and Vince 2012; Dreyfus 1996; Meyer and Land 2005). In the conference presentation, we will also review some of the more populist ideas, including emotional intelligence, presence and mindfulness (Boyatzis and McKee 2005; Senge *et al.* 2005; Goleman *et al.* 2002), which have become established in leadership and management development practice, aiming to consider whether their application to the analysis of research results may offer benefits in the dissemination and interpretation of arts-based research for practitioners. The paper concludes by considering potentially appropriate research methodologies and other recommendations for future research into ABIs, and by inviting debate and feedback.

Purpose - The aim of this paper is to inform future research in arts-based practises in organisational and management development by exploring potentially fruitful theoretical starting points, and relating those to applicable research methodologies.

Design/methodology/approach -The approach adopted here is both interdisciplinary and research-focused. The paper considers theoretical insights from the work of philosophers, psychologists and educational theorists, and considers for each the research disciplines that might effectively be applied to future research into the processes and impacts of arts-based practices in management development and education. By doing so, the hope is to encourage the future development and implementation of ABIs by identifying both their personal and their organisational impacts.

Originality/value - Evidence for the impact of ABIs is needed if the potential organisational and educational benefits of this evolving interdisciplinary field are to be realised. The theoretical toolkit that could be applied is of considerable intellectual breadth. The opportunity of this paper is to present, for debate, something of this breadth, to consider how these and other theoretical insights might inform research initiatives that

will benefit management practitioners as well as scholars and educators, and to present the results of a pilot study.

Practical implications - The outcomes of this proposal lie in its potential to support and inform the design of future research in arts-based practices in personal and organisational learning, as well as the effective dissemination and application of those research findings in organisational contexts and HE teaching.

Keywords - Arts-based management, Arts-based innovation, Theory of arts in management, Research and arts-based management

Paper type - Academic Research Paper

1 Introduction

This paper considers theoretical frameworks which could inform research into the impact of arts-based initiatives (ABIs) in management and programmes of study offered within higher education. The discussion both confirms and extends Schiuma's (2011) analysis, and supports his recommendations that the aims and process of such initiatives must be planned with care, are fundamentally cultural, and require the establishment of a climate of trust. This paper also identifies exemplar research processes; and concludes by offering recommendations to inform the planning and analysis of future ABIs in both organisational and HE settings.

2 Researching arts-based management practices

As Schiuma (2011) identifies, art-based initiatives (ABIs) in organisations can be implemented to address a people-centred issue (eg 'to engage people's dreams, emotions and energy to achieve challenging organisational objectives that require people's engagement and passion', p.212) or a strategic one (to 'build arts capital', p.213), though their potential is most fully experienced where these two aims combine in 'artful organisational development' (Schiuma 2011, p.213).

In this paper, the focus is on theoretical frameworks and previous research that might inform the design and analysis of future research into the potential personal and communal effects of ABIs, as distinct from their possible strategic outcomes. This represents a complex, interdisciplinary research challenge which is likely to benefit from mixed-method research and disciplinary collaborations.

3 Theoretical frameworks and potential research approaches

3.1 Pedagogical and philosophical models

Habitus: Bourdieu

The notion of *habitus* might usefully support the analysis of shifts between individuals in group interactions through an ABI. The concept was introduced by Bourdieu (1977, quoted in Becker 2001, p.137) in place of previous scholars' theoretical emphasis on 'culture':

'The structures constitutive of a particular type of environment (e.g. the material conditions of existence characteristic of a class condition) produce *habitus*, systems of durable, transposable *dispositions*...' (Bourdieu 1977, p.72)

His additional explanation of 'dispositions' relates to the embodiment theme outlined under a separate heading below:

'The word *disposition*... expresses first the *result of an organizing action*, with a meaning close to that of words such as structure; it also designates a *way of being, a habitual state* (especially of the body and, in particular, a *predisposition, tendency, propensity, or inclination*.' (Bourdieu 1977, p.214, f.1)

Artistic source: Buber

The work of the philosopher Buber (1937) relates both to the human artistic impulse, and to the experience of relatedness to life and between individuals. His work may therefore usefully inform both the planning of ABIs (including the depth of their potential impact, and the associated need to minimise emotional risks to the participants) and the analysis of qualitative findings relating to participants' experiences.

These quotations from his seminal work, *I and Thou*, relate to the human source of art; the human role in 'bodying forth' art; and his frequent theme of 'meeting' life, whether in the world or in one another:

'This is the eternal source of art: a man is faced by a form which desires to be made through him into a work. This form is no offspring of his soul, but is an appearance which steps up to it and demands of it the effective power. The man is concerned with an act of his being.' (Buber 1937, p.9)

'To produce is to draw forth, to invent is to find, to shape is to discover. In bodying forth I disclose. I lead the form across – into the world of *It*. The work

produced is a thing among things, able to be experienced and described as a sum of qualities. But from time to time it can face the receptive beholder in its whole embodied form.’ (Buber 1937, p.10)

‘All real living is meeting.’ (Buber 1937, p.11)

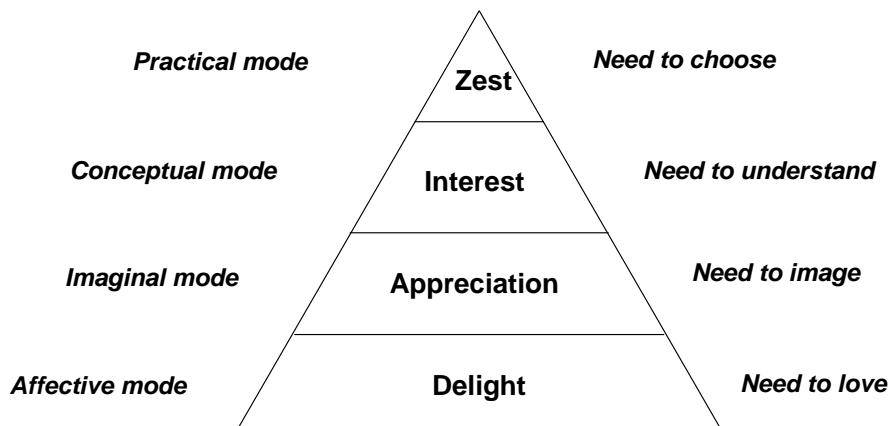

Basic Active Emotions: Heron

In his 1992 book *Feeling and Personhood*, Heron defines an ‘Up-Hierarchy of Basic Active Emotions’ below (1992, p.122) as one exploration of his proposed ‘model of personhood’. For Heron, spiritual and existential dimensions are core to being human: ‘a person is an embodied spiritual presence’ (Heron 2001b: 33). At the same time, action through ‘participation’ is implicit in his theory of the person:

‘From our felt participation in the world, we open intuitively to grasp a total situation, then discriminate thoughtfully in order to act within it.’ (Heron 1989: 17)

Heron defines these four modes of being:

- Delight** ‘Appreciation is a delight that springs from the love of aesthetic form; interest a delight that springs from the love of knowledge; zest a delight that springs from the love of action.’ (Heron, 1992, p. 123)
- Appreciation** ‘The emotions of a fulfilled imaginal sensibility are of a range and subtlety that outstrip the power of language to symbolize them. Hence they are conveyed by the non-discursive symbolism of drawing, painting, sculpture, music and dance.’ (Heron, 1992, pp. 122–3)
- Interest** ‘When the need to understand is realized, we experience interest, extending into curiosity and fascination, the passion for truth, excitement in intellectual discovery, pleasure in the clear communication of ideas.’ (Heron, 1992, p. 123)
- Zest** Heron uses the word ‘zest’ to encompass ‘the emotions involved in the fulfilment of free choice and effective action’, which he identifies as including ‘relish, gusto, exhilaration, achievement and work satisfaction’ (Heron, 1992, p. 123).

Heron’s identification of the ‘imaginal’ capacity, encompassing our inner potential, the imaginative and the artistic, might helpfully inform analyses of the experience and outcomes of participants in ABIs. ‘Entelechy needs’, he argues, also underpin the formative potential of the whole person:

‘... the spiritual life within harbours spiritseed, entelechy, the formative potential of my becoming.... entelechy guides the emergence of, and is progressively realized in, the actual entity.’ (Heron 1998, p.52)

Multiple Intelligences: Gardner

Gardner’s definitions of different forms of ‘intelligence’, and ways of identifying them in practice, could also support the analysis of the intrapersonal and organisational effects of ABIs.

Intelligences	Description
Linguistic	An ability to analyze information and create products involving oral and written language such as speeches, books, and memos.
Logical-Mathematical	An ability to develop equations and proofs, make calculations, and solve abstract problems.
Spatial	An ability to recognize and manipulate large-scale and fine-grained spatial images.
Musical	An ability to produce, remember, and make meaning of different patterns of sound.
Naturalist	An ability to identify and distinguish among different types of plants, animals, and weather formations that are found in the natural world.

Bodily-Kinesthetic	An ability to use one's own body to create products or solve problems.
Interpersonal	An ability to recognize and understand other people's moods, desires, motivations, and intentions
Intrapersonal	An ability to recognize and understand his or her own moods, desires, motivations, and intentions

Source: Davis *et al.* 2012, pp.6–7.

In addition to these eight intelligences which, Gardner argues, passed necessary 'tests' as distinct intelligences, he and his colleagues have speculated that there may be one more (which he calls '8½'): 'existential intelligence', an innate intelligence which inquires after broader purpose (as distinct from the labels 'spiritual' or 'religious') (Gardner 2012).

3.2 Psychological frameworks and complexity theory

Self-efficacy: Bandura

A well-established tradition of research in organisational psychology and educational studies has developed from Bandura *et al.*'s (1997) definition of self-efficacy, including:

- Efficacy expectancy: 'the conviction that one can successfully execute the behavior required to produce [a desired outcome]'
- Individuals' 'expectations of personal efficacy stem from...':
 - 'Performance accomplishments'
 - 'Vicarious experience'
 - 'Verbal persuasion'
 - 'Emotional arousal' (Bandura, Woods and Beyer 1997: p.126)

Self-efficacy research frequently defines questionnaires which participants complete before and after an event or intervention, with both standardised measures relating to their general levels of confidence that their actions will be effective and other questions relating to the specific intervention.

Distributed Cognition: Hutchins

Distributed cognition may also offer fruitful insights into the emergent, shared nature of group and individual learning through ABIs. Hutchins (1995) identified how skilled understandings operated across a naval crew in a crisis situation, an example of 'situated seeing' (Hutchins 2000). With research collaborators (Hollan *et al.* 2010), he recently defined the process of distributed cognition research:

‘Distributed cognition looks for cognitive processes, wherever they may occur, on the basis of the functional relationships of elements that participate together in the process.’ (Hollan *et al.* 2010, p.175)

Such research typically applies ethnographic research methods, including both observational and media analysis techniques. Through the analysis of language, Hutchins and his collaborators aim to identify shared representations that emerge within a group. They carry out their research ‘in the wild’ (as opposed to in research laboratories) (Hollan *et al.* 2010, p.176), and seek to identify how processes (especially expert practices) operate in groups. The context of such research also respects both the physical body and the physical environment:

‘... the organization of mind – both in development and in operation – is an emergent property of interactions among internal and external resources. In this view, the human body and the material world take on central rather than peripheral roles.’ (Hollan *et al.* 2010, p.175)

Like ABIs, this approach also focuses on practice and ‘events’:

‘Since the cognitive properties of systems that are larger than an individual play out in the activity of the people in them, a cognitive ethnography must be an event-centered ethnography.’ (Hollan *et al.* 2010, p.179)

System dynamics

Mowles *et al.* (2008) define the interrelatedness of organisations in terms which may also support the analysis of the impact of ABIs:

‘What systems theories have in common is the concept of an organisation as a whole with a boundary.... realigning the parts can influence the whole....’ (Mowles *et al.* 2008, p.807)

Quoting both Elias (1978) and Bourdieu, Mowles *et al.* endorse ‘the “art” of the *necessary improvisation* which defines excellence’ (Bourdieu, 1977, p.8) in effective management and organisational practice. They unfavourably contrast this improvisatory potential with processes of organisational target-setting – a tension which is also likely to apply to ABIs aligned to specific organisational outcomes. Bourdieu’s definition of ‘practical logic’ also confirms the need for both participative and reflexive processes, and the improvisational nature of such practices:

“‘The idea of a practical logic, a ‘logic in itself’, without the conscious reflexion of logical control, is a contradiction in terms, which defies logical logic. This

paradoxical logic is that of all practice, or rather of practical sense. Caught up in ‘the matter in hand’, totally present in the present and in the practical functions that it finds there in the form of objective potentialities they contact; it can only discover them by enacting them, unfolding them in time” (Bourdieu, 1990, p.92).’ (Mowles *et al.* 2008, p.814)

Mowles *et al.* also cite Taylor (2002) in arguing that the outcomes of such emergent experiences are, by definition, unpredictable:

‘We are drawing attention to the radical possibilities of responding to emergent phenomena which could genuinely transform our relationship with others and the work that we do together. This involves our acknowledging both intended and unintended consequences of acting together to bring about change and negotiating what we think it might mean.’ (Mowles *et al.* 2008, p.818)

3.3 Models applied to research in the creative arts

Aesthetic distancing

In order to analyse the content of ABIs that draw upon traditions of drama and theatre, including role playing, we must also consider aesthetic distancing (Brecht 1964). Brecht reconceptualised the illusion of theatre with what he called *Verfremdungseffekt*, the “alienation effect”, referring to the audience member’s role as observer and experiencer rather than one who is involved in the drama. Boal’s work (eg 1995), inspired by this idea, informs current practices in both acting and education therapy (see also Holtham *et al.* 2013; Pässilä and Vince 2012).

Threshold concepts and the role of boundary objects in pedagogy may also be helpful here:

- Threshold concepts are defined by Meyer and Land (2005) as including the concept of irony for students of literature, of pain for medical students, or entropy in physics. They act as major building blocks of knowledge or insight which enable a student to understand and therefore apply a theoretical concept:
 - ‘... such conceptual gateways... may be *transformative* (occasioning a significant shift in the perception of a subject), *irreversible* (unlikely to be forgotten, or unlearned only through considerable effort), and

integrative (exposing the previously hidden interrelatedness of something).’ (Meyer and Land 2005, p.373)

They also draw upon the theory of liminality (itself another potentially useful concept for the understanding of the impact of ABIs), citing the work of Turner (1969). Moving to an understanding of threshold concepts can, they argue, be a liminal experience of transition from one state of being or identity to another.

- Boundary objects can be ‘stuff and things, tools, artefacts and techniques, and ideas, stories and memories’ (Bowker and Star 2000, p.298) which can help to build understanding between different groups or ‘communities of practice’: ‘they enable co-ordination, but they can do so without actually creating a bridge between the perspective and the meanings of various communities’ (Wenger 1998, p.107). Edwards (2005) considers their role in ‘mediating’ learning: citing Tuomi-Gröhn and Engeström (2003), she reviews their function in participatory learning which promotes ‘boundary-crossing and border-crossing’ (Edwards 2005, p.5).

Embodiment: Merleau-Ponty

Embodiment is an important theoretical reference for future research into the process and impact of ABIs. Holtham *et al.* (2013) quote from the work of Merleau-Ponty and his definition of the intentional arc (1962, p.136) as a starting point for the analysis of ‘the interconnection of skillful action and perception’ (Dreyfus, 1996). A considerable body of research, related to the learning of physical skills and sport as well as arts-based practices such as dance and music, explores embodied experiences in the acquisition of skills. Standal and Engelsrud (2011), for example, analyse semi-structured interviews and observations (including of physical imitation) with the aim of understanding ‘the lived experience of the research participants, and the way their experiences are expressed through actions, speech and silences’ (p.156). They also quote Merleau-Ponty as an authority for the development of learned, automatic skills:

‘[Habit] is knowledge in the hands, which is forthcoming only when bodily effort is made, and cannot be formulated in detachment from that effort. The subject knows where the letters are on the typewriter as we know where one of our limbs is, through a knowledge bred of familiarity.’ (Merleau-Ponty 2002, p.166, quoted in Standal and Engelsrud 2011, p.157)

4 Research frameworks

These are some of the research methodologies and data types identified through this initial study which might inform future ABI research:

Topics/type of research	Data sources / methodologies
Creativity in UK schools: pilot study	A ‘collaborative, inquiry-led approach’ to define and pilot a ‘creativity’ self-assessment tool for use in the classroom. Data sources: ‘Portfolios/passports Diaries/journals/blogs Learning stories/journeys Teacher observations Testimony from others Evidence from “products” [of the pilot research] Reports Reflective interviews Progress reviews Other’ (Spencer <i>et al.</i> 2012, p.117)
Human interaction research	Video of interactions, inviting participants to support the coding process, including identification of key incidents (eg Gottman and Levenson, 1985; Levenson and Gottman, 1983)
Emotional response research, applying repertory grid techniques	Asking respondents to compare and categorise emotional terms or scenarios; can produce a range of data with some consensus as well as individual responses (eg Parkinson and Lea 1991; Reizenzein and Hofmann 1990)
‘In the wild’ cognitive ethnography	Interviewing, surveys, participant observation, and video and audio recording – especially ‘the analysis of recordings of events’ (Hollan <i>et al.</i> 2010, p.179) (eg Goodwin and Goodwin 1996; Suchman 1987); other research projects have also analysed automated recordings in digital technology contexts (eg Hill <i>et al.</i> 1992)
Pedagogical research related to disciplinary integration in an HE programme	Thematic analysis of teaching content, marked assignments (including an oral presentation) and student notebooks (Nowacek 2011)

5 Conclusions

This paper offers an initial review of theoretical frameworks which may offer analytical insights into ABIs. Further promising theoretical underpinnings might include: threshold concepts (Meyer and Land 2003); metaphor and narrative theory (McGilchrist 2009 and Goodson 2013); the potential application of Bateson’s (1979) definition of ‘levels of learning’ (Tosey *et al.* 2008); ludic play (Kolb and Kolb 2010); storytelling (McDrury and Alterio 2003; Moon 1999), and neurophysiological models that relate to artistic experiences as well as organisational behaviour (eg Rock 2008 and Rock and Cox 2012; Oatley 2011; Lieberman 2014), especially towards research to explores

physiological and entrainment effects in music and other artistic experiences (Becker 2001). The associated conference presentation will also consider how the concepts developed by some of the more populist theorists, including emotional intelligence, presence and (Boyatzis and McKee 2005; Senge *et al.* 2005; Goleman *et al.* 2002), might support the dissemination of research findings associated with ABIs.

The concepts and research reviewed here begin to indicate both the breadth and depth related to researching the processes and impacts of ABIs on both individuals and organisations – and of the potential impacts on the participants. To quote from Wenger (1998):

‘Because learning transforms who we are and what we can do, it is an experience of identity. It is not just an accumulation of skills and information, but a process of becoming – to become a certain person or, conversely, to avoid becoming a certain person.... To support learning is not only to support the process of acquiring knowledge, but also to offer a place where new ways of knowing can be realized in the form of such an identity.’ (Wenger 1998, p.215)

For both practitioners and researchers of ABIs, my concluding recommendations are therefore that:

- We should integrate both reflective practices and a reflexive, critical stance in our research planning and processes, with the aim of both exploring the emergent, active experience of the participants (including the researchers) while also seeking to surface and critique assumptions, as they emerge, such as expectations of predictable, specific or even benevolent outcomes from ABIs.
- In planning our interventions and associated research, we prioritise the establishment of supportive learning and research cultures after the period of the intervention, to acknowledge the depth of potential impact on both the learners’ and the researchers’ identities.

Clay workshop as a research method. Research – design - discussion

Päivimaria Seppänen*

LUT School of Industrial Engineering and Management
Lappeenranta University of Technology, Lahti School of Innovation
FI-15140 Lahti, Finland

Structured Abstract

Purpose – The aim of this paper is to examine an arts-based research method in practice and methodological issues related to it. To test the method, a clay workshop will be organized during the 9th IFKAD Conference. Testing is important, because clay workshop has rarely used as a research method before, and it will be used in my dissertation. The aim of my dissertation is to investigate institutionalizing arts in social and health care service strategies; especially the management of multiprofessional employees; how the manager recognizes employees who have many professionals and divergent knowing.

Approach – The approach to research is, that clay shaping will be inspiring and the participants will have rich discussions. First, because the shaping is multidimensional and will stir up a lot of thoughts and knowing. Secondly, shaping is a very old way to express oneself. Thirdly, the clay workshop has an embodied knowing dimension. It may give a space to express issues that one rarely do otherwise. The workshop will be filmed and recorded and the analysis will be done afterwards.

Value – The value of this arts-based method is multidimensionality. It has been noticed that by arts-based methods the researcher is able to get answers that are challenging to find with traditional qualitative inquiry methods, for example, interviews or empirical observation. The arts are likely to make people more sensitive and open, and give a possibility to express issues that cannot be expressed in other ways. The arts may also cause some unexpected reactions that the researcher is not prepared to encounter. The arts can raise the research onto another level and can give more value for the aim researched.

Practical implications – The clay workshop will be a participative method testing workshop. The aim is to find out how the clay workshop serves multiprofessional groups, and how it should be developed to be an effective research method which can be used in the social and health care services.

Keywords – Arts-based research method, management, multiprofessionality, knowing

Paper type – Academic Research Paper

1 Introduction – The map and the compass

This study is a part of the dissertation, which aim is arts in social and health care services. The main issue in the dissertation is to study what kind of multiprofessionality there is in social and health care and how it could be noticed and deployed. There can be employees with two or more professions; they have changed careers because of different reasons and have many skills and knowledge obtained and learned in schools, at work and in life (Küpers 2005). In this study, they are called as multiprofessional employees: they have wider readiness and more versatile know-how than those employees with one profession. The issue has not been sufficiently recognized or discussed in scientific research, although this kind of multiprofessionality is vitally important during and after organizational changes.

In social and health care services supervisors need tools to first recognize the multiprofessionality to be able to manage the multiprofessional diversity of their employees. To find and test instruments, this study deal with arts based research methods and methodological discussion. The background will be introduced and then some thoughts of practice-based innovations will be considered. The presentation at the 9th IFKAD conference is a practical clay workshop where participants will have a possibility to test the research method designated later in this article.

2 Terrain of the journey

There is growing criticism towards siloed structures, and after practice-based innovations the silos are usually broken into knowledge-based networks. “*Innovations emerge more and more often in practical leading to, for example, middle-ground innovations*” (Melkas, Harmaakorpi 2012.) In prevailing circumstances there should be space for practice-based innovations and for a new kind of multiprofessionality which strive for sustainability and the client’s needs. Also, there has been a demand for service-innovations in social- and health care (ibid.). The breaking of the silos has aroused from the client’s needs: they have different kind of problems like drug, mental health, money and social problems, and all of them have taken care in different clinics and by different specialist. The patient has had to spend a plenty of time crossing over services, it has been like a full time job when trying to get help, and unfortunately this organizational problem

has not solved yet. In the new model the process will attend to the client, whose problem will first be examined and then the employees of all clinics will be working together. It is essential to apply new aspects while treating clients who have not gotten better in conventional processes. It could be fruitful to deploy different knowing and multiprofessionality in the new kind of organizations. (Smith et al. 2012; DeArmond S et al. 2006.)

Next illustration draws a picture of what happens when the organizational silos are restructured. If the multiprofessionality as well as divergent knowing (Melkas, Harmaakopi 2008) are not noticed at the same time, all traditional borders between professions will stay as they are. If all professions like nursing, social work, mental health professions etc. stay as they are, what will change in the reality and at the operational level? It is not easy to break the silos at the level of grassroots if there are actors with the lack of innovation (Saunila et al. 2012) or people who won't allow change. Employees do have special skills they work with, they have a certain kind of roles and there are also rules in the orchestration; e.g. some images (Warren, Parker 2009, Banks 2001) are connected to professions.

Employees have divergent knowing (Saunila et al. 2012) which enable the organizations to go forward and increase their capability. On the other hand, if there are siloed thinking and constricted beliefs remaining, these issues are conflicting and complicating both development and innovative opportunities. Divergent knowing should be noticed, and managers do need tools for that. Inside the organizations, it is important to recognize the significance of values and wellbeing (Harmaakorpi, Melkas 2012; Smith et al. 2012) and effective divergency management may require that communicate models are renovated, too (Saunila et al. 2012.). The managers should help to break boundaries, create opportunities and new ways of cooperation. Also, employees have several knowing they have a certain space, role and working mode. Sometimes denying the divergence can also lead to overreactions: An employee who has different shoes at the pathway; will e.g. be excluded (Smith et al. 2012.) and closed outside.

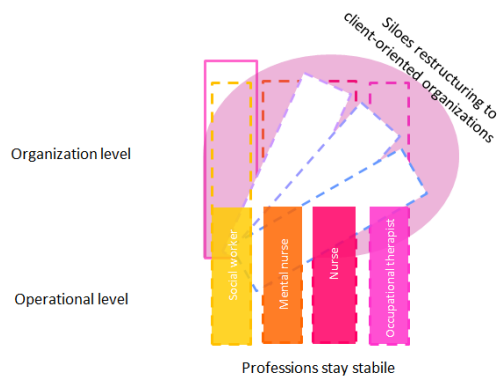

Illustration1 Organization's transformation

3 Sign posts

The journey of this study is based on theories of multiprofessionality and diversity management. As mentioned earlier, diversity is a challenging and multidimensional issue in management. It is obvious that operative managers are not always aware of employees' multiprofessional backgrounds. Focusing on possible solutions, clay workshop is designated as a method, as a management tool and as a discussion awakener, and it will also be tested in practice at the conference.

The main research questions in this article and the connected workshop are

1. what kind of phenomena rise up during the workshop and how can they been utilized in the research of multiprofessionality and organizational diversity, and
2. what kind of processes during the workshop lead to new attitudes or to a new kind of professional self-understanding.

4 The bridge

A polyphonic pattern of multiprofessional employees gives an option for practice-based innovations, which rise from the diverse multiprofessional networks or from the client oriented approaches (Melkas, Harmaakorpi 2012). Multiprofessionality make organizations diverse and challenging to lead. Sometimes there are strong beliefs and rebellions against transformation and employees acting intentionally differently. *“We recognize a cultural pattern and then look to see if the individual fits that pattern”* (Galanti 2001). Sometimes diverse attitudes or modes can be desired in organizations,

but in the opposite circumstances there is a risk for exclusivity against those who work differently. With weak leadership (Patrik, Kumar 2012; Smith et al. 2012.) diverse organization is ineffective, expensive and defective. Employees are conflict-oriented and are not doing well.

In social and health care, polarization between the multiprofessionality and the diversity makes it an interesting research phenomenon. Diversity management (Madera 2013; Patrik, Kumar 2012; Mallow 2010; Galanti 2001) has been used as a theoretical framework also earlier when researching multicultural employees, genders and so on. In this study diversity management will be applied to the multiprofessional employees. There can be found similarities in multiprofessionality and in multiculturality: Like employee (Patrik, Kumar 2012; Morrison et al. 2006) from another culture has a different stance to work as native a person, employee with two or three professions has different stance and knowledge e.g. to social work as an employee with one profession.

5 A pathway to the field

Managers need tools to become aware of their employee's multiprofessionalities and to lead to diversity. Diversity is not (Patrik, Kumar 2012; Morrison 2006) an easy task. Diversity creates a breeding ground for misunderstanding and tension in the organizations and potential for conflicts, too. On the other hand, diversity can be a value and add the human capital of the organization (Morrison 2006). Effectual multiprofessionality is adaptive and there is space for different actors. (DeArmond et al. 2006, Mallow 2010, Morrison et al. 2006) If the employee has two or several professions, his or her working mode is different and also working methods may differ, which can be another reason for misunderstandings and tension. In these kind of displeasing situations, people often see only negative aspects (Madera 2013; DeArmond et al. 2006.). It looks like there is a need to find space (Mallow 2010) for different ways to work. It is clear, that these kinds of situations are very worthy of research, although multiprofessionality has not widely discussed in scientific research yet.

I have three professions. In healthcare, a primary nurse, in cultural policy and in social work. Since the beginning I have been curious to find out the possibilities of arts-based approach in social and health care. Researching falling into this genre, interrogate the field of own profession is also a question of subjectivity and research position (Anttila

2003). It could be attractive to set autoethnographic position. Actually, it could make researcher in pressure where the organization was too close and then relevance of the study suffers. To avoid this researcher need distance to the research field, spiritually or physically. To realize ethical issues in research, it is important to avoid being too close at the research field. When the research question discusses of management and the researcher is working in management some kind of reflection is necessary. Researchers need to self-reflect and be aware the social construction, is researching in. Also to be open to the material, not own experiences, beliefs and presumptions. Also, there may be a pressure to act as a counselor or a listener, when the researcher is well-known and the research field is complex after organizational transformations. (Niiranen-Linkama 2005; Juhila1999.)

6 A road choice

Diversity defies standards. Researching the diversity of complex systems is an exploration to the unknown and this exciting journey will be done with an arts based research method. Arts based research is active, inspirational (Fraser, al Sayah 2011) and creative: it can confront emotions, create sensory experiences and, just like knowing, respond to the world in different ways (Finley 2008). Research can be posed entirely new ways (Finley 2008; Leavy 2008), questions can be asked and the answers can be found through experiences.

Arts based practices are particularly useful for research projects that aim to describe, explore, discover (Leavy 2008).

Finley (2008) points out that at the stage of flow, open dialogue and ideas are needed. Examinees go through multidimensional creative and epistemological process, that integrates artistic knowing and academic professionalism. Also, there is an aesthetic dimension which allows emotions, group dynamics and social constructions to be handled. Art is emotional, politically evocative, captivate and moving phenomenon. Although there are no right questions or answers or any single right way to go, art can grab attention in a powerful way. (Finley 2008; Leavy 2008.) As Finley (2008) describes, arts based research dive behind social science research methods. The catch is multidimensional, only one truth cannot be found, and the purpose is to advocate social transformation. Creativity, observationality, analysis, storytelling skills, symbolics and

metamorphisms are critical aspects in arts based research, like in all qualitative research, too. (Fraser, al Sayah 2011, Leavy 2008.)

There are several fields where to operate in divergent organization: by using metaphors, they have flora, fauna and earth. Finley (2008) points out that arts based research methods are able to shake ossified thoughts and give space to rising activism and criticism. The harvest is not reaped. The natural order is going to be reformed (Fraser, al Sayah 2011) and the plants will get new soil to grow. Eisner (2008) sees arts based research methods as flexible in divergent organizations; arts can be a shortcut to study the diversity. Artistic methods let the participants examine the transformation from several perspectives. They can have several soils where they can bed different plants with different lengths. (Warren, Parker 2009.) Pässilä (2012) points out that by using arts based research methods, participants are able to have opportunities to set themselves in different positions and discuss e.g. how does it feel, what does the organization look like from different positions, how do they imagine they could work there and what kind of outcome there could be. When the research is made by arts based method, there is a special place to the biodiversity: there are soils for embodied knowing, visual images, plants, landscapes and soundscapes, all of them created by doing, by hands, by feet and so on. Artistic methods have an inventive impact to get talk and think about new polymorphism of the whole organization. (Pässilä 2012; Warren, Parker 2009; Leavy 2008.)

6.1 The Field

Arts based research methods have been used in different variety of research. In management research Pässilä (2012) has created a model for research based theatre. The method is practice-based and makes a space for reflection in communities. Participants reflect their assumptions and learn together to break down assumptions that are old-fashioned or unnecessary. Research-based theatre session begins with photographs describing the situation or undesirable assumptions. There is able to rise (Fraser, al Sayah 2011) knowledge or already active knowledge can get new meanings and aspects. Photographs are being used as well as a research method and independently. Warren and Parker (2009) has researched organizations using photos. One photograph can include wide spectra of the organizational hierarchy and culture and the state of power. Also, the photographs (Byrone 2008) like all arts can draw a picture of professional identity and

impart one's self-esteem. It is possible to explore diverse (Fraser, al Sayah 2011) details using photographs, too, because all different artifacts tell something about the workplace and as scientific and artistic phenomena are essential issues to observe (Byrone 2008).

Personally, I am very interested to use clay and to see how does a clay workshop awake us; can the clay work as a catalyst, helping to formulate own experiences, imaginations, emotions and relationships. It is interesting to see how will participants discuss (Fraser, al Sayah 2011) and cooperate during the workshop, and how will the research theory (Byrone 2008) work when using the arts based material. Last November I had a short clay workshop at a conference in Tampere. The participants had ten minutes to formulate their opinions about the state of the management research in Finland. During the short while they discussed wildly and intensively and found also a way to act and discuss at the same time. The experiment made me to believe that this kind of workshops are good options and fruitful methods also in the field of diversity management.

Despite the rising use of arts-based methods in organizational development and change, clay is rarely used as an instrument to shape thoughts and innovations. It also appears that using clay has not been discussed in management research literature. Nevertheless, clay is eternal material and has always been utilized to increase surviving possibilities; it has been and still is an important building material and it is used for cooking pans, water tanks and preservation vats. In addition to that, it has always been an artistic artifact: people have e.g. painted their histories in clay pots, written their stories in clay tablets, etc. Historians have examined the prehistory of human colonization using small pieces of clay artifacts and findings. The clay has been always there where people have lived or worked. In the upcoming workshop and by the aid of the eternal clay it is now possible to take care of mental basic needs such as creativity and self-respect and enhance possibilities for innovative thinking. (Honor & Fleming 1994)

As a research material, artistic inquiry is multidimensional (Fraser, al Sayah 2011). Usually we observe issues and nuances which are important (Warren, Parker 2009) for ourselves and all the rest can stay unnoticed. However, those hidden things may contain issues which could be very crucial in research. Therefore, it is important to observe the phenomenon critically (Finley 2008b) and take account all processes, actions and ways how people behave and work. On the other hand, making art is usually inspiring journey and people have great fun at the time. When having a good time, it may be challenging to start discussion about unpleasing things or difficult topics. (Berthoin Antal 2009; Warren

2009). But the action-oriented and inspiring situation (Finley 2008b) can also force people to rise up both positive and negative things. The role of the researcher is observative, and because the seedlings in the gardens are sensitive, ethical awareness is very important. Researchers have to respect the openness and enthusiasm of the participants, too.

(Finley 2008b)

Sometimes the artistic project itself (Berthoin Antal 2009) has been successful for the organization, but artists have been unsatisfied to the quality of art or to the whole process. When using the arts based method in the research, it is relevant to notice that the outcome is not an artistic product; arts based research method (Fraser, al Sayah 2011) is precious and important *per se*, through itself. Other theoretic frames are sometimes weak and not helpful when modeling research questions or trying to be precise with the material. As Fraser and al Sayah (2011) have recognized, arts based research methods in health care research have been very useful because they do not include such limitations like the traditional frames of qualitative research. When researching the divergency, the research itself can also produce more dimensions when arts based methods are dealt with.

Also the impact of an artistic intervention for the organizational development is multidimensional. The experience can be powerful, but both in good and bad ways, and increasing cooperative work behavior is always a voluntary process (Fraser, al Savah 2011) where forcing statements are ineffectual. Concurrently, arts awake criticism of the so called normal behavior and order, like Finley (2008) writes.

7 A path choice

Using clay workshop as a research method in organizational management is an enthusiastic idea. At the workshop the group will have space enough to shape their own thoughts, i.e. opinions of the professionalities and feelings of the archetypes in their own workplaces, and to discuss about those themes. The main issue is to observe, how they do it. How do they shape the professions and how do they share the divergence when discussing with other group members. In the atmosphere of trust there is a space to share divergence and to find fresh knowing, which is relevant in their work or in their professions, but has not been unrecognized before.

To shape the clay, the artifacts must be looked from different perspectives all the time; the clay call for to use the body, it does not let sit down. It is fascinating to see, what can

the phenomenon called embodied knowing add into shaping. Embodied knowing is a mixture of “*bodily gestures and postures, facial mimic, tones of voice, and other forms of expression*” (Küpers 2013). Can art be a bridge between mind and body. “*Conceptualizing arts as embodied learning; thinking and knowing are not limited by words*” (Moore 2011). Because shaping is multidimensional and there are bodily gestures (Küpers 2013) included, could the shaper be like a dancer, who recreates his or her own experiences at the scene? (Blumenfeld-Jones 2008.) According to Küpers (2005) embodiedness is the spring where the streams come from, and there is no need for words.

In this study also the discussions are in important role. It is interesting to observe, how the language lives with the action. It is interesting to observe, how the language lives with the action, the clay. Things and questions which recur, coming up again during discussions, are remarkable and should be taken into account later, when developing management and leadership. (Küpers 2013). Recurrence also tells, is the terrain in the workplace fruitful for the divergency or not.

8 At the garden

As mentioned earlier, the clay workshop will be held during the IFKAD conference, in the historical town of Matera, in very inspiring atmosphere. The participants of the conference will come from different backgrounds and the group diversity will be high.

The workshop will be videoed, and before the session, participants will be asked to give their agreement for videoing. In the beginning of the clay session, participants will have an instruction to shape from clay “what they have learned during the day”. Artistic work will begin after the first chaos, and conversations will arise...

The research method is new, so the researcher is interested in how useful the method will be and how all the material (clay sculptures, discussions, embodies language) can best utilized. It is also good to see what kind of challenges will occur when finding suitable analyzing methods for the material.

8.1 The play

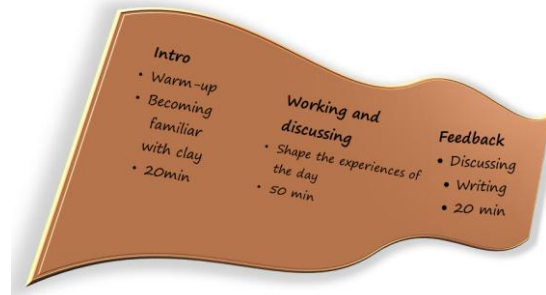

Illustration 2 The workshop plan

The workshop will be held in the garden, surrounded by inspiring eternity of the area. At the beginning the participants will be asked agreements to the research and videoing. Videod and written material will be analysed afterwards for the methodological discussion of the dissertation. The material will be used in this research only.

Creating a creative space. A case Study of the artistic and participatory urban camping “Yes We Camp!”

Alena Siarheyeva

ISEN-Toulon, école d’ingénieur

Maison des Technologies, Place Georges Pompidou

Téluq – Université du Québec

Structured Abstract

Object – We describe the organizational design and the spatial characteristics of the artistic and participatory urban camping “Yes We Camp!”. It was designed on the occasion of Marseille Provence European Capital of Culture 2013, built on the banks of Estaque, Marseille Area, and open to all from May to September 2013. “YesWeCamp” is an experimental project, combining ecology and performative architecture, hosting artists in residence and offering an alternative cultural agenda for campers and visitors. It also had a strong social dimension. It hosted youth in process of professional and social (re)integration, and worked closely with local communities to sensitize poor, often migrant, populations to culture. It promoted such values as sharing, convivial atmosphere and mix of publics. The camping was mainly run on volunteer basis. The core collective which built, run and deconstructed the camping was approximately composed of 20-40 individuals, aged between 20 and 40 years old, constantly present and living at the camping place. Most of them had creative and artistic professions: architects, green and urban space designers... More than 200 volunteers contributed to the project at various stages of its existence. Yes We Camp hosted 11 artists in residence and organized more than 50 cultural events. During the summer time, on average, the camping hosted 130 campers per day and up to 800 visitors during cultural events and festivities.

Purpose – The purpose of the research is to describe how the organizational design and socio-material space characteristics of the camping enabled the creation of a particular atmosphere nurturing creativity, understood here as a collective outcome; and how the collective creativity was embedded into the physical space of the camping.

Theoretical framework – The case study bridges the organizational psychology literature stream on on creativity in organizations (Klijn & Tomic, 2010) (Zhou & Shalley, Handbook of Organizational Creativity, 2008) and workplace creativity (Baas, De Dreu, & Nijstad, 2008; George, 2007; Hennessey & Amabile, 2010; Runco, 2004; Shalley, Zhou, & Oldham, 2004) with the sociomateriality stream in organizational literature (Pickering, 1995, Dale 2005, Leonardi 2008, Orlikowski 2007, 2010).

Methodological approach - We used the grounded theory approach ((Glaser, 1992) and (Charmaz, 2006)) to derive a posteriori a theoretical framework from data systematically obtained from field observations. We chose this method to uncover processes, relationships and behaviors of individuals in an organizational context that has been little explored up to now. That enabled us to grasp the complex nature and to create a grounded understanding of the project under study.

We used overt participatory observation as data collection method ((DeWalt & DeWalt, 1998) and (DeWalt & DeWalt, 2002)). The decision to be embedded in the action and

context of the social setting of the camping is motivated by the opportunity to be accepted in the community of volunteers, to have access to their "backstage culture" and to view or to participate in unscheduled events (DeMunck & Sobo, 1998). To complement data obtained from the observation, we conducted a set of individual interviews.

Main results – Our main finding is that socio-material characteristics of the camping site encapsulated the root values on which the project was built and predetermined the camping's collective dynamics. Democratic participation and the quasi-absence of vertical hierarchic relations as the principle of the organizational structure favored free flow of ideas and interaction between volunteers. The implicit organizational work processes such as "participative assessment" and "functional legitimation" by peers contributed to consolidation of the project around a collective of highly dedicated volunteers; with a sense of initiative and willingness to participate. The created camping's creative atmosphere, understood as cognitive representations and interpretations of its organizational setting and of its socio-material space was "a place of realization of dreams of artists *bricoleurs* and performers" but also "a place where one feels good and where one stays, for a drink or for a long weekend", a "sort of summer 1936, where perfume of possible is floating in the air".

Keywords – Creative space, creative atmosphere, creativity, socio-materiality of space

1 Introduction

1.1. Description of the project Yes We Camp

The artistic and participatory urban camping "Yes We Camp!" was designed on the occasion of Marseille Provence European Capital of Culture 2013, built on the banks of Estaque, Marseille Area, and open to visitors from May to September 2013. "YesWeCamp" is an experimental project, combining ecology and performative architecture, hosting artists in residence and offering an alternative cultural agenda for campers and visitors. It also had a strong social dimension. It hosted youth in process of professional and social (re)integration, and worked closely with local communities to sensitize poor, often migrant, populations to culture. It promoted such values as sharing, convivial atmosphere and mix of publics.

The camping was conceived as an ephemeral space. Its purpose was to recycle and to promote a deserted space and then to give it back to its inhabitants. Many objects and elements for constructions were collected from Emmaus, an international charitable movement to combat poverty and homelessness. At the same time, it served as a test bed for innovative enterprises offering dry toilets and water recovery systems. At the end of the summer period, the camping was dismantled and pieces of constructions, objects and equipment were sold out at a big garage sale.

The camping was mainly run on volunteer basis. The core team which built, run and deconstructed the camping was approximately composed of 20-40 individuals, aged between 20 and 40 years old, constantly present and living at the camping place. More than 200 volunteers contributed to the project at various stages of its existence.

Yes We Camp hosted 11 artists in residence and organized more than 50 cultural events. During the summer time, on average, the camping hosted 130 campers per day and up to 800 visitors during cultural events and festivities.

1.2 Creativity and innovation at workplace

Creativity can be defined as the ability to produce work that is novel (original, unexpected) and appropriate, (i.e. useful, adaptive concerning task constraints) (Sternberg & Lubart, 1999) or as a “mental process that allows people to think up new and useful ideas.

Drawing on the definition and findings in psychological literature, organizational research stream places individual creativity into social context, opening the venue to investigations on creativity in organizations (Klijn & Tomic, 2010) (Zhou & Shalley, Handbook of Organizational Creativity, 2008). The definition, initially proposed by (Woodman et al. (1993)) seems to be widely accepted: “creation of a valuable, useful new product, service, idea, procedure, or process by individuals working together in a complex social system” (p.293). Amabile et al. (1996) point that such definition is closely related to innovation, and delineate the line between them: “All innovation begins with creative ideas . . . We define innovation as the successful implementation of creative ideas within an organization. In this view, creativity by individuals and teams is a starting point for innovation; the first is necessary but not sufficient condition for the second” (p. 1154-1155). Montag et al. (2012) stress the difference between creative behavior or process, understood as sequence of thoughts and actions that lead to novel, adaptative productions” (p. 1366) and the outcomes of this process – that is, prototypes, products, business models, work methods or management processes. Based on reviewed literature, they also differentiate the creative behavior from innovative performance behavior, defined as “the development *and* implementation or application of a novel, useful idea” (p.1366). Woodman and his co-authors characterize creativity at three levels: individual, group and organization (Woodman, Sawyer, & Griffin, 1993).

Another stream of literature tend to use the term workplace creativity, see for instance reviews by (Baas, De Dreu, & Nijstad, 2008; George, 2007; Hennessey & Amabile, 2010; Runco, 2004; Shalley, Zhou, & Oldham, 2004). The definition adopted by its proponents seems to converge to that of organizational creativity.

Placing individual creativity into social contexts and constructs inherently raises the question about the set of factors that influence creativity, as a process and as an outcome, at various levels (Andriopoulos, 2001), (Montag, Maertz, & Baer, 2012), (Zhou & Hoever, 2014) . The latest trend is to consider multi-level interrelated factors affecting creativity (Hennessey & Amabile, 2010) and their nonaddictive effects (Zhou & Hoever, 2014). This interactionist perspective was already suggested in the early 1990s by Woodman and his colleagues. They proposed an analytical framework in which different types of influences interact with each other to affect creativity across various analysis levels and mutually shape each other. Besides significant advances in the organizational psychology, little attention has been drawn on the interplay between creativity and physical environment.

1.3 Physical space, creativity and social interactions

A recent review of psychological, organizational and facility management literature by (Martens, 2011) reveals knowledge gaps and fragmentation in research about the complex and plural connexions between creativity and physical workplace. In ergonomics discipline, new axis of research has recently emerged in designing work environments comprising personal, social-organizational and physical factors favoring creativity (Dul & Ceylan, 2011).

The influence of space on organizational dynamics is analyzed in organizational literature. It is built upon insights from sociology that space makes sense as a socially constructed material property (Simmel, 1908; Lefebvre, 1991; Giddens, 1981, 1984). The main postulate is that workplace and its configuration initiate and influences social behavior; organizational practices are embedded into organizational space. Clegg and Kornberger (2006) stipulate that “Human and non-human elements constitute the experience of space through their form of occupation, activity and movement such that they are constituted through those spaces that enable and restrict certain events” (p.144). Carr and Hancock examine how conceptions of time and space are “a symbolic order inter-related to themes of power and control” (p. 545). The sociomateriality stream goes

beyond discrete entities and emphasizes mutually constitutive relationship between social and material (Pickering, 1995, Dale 2005, Leonardi 2008, Orlikowski 2007, 2010). The affordance stream builds on the postulate that the properties of space and organizational culture can shape organizational practices. For example, Fayard and Weeks (2007, 2011) demonstrate how three social affordances – privacy, proximity and permission – can foster informal interaction within a workspace.

1.4 Purpose

Bridging both types of literature - organisational psychology and sociology of space - would open a new perspective for understanding creativity at workplace. This approach is applied to study the urban and artistic camping “Yes We Camp!”. More specifically, the purpose is to describe how the organizational design and the socio-material space characteristics of the camping enabled the creation of a particular atmosphere nurturing creativity, understood here as a collective outcome; and how the collective creativity was embedded into the physical space of the camping.

2 Methodological design

2.1. Research method

The relationship between creativity and space has been little explored up to now, even less in the organizational context of voluntary association. In this context, the grounded theory approach (Glaser, 1992) and (Charmaz, 2006)) seemed to be an appropriate method to start. Emerging concepts derived from data systematically obtained and analysed from field observations were confronted to theoretical and empirical findings documented in related literature. Such approach enabled to grasp the complex nature and to create a grounded understanding of the camping project and to position the results of the research with respect to previous contributions. To capture the subjective dimension of individual creativity in the specific context of the camping we opted for an empirical and interpretative qualitative research design (Paillé & Mucchielli, 2007). We chose an ethnographic approach to study spatial, organisational and work routine of the Yes We Camp (De Certeau, 1984). We joined the YWC initiative as volunteers, to engage into overt participatory observation as data collection method (DeWalt & DeWalt, 1998) and (DeWalt & DeWalt, 2002)). The decision to be embedded in the action and context of

the social setting of the camping is motivated by the opportunity to be accepted in the community of volunteers, to have access to their "backstage culture" and to view or to participate in unscheduled events (DeMunck & Sobo, 1998). To complement data obtained from the observation, we conducted a set of unstructured individual interviews. The motivation for choosing this format was to get participants to share stories, in line with the exploratory nature of the research project (Guillham, 2005) (Gubrium & Holstein, 2003).

2.2. Data Collection and Analysis

A variety of sources was used, including i) overt participant observation at the camping, ii) interviews with the volunteering workers and the project leaders; iii) secondary data, such as minutes of meetings from the YWC association meeting and articles in the press.

The investigation departed with volunteering work during 3 days at the camping space. It was a period of total immersion into the camping routine and space, of interaction (mainly in the context of doing a specific task) with various people: volunteers, project leaders, campers and visitors and of "feeling of the camping's atmosphere". Photos of the camping were taken and used as visual documentation. After that period we continued volunteering work on administrative tasks during one week, outside of the camping place. We were offered a possibility to attend the annual meeting of the association running YWC and produced the minutes of meeting. During the whole period of the camping functioning we also attended its flagship cultural events.

The ethnographic observation was complemented with a series of unstructured interviews with the volunteering workers. We informally interviewed 15 volunteers. Some of them joined the project from its early stages and were recognized its "pillars". Others were volunteering on a relatively short time span, up to 3 weeks. They were all aged between 20 and 36 year old, belonging to various professions: architects, an urban planner, a green urban designer, graphic designers, development economists, social animators, artists, an electrician, a construction worker, an apprentice cook.

Additional information about the camping was collected in press articles (about a dozen) and triangulated with information collected through the observation and the interviews.

A thematic content analysis of the collected information was conducted with NVivo (version 10). Following the grounded theory approach, representative concepts of the phenomenon from the field data were generated. They were confronted with those discussed in the related theoretical and empirical literature. At the end of this process, a grounded model of creative space was sketched.

3. Yes We Camp, a space for creativity

3.1. Socio-material characteristics of the camping

The socio-material characteristics of the camping encapsulate the root values on which the project was built and predetermine the camping's collective dynamics.

The site on which the camping was built is a deserted industrial site on the banks of Estaque. The adjacent areas are often characterized with a spread of poverty and insecurity. One of the ambitions of the project was to “recycle” and to revitalize the abandoned place and to propose a « real alternative to luxury hotels of Noailles »¹. The reference was made to ambitious urban construction and reconstruction projects initiated at the occasion of the European Capital of Culture, which were highly contrasting with the reality of some poor and deserted urban areas of Marseille and of neighboring towns and villages.

The camping was conceived as an « event-place ». That is, it was itself an artistic event, adding value to the place where it was run. The notion of event also implies that the camping constructions were designed as ephemeral, i.e. to serve for a limited period of time. At the same time, the camping was conceived as a place hosting cultural events and projects to bring socio-cultural dynamic to a place where nothing usually happens, “snubbed” by the official cultural events of the European Capital of Culture. The ambition was to change the negative image of the site, to show to neighbouring inhabitants the value of the place, to involve them into the collective dynamics and to bring culture (in a broad sense) closer to deprived citizens.

The place was initially completely unoccupied and empty, with no constructions and little facilities. The challenge and the charm of the camping project were to build

¹ <http://www.marsactu.fr/culture-2013/yes-we-camp-nous-sommes-encore-entre-utopie-et-la-realite-30420.html>

everything from scratch. The area is located between the city, the sea and the mountain, a sort of condensed Marseille.

The site is quite isolated, relatively far from urban life, with little public transportation from Marseille. By the time of opening of camping to tourists, a ferry boat linking Estaque to Marseille city center started circulating. Once arrived at the camping place, one was completely immersed into the camping life.

The camping was designed as a mini-village, of a radial shape with a central place, the “agora”, many places where one could isolate oneself, private spaces, artistic work and bricolage spaces, spaces for social life and a totem place, above all constructions, wearing the symbol of the camping.

The architectural approach used to design the main camping’s constructions is known as performativity. The main postulate is that additionally to aesthetic and functional aspects, “the actuality of the building consists largely in its acts, its performances” (Leatherbarrow, 2005).

The “design process reacts to external stimuli and transforms a situation through feedback between a subject and the environment and between architecture and its milieu. The material, organizational and cultural change that occurs as a result of this perpetual feedback and two-way transfer of information is performativity. [...] The mechanisms of performativity are nomadic and flexible instead of sedentary and rigid. Its spaces are networked and digital rather than enclosed, and its temporalities are polyrhythmic and non-linear. Performativity produces new subjects of knowledge, hyphenated identities, transgendered bodies and digital avatars.” (Rahim, 2005, p. 179) “Performativity influences the outcome of habitational, material and ambient effects perceived by users and the effects they have on their milieu by reconstituting our sensibility of architecture” (*ibid.*, p. 180)

Finally, the project was rooted in environmental values. For this reason, but also for the reason of scarcity of resources, many constructions were realized out of recycled or reusable materials.

3.2. Organizational design

From organizational theory perspective, organizational design can be understood in the meaning of structure: a set of rules defining roles, processes and relationships that

enable an organization to realize its goals. It is also a process of (re)shaping organization structure and roles (Nadler, Gerstein, & Shaw, 1992).

The project was initiated and run by a non-profit association. This legal form requires democratic and transparent decision making about the strategic developments of the project. The project mainly relied on volunteer work for financial reasons. Professionals were solicited only for specialized construction tasks where volunteers' amateur skills were insufficient and where security requirements were strong (constructions on scaffolding, electricity and plumbing). Volunteers who joined the project were running hard physical construction and site maintenance tasks outside of prescriptive employee relations. That is, the organizational rules and productive processes could not be imposed, only proposed by the project leaders; they needed to be explicitly or implicitly legitimized by the volunteers. A volunteer joining the camping is given the liberty to choose what he/she wants to do, out of the list of tasks that are communicated by the project leader during regular volunteer team meeting: *"There is no chief, no timetable, no one obliges you to do that if you do not want to."* (volunteer A, member of the core team). The negative side of such loose productive organization is *"too much of freedom also brings screwing around. People choose to do nothing, they do nothing. It happens."* (volunteer A, member of the core team).

At the same time, an implicit rule of admission to the team by peers was in place, serving as a motivating factor: *"There is an important group dynamic... We make fun of those who do not do anything, on purpose: hey, you don't do anything... we motivate ourselves"* (short-term volunteer E)

Those who were not willing to fully invest into the project had a feeling of not being part of the collective: *"There is a closed bubble mentality in here... people always do something... You feel like why you don't do anything, it is a kind of motivation"* (a short-term volunteer C)

The "management" team was limited, compared to the size and the amount of work required. In July, when the observation was conducted, it seemed to take the form of a core group of about 20 volunteers anchored around the camping director, identified as the project leader: *"There was only one guy who was holding everything before. Well now we know each other well. But [the project leader] is still the key person"*. (a volunteer A, member of the core team)

The members of the core group were highly dedicated volunteers who took the lead over organization and implementation of various functional tasks of the project: management of volunteers, camping reservations, camping desk, bricolage and realization of small constructions, safety maintenance, stage management, bar holding... Some of them were professionals in the area of their exercise, but many of them learned the profession by doing. One volunteer qualifies the tasks they execute as “false professions”.

The overall rolling of the volunteering team was relatively high, with departures of some volunteers and arrival of others. Its size was also variable depending on the season: it was expanded in July and August, the high touristic season and more reduced at the construction and deconstruction periods. In July, when the observation was made, the rule for joining the YWC team was to volunteer for 3 weeks or more. Although the functional roles were more or less explicitly defined for everyone, the operational process design implicitly agreed by the collective was open to opinions of everyone in every functional domain:

“Sometimes there are meetings where all problems are exposed [...] Everyone [...] expresses one’s discomfort about things going wrong, and there is a catalog of things going wrong [...] Everyone has his/her own piece of work and works on it [...] I do communication with [another volunteer] and there are problems in the kitchen. You see, I cannot give my opinion, it is useless... But it pisses me off to see there are problems in the kitchen. So, I do not want ... If I want to know, it is terrible because at the same time you feel you cannot do much excepting giving ideas, new concepts, processes. It’s fun, so everyone gives one’s opinion” (volunteer F, member of the core team)

The team is also open to new comers: any person joining the project could make propositions about implementation or improvement of specific areas of camping life-processes: *“Sometimes there are volunteers who have been here for two days and could give an idea ... it’s funny”* (volunteer F, member of the core team)

However, it is not sufficient to bring an idea; it needs to be implicitly approved by the others. When other volunteers see the value added of the initiative, they were progressively coming to help out and the initiator was recognized by the community as a task leader.

“Everyone has a small plot and everyone has his own ideas, there is no one person who holds things. Everyone has ideas ... and then there is an idea and when the idea

becomes interesting, everyone joins and then it goes in one direction, but it is not one person who will change things. That's how it works". (a short-term volunteer D)

The degree of implication is another important criterion to achieve the status of the task leader: *"I think when there are people who want to share but not enough, really giving little, it does not work. You really have to give fully here to make things work"* (a short-term volunteer D)

Broadly speaking, personal self-motivation and implication are the key requirements to be fully integrated into the dynamic of the collective:

"It really depends on you ... You get what you bring ... The more you invest, the more you try to understand, the more you'll understand. The less you do, the less you'll get the hang of everything. It's like everywhere in life situations ... the more you'll understand, the more you'll be comfortable". (a short-term volunteer E)

In sum, the camping's organizational structure is characterized by the absence of hierarchic relations in the sense of standard employee-employer relationship. The organizational process is democratic and open to idea expression. The recognition of being part of the volunteering team and the position of a task leader is acquired through "participative assessment" and "functional legitimation" by peers. As a result, the project consolidated around a collective of highly dedicated volunteers; with a sense of initiative and willingness to participate. The core team members completely appropriated the camping project collectively shared the responsibility about the project outcome: *"There is responsibility, we are all responsible [...] Everyone wants that the project works out. This is crazy, this is a project that belongs to no one, we are all concerned"* (volunteer F, member of the core team)

The personality of the project leader undeniably contributed to project realization. Many members of the core team joined and stayed at the project thanks to his charismatic personality, his ability to enroll into the project he leads:

"And then there is [the project leader], he is nice. I'm still working for [his previous employer] but I came to Marseille. Because he talked to us about the project as it was advancing... So [...] I knew there was work and I was here". (volunteer B, member of the core team)

Some volunteers have even expressed emotional affect:

“It is the heart! I've always liked this guy, when I saw him for the first time I thought I've known him longtime before [...] He is adorable [...] I am still here is thanks to him.”
(volunteer A, member of the core team)

4. Shaping a creative atmosphere

Based on the contribution of (James et al.,1978), (Scott & Bruce, 1994) define climate as individual cognitive representations of the organizational setting "expressed in terms that reflect psychologically meaningful interpretations of the situation" (p. 581). Physical space is subject to perceptions and interpretations by users. Many experiences and emotions are attributed to physical space. Building on works on embodied cognition, (Kristensen, 2004) describes the process of “scaffolding”, that is any cognitive process happens within a mediating cultural and physical context. According to him, “the scaffolded environment is part of the creative brain and is an implicit factor”. (Kelley & Littman, 2001) highlight that any studio or laboratory scaffolds its specific activities to their work style. Based on these contributions, the camping creative atmosphere can be then understood as cognitive representations and interpretations of its organizational setting and of its socio-material space.

4.1. Combination of organizational and spatial characteristics favoring creativity

It is possible to disentangle some particular combinations of organizational and spatial characteristics favoring the collective creativity of the camping out of a rich mix of ingredients.

The combination of the ephemeral nature of the constructions with the democratic organizational design is interpreted as an encouragement for risk-taking, experimentation and initiating original solutions:

“For the ephemeral [nature], there are several things at once, but one important thing is that it opens a venue for testing, experimentations. It is less risk-taking compared to long-term projects, you learn things without leaving traces too long”. [...] The project confirmed what I wanted to do: to be free in what I do, to be able to lead projects rapidly... Waiting for 20 years in an architectural agency in order to build a building is of a lesser interest to me ... so, to initiate small things that are within reach of someone young, like me” (volunteer G, a core team member)

The teams diversity, in terms of professional occupations of volunteers, its size flexibility and openness to new comers, combined with large needs for construction, maintenance and animation of the camping site provided with unlimited opportunities exchange of ideas and collective experimentation.

“Everyone feeds with the vision of another. This happens when sharing around a table, or at a construction site. “Look, I see it more like this” – “Yes, you’re right”. And we try. And if it does not work we undo and redo it differently, and if it works then we make it even better... and it’s true that it works well” (volunteer H, member of a core team)

Recycling as a ground philosophy and as a solution to scarcity of available means further nurtured the collective creativity and experimentation. Recycled materials and objects served as a raw material for realization of some camping’s constructions and furniture, realization of small objects - camping’s “goodies”, or equipment for specific events. For example, the Yew We Radio space for the camping’s radio broadcasts, equipped with relooked old radio stations; realization of costumes out of a recycled tissue and of a giant grill out of old cycles for the festive event “Marseille, European Culture of Merguez”.

4.2. Creativity embedded in the camping space²

During the project period, 11 mini-housing constructions were realized. The flagship constructions included “les Cabanons perchés” (Perched huts) - 2-level perched and shady platforms for tents built on scaffolds (photo 7); “Moisseuneuses” (“Combines”) and “Semeuses” (“Sowers”) – dorms and small rooms built on scaffolds out of wooden materials and recycled pallets (photos 4 and 5); la “Gygagone” – version 3.0 of Moissonneuses, a dorm for 16 people; “Hameau de caravans” (hamlet of caravans) – caravans perched on scaffolds on two levels (photo 7); “Valcoucou SDF-hotel” (Valcoucou, a hotel for homeliness); la “Maison bulle” (“Bubble house”) (photo 6). Moreover, nine old caravans and one boat were customized by artists and exterior designers (photo 2)

Numerous landscape constructions and “bounty spaces” were created: Big stares and the agora of the camping; the garden – experimentation with aboveground permacultures

² http://issuu.com/camping2013/docs/ywc_bilanmarseille2013#

adapted for urban life that made the camping green (photo 10); a hive Be-Pass equipped with a smokestack of 2.5 meters high that allows bees to live in proximity with humans; “Passage au frais” – a system of water spray constructed out of plastic boxes; an open kitchen with barbecues (photo 2); Ranch Poney – a two level construction of scaffolds out of recycled wood for a bar at zero-level and a terrace on the floor (photo 9); a reception desk – the caravan YWC perched onto a container augmented with a construction out of recycled pallets (photo 8); la gastonette – a customized caravan for “currency exchange” (the YWC had a local currency in circulation, Gastons); “Chéri, j’ai agrandi la cuisine” – an extension of the caravan for serving breakfast and snack, realized with recycled wood, concrete, with a phytoremediation system.

A 3-level shower systems was realized on scaffoldings, with a solar energy water heating system on the top, showers in the middle and a water recycling system on the ground. Dry toilets were also constructed on scaffoldings with recovery tanks located on the ground and toilet cabins on the top.

Four stages for artistic performances were constructed: “La Caravane Spectaculaire” (Spectacular caravan) a caravan transformed into a stage, “C60” – a stage structure of an O-shape composed of a central hexagon with connected structured of C-shape; “Scène DJ” – a steel cab covered with wood and raised floor; “Scène et Bar-plage” (stage and bar beach) – a stage realized with sand.

The initial ambition of the project founders was to create a “multifunctional space, with different equipment and activities that make it attractive for various reasons and by their mutual proximity and by their organization on the site enable a mix of uses and of publics”³; “a place of realization of dreams of artists *bricoleurs* and performers”⁴ but also “a place where one feels good and where one stays, for a drink or for a long weekend”⁵, a “sort of summer 1936, where perfume of possible is floating in the air”⁶.

The ambition was successfully realized, as attested by some volunteers.

“At the beginning, I came as a camper, I stayed for one week and after that I never wanted to leave. I became a volunteer, I’ve being here for two and a half weeks. [...] I fell in love with the project” (Short-term volunteer D)

³ *Ibid.*

⁴ *Ibid.*

⁵ *Ibid.*

⁶ http://www.apeas.fr/IMG/pdf/Projet_YesWeCamp_8janv.pdf

“ I just came to see my buddy [...] He talked me about volunteering quickly. I said hey, I was on vacations, I planned to go on holiday and in fact I found myself doing everything and anything. [...] And it's good, it changes the normal life, it is a bit like rush, that's cool. [...] Yes, there is a good atmosphere” (Short-term volunteer E)

The architectural and artistic realizations coupled with the human dynamic impelled by the camping stimulated collective creativity and transformed the understanding about the way public spaces can be shaped:

“I think projects as YWC bring a lot of different elements, that it is people who come by curiosity, people who do not have a lot of means and want to live at low cost rate during the summer season, people traveling through or any other ... but also volunteers who are here, who know the site [...] there are so many things I think it feeds the project and the way to design spaces created either for housing and for other activities” (volunteer H, member of a core team)

Arts in Business – Why and What For? Phenomenological Approach to Creativity¹

Paulina Bednarz-Łuczewska

Kozminski University, Warsaw, Poland

Structures Abstract

Purpose - We aim to theorize about the selected aspects of the relationship between arts and business in the context of the recent proliferation of Art-Based Initiatives. The popularity of ABIs urges us to ask some fundamental questions about the nature of such interventions: What is really happening when arts is brought into the business context? Why does it “affect value-creation capacity”. Develop employees and infrastructure?

Methodology - The paper has theoretical and speculative character. It is based analysis of literature and implementing a classical, widely recognized theory into the new field.

Value- By extrapolating the theory of the phenomenologist Roman Ingarden from the field of aesthetics into management the paper provides a new framework for analysis of the process of creativity and innovation. The framework differentiates between three moments of the creation process: material basis, act of consciousness of the creator and concretization performed by the recipient. Each category requires different research methodology and plays a different role in the value-creating process.

Practical Implications - By providing deeper understanding of the relation between art and business, which underlie any Art-Based Initiative, the paper contributes to more efficient and more precise application of such procedures. The findings will shed the light on the questions of “when?”, “where?” and “how?” to use ABIs.

Key words: Arts-Based Initiatives, phenomenology, innovation, creativity, aesthetics

Paper type: Academic research paper. First draft.

1 Introduction

Art is in the air, at least in the air that business people breath nowadays. In the recent decade, we have observed a of growing interest in the world of art among management scholars and practitioners. The world of business reaches for artists and artistic projects in the hope of acquiring knowledge and inspiration (Nissley 2010; Daum 2005)(as opposed to interest in arts as sheer source of pleasure, CSR-opportunity or financial investment).

¹ *Work in progress. Do not cite without author's permission*

Probably the most intensive manifestation of that interest are various forms of the so-called Arts-Based Initiatives (ABIs) defined as “planned managerial use of art forms to address management challenges and business problems with the aim of developing employees and infrastructure that affect the organisational value-creation capacity”. (Schiuma 2011: 2)

The literature on the issue grows, yet it is scattered and lacks universal, unifying concepts and language. There is a consensus that performing arts is correlated with increased creativity and innovativeness (the terms are sometimes used interchangeably). (Pässilä, Oikarinen, Parjanen & Harmaakorpi 2013; Pässilä 2012; Styhre & Eriksson 2007) Yet despite of many reports that it actually is the case, the process of art positively affecting business remains a black-box, the quasi-magical area of non-theorizing. This situation might be partially traced back to the bad reputation that theorizing has among researchers dealing with creativity who have been all too often criticized from strictly positivistic position for lack of rigor and unscientific reasoning.

We aim to theorize about the selected aspects of the relationship between arts and business. The recent proliferation of Art-Based Initiatives urges us to ask some fundamental questions about the nature of artistic interventions: What is really happening when arts is brought into the business context? Why does it “affect value-creation capacity”? How can art help “develop employees and infrastructure”?

Further we claim by theoretical extension (Snow, Morrill, Anderson 2003) of the aesthetic theory of the 20th century phenomenologist Roman Ingarden we might (1) develop framework for systematizing and unifying the scattered body of knowledge about artistic interventions into business; (2) enrich our methodological tool-set with phenomenological analysis akin to the one used by Ingarden; (3) gain some non-trivial, contentious insights about how the creative process takes place and how it is linked to value creation.

2 Ingarden’s original contribution

Roman Ingarden was a prominent Polish philosopher of the twentieth century. At the early stage of his career he became a student of the founding father of phenomenology – Edmund Husserl. Ingarden shared Husserl’s passion for phenomenological analysis, the need for systematic reflection upon the experience of phenomena as they appear in human consciousness. He was an important and influential member of the phenomenological

circle collaborating with thinkers such as Max Scheller or Edith Stein. However, despite of his deep appreciations for Husserl's work, Ingarden developed his own position and distanced himself from Husserl's transcendental idealism. (Mitscherling 1997; Thomasson 2012)

Large portion of Ingarden's work – including his magnum opus *The Controversy over the Existence of the World* (1960) revolves around the basic questions of ontology. Ingarden understood ontology as based solely on *a priori* inference and “concerned not with what actually exists, but with what could possibly exist (which concepts are non-contradictory), and with what (according to the contents of the relevant ideas) it would take for objects of various kinds to exist, or entail if they existed. He thus contrasts ontology with metaphysics, which is concerned with answering factual questions about what sorts of things actually exist and what they are like.” (Thomasson 2012) By examining essential features of any experience connected to the objects under inquiry, Ingarden could determine what the ontological structure and status of these objects must be.

By conducting systematic ontological reflection, he contributed significantly to aesthetics. The work that has gained him international reputation was *The Literary Work of Art*, first published in 1931 (in German, first English edition in 1973). Ingarden applied there the method of phenomenological analysis to the notion of literary work. He followed later with similar scrutiny of music, visual arts and architecture. (1973; 1986) Thus Ingarden created a systematic and coherent understanding of what works of art are, how they exist and how can they be judged. This part of his reflection, as we claim further, provides insights valuable for management academics and business practitioners.

According to the Polish philosopher, works of art are “purely intentional objects” i.e. they owe their existence and nature to acts of consciousness of a subject. The mode of existence of the artworks is totally dependent on intentional acts of their makers. (Ingarden 1973; 1986) Having said that, one can distinguish between three different moments of the process of existence of an artwork.

First, artwork is embedded in some physical object – physical copy of a book, musical score, piece of architecture or a canvass covered with paint. This is the realistic ontic base upon which the proper artwork is built. It would be absurd and contrary to human experience to claim that an artwork equals its physical base. Such a claim would entail that the difference between, say, “Hamlet” and “King Lear” lies in chemical composition

of the copies of both literary works. On the other hand, it is important to note that Ingarden recognizes the fact that even such purely intentional objects as works of art of various kinds are founded not exclusively in consciousness, but also on real spatio-temporal objects. (Ingarden 1973; 1986; Mitscherling 1997; Thomasson 2012)

Second moment is the artwork as such. Its “mode of existence” cannot be classified as “ideal” (in the platonic sense), since one cannot claim that it has always existed and has been merely discovered by the creator. To the contrary, it has been called to existence by the creative act of consciousness of an artist. As it was explained above, artwork cannot be identified with its physical base and thus classified as ‘real’ in the ontological sense. The recognition of existence of the works of art require us to accept the existence of things in a category distinct from either of the real/ideal dichotomy, namely that of purely intentional objects. . (Ingarden 1973; 1986; Mitscherling 1997; Thomasson 2012)

The third moment of the artwork seems to be particularly interesting. Works of arts regardless of their particular genre (literary work, visual art, music etc.) remain open, full of gaps and indeterminacies. The “aesthetic object” arises through “concretization (concretion) of the artwork” and it is a common enterprise of the author and the receiver. In the act of perception the latter reconstructs the work of art created by the former. On the top of that, the receiver fleshes out the skeleton of the work of art with his own, idiosyncratic content. By the same token, the receiver brings out the potential value inhered in the work of art itself. In other words, the process of concretization of the work of art has a form of a quasi-dialogue, a dynamic and exchange between the creator and the recipient. The concretization always takes place in concrete, defined spatial and temporal settings. Therefore one work of art can have a plethora of unique concretizations. (Ingarden 1973; 1986; Mitscherling 1997; Thomasson 2012)

The three-fold distinction between physical object, work of art, and aesthetic object is mirrored with three different ways of having or not having value. Every work of art, according to Ingarden, has moments that are “axiologically indifferent” and some that are “axiologically significant”. Physical foundation of the work of art is axiologically neutral. Ingarden claims every artwork has a set of axiologically neutral moments that together form an “axiologically neutral skeleton of the work of art”. The significant moment (artistic and aesthetic values) appear on the basis of this skeleton but only in connection with intentionality of the author (artistic value) or concretization of the art form performed together by the artist and the perceiver. Applying different language to

Ingarden's framework one can say that value emerges only insofar as human intentionality and agency is involved. (Ingarden 1973; 1986; Thomasson 2012)

3 Bringing Ingarden to a firm

Ingarden's theory might be useful with regard to the analysis of the relationship between arts and business in at least three distinct ways: by providing a unifying framework for the extant body of knowledge; by pointing to a potentially fruitful method of inquiry, namely that of phenomenological reduction, that could be used within the field of management; by extrapolation of his findings, Ingarden thought is full of unique, non-trivial insights into the process of creativity and innovativeness leading to value-creation.

3.1 Framework

The first way that Ingarden's thought can be applicable within the field of management science is by providing a coherent framework for analysis of the process of creativity and innovation, the very core of any artistic endeavor. We claim that Ingarden's phenomenological description of the artistic process can be extrapolated to any creative process, above all to the one taking place in a value-creating firm. Thanks to its coherence and relevance, Ingarden's set of concepts might serve as a unifying framework for the whole emergent field of "arts in management". On the one hand, the framework distinguishes between three ontologically and epistemologically different moments of creation that require different methods of inquiry and different language of description. On the other hand, the framework helps us see interconnections and various other relations between the three separate moments.

The first moment, the physical foundation of the creative act corresponds with everything that is necessary yet not sufficient for the act of creation. First of all we might include here a reflection on the resources a firm has at its disposal or might acquire. Here we might also analyze the whole ontogeny and phylogeny of creativity - the context in which a conscious, creative act takes place both on the level of creative individual as well as on the level of the whole creative community. This category could encapsulate: psychological insights into the creative process, material resources, ways of managing the team etc. Ontologically speaking, this moment belongs to the realm of the "real" therefore - epistemologically speaking - the scientific, positivistic methods are the best match for the research within this realm.

The second moment, the intentional act of the author (individual or collective) corresponds with the unique, idiosyncratic way a firm consciously projects its imagination into the realm of the real world marked by Knightian Uncertainty (cf. Spender 2014). Under this umbrella one may gather various analysis of the imaginative and intentional components of innovation, i.e. the necessity of human consciousness and agency in any value-creating act. As this is a realm of “phenomena”, the traditional scientific methods could be of no use – as long as we analyze what determines creativity, its “structure”, we remain within the first moment, the real basis upon which the actual creation takes place. If we, however, apply the method based on causality to the realm of creativity (its agentic component) we fall prone to a common methodological mistake that Margaret Archer would call “downward conflation” (2000) i.e. denying causal autonomy of human agency. In order to inquire into the creative process one has to look for methodologies provided by humanities, among which phenomenological analysis might play a significant role. The epistemology of creative act is in itself a vast problematic that cuts across cleavages between disciplines. It definitely requires serious methodological reflection, above all within management science.

The third moment, the concretization of the work of art when the recipient supplements the “schematic formation” might provide heuristics for understanding the all too often omitted part of the value creative process – i.e. the interaction with the final recipient of a good or a service. The real value is actualized only when it finds a beholder. Moreover, the recipient might play a quite concrete and non-metaphorical role in the creative process as it is the case in participatory design, crowd design and participatory creation process that involves the recipient of the created good. Thanks to Ingarden’s framework we can incorporate all the robust literature about the participatory aspects of innovativeness into one roughly coherent body of knowledge. Methodologically speaking, this part of the process can be researched with the help of both scientific as well as interpretative method, depending on the particular aspect of the inquiry.

3.2 Phenomenological method of investigation

Ingarden’s reflection on arts could be also inspiring methodologically. After some modifications, the method of phenomenological analysis could be successfully implemented into management research.

Ingarden perceived phenomenology as a descriptive domain – in this respect he opposed the transcendental dimension of Husserl’s thought. Ingarden was one of the

phenomenologists – like Alfred Schutz or Max Scheller – who believed philosophy can gain a new momentum thanks to thorough analysis of objects as they are given to a subject, as they are being experienced in their core, independently of any contingencies.

Phenomenological method also called phenomenological reduction consists in bracketing all theories about the object, all pre-existing meanings attached, even the belief in what is real. All these issues are left aside for different methods of cognition such as the scientific one. Phenomenological reduction's aim is to evoke a concrete, living meaning of a phenomenon as it is present in a person's consciousness. In practice, such analysis included a lot of reflection on the language, the concepts that we use, as they reveal hidden assumption and true nature of our cognitions and experience. The phenomenological method is based on the assumption that there are essential correlations between kinds of objects and the modes of cognition by means of which they can be known.

The method of phenomenological analysis of the concepts applied to the field of innovation management could provide us with a lot of valuable self-knowledge as well as potentially open new spheres for inquiry.

3.3 Contentious insights

One important yet controversial insight from the extrapolation of Ingarden's framework into the field of innovativeness and creativity in business context concerns the relationship between resources and value creation. Just like no physical object can provide artistic value so no resource as such or combination thereof can bring about value. Value is created only insofar as human consciousness and intentionality are involved in an act. (cf. Spender 2014) Resources are necessary, yet secondary component of the creative process. With the help of intentionality, one can often compensate the lack of a particular type of resource. No resource, however, provides means to by-pass human imagination in the value-creation, unless we use the term "resource" in reference to human agency making thus the term either internally contradictory or tautological. Value creation does not happen by the virtue of combining resources but by intention of the author concretized in spacio-temporal act of reception.

Since creativity is primarily about intentional acts of consciousness that cannot be reduced to resources used in the "production" or to the context in which the creative act took place, we might rethink the metaphors we use to describe that context. Creative act might be facilitated by various contextual factors, yet they are not determined by them,

agency might be “constrained” but never “caused” in the proper sense of the term – it possesses its causal autonomy. The source of innovation is the creator: his imagination and agency. Therefore various organic metaphors that depict the context of innovation as “ecology” or a “system” might be misleading exactly because they exclude any external causality such as “deus ex machina” of human agency. Since metaphors are very powerful heuristics, an inadequate metaphor can seriously hinder our understanding and praxis. Following this insight, there is a need for developing new metaphors, free of the pitfalls described above. It is important to note, that the process of developing a metaphor might in itself be an act of artistic creation.

Third, Ingarden’s framework draws our attention to the sphere that has been only marginally linked with the process of innovation, namely the moment of concretization. One way to extrapolate this part of Ingarden’s aesthetics onto the field of management is to consider all the instances of clients co-creating the product or service they receive. However, following Ingarden’s intuition that the “aesthetic value” in the proper sense emerges only through the process of concretization, we should scrutinize all the value that is being produced at the final stage of the economic exchange. These values might be of different nature and could include socially-beneficial imponderabilia such as trust, joy or friendship, but could also close the feedback loop and affect to potentiality of value creation of the firm by providing knowledge, skills or even eagerness to innovate among the people who have been involved in the creative process in the first place.

4 Conclusions: Practical Implications

The practice of introducing arts into the business context has already turned out to be fruitful. It is our claim that the more we understand why and how arts could enrich practice the more precisely can we apply the artistic tools such as the ABIs. The three-fold distinction of the creative process might turn out to be a particularly useful heuristics for the business practice for several reasons.

First, it differentiates between the structural and the agentic component of the creative process thus enabling a manager to know what can be expected from each of them. For instance, it becomes clear that the investment in infrastructure might but does not necessarily have to trigger innovation; on the other hand, sometimes creativity takes place despite of very limited resources.

The framework humanizes a firm, reinstalls people as the source of value the firm produces. Such act of placing people in the center of our thinking of the firm (and not as “human resources” but - to the contrary – as human agents) could have far-reaching consequences in various dimensions: ethical, financial, strategic and political.

Moreover, the third moment, that of concretization of the artwork should draw the attention of management to the final, interactional stage of the creative process that is often not even considered to be linked to innovativeness. Perhaps this underexplored field might turn out to be of crucial importance for as it is able to generate values that cannot emerge otherwise.(see also: Dell’Era & Landoni 2014)

Structured Abstract

Purpose – The street-building with “arcade” as frontage was one of the particular image in the old Asian city centres. However, by the urban alteration, the commercial function was moved out. Arcades don’t have to support the activity for trading and exchanging any longer and become the fresh “lost spaces”; moreover, this new kind of “non-places” stop the urban development. Yet, are arcades merely negative in the “new age” entitled of knowledge economy? For the interrogation, the space character of arcade, its potential for the knowledge production and the opportunity for urban regeneration with knowledge activity (various dialogs) were tried to illuminate.

Design/methodology/approach – For knowing this, an approach to combine two perspectives was proposed. (1) Cities as knowledge tools: social and physical set-up of urban environments determines human communication, information exchange, and collective thinking (Edvinsson, 2006). (2) Cities as diagrams of knowledge: knowledge is regarded as a major force shaping cities into specific patterns (Alexander, 1972). Arcade provides an intensive interaction of private commercial territory and public access atmosphere. Its public sphere (Habermas, 1989) and “soft boundary” (Hertzberger, 2005) encourage communications, interactions and divergent territorial claims. Arcade offers people the heterogeneous and flexible possibility of gathering, intensive communication and appropriate atmosphere: creative milieu.

Originality/value – The interrelation between knowledge and space can be realized through a matrix with the two-dimensional array to identify the physical and social environment set-up: “heterogeneity” and “flexibility”. Four kinds of spatial patterns are recognized by four quadrants and directly reflect in urban configuration. Space structure of arcade is classified in the high heterogeneity and high flexibility quadrant in this methodology. It offers the safety sense of meeting and the spatial condition for the intensive dialogue: more property for knowledge economic production. As the study result, different types of arcades are classified by the density of knowledge activity and space structure.

Practical implications – It is explained by the Model, that the “knowledge activity” - various dialogs - could be coming back to the “ruins” in the city centre. This phenomenon is beginning to be observed in the arcades in Minguan Road, the past business street in

Tainan with ca. 400 years history. If the spaces of arcade could be identified as one of the potential place for knowledge production, the importance of arcade in the old city centre had therefore a chance to be revalued. It might be one of the demonstrations of the strategical application for knowledge based urban development and regeneration.

Keywords – Arcade, Creative Milieu, Knowledge based Urban Regeneration, Soft Boundary, Tainan.

Paper type – Academic Research Paper

1 Introduction

Old city centre, which was developed by commercial gathering in the past years, became a place for trading and information exchange. Nowadays, however, through the urban expansion, the old city centre loses its advantage of commercial location and becomes “a shell” which hinders the urban development. In this condition, could the pattern of the location and space characteristics in old city centre become a new resource of the knowledge based urban (re-)development?

There are two perspectives on knowledge production and city:

- 1) Cities as knowledge tools support intellectual capital (Edvinsson, 2006).
- 2) Cities as diagram of knowledge (Alexander, 1972).

The perspectives above shows that the existence of “knowledge” is represented by the cities and it is a major force for shaping cities into specific pattern.

Based on these two perspectives, the relation between knowledge and space patterns can be realized through a matrix with two-dimensional array to identify the physical and social environment set-up which depend on its very resources of relational and structural capital. Through this model, we can clarify the interrelation between knowledge and space in four different kinds of spatial patterns, which can support knowledge production and those patterns which directly reflect in urban configuration.

However, not all of the place (Norberg-Schulz, 1980) for knowledge production can go through the knowledge process (Bose, 2003). To make the conversion and creation of knowledge, knowledge spiral (Nonaka and Takeuchi, eng.1995, ger.1997) could be expressed by continuous dialogue, organization, implementation and cooperation for leading knowledge production to a higher level.

Therefore, the place for intensive interaction and dialogue needs “catalysis” (Oswalt et al., 2013) to inspire the reaction and “creative milieu”, a place that contains the necessary requirements in terms of hard and soft infrastructure to generate a flow of ideas and inventions, can be such “catalysis” to motivate process into knowledge spiral. This kind of space have three characteristics as following:

- 1) Public sphere which stimulates communication (Habermas, 1962, 1990, 2013).
- 2) The intermediary space provided by “in-between” (Hertzberger, 1991).
- 3) Cluster of space unit (Frey, 2009).

As an unit, arcade, a general image and space pattern in old city centre, could provide characteristics of creative milieu as above. As a corridor to string the units, which embedded in a continuous wall-adjacent building for public accession, has one-sided colonnade separating the street and the other side for commercial purpose. By its heterogeneous space unit clustering together and variety type of territorial claims, arcade provide a half in-close and safety place for public communication and dialogue (Jacobs, 1984) which highly accelerate the reaction of knowledge process.

With the features of creative milieu, arcade might also play a valuable role - such as the “second hand spaces” (Ziehl et al., 2012) - in urban regeneration in old city centre. Especially under the location conditions with low land price, arcade can be regarded as opportunities in arising creative milieu in large scale. Moreover, by combining series units of arcades, it can become the urban knowledge corridor. This research would take Minquan Road in Tainan City, which went through from depression to retrieval, as an example, and it can be proved that the activity has gradually revived by its creative milieu and the arcades in Minquan Road become instruments for knowledge production.

2 Knowledge based urban (re-)development

Subject to development spindle of the intellectual capital in recent years, we must start with how knowledge is produced in the city and what kind of specific pattern carry the knowledge, to prove that a particular pattern of old city centre with possibility to produce knowledge and provide creative milieu.

2.1 Knowledge cities

There are several of attempts to interpret the functions of cities. From the perspective of knowledge economics, cities might be seen in the context of more or less good city

regime to support the value creation from and for the knowledge workers. Therefore, there are two views should be concerned. Cities can be viewed as knowledge tools and diagrams of knowledge.

City, the place for people exchange intensively, can be viewed as knowledge tools which support intellectual capital. Depending on its very resources of relational and structural capital, social and physical set-up of urban environments determines human communication, information exchange, and collective thinking (Edvinsson, 2006). In the case, the place which encourage and nourish knowledge process do have significant impact on knowledge production.

Besides, cities can also be viewed as diagrams of knowledge. Knowledge is regard as a major force shaping cities in to specific patterns, a powerful urban driver which directly reflects in urban configuration (Alexander, 1979). Thus, in knowledge society, the city should have some specific pattern to support the process of knowledge production.

2.2 Space patterns: a model for knowledge production

To clarify the interrelation between knowledge and space, it can be realized thorough a matrix with the two-dimensional array, concerning “heterogeneity” and “flexibility” to identify the physical and social environment set-up which depending on its very resources of relational and structural capital. The dimension of value about heterogeneity is the characteristics of physical environment of urban spaces, which could be multiple or single. Meanwhile, the dimension of value about flexibility is the characteristic of social environment of urban spaces, which indicates the number of different kinds of activities.

Through this model (fig.1), four different kinds of spatial patterns, which can support knowledge production, could be recognised. In addition, when different kinds of thoughts or perspectives gather in a space, there is a great chance to “encourage and nourish the collective knowledge.”

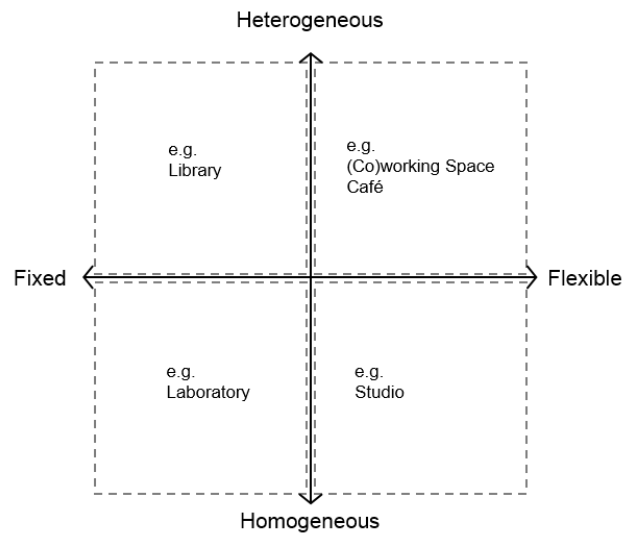

Fig. 1. Matrix of four kinds of places for knowledge production

Flex-Hetero-Quadrant, which is in first quadrant, contains different kinds of space patterns and there is no specific activity within, which means there is no specific kind of knowledge production or discussion and the capacity is unpredictable as well.

The activities provided by the place in the second quadrant are various characteristics or physical environment, but these multiple spaces only provide one particular activity. Therefore, the aim of knowledge production in “Fixed-Hetero Space” is fairly clear.

The aim of knowledge production in “Fixed-Homo Space”, which is in third quadrant, is also fairly clear and the knowledge and perspectives which produced by activities within these spaces focus on particular field with high capacity.

In the last stage, the place in the fourth quadrant contains the relatively complex activities compared to the space in other quadrants. Moreover, the knowledge and perspectives which produced by the activities within these spaces generally focus on particular field while the capacity is unpredictable.

It’s evident that the activities in the place of Fixed-Homo-Quadrant, Fixed-Hetero-Quadrant and Flex-Homo-Quadrant are defined clearly that the space arrangement and management within these places support particular activities. However, in Flex-Hetero Quadrant, two of spatial dimension of values are unstable. Hence, social and physical environment set-up cannot describe or even identify the characteristic of “In-Between” (Hertzberger, 1991) which actually is an indispensable factor to attract people to stay.

2.3 Knowledge process

Knowledge process is usually explicated by the “knowledge spiral” (Nonaka and Takeuchi, 1995), which is a dynamic model illustrates the transformation of implicit knowledge to explicit knowledge, and demonstrates the process of knowledge creation.

In this model, there are four phases of knowledge process cycle. First, humans get implicit knowledge from social groups. Through their comprehension, the implicit knowledge transits into explicit knowledge by dialogue, and then externalize. Then, the explicit knowledge links to another explicit knowledge and have a combination to become a new knowledge. The previous results of the last state turn into new implicit knowledge through continual learning and doing, finally become a common sense. The knowledge spiral repeats on and on by "externalization", "combination", "internalization" and "socialization", this continue transformation process urge the knowledge into higher level of personal knowledge.

In addition, the knowledge transfer and related changes can occur at the level of the individual or organization, which represents the transition from individual knowledge into collective knowledge.

2.4 Creative milieu: a place on knowledge process

When different kinds of thoughts or perspectives gather in a space, there is a great chance to “encourage and nourish the collective knowledge” (Edvinsson, 2006). For this purpose, there may be some of space pattern can give the chances to more communication. The space with “creative milieu”, as a catalyst, is an indispensable element to inspire the interaction and go into knowledge spiral. Creative milieu typically contains the following three features: public sphere, in-between and cluster (Frey, 2009). The following are the perspectives of these feature:

- **Public Sphere:** The public sphere (ger. Öffentlichkeit) is an area where individuals can come together to discuss freely and identify societal problems, and the political action would be influenced through the discussion. Therefore, the space with the public sphere can induce interaction, and promote knowledge renovation, such as courtyard (ger. “Hof”), with its harboured shape, make people feel safe that people would be willing to stay in space and discuss.
- **In-Between:** *“The in-between concept is the key to eliminating the sharp division between areas with different territorial claims.”* (Hertzberger, 1991:40)

This kind of “soft boundary” characterised by “In-Between” doesn’t only provide a place to communicate for the customers and the shops but also plays as the key role to the transition and connection between areas with divergent territorial claims. Moreover, *“concretization of threshold as an in-between means, first and foremost, creating a setting for welcomes and farewells, and is therefore the translation into architectonic terms of hospitality.”* (Hertzberger, 1991:35) Hence, the space with “in-between” is one of important space character of creative milieu.

- Cluster: The concept of cluster could usually be defined as units such as firms in similar and related industries. With this concept, the benefits in terms of innovation and learning might grow from close geographic proximity (Malmberg and Maskell, 2002). Mostly, the greater opportunities for specialization could drive the innovativeness in industrial clusters – especially while the role of knowledge spill overs has likely been overstated (Caniëls and Romijn, 2005). Cluster could be one of the most important space patterns for knowledge production and innovation (Landry, 2000).

3 Spatial character of arcade

The street buildings with arcades is a common “image” (Lynch, 1960) of the old city centre in Taiwan. It appears from buildings on private land with public access embedded, and the colonnades separate the streets and internal pedestrian space (fig. 2). Due to the cover from three surfaces, the semi-open space makes people feel free, content and deprived from the effect of outer transport. In addition, the passage arise opportunity to cotton to the shops. On account of the space is part of the private sphere of townhouse buildings, each building unit has authority to claim their right of territory and enables the space of arcade appear diverse complexions.

Fig. 2. Space structure of arcade

In the past, arcades in old city centre are generally accompanied with bustling commercial activities, but with the decentralization of commercial function, such semi-open space transferred into a lost space. The spatial pattern for exchange and dialogue are still maintained, which might provide chance to insert knowledge production, an industry which needs intensive interaction. On the premise of knowledge economics generation, can arcades turn out to be the space animates old city centre?

In order to prove whether arcade have the ability to produce knowledge and possess creative milieu, two methods are executed as following: (1) the space pattern of arcade in knowledge production through biaxial judgement, and 2) induct different pattern of arcade to find out the public sphere, in-between, and cluster space character.

3.1 Type of knowledge production space pattern of arcade

By identifying its physical and social environment set-up character can find out the types of knowledge production space which arcade belongs to in the matrix which defined by heterogeneity and flexibility.

On the aspect of physical environment, the space units are defined by the first floor ceiling, ground floor, storefront wall and two columns. The most special character of arcade is that it has three opened surface for access purpose and the margins between the space units are invisible. Because the depth from street to storefront are the same, which could also connect every unit together, this space has a function to allow public accession. On the other hand, due to the difference in landownership, the width of every store is different.

From the above characteristics, it can be summarized that the spatial shape is not easy to define and regulate, and it changes easily. Therefore, the physical environment set-up of arcade belongs to the heterogeneity space. And from the following survey, it can be found that the activities inside every arcade unit are very different. Thus, the social environment set-up of arcade belongs to the flexibility place.

In conclusion, arcade belongs to “Flex-Hetero place”, which the transformation is difficult to classify and describe. Hence, it is necessary to identify the characteristics and in-between space through a more detailed observation method.

3.2 Arcade and creative milieu

To prove that arcade can provide creative milieu, its spatial characteristics must include the public sphere, in-between and clustering. In this study, architectural transformation and typology are used as analysis method to identify the spatial rules of arcade.

3.2.1 Public sphere and cluster

A space with public sphere can induce more dialogue, and its spatial qualities usually make people a sense of security. For example, the void space of courtyard (ger. “Hof”), which Jürgen Habermas views as a kind of space pattern which expresses public sphere, surrounded by the covered building inspire people to communicate and discuss.

However, by turning this space (architectural transformation) into different direction like arcade, the void change to open horizontally and transparently (fig. 3). The special space character of arcade is that it shapes the spatial extent by the invisible boundaries and its openings are for people to access and gather. The difference between arcade and courtyard is that arcade has more openings than courtyard, but doesn't change its pedestrian safety (Jacobs, 1984) given by shelter atmosphere (Böhme, 1995). Thus, the space pattern of arcade includes public sphere which is proved by the structure of courtyard.

Whether arcade has the space characteristics of “cluster” can be observed from physical and social environment set-up. For the physical set-up, arcade is meaningful only through the combination of numerous spatial units, because a single arcade unit cannot combine void to an apparent corridor. Through this combination of process, it can be confirmed that arcade has the space characteristics of “cluster”. And for social

environment set-up, due to the mutual corridor in the front of the stores, the activities in store may extend in arcade and made the variety of activities in this corridor, which can be concluded that arcade also has the activities characteristics of “cluster”.

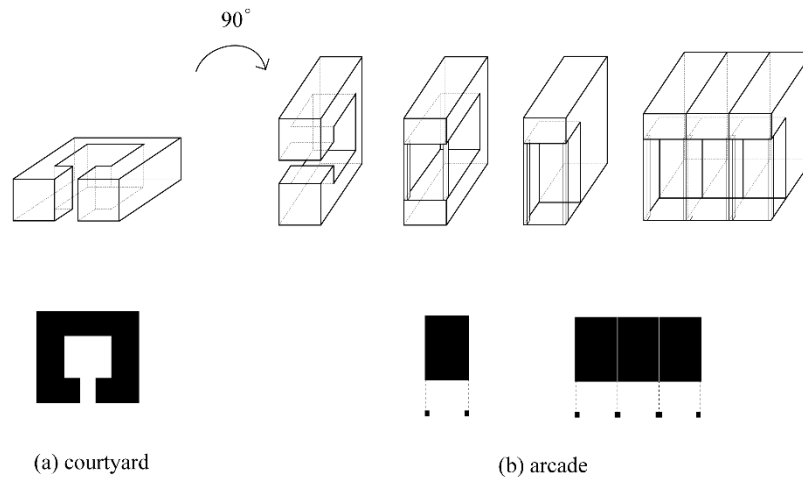

Fig. 3. An architectural transformation from courtyard to arcade

3.2.2 In-between and territorial claim

Arcade has both public access and private territorial claim and such “in-between” qualities evoke more dialogue which means arcade plays an important role as catalytic in knowledge spiral. In order to prove the characteristics of in-between, the study would summarize the public and private claim pattern in arcade by defining the boundaries of every unit and typology.

For the access purpose, each spatial unit does not have clear boundaries, but the extent can be defined by extending the virtual line from column to the wall, which formed an invisible boundary for private sphere unit. And because there is no clear boundary for spatial extent, the activities in public and private areas appear diversity.

To know the extension of public and private territory, the study separate arcade unit into nine part based on each person walking scope ,1.2m-1.5m, as cutting standards (fig. 4). Because an open area, room or space may be conceived either as a more or less private place or as a public area, depending on the degree of accessibility, the form of supervision, who use it, who takes care of it and their respective responsibilities

(Hertzberger, 1991). Therefore, we can know the territory claim by recording their access possibilities and visual permeability in this nine grid space unit. Accessibility in arcade depends on the occupation of private sphere. For example, snack shops extend the space by putting the seat into the arcade, and clothing stores put out the hanger to the arcade. However, for more access, the occupation usually doesn't completely block the passage of the arcade. Therefore, this study records the occupation of arcade space. As the following chart, we can find that there are various territorial claims which can be proved the character of in-between in arcade.

Fig. 4. Method to measure public and private territory

4 Case study : Minquan Road in Tainan City

Arcades in Tainan City, the very first reclaimed region in Taiwan, is a typical case regarded as potential places for knowledge production. Minquan Road was one of the most prosperous street which has variety of traditional industries gathered since initial stages of Tainan. After automobile oriented development occurred, arcades become a safe and comfortable commercial exchanging places for pedestrians and stores at Minquan Road. However, with urban sprawl, the commercial location condition of city centre had changed; Minquan Road was no longer a thriving road in the old city centre, which get void and become the lost space.

In recent years, the knowledge-based economy becomes the new opportunity for urban (re-)development. In order to make the product have more chance to interact with people –either residents or tourists, this kind of industry look forward to centre location, this owns place with low using price and creative milieu for more innovative thinking. According to the survey, the phenomenon began to appear in Minquan Road and have returned the activities back to old city centre; many new industries start to incubate.

Therefore, in order to realize the space characteristics of Minquan Road as the case for the knowledge production in old city centre, this study will go through actual investigation and type analysis to find out the following prototype of arcade.

Through fieldwork, the current situation of arcade in Minquan Road is being comprehended, which has 136 arcade units on the north side and 145 on the south included. According to the analysis, there are about 63% arcade units for commercial using, 32% for residential. To mention the circumstances of the commercial development, there are 41% of the stores have grown, 36 % stay same and other 22 % are declined. On the basis of the ratio of development, we can declare that the commercial condition gradually recovered in recent years.

Then, through the research methods we have mentioned above, keep track of the occupied space and activities in the arcades. In the light of accessibility for passenger and stores of 281 arcade units, six prototypes (fig. 5) are summarized as following:

Prototype 1: two-way flow.

Prototype 2: two-way flow, several spaces are occupied then reduced the area of passage.

Prototype 3: one-way flow, leaving only one passage in arcade, the entrance from store to street was blocked.

Prototype 4: one-way flow, leaving only narrow passage in the arcade, the entrance from store to street was blocked.

Prototype 5: one-way flow, leaving only the passage from store to street, but the passage for passenger was blocked.

Prototype 6: impassable, blocked by multiple items, arcade is unable to pass smoothly.

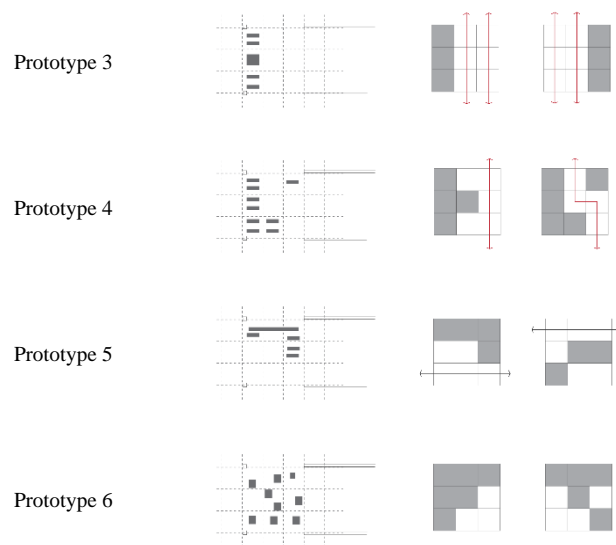

Fig. 5. The prototypes of arcade

Then, connected all record of arcade unit in Minquan Road, can find out the diversity of passage width in arcade and the extension of private sphere that made by the space occupation. (fig 6)

Fig. 6. The distribution of prototypes in Minquan Road

From the above characteristics, can attribute that the arcade in Minquan Road has properties of public sphere, in-between and cluster. Comply with the conditions of the space pattern, which means that it has the ability for knowledge production and given the opportunities to induce a knowledge spiral. In recent years, the store categories both sides gather more and more knowledge production-related industries which extent their private

sphere for communication and to attract the customers. Arcade can provide the creative milieu for all the possibility any dialogue and interaction.

5 Conclusions

The street-building with “arcade” as frontage was one of the particular image in the old Asian city centres. As the space patterns and the stringed units, arcades can viewed as corridors which embedded in a continuous wall-adjacent building for public accession, which has one-sided colonnade separating the street and the other side for commercial purpose.

With this open space structure, it provides an intensive interaction of private commercial territory and public access atmosphere by alignment column corridor. This public sphere which excessive between the private and public might encourage communications and interactions. Besides, the “soft boundary” characterised by “In-Between” doesn’t only provide a place to communicate for the customers and the shops but also plays as the key role to the transition and connection between areas with divergent territorial claims. Due to this significance, arcade offers people the heterogeneous and flexible possibility of gathering, intensive communication and appropriate atmosphere: the creative milieu.

In our methodology, the open space structure of arcade can be classify in the high heterogeneity and high flexibility quadrant, in which intensive dialogue causes the knowledge production process. In this case, the old city centre could offer the sense of safety meeting and the spatial condition for the dialogue between areas of different orders: more property for the new knowledge economic production. As the perceptive and experimental result, different types of arcades were classified by the density of knowledge activity and space structure. It demonstrates that arcade could provide creative milieu on aspect of knowledge process in the old city centre. In the “new age” entitled of knowledge economy, arcade is not merely negative spaces. Even more, it could be one of the most potential places for knowledge production. The reasons are as following:

1. The space units of arcade could be diverse from the arrangement of private claims and the way of public using. For this flexibility and heterogenetic character of arcades, the space belongs to the “Flex-Hetero-Quadrant” in knowledge-based urban (re-)development model.

2. On the basis of architectural transformation and combination, arcade provides public sphere and gather lots of activities by clustering arcade units. This kind of space pattern provide a good voids to accommodate the diverse interaction and knowledge purification.
3. As a public accessibility of private space, arcade gives rise to the “in-between” and inspire the intensive dialogue. The creative milieu of arcade urges the knowledge process to knowledge production.
4. Minquan Road, the oldest streets in Tainan, passing from the prosperity to deterioration, recently gradually recover with the base of knowledge economy. There are more and more knowledge activity presence in the arcade, such as cafés, private galleries and lounge bars and the other “great good places” (Oldenburg, 1989).

Through the explanation of the Model, the “knowledge activity” - various dialogs - could be coming back to the “ruins” in the city centre which left behind in the recession. It could also be observed in Minquan Road in Tainan City, one of the oldest business streets in Taiwan with ca. 400 years history and currently by the process of de-urbanisation. This phenomenon might be explained by the theory of knowledge processes and as the demonstrations of the strategical application for knowledge based urban (re-)development.

Under the background of knowledge economy, the importance of arcades had a chance to be revalued, caused by the spatial condition, might regain their vitality. Facing the situation of shrinking cities, this essay identified a new way: forward to knowledge based urban (re-)development. Taking lost spaces as potential - or even necessary - places for knowledge production could develop into strategy of urban regeneration.

Structured Abstract

Purpose – Study the effects of cognitive style on interdisciplinary scientific collaborative group performance and group satisfaction.

Methodology– We propose an approach of measuring group cognitive style to investigate the relationships between group cognitive style, demographic factors, group performance and predictors of group satisfaction. Group cognitive style will be measured by five psychometric instruments: the Cognitive Style Assessment (CSA), the Kirton Adaption-Innovation Index (KAI), the Herrmann Brain Dominance Instrument (HBDI) and the NEO-Five Factor Personality Inventory (NEO-FFI). Group performance will be measured through authors from different institutions, either as co-authors in a scientific publication or as colleagues within a research project. A ten-items questionnaire will be administered for the measure of group satisfaction.

Value –This methodology puts in evidence that group cognitive diversity may have significant effects on the effectiveness of interdisciplinary scientific collaboration.

Practical implications – The outcomes of the application could optimize the resource sharing and knowledge transfer within the interdisciplinary collaborative groups, and improve the effectiveness of interdisciplinary scientific collaboration. It can be extended in large scale with no limit in academia. Our study could help practitioners, managers and designers make right decision when they design their own collaborative work group.

Keywords – Cognitive style, collaboration, group diversity, interdisciplinary, knowledge work

Paper type – Academic Research Paper

1 Introduction

Knowledge work and knowledge worker are emerging and developing with the novel knowledge economy. The notion of knowledge work and knowledge worker are emerging and developing with the novel knowledge economy, which affect the interpretations, evaluations and practices in different organizations. One paper (Rylander, 2008) argues that knowledge work and design thinking are two different solution-based methodologies. They are different from epistemologies. The former is intellectual or so called analytic approach; the later is an interpretive, emergent and practical embodied approach. However, they also have similarities: highly qualified people are engaging in creative problem solving in both knowledge work and design thinking, and they are having value creation logic base on intensive problem solving. Additional research, Rylander (2009) points out that it is difficult enough to understand design and thinking, so let alone design thinking. Therefore, there is no surprise that people who are trying to apply design thinking to business or more broadly to public service or solve social problem, facing trouble of expressing what it is exactly (Kimbell, 2008). Simon (1969) identified design as knowledge that is in the domain of professions for instance management, engineering or medicine, in his book *The Sciences of the Artificial*. He believed design as a rational set of procedure that response to well-defined problem. But he didn't consider design thinking in his work. Peter Rowe initiated one of the earliest discussions on the concept of design thinking base on his teaching of architects and urban planners (Rowe, 1998). Among huge amount of discussions, design thinking has been featured as what individual designers know, how they approach their work, and as well as how they actually conduct it (Kimbell, 2008). It can be described as a cognitive style (Cross, 1982, Schön, 1983, Dorst, 2006) toward to problem solving. According to this description, design capability of individuals was considered as a form of intelligence, reflection in action and adductive thinking to solve problems.

The growing complexity of products, services, and experiences has been transformed the myth of the solo creative work with the reality of the enthusiastic collaboration (Brown, 2011). Design thinking is a process that bringing integrative thinking, experimentalism, collaboration and empathy in a structured way¹. Collaboration as one of the four key components of design thinking process enables designers find out the interdisciplinary ideas to solve the complex problems and challenges. Collaboration

¹ YouTube: <http://www.youtube.com/watch?v=2-tQJ9RHKRw>

as well as known as one of the major trends of knowledge work, which attracts huge amount of research interest in management theories. It exists in nearly all of the projects-based education and industry, and within or beyond same field.

Many believe that diversity on work groups or teams allows for the richest learning experiences and innovative outcomes (Kress et al., 2012). Diversity is typically addressed as the differences between individuals on any attribute that may indicate that another person is different from self (Jackson, 1992; Triandis et al., 1994; Williams & O'Reilly, 1998). Therefore, it is not limited to race, ethnicity, gender, nationality, income and education level, and any other factors may lead to individual differences. Diversity can be divided into two categories: surface-level and deep-level (Harrison, Price, & Bell, 1998; Milliken & Martin, 1996; Moreland, Levine, & Wingert, 1996).

Group diversity has been found that provide desired effect of affording a variety of perspectives and problem solving approaches, encouraging creativity and performance. However, there is a conflict study indicating that diversity within team or group may have a negative impact on group performance because of creating social divisions (Mannix & Neale, 2005). Furthermore, the results of using demographic indicators to predict group performance have no effect or slightly negative effect on any of the group variable (Mannix & Neale, 2005), which were measured at surface-level in terms of race, gender, age etc. to explain differences in the outcomes of group performance.

Recent researches attempted to examine diversity by linking psychological and cognitive mechanism to group performances. Cognitive diversity in the group is associated to differences in deep-level, or non-visible level (Harrison, Price, & Bell, 1998; Milliken & Martins, 1996; Moreland, Levine, & Wingert, 1996). The characteristics of the group members comprise knowledge, perspective, and information-processing styles (Williams & O'Reilly, 1998).

Cognitive style offers a way to inspect the deep-rooted cognitive distinctions exist in functionally varied groups. A neurologist from Harvard stated that cognitive style is a relatively stable individual difference in which individual preferred organizing and processing information (Kozhevnikov, 2007). There are three types of cognitive style are particular interested: verbalization, spatial visualization, and object visualization. The people has highly potential in verbalization tend toward using verbal analytical strategies; those who has highly potential in visualization perform their cognitive tasks primarily depend on imagery; individuals with spatial visualization potential use analytic process,

and use spatial relations to arrange and analyze components; nevertheless, people with objective visualization attempt to use holistic processing on better tasks performance that require identifying global properties of shapes (Kozhevnikov et al., 2005). Researches indicated that cognitive style not only affect a person's performance on information processing, decision making, problem solving, and creative tasks (Chabris et al., 2006; Kozhevnikov et al., 2005; Woolley et al., 2007), but also differentiate individual's profession option and occupational areas (Blazenkova et al., 2006; Kozhevnikov et al., 2005).

Baer et al. used the Big Five personality type predictor (high extraversion, high openness, high emotional stability, low conscientiousness and low agreeableness) to identify individual characteristic related to group creativity (Baer et al., 2008). They indicated that high creative confidence could foster overall group creative performance. Researchers examined high and low spatial and object cognitive style capability. They revealed that when task assignments match to individual capabilities lead to better group performance (Woolley et al., 2008). Another relevant study revealed that cognitive-based social sensitivity or empathy factor, and the distribution of conversational turn-taking affect group performance (Woolley et al., 2010). Kress et al. proposed a model to measure group cognitive diversity through by aggregate from individual psychometric tests, such as Kirton Adaption-Innovation Index (KAI), the Big-Five Personality Index, the Herrmann Brain Dominance Instrument (HBDI) and the Wilde-Type Teamology (Kress & Schar, 2011). This study found the evidence that the presence of certain personal cognitive characteristics can affect group performance.

This paper concentrates on the interdisciplinary collaboration through cognitive style. We review relevant literatures regarding the concept of cognitive style and the available psychometrics instruments to test individual cognitive style. Riding (1994) suggested that cognitive styles affect the individuals' focus and types of activity.

2 Hypotheses

During the past decade or more, there has been a makeable shift toward scientific research that spans disciplines and organization boundaries conducted by groups rather than individuals. Science tends toward highly specialized but the complexity and scope of the huge challenges facing the world today is global problems like climate change, human disease and lack of natural resources, these pressures cannot be addressed by individual

scientists working alone within single disciplines.

Therefore, collaboration from various disciplinary to foster novel knowledge generating is highly required.

Interdisciplinary collaboration plays a critical role in fueling new discoveries and forging innovative solutions to global challenges. In academia, it can be achieved by promoting scientists, with different backgrounds or cross disciplines, work together. Interdisciplinary collaborative group contains both visible (or demographic) and non-visible (or deep-rooted) varieties. The visible variety is easy to see such as age, ethnic, sex; the non-visible variety involves education, personality difference, value, attitude, how they see the problem, and how they solve the problem.

We advanced two hypotheses to study the effects of group cognitive diversity on interdisciplinary collaboration.

Hypothesis 1 — Higher level of cognitive diversity obtain better outcomes of interdisciplinary scientific group performance.

Hypothesis 2 — Greater cognitive diversity associate with lower level of group satisfaction.

3 Measurement of cognitive style

Messick (1984) describe cognitive style as consistent individual differences preferred way in which processing information and experience. Sternberg and Grigorenko stated cognitive style as representing “a bridge between what might seem to be two fairly distinct areas of psychological investigation: cognition and personality” (Sternberg & Grigorenko, 1997: 701). Cognitive style includes plenty of constructs, for instance field articulation, extensiveness of scanning, cognitive complexity vs. simplicity, leveling vs. sharpening, category width, reflection vs. impulsivity, automation vs. restructuring, and converging vs. diverging (Lohman & Bosma, 2002). Within the framework of information processing, cognitive style was interpreted narrowly as consistencies in modes of perception, memory and thought (Messick, 1989).

Various psychometric tools are available to assess individual cognitive style. Messick (1984,1996) suggested cognitive style can be observed through bipolar scores and value differentiated, as well as performance and use ipsative or contrasted scores. For any given cognitive style measure contains 3 steps (Kress & Schar, 2011). The first measure is a group mean score. This is simply sum of the individual scores divide the

number of group members. The second measure is standard deviation (SD). It is the measure of the variance of scores within the group. The third measure is Cronbach's D (D).

In this study, the psychometric instruments we intend to use include the Cognitive Style Assessment (CSA), the Kirton Adaption-Innovation Index (KAI), the Herrmann Brain Dominance Instrument (HBDI) and the NEO-Five Factor Personality Inventory (the NEO-FFI also known as Big-Five Personality Index). These four instruments are selected from great number of potential psychometric instruments base on the relevancy of our construct of cognitive diversity and extended scientific support in the literature.

Cognitive Style Analysis — Riding's Cognitive Style Analysis (CSA) score has been used to test cognitive style in two dimensions: wholist-analytic (WA) and verbalizer-imager (VI). Wholists are those who process and organize information from a global viewpoint. Verbalizers are the individuals "consider information they read, see and listen to, in words or verbal associations" and experience "fluent spontaneous and frequent pictorial mental pictures" (Riding, 1994: 48). Riding (1994) has indicated that cognitive styles can affect the individuals' focus and types of activity. The verbalizers prefer a stimulating and social environment in which they can find themselves as an extension of themselves. While the wholists tend to be dependent and gregarious, they interact with the structure information and organization of the contents of instruction, and favorably by different cognitive style groups.

CSA is presented and scored by means of a PC. It is comprises of four sub-tests for measuring two dimensions. The first part of CSA is a test of the VI dimension describes a person's habitual mode of representing the information in memory during thinking. Subjects will be asked to judge whether a number of statements relate to visual experience are true or false; The second part is asking verbal-imagers to judge whether a number of statements relating to conceptual categorization are true or false; The third part is to measure WA dimension that describes the habitual way in which a person process and organize information. Subjects are required to judge the similarities of pairs of geometrical shapes are true or false; The last part is to measure WA dimension by requiring subjects to judge whether a simple shape is contained in a simultaneously presented complex geometrical shape is true or false.

Kirton Adaption-Innovation Index – Michael Kirton developed KAI in 1976 to explain cognitive tendencies and problem-solving styles. The KAI is a 32 items self-

reported instrument that requiring the respondents to indicate their ease or difficulty in presenting themselves, consistently, over a long period, in various situations (32-items). It returns a single preference score on a bi-polar scale ranging from “adaptor” to “innovator”.

Adaptors are the individuals tend to prefer the adaptive approach to problem solving, and desire to do things better. They like to solve problems within the existing framework (Kaufman, 2004), and concern with solving problems rather than finding them, seeking solutions to problems in tried and understood methods with habits of precision, reliability, efficiency, methodical, prudence, conformity (Kress & Schar, 2011). The adaptors also rarely challenge rules and sensitive to maintaining group cohesion.

While the innovators, prefer the reverse, seeking beyond the existed approaches to solve problems with an aid of innovative technologies. They would prefer to do things differently. Innovators seemingly undisciplined, approaching tasks from unsuspected angles, treating accepted means with little regard, providing dynamics to periodic revolutionary change and having low self-doubt in generating new ideas (Stum, 2009).

Kirton has adopted an orthogonal, one of the axis namely problem solving level that reflect the experience with problem solving (Kress & Schar, 2011). The high level adaptors understand adaptive technic best, and they can recognize when is valuable to break a rule. Also, the high level innovators understand when it's not wise to break a certain rule.

Herrmann Brain Dominance Instrument (HBDI) – The HBDI is accomplished through a 120-question survey, four different thinking quadrants and compares each to one another. This results in a four-quadrant profile of degree of thinking preference or cognitive style.

Quadrant A reflects a preference for solving problem in logical, analytical, quantitative, factual and critical solutions; Quadrant B shows a preference for sequential, organized, planned, detailed and structured reasons to solve problems; Quadrant C demonstrates a problem solving preference of emotional, interpersonal, sensory, symbolic and kinesthetic rules; Quadrant D indicates a preference of visual, holistic, innovative solutions to problems (Kress & Schar, 2011).

Herrmann states that around 60% of the human being have two dominate preferences toward problem solving; around 30% of the human being have three dominate problem-solving preferences. Results of Quadrant A analysis, and Quadrant B

methods and procedures, and Quadrant C (teamwork, communication) and Quadrant D (creative problem-solving, system thinking, synthesis and design) have positive correlations; Quadrant A and Quadrant C, Quadrant B and Quadrant D have negative correlations (Felder, 1996).

NEO-Five Factor Personality Inventory (NEO TIPI) – Costa and McCrae’s NEO Personality Inventory was developed with the aim of evaluating the five domain of the five-factor model (FFM) of personality: neuroticism (N) refers to the tendency of experiencing unpleasant emotions and psychological distress in response to stressors easily; extraversion (E) represents the degree of sociability, positive emotionality and general activity in the company of others, and talkativeness; openness to experience (O) reflects the levels of intellectual curiosity, independent judgment and conservativeness; agreeableness (A) indicates altruistic, sympathetic, and cooperative tendencies; conscientiousness (C) shows level of self-discipline, aim for achievement in planning and organization rather than spontaneous behavior (Rosellini & Brown, 2011).

NEO FFI is a 60-item self-report instrument to measure the five personality domains according to FFM. It includes self-descriptive statements of Likert-type scale 1 (strongly disagree) to 5 (strongly agree). The TIPI is a ten-item version of the NEO FFI. It was developed as a replacement where very short measures are desired, personality is not the primary research interest, or researchers can tolerate the diminished psychometric properties with very brief measures (Gosling et al. 2003).

4 Descriptive study

In order to examine the diversity of cognitive style in interdisciplinary scientific collaborative group, we plan to conductive an observational descriptive study in 15 interdisciplinary research groups, with around 200 individual scientists.

4.1 Subjects

This study will examine 15 independent research groups within the context of interdisciplinary collaboration in Dresden University of Technology and other independent research institutes in Dresden, Germany. Each of the participated group has to contain more than two disciplines. There is no specific limitation for group work context. In terms of the group size, the extremely large group may not be concerned in

present study because of statistic consideration.

4.2 Measures

4.2.1 Independent variables

We will administrate four psychometric instruments comprising the Cognitive Style Analysis (CSA), the Kirton Adaptation Innovation Index (KAI), the Herrmann Brain Dominance Inventory (HBDI), the NEO Five Factor Personality Inventory (NEO FFI) as evaluated by the Ten-Item Personality Instrument (NEO TIPI). All these four instruments are the self-reported survey. We will collect the standard demographic data (such as age, gender, group size etc.) simultaneously with psychometric instruments.

4.2.2 Dependent variables

We will examine performance of interdisciplinary collaboration and group satisfaction as dependent variables. Precedent researches suggested using scientometric and bibliometric to study interdisciplinary collaborations (Bordons et al., 1999). According to scientometric approach, such as co-word and co-classification analyses were initiated mapping a specific research field works as tool for cross-disciplinary study. Bibliometric approach is base on the analyses of documented references that include different disciplines (Porter & Chubin, 1985; Tomov & Murafov, 1996). An earlier study attempted to study interdisciplinary collaboration by analyzing the authors from different backgrounds like thematic designation of their institutions (Qiu, 1992). Some other researchers measured cross discipline collaboration by analyzing the number of disciplines cited in a given journal (Qin et al., 1997). Some other researchers (Qin et al., 1997) has combined the scientometric and bibliometric approaches and analyzed the relationship between research collaboration and interdisciplinarity. They measured interdisciplinarity by the number of disciplines cited in a given journal.

In present study, the performance of interdisciplinary research collaboration will be measured through authors from different institutions, either as co-authors in a scientific publication or as colleagues within a research project within research network in Dresden. The scientific publications will be selected from the year of 2012 to 2013 covered by Scientific Citation Index (SCI) and Social Science Citation Index (SSCI).

In terms of the measurement of group satisfaction, subjects will be asked to finish a satisfaction survey. It will investigate the conflicts and conflict resolution with the group,

sharing objectives, appreciating and closeness of group members, leadership, group work capabilities and overall satisfaction with group performance. This survey will be administered on a Likert-type scale.

4.3 Expected results

After data collection, factor analysis will be employed for data analysis. Our expected results including:

1. Relationship between demographic factors and group cognitive diversity;
2. Relationship between demographic factors and group performance;
3. Relationship between demographic factors and group satisfaction;
4. Relationship between the measurements of cognitive styles and group performance;
5. Relationship between the measurements of cognitive styles and indicators of group satisfaction.
6. Relationship between the group cognitive diversity and group performance.
7. Relationship between the group performance and group satisfaction.

5 Conclusion

This paper reviewed relevant literatures of the concept of cognitive style, available measurement of psychometric instruments, and described our proposed study in the context of interdisciplinary scientific collaboration.

Structured Abstract

Purpose – Ever since it was argued that the process of knowledge creation can be modelled [Nonaka & Takeuchi 1995], the literature on designing spaces conducive to innovation and knowledge management has grown tremendously. While most of the theories and models are implemented at organisational level in the companies, the paper examines the applicability of theory to an educational campus. As much as the need for informal interaction has been emphasized upon by various knowledge creation and knowledge management models, as much has it been compromised upon in practice, more so, because of the limited knowledge on how to purposefully create such spaces.

Design/methodology/approach – The paper is based on the assumption that when users are responsible for the design of their environment, they connect better and as a result the spaces produced are used to their maximum potential. Besides creating diverse working environments, it also increases the probability of knowledge creation. It has been proven before that process of design of spaces intentionally for innovation can at times be too obstructive or imposing ^[2]. Hence, it's best to let the users shape their working environment as per their needs.

To support the argument, the paper evolves a toolkit, which may essentially act as a DIY-Space kit for the design of informal learning spaces. The insights from the research highlight the spatial requirements for innovation across cultures.

Originality/value – The paper challenges the traditional assumptions about learning spaces and rethinks over informal spaces as the torchbearers for knowledge creation. It also reviews the growing literature on knowledge architecture, critiques it, and develops some of the research questions that could be explored to contribute to campus planning and to the theoretical perspectives that underpin the literature.

As is said, failures are the best teachers. The paper reiterates that the spaces that support failure are the ones that support knowledge creation. Adaptability and flexibility (in terms of space, furniture and technology) have been demonstrated as the two overarching criteria which determine the usability of a space. DIY approach allows users to be the controllers of their environments and shape it to their needs.

Practical implications – While knowledge creation model in an organisation restricts the knowledge among the employees of a company or type of company (when the person switches job), the knowledge creation in a campus is all the more dynamic. As people from various disciplines use and shape the space as per their needs. Findings of the research will add to the knowledge and understanding of the subject of knowledge creation through informal interactions on educational campuses. This study should be significant in the sense that it will allow the identification of spatial characteristics of informal spaces in educational campuses, support and enrich campus planning theory and model of learning beyond classrooms. DIY Urbanism has been used as a manifestation of participatory design approach which connects the users to the space. As a user is more conscious of the spatial response generated, he attempts to deliver responsive spaces. The campus is a scaled down version of a city, where experiments are easy to implement and the results clearly visible. If this knowledge creation model can be effectively applied at campus level, strategies can be drawn from it to make the whole city as a knowledge hub.

Keywords – Campus Design, DIY Urbanism, Interaction, Knowledge architecture

Paper type – Academic Research Paper

1 Introduction

The world has always appreciated and acknowledged the revolutionary ideas. We also generally tend to appreciate the product more than the process. That may be a reason why we generally tend to neglect the inspiration behind the idea and the space which facilitates the development of the idea. The inspiration could be any object or phenomenon in the space or the space itself.

It is difficult to design a space that will not attract people. What is remarkable is how often this has been accomplished – William H Whyte

The words stand true particularly in the case of educational campuses which are witnessing drastic variations, many degrading over time. Issues of rising absenteeism and increased engagement among youth on social networking platforms bears a testimony to the fact that our spaces fail miserably in inviting and engaging students. Besides lacking any spatial and architectural definition, educational campuses are also failing as centers of knowledge creation.

However, students for the thick of their academic life are seen perpetually engaged in cafeterias and canteens, indulged not just in food but also in discussions and debates over topics that excite them or interest them. The “informal spaces” on educational campuses, as these are most frequented by the students for a “change of place”, “hanging-out”, interaction, and group activity and so on. These places are generally identifiable for the “gastronomical” delights they offer. But a closer observation reveals that it’s not just food that these places offer, but also “food for thought”(ideas) and spaces to facilitate the thought through communication (interaction). It’s not just coffee/tea brewing, but umpteen ideas as well. Knowledge is constantly being created and shared.

Famous Urbanist William H Whyte in his book, the social life of small urban spaces, states that

Food serves as people’s magnet

“What attracts people most, it would appear, is other people.”

Food attracts people who attract more people

The central idea of the paper is to identify the spaces that bear huge social potential and to develop a methodology to translate that immense social potential into knowledge potential.

2 Knowledge sustainable campus

2.1 Knowledge dynamics

While urbanism aims at addressing the issues of interaction of the inhabitants with the built environment to find solutions to issues like infrastructure, imageability, transportation, etc. The focus of knowledge urbanism lies on the campus (schools and universities) and its relation with the city. It attempts to develop spaces and strategies to maximise intellectual collisions, which further lead to knowledge creation. The SECI model [Nonaka & Takeuchi 1995] proposes knowledge as a continuous loop extending through the phases of socialisation, externalisation, combination and internalisation. We can decipher from it that Interaction is directly proportional to knowledge creation. The interaction may happen directly amongst people, or among people mediated through technology or among people and technology. The only places on campus which provide freedom for exchange/discourse, retreat and speculative experiment are the informal

spaces. Hence the potential of these informal spaces in creation, and sharing of formal knowledge cannot be undermined.

2.2 Knowledge sustainability

A knowledge society generates, processes, shares and makes available to all members of the society, knowledge that may be used to improve the human condition [Wikipedia]. The concept of knowledge society differs from the earlier concept of information society. While the information society was focussed in codifying the information to form a product which would ultimately reach larger audiences, knowledge society is more focussed on making raw knowledge available to the masses.

In order to promote the development of knowledge societies, platforms are needed for dissemination, transfer and utilisation of knowledge. The role of an educational campus hence is very critical as it is situated at the intersections of research, innovation and education and has much wider implications on knowledge economy and knowledge society. The educational campuses world over are dawning upon a new image of knowledge institutions or research institutions, because of the realisation of their significance for the development of knowledge societies.

Knowledge societies need to focus their attention on the development of the concept of sustainability as it can transform into a future strategy for its development. The term sustainability also needs to be looked into not just from an environmental perspective, but also from an economic and social perspective. The paper hence proposes the idea of designing informal learning spaces as an imperative to deliver knowledge sustainable campus. While the economic, social and environmental factors are already crucial and important for these informal spaces, addition of knowledge as the fourth dimension could help transform them into a learning space.

A knowledge sustainable campus, where knowledge is constantly created, shared and added to may sound like a utopian concept, but it essentially talks about a few things

- a. A symbiotic relation between the campus and the city where both benefit from the resources and infrastructures of each other.
- b. Where while newer forms of learning are introduced to students in formal learning spaces, they are experimented with in the informal learning spaces.
- c. The three key elements at play to achieve desired results are people, place and pedagogy and the interrelations amongst them.

3 Campus planning and Design

3.1 Campus spaces

A campus structurally and functionally resembles the model of a city albeit at a reduced scale. As it provides a much controlled and implementable scale, it can also be experimented with to address the issues and concerns for knowledge cities. The inferences drawn from the campus level experiments can be multiplied in magnitude and complexity to address concerns of a knowledge city.

Before we dwell into the details of campus spaces, it is critical here to understand the relation, a campus shares with the city. Based on observations, there are three types of campus-city relations.

- a. Campus in the city – A model which can be seen in many of the western universities, wherein the elements of a campus are scattered in the fabric of the city. These campuses do not have a boundary wall and hence allow for a symbiotic relation between the campus and the city. The campus benefits from the spaces and infrastructure provided by the city and the city benefits from the knowledge generated by the campus.
- b. Campus and the city – A model of campus which is common in India and a few Asian countries, wherein the campus in itself is a complete entity within the city. A boundary wall acts as an interface and segregates the two entities. The more porous the boundary, the better knowledge flow within the city.
- c. Campus as the city – Sometimes owing to the high density in the urban core the campuses emerge at the outskirts of the city. The campuses in such cases are an extension of the city.

Inferences drawn from various knowledge architecture models are being used to create workspace design for organizations to foster creativity and innovation. The paper attempts to draw the attention of the pedagogists, administrators and architects towards the benefits of implementation of such models for

educational campuses.

Firstly, In an organization, many initial concepts generated go through various stages of processing and refinements to develop into ideas and finally into design products which ultimately reach the market. While the finished product does reach wider audiences, the knowledge behind it does not. In contrast to it, in an educational campus it is the process and the knowledge about a product which reaches larger audiences. Secondly, every organization would generally be dealing with a similar knowledge base, while educational campuses on the other hand would be dealing with multiple disciplines which add to the possibility of interdisciplinary research.

Thirdly, employees of an organization, tend to settle in the same or similar organizations. It creates a possibility of knowledge stagnation, unlike an educational campus where knowledge is constantly shared and re-built. Lastly, as thousands of students enter and pass-out of college each year, it serves a large number of audiences and hence the knowledge impact is even more dynamic

3.2 Placemaking

There exists a dichotomy in the planning and design of informal learning spaces. While literature says that informal spaces must be designed to enhance the learning experience, it also has been proven before that process of design of spaces intentionally for innovation can at times be too obstructive or imposing.^[2] The issue of the design of informal learning space can be dealt by the concept of placemaking through “Power of 10” presented by PPS – Project for Public Spaces. Placemaking is a term that architects and planners use to describe the process of creating ‘Urban Spaces’ which attract people because they are pleasurable or interesting. Campus planning is one such niche where careful dynamics of formal and informal public spaces come into play to create activity- based environments conducive for healthy interaction and calibrated isolation

Based on a nine minute movie by Charles and Ray Eames, the “Power of 10” concept essentially states that a place should not be mono-functional. Every place should offer multiple activities to keep the user engaged with the space. The approach for the design of informal learning spaces should hence be an activity-based one. It would be a conscious approach to deliver contextual spaces. It would enable an architect to consciously think of the architectural design attributes essential to fulfil the requirements of a particular

activity. Besides promoting better usability and enhanced user experience, it would mark a transition from pretty architecture to serious urbanism.

Priming a concept presented by Nobel laureate Daniel Kahnemann in his book thinking fast and slow gives a cue on how to translate the casual conversations (informal activities) into meaningful discussions (informal learning activities). It can be seen as a subliminal effect wherein exposure to a stimulus causes impact to other. The easiest and the strongest impact is created by the activities that other people sharing the same space are engaged in. Hence the activity zoning is a crucial primer besides visual, audio, textual and interactive primers.

3.3 A review of architectural practices

Ocularcentrism has indeed failed to engage the sensibilities of vivid users, reducing the entire experience of architecture to two-dimensional thereby reducing the places to spaces. The restlessness and failure of sensory stimulation in spaces has translated into an “emotionally unstable architecture” which in its random forms, shapes and colours, violates the basic essence of socially responsive and interactive “places” and not just spaces.

The role of an architect is similar to that of a doctor; both can enable the disabled or disable the enabled. It is essential here to understand the role of an architect as a facilitator rather than a dictator for what happens within the space. This makes it critical to review the state of the art practices and trends for the design of campuses in general and informal learning spaces in particular. The review is essentially contrasts campus planning process in India and the west, based on intercepts from the interviews of architects.

While the concept of hybrid buildings, collabratories, etc. are gaining momentum in the west. In India Architects fancy the idea of distinctive zoning. Clearly defined and segregated zones, which essentially reduce the multifunctionality of a space, possibilities of interdisciplinary intellectual collisions or collaborations, are hence contradictory to the idea of knowledge urbanism.

Secondly a large part of the stakeholders, students, teachers, administrators and architects alike are stuck with the image of an informal space as one which can be used for socializing and eating. While it is true, but it has many more facets as well which have

not been experimented with and hence the idea of informal learning space has not been much explored.

4 Methodology

4.1 Design Approach

As witnessed through surveys and case studies Specificity and Formality determine the preference of the user for a particular place. While the user prefers spaces that are multipurpose instead of being specifically dedicated to one activity, there is also a greater affinity for spaces that are neither completely formal nor completely informal, but strike a balance.

Spaces are also re-moulding themselves to change to the needs of the new age societies. The active studio culture has been more effective than the classrooms. Libraries with café's and student interaction areas are more inviting than the traditional ones.

The design approach for designing informal learning spaces will hence be based on:

- a. Informal space indicators
- b. Design of multi-activity spaces

Informal space indicators: Mc Grawhill foundation defines informal spaces as spaces that are highly mobile and maybe changed quickly. The goal is to identify the indicators which determine the informality of a space, using them wisely to create a space that exhibits both formal and informal characters.

- Access to all: Informal spaces are “anyone, anywhere, anytime” spaces. They are used by all and should not be discriminatory on the basis of gender, occupation or disabilities. They can be found outside the building in the form of cafeteria's and parks, inside the building as lobby, foyer or courtyards and even as connecting spaces.
- Freedom of:
 - interaction
 - collaboration
 - physical movement
 - social engagement
- Retreat and Relaxation: Informal spaces are enable disconnecting from an engagement to re-connect better.

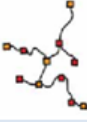

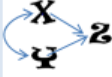

- No monitoring : Though keeping a vigil to ensure no wrong doing within the space is essential but direct monitoring and guiding the user through space can become to oppressive.
- Proxemics : Based on E.T. Hall's theory of proxemics, informal spaces should provide for both private space for personalised discussions and public space to address the gathering
- No time restrictions: As the work cultures are changing, provision of 24x7 spaces has become essential to facilitate the users
- Flexible spaces: They should be flexible in the face of changing needs of the varied user groups.
- Highly Interactive: Technological connectivity enhances the quality and extends the physicality of informal spaces.
- Collaborative layout: Besides, relaxation and interaction, these spaces need to accommodate the various learning styles

4.2 DIY Toolkit

The toolkit proposes a methodology for the design of informal learning spaces. Since the methodology focuses on an activity based design approach, it enables the stakeholders to evaluate their space.

An activity based design approach negates the idea of standardising design solutions based on dimensions, shapes and sizes. It instead figures out the activity/activities that the user/stakeholder wants to carry out in a space. Based on the nature of the activity, the qualities of spaces are listed. Further an architect consciously thinks of design attributes which will help deliver the qualities of the space required. As it does not use an extensive jargon of architectural and construction terms, it helps a user understand the design process and put forth his valuable suggestions. Further since every place would have a different activity requirement, it would help deliver place specific design solutions which would contextually be more relevant. Also instead of handing over all the power in the hands of the architects it enables the user also to evaluate and critique architect's work, the process may go on until a design solution acceptable to the user is arrived at. Further this toolkit particularly deals with existing educational campuses

-----QFD(House of Quality)-----

LOOK	OBSERVE	IDENTIFY	INTERPRET	CORRELATE	PROPOSAL	EVALUATE	DESIGN
			$1+2=3$				
... at campus as an informal learning community. Understand issues	...establish a typology of spaces. Choose target location	Identify users and activities associated with such spaces	The quality and design attributes of the space	The activities (user requirements) with design attributes	Summarize findings and create draft design proposal		An iterative process.

Look: The first stage would include walking around and looking through the campus, without formulating any prior definition about informal and formal spaces, so as to avoid missing out on any. This includes preliminary surveys, photographic surveys and site documentation

Observe: The second stage deals with organising the information gathered. The spaces documented and analysed are grouped to create a typology of informal spaces. A space from each typology is then chosen to analyse the design considerations and applicability of the toolkit.

Identify: conduct an activity based audit of the space to understand the specificity or multiplicity of space. It also helps understand whether the space is underutilised or lively. The users/stakeholders of the space need to be identified and questioned on the kind of activities they would want to happen within the space. This list of activities generated also needs to be prioritized based on the preference of the users.

Interpret: Every activity on the list would require a particular environment or a spatial quality. A list of spatial qualities and architectural design attributes important for delivering the desired quality within the space needs to be formulated.

Correlate: Using the Qualitative function deployment approach and House of quality as the tool, the activities can be correlated with the spatial qualities, to arrive at the prioritized qualities of a space. Further, the prioritized spatial qualities can be correlated with architectural design attributes to arrive at a list of prioritized design attributes.

Proposal: The prioritized list of design attributes is then used to create design proposals with required design interventions.

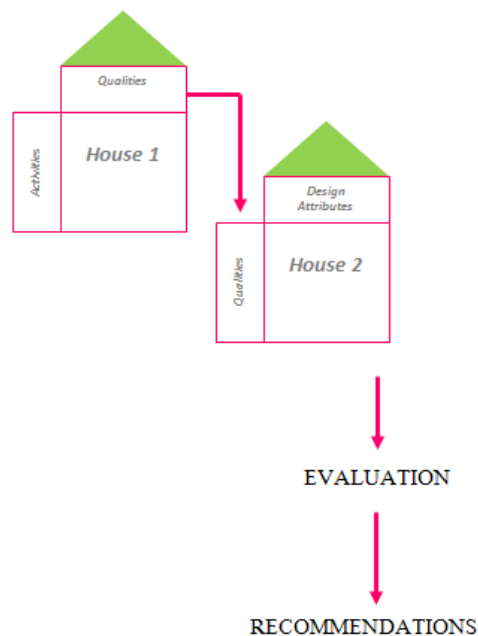

Evaluation: The architects would then be required to explain their design proposals to the users, who again using the Qualitative function deployment- house of quality tool will evaluate each design option against how well does it cater to each activity suggested.

Design: The evaluation and design process is an iterative one to ensure maximum user satisfaction.

7 Conclusions

As shown though the paper, the design of the process for creating informal learning spaces holds more potential than the design of an informal learning space in itself. Care has been taken to ensure context specificity in the design outcome arrived at through the given approach. The paper also attempts to clear the misconceptions about toolkit approach for design. Firstly, the idea that a toolkit for design would kill design creativity, the notion has been put to rest as the toolkit is not a design technique but a guide through the design process. It is a systemized process to present, correlate and ultimately evaluates design solutions through an iterative design process.

Secondly, the idea that a good design professional does not need QFD approach has been put to rest. As while the design carries the voice of an architect it needs to be in sync with the needs of the user. QFD is one such approach which carries the voice of the customer/user through various stages of the design process. It also empowers the customer/user to challenge the design of the architect on parameters understood by hi, i.e. the activities.

Structured Abstract

Purpose – The goal of this research is to find an alternative theoretical and technical method of urban environment's management. This method should solve current town-planning problems connected with the coexistence of urban systems. The received method must be adaptable to the management of any urban object. It must be orientated both on the improvement of urban structure's sustainability and flexibility during its formation, functioning and development. The result of received method's application must be the improvement of urban environment's state due to any need of the modern society.

Design/methodology/approach – I propose the application of system principles in formation of urban objects and the Control Theory's methods in their cooperative formation, functioning and development. Both approaches, which are applied in different disciplines, should be adapted to the specific field of urban planning and urban management. However, the first step, that should precede two mentioned processes must be the analysis of current problems in interaction between any considered system and its external environment. This analysis has to be based on the particular features of systems' interaction.

Originality/value – This research puts in evidence that adapted Control Theory's methods and renovated synthesis of System's Theory's and Control Theory's methods can be applied to the modern tasks of urban planning and management. In addition, the uniform model of any urban object's development management will be received. This model will consider such properties of urban objects as self-organization and self-regulation during their cooperative formation, functioning and development. The realization of this control model should lead to the minimization of the indicated tendencies and of the urban environment's stochastic behaviour as a result.

Practical implications – Outcomes of the application lead to the increase of experts' work quality (minimization of the mistakes during the full cycle of any urban object's adjustments) in urban environment's management. The results of received control model's realization should become: quicker reaction of each urban object on the external factors – quicker improvement of considered object due to the needs of modern society and other urban systems; improvement of urban systems' coexistence; improvement of urban environment's sustainability and flexibility; and minimization of its stochastic behaviour.

Keywords – Urban management, urban development, urban systems, Control Theory, Systems' Theory.

Paper type – Academic Research Paper

1 Introduction

Urban environment is constantly in a state of functioning and development. Both processes are significant features of the city and all urban systems that make it up. Due to quick changes of modern cities, the increasing importance of urban objects' functioning and development monitoring becomes more evident.

Among different approaches of urban management, the one that is not used nowadays is – the Systems' Control Theory, even despite the fact that development of the Control Theory is directly connected with the development of cybernetics, which is actual today. Mainly, it is connected with the stagnation of system principles' application in the field of solving urban tasks. It should be noted, that this fact deprives experts of the Control Theory as an alternative method of urban environment's management. Certainly, before the application of this theory in urban objects' development management, it is necessary to identify all urban systems with their structural components, which need to be regulated during their development.

Adaptation of the Control Theory to urban objects' functioning and development management can become one of significant and perspective directions of research activity with integration of the received results in the everyday practice. Therefore, in this article both the features of urban objects' functioning and development and the Control Theory schemes with their adaptation to urban objects' functioning and development management are considered. As an example of town-planning objects existing urban hubs are used, the sum of which will construct urban environment's MPCKs'* system.

* MPCKs' - multicomponent production and communication knots (or hubs, or town-planning centers) of an urban environment, which are localized on the intersection of the transport communications, include in their spatial organization all elements of production and non-production spheres, and also objects of the transport sphere, and are characterized by the raised intensification of functional processes.

2 Features of urban objects' functioning and development

The first step of this research is the identification of distinctive features of urban objects' functioning and development that means the analysis of their behavior during short-term and long-term periods. This allows to focus on positive and negative tendencies of mentioned processes for their consideration in the process of objects' functional and spatial structure management.

2.1 Interaction between urban objects and their external environment

The external environment affects functional and spatial structure of any urban system, in turn; the urban system has an impact on its environment as well. In this case the external environment is – all other components of the city. The result of external environment's impact on the urban system's structure, and changes in the structure after this impact, is the system's adaptation to external conditions. Urban systems, which do not interact with other city's components, are deprived of: informational input signals from other urban systems (about necessary adjustments due to the modern conditions of artificial environment's functioning); input signals of changes in any urban system (which cause necessary adjustments in the other). Therefore, such systems cannot be harmonized in the aspect of their cooperative functioning.

Objective criteria of urban systems' coordinated functioning and development are: their capacity to interact and control of this interaction implemented by the experts. In case, when no control apparatus is included in the process of systems' interaction, the influence of one system on the functioning and development of another can lead to macroviolations of its structure, up to a total collapse of the system, and to microviolations – deterioration in functioning and development of some components.

Functional and spatial structure of existing urban hubs is in close and not regulated interaction with external environment. Non-use of system principles in formation of urban objects, associated with identification of urban objects' structure and all components related to it, cause difficulties in identification of functional and spatial boundaries between urban objects and their external environment. Thereby, determination of external environment's impact, as well as the results of this impact (transformations of object's functional and spatial structure), becomes impossible.

The interaction between existing urban hubs and their external environment is characterized by self-regulation, which leads to the stochastic behavior of hubs' functional and spatial structure. Therefore, the main problem of the objects' response on external influence is not the criteria of their structure's flexibility – ability to be transformed, but stochastic behavior and stochastic changes of their structure due to external impact.

Stochastic transformations of existing urban hubs may cause both: their development, and harmonization of cooperative functioning with other urban objects; as well as the regression of their state and deterioration of cooperative functioning and development with other urban objects. Regressive changes in the structure of urban hubs can start due to

numerous destructive external factors, such as: interaction with lagging in development urban objects (there is no need for urban hubs' improvement); ignoring some needs of the population (with the time urban hubs do not satisfy needs of the population), non-use of modern technologies, design solutions, scientific methods (creative possibilities and development of science exceed methods of urban hubs' formation and modernization), etc.

Fig. 1. Interaction between urban objects and their external environment:
 A) Regulated interaction; B) Self-regulated interaction (existing urban hubs)

For best understanding of system's transformations under the influence of external factors, it is necessary to analyze schemas of its interaction with other urban environment's systems. Interaction between the system and its external environment is shown in schemas of open and closed loop systems, offered by K.J. Astrom and R.M. Murray [1] (Fig. 2). In these schemas of systems' behavior models, one will always be the external environment for another. Authors insist that in interaction between two or several various systems, it is admissible, both existence of systems' feedback, and its absence.

Fig. 2. Open and closed loop systems (Authors K.J. Astrom and R.M. Murray)
 A) The output of system 1 is used as the input of system 2, and the output of system 2 becomes the input of system 1, creating a closed loop system; B) the interconnection between system 2 and system 1 is removed, and the system is said to be open loop

In the scheme of connection between MPCKs' system and other urban system (Fig. 3), becomes obvious, how many cycles of systems' transformations can exist, caused by slightest changes in any of them, and properties of "final" functional and spatial structures can differ so strongly from properties of their "initial" state. In this scheme the level of sensitivity of system's functional and spatial structure to external influence is more detailed. The conclusion about need of numerous and, as a rule, continuous systems' ad-

justments for achievement their harmonious coexistence, increases the role of control apparatus. Addition of control apparatus in the interaction between any system and its environment accelerates stabilization of objects' coexistence.

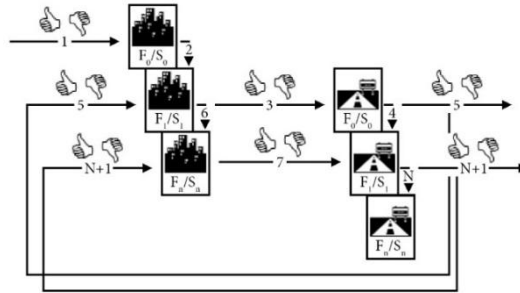

Fig. 3. Connection between MPCKs' system and other urban system (without their development management, but with their emergent property formation)

2.2 Transmission of urban objects' external interaction in their internal organization

Any external factors impacted on the system should cause the response of system's functional and spatial structure – its changes. If after external influences there are no structural changes, the considered system is a closed one – not capable for interaction and cooperative functioning and development with external environment. The regulation of transmission of external interaction in internal organization is the process of experts' work (designing adjustments of system's structure that are necessary due to problems and violations from external environment).

The lack of regulation algorithm in the interaction between existing urban hubs and their external environment is the reason why external factors cause uncontrolled chaotic transformations of urban hubs' structure. In this case, as a rule, specialists do not create adjustments for the object's structure (design decisions for its intensification/modernization). This tendency prevents the formation of the urban hubs' framework, which functional and spatial structure will meet the requirements of balance, proportionality and necessary localization of all components according to the population's needs.

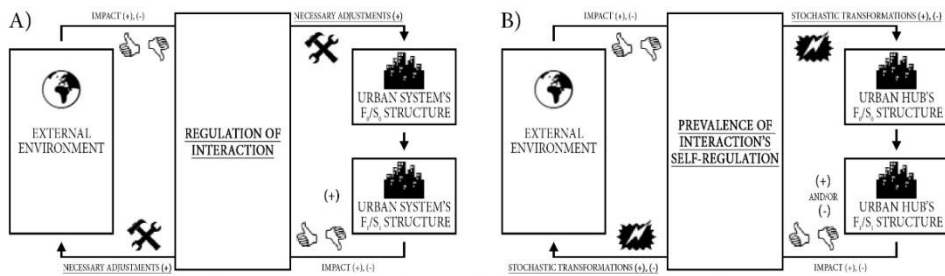

Fig. 4. Transmission of external interaction between urban objects in their internal organization:
 A) Regulated transmission; B) self-regulated transmission (existing urban hubs)

2.3 Reorganization of urban objects due to their internal functions

System functioning and development, regulation of these processes' coherence (not only between the system and its external environment, but also between components inside the system) leads to strengthening, quantitative increase and redistribution of internal components' connections – exchange of matter, energy and information. Urban system's structure, which is characterized by the presence of all necessary components, strong connections between these components, and which has qualitative and quantitative growth of the components and their connections, does not have the entropy tendencies.

Today, existing urban hubs do not have complete functional connections between their components. Both urban hubs' components and urban hubs by themselves in connection to each other function in most cases autonomously. This tendency is caused by the lack of their perception as integral parts of a single system, and each urban hub of this system will be responsible for such functions as: urban-forming, system-forming and connecting point of matter, energy and information exchange.

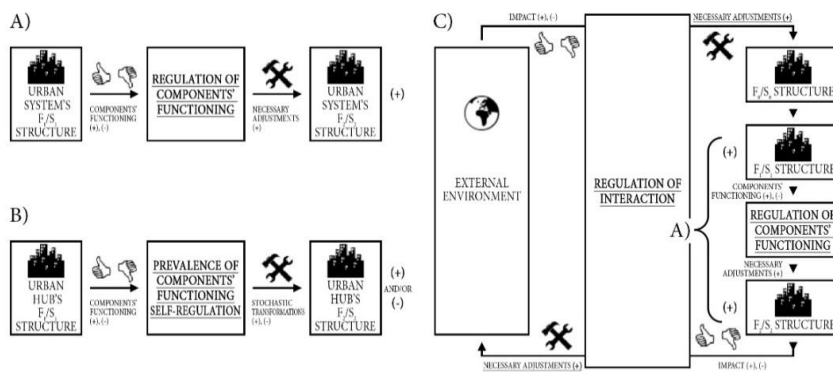

Fig. 5. Reorganization of urban objects due to their internal functions:
 A) Regulated reorganization; B) Self-regulated reorganization (existing urban hubs); C) Integration of regulated reorganization due to internal functions in the process of interaction with external environment

Urban hubs, that were formed without application of system principles, are characterized by entropy processes' intensity. The main reason of entropy processes are difficulties in determination of functional and spatial structure's components, and accordingly, difficulties in formation of their strong connections. No regulation of components' functioning, development and interaction makes possible the exchange of matter, energy and information between object's components and the dispersion of the functional processes in the external environment at the same time.

2.4 Coordinated interaction of urban object's components

Those systems and their subsystems, which represent the indivisible objects, are characterized by strong internal connections, coordinated functioning and development of their components. In addition, this means that the system retains its properties, despite external influences and internal changes. Information about the system's structure, the nature of external factors (which cause the necessity of system's transformation), methods of harmonizing component's functioning and development and the application of control theory – the presence of all listed points at the step of designing structure's adjustments makes possible to improve coordinated functioning and development of the system's components. The presence of strong connections between existing components allows new components to be integrated into the system without causing macroviolations in its structure.

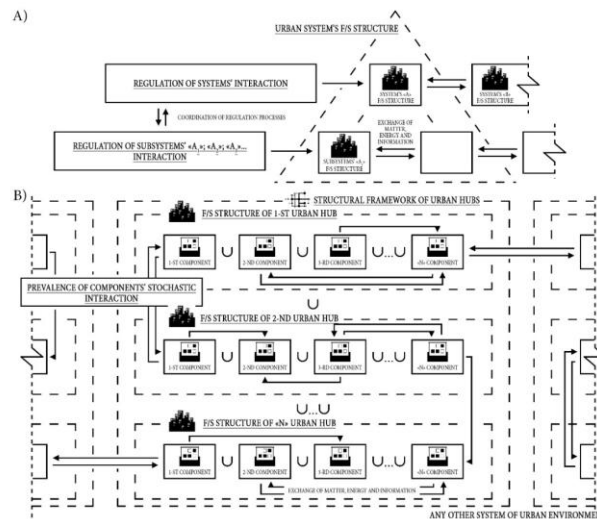

Fig. 6. Interaction between urban objects' components: A) Regulated interaction; B) Self-regulated interaction (existing urban hubs)

During modernization of any subsystem, for more coordinated system's functioning, it is better to improve all other subsystems. However, due to complexity of urban systems' functional and spatial structure, its multicomponent property, the realization of this condition is not feasible in reality. Regulation of system's functioning and development, allows to harmonize the interaction of modernized objects and objects left unchanged.

Today, only some components of urban hubs have coordinated functioning and development due to single regulations or spontaneous self-regulation of their interaction. Pre-dominance of urban hubs and their components, which are functioning and developing autonomously, is a consequence of system logic' non-application in the process of their formation. For existing urban hubs' components, like for most other planning components of the urban environment, asynchronous development is relevant. This tendency is caused in most cases both by interests of private investors in building profitable objects (which do not always meet the real needs of the population) and lack of financing during modernization of other urban hubs' components.

3 Adaptation of the Control Theory to the management of urban development

After the consideration of all these conditions for urban objects' functioning and development and identification of existing urban hubs' current state, it is necessary to focus attention on the importance of urban objects' regulation process during their evolutionary changes. «Here the relation of dynamical system theory to control and control theory becomes apparent: control essentially means that a system which is not asymptotically stable is made so by incorporating a controller counteracting motion of the system away from the stable state. For this reason the theory of stability in internal description or dynamical system theory converges with the theory of (linear) control or feedback systems in external description» [2, 92 p]. Control theory methods can be expedient in the regulation of urban hubs that are functioning and developing, changing their structure, and possessing dynamical properties. Regulation of urban hubs' (MPCKs') system formation, functioning and development leads to improved sustainability of structure and its properties. «Sustainability, however, is not just about the physical environment; it is about preserving and, indeed, enhancing the quality of life for future generations» [3, 161 p].

3.1 Adaptation of the classical control model

Scientific researches in the field of Control Theory use such definitions, as input, output, message, feedback, receptor, effector, control apparatus, etc. L. Von Bertalanffy was one of the first who mentioned the definitions stated above, and offered the scheme of simple feedback (Fig. 7).

Fig. 7. Simple feedback (Author L. von Bertalanffy)

“The system comprises, first, a receptor or “sense organ”, be it photoelectric cell, a radar screen, a thermometer, or a sense organ in the biological meaning. The message may be, in technological devices, a weak current, or in a living organism, represented by nerve conduction, etc. Then there is a center recombining the incoming messages and transmitting them to an effector, consisting of a machine like an electromotor, a heating coil or solenoid, or of a muscle which responds to the incoming message in such a way that there is power output of high energy. Finally, the functioning of the effector is monitored back to the receptor...” [2, 42 p].

Applying the scheme of simple feedback for modeling the scheme of MPCKs’ system’s development management (Fig. 8), the following changes of the prototype scheme’s blocks are made (with preservation of their initial author's sense). The input or stimulus is meant as impact of positive and/or negative external factors on the receptor, or in this case, on the existing system’s structure. Interaction of various external factors and receptor forms the message that is information about structure’s transformations and violations, this message arrives to the control apparatus. The control apparatus is the team of highly qualified specialists who produce design decisions (structure’s adjustments). Experts recombine received message in the message of information about necessary adjustments of system’s structure, then they implement the adjustments, forming by this way the effector. Effector in this case is the system’s structure after its adjustment. Information about state of the structure after its adjustments serves as the response of the scheme, and at the same time, it can be positive and/or negative input for another urban system. While the information about new state is producing, the feedback is happening as well; moreover in the considered scheme feedback is also the information about the new state. This information goes to external factors and forms new cycle of scheme.

After each cycle of regulated system's adjustments, which necessity is caused by impact of various external factors, the updated system's functional and spatial structure representing the improved version of the previous is formed. Each new system's structure in relation to previous has emergent property, at the same time, both structures are similar, but new one possesses some other characteristics. Differences of external system's functional and spatial structure from the "final" one depend on the quantity of the implemented cycles of adjustments and on "force" and "volumes" of external factors.

This way of management considers system's emergent property formation and the idea of repeated recurrence of functional and spatial structure's adjustments. Emergent property and the property of systems' complexity started being actively discussed by scientists only from 90th of the XX century.

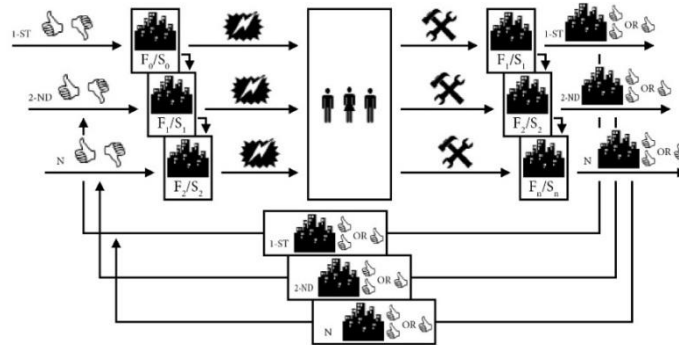

Fig. 8. Development management of MPCCKs' system (with its emergent property formation)

It is important to notice, that the meaning of such steps as the input and output, which appeared in the last scheme, matches with definitions of these steps, formulated by the founder of cybernetics N. Wiener [4]. He said that the output is understood as a change of environment made by the object, and the input is understood as an external event that changes this object.

3.2 Adaptation of the multilevel control model

The Control Theory consider splitting of system's management process into hierarchic levels, that allows to concretize tasks in drawing up design decisions, to reveal the priority of the adjustments' purposes and etc. Modeling of subsystems' management, mainly, increases efficiency of experts work.

In the scheme of multilevel multi-purpose system (Fig. 9), offered by M.D. Mesarovic, D. Macko and Y. Takahara [5], the process of control is directly connected with

subsystems of the lowest level by the signals of management arriving from subsystems to the block of the process and by signals of feedback from operated process. In turn, subsystems are connected by coordination signals from lower to higher and by informative communication from higher to lower.

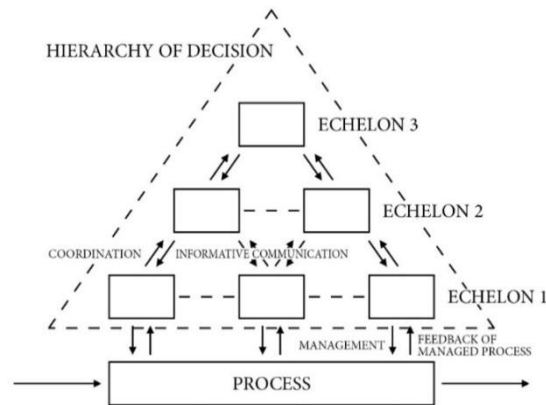

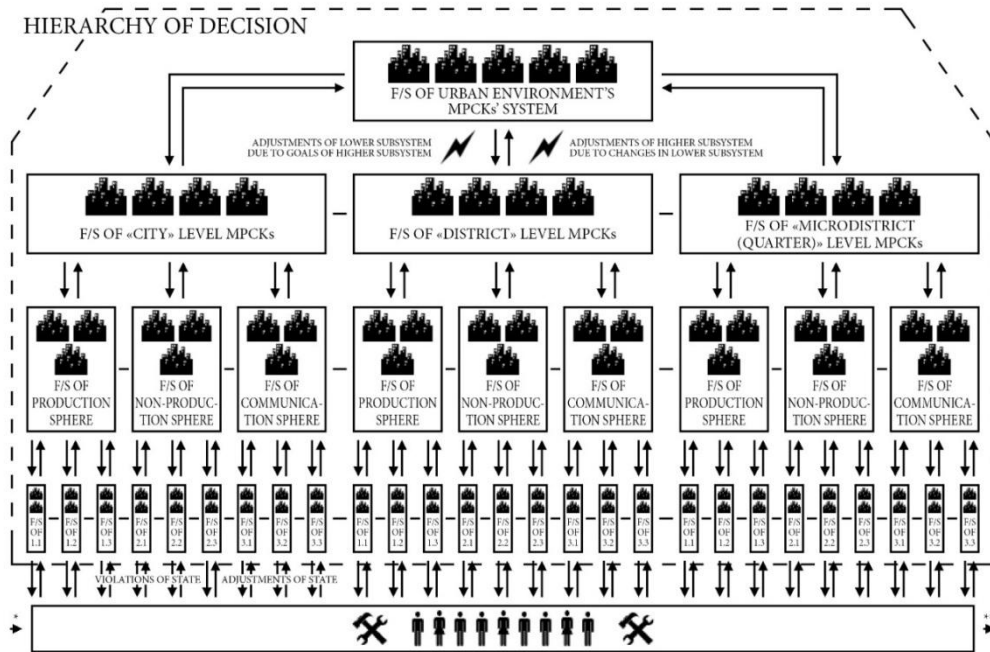

Fig. 9. Multilevel multi-purpose system (Authors M.D. Mesarovic, D. Macko and Y. Takahara)

The subsystems of MPCKs' system are presented by the following hierarchical levels (from higher to the lower): MPCKs of different hierarchical levels; various profile spheres of MPCKs; various components of MPCKs' profile spheres; various objects of profile spheres' components.

According to the scheme of design decisions hierarchy for MPCKs' system formation (Fig. 7), the block of process is meant like the management of development of system's structure. The input of this block is information about desired state of system's functional and spatial structure, the output of considered block is information about developed condition of the structure after implementation of the management process. The block of process is directly connected with subsystems of the lowest hierarchical level, namely components of profile spheres of MPCKs. Corrections of system's functional and spatial structure act as influence signals from operated process. Interrelations of subsystems are corrections of lower hierarchical level subsystem's structure according to the general purpose of higher subsystem functioning and information about necessary adjustments of higher hierarchical level subsystem's structure in connection with changes in the structure of lower hierarchical level subsystem.

Certainly, the nature of functioning or development of any subsystem is caused by the purposes of higher subsystem's functioning. Such impact of the purposes of higher sub-

system's functioning on the lower subsystem has binding character, in this case affects intervention, and in any determined system is shown in changes of lower hierarchical level subsystems.

Components: 1.1 "Material production"; 1.2 "Science and government"; 1.3 "Energetics"; 2.1 "Consumer service"; 2.2 "Culture and education"; 2.3 "Recreation"; 3.1 "Transport communications"; 3.2 "Pedestrian communications"; 3.3 "Communication connections"

*Desired state of system's functional and spatial structure

**State of system's functional and spatial structure formed after its development management realization

Fig. 10. Design decisions hierarchy for MPCKs' system formation (with realization of system's development management)

3.3 Adaptation of the modern control model

In the schemas of information structures, offered by J. Lunze [6] (Fig. 11), scientist suggests to implement management by uniform control apparatus that forms structure of system's centralized control or to break the uniform control apparatus into a set of devices.

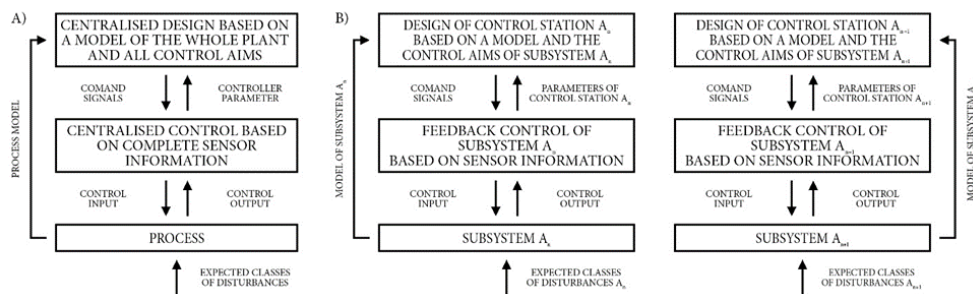

Fig. 11. Information structures (Author J. Lunze): A) Centralized control; B) Decentralized control

Modeling the scheme of development management of MPCKs' system (Fig. 12), in case of centralized control the uniform team of the experts, which is responsible for all adjustments in system's developed structure, is involved. In case of decentralized control, several teams of experts are engaged in management of subsystems. The number of such teams can be equal to number of subsystems or one team of experts can control several subsystems at the same time. The quantity of involved teams of experts depends on the condition of system's structure and amount of adjustments' goals of any subsystem, etc.

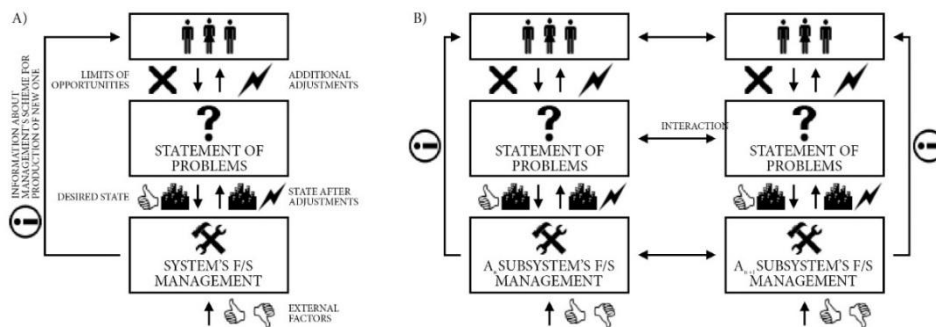

Fig. 12. Development management of MPCKs' system: A) Centralized control; B) Decentralized control

Along with methods of centralized and decentralized control, process of management can be carried out by the principle of long-term and short-term planning or combination of these two principles. The last way is displayed in the scheme of multilayer system, offered by J. Lunze (Fig. 13). Here system's management consists of several stages: strategic layer planning scheduling caused by a signal of long-term prediction, that arrived from environment; the layer of tactical optimization adaptation caused by short-term prediction, that also arrived from environment; layer of feedback control and layer of process.

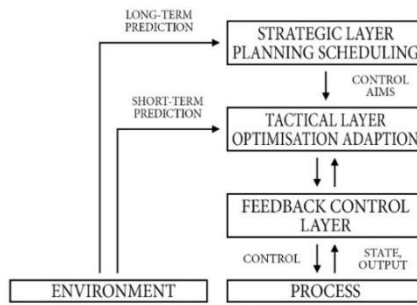

Fig. 13. Multilayer system (author J. Lunze)

The scheme of multilevel development management of MPCKs' system (Fig. 14) is an example of combination of long-term and short-term prediction. Therefore, the team of experts for long-term prediction forms the layer of strategic planning of system's functional and spatial structure, and for its short-term prediction forms the layer of its tactical optimization. Both layers are interconnected by necessary adjustments for achievement of compliance of their purposes and tasks. Thus, the layer of tactical optimization, which is more capable to fast reaction, is interconnected with the layer of control of system's feedback by a signal of a desired state of its structure and receive from feedback layer information about structure's developed state. The layer of feedback's control also sends the message about structure's desired state to the layer of management process, and receives information about structure's developed state, finishing thereby the cycle of system's management.

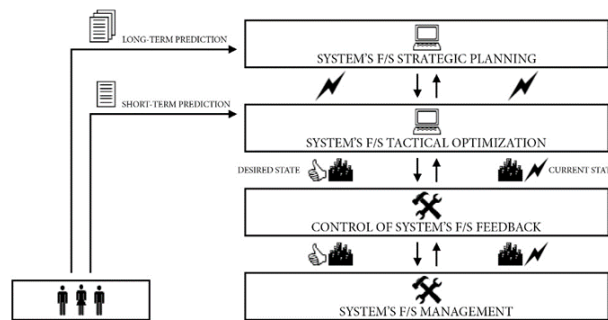

Fig. 14. Multilevel development management of MPCKs' system

3.4 Received model of urban objects' management

On the base of all considered schemes was created the General scheme of development management of subsystems of MPCKs' system (Fig. 14). Transition from the detailed description of the system's control to the detailed description of its subsystem's

control is more correct as splitting the whole into parts and regulation of each part minimizes risks of mistakes.

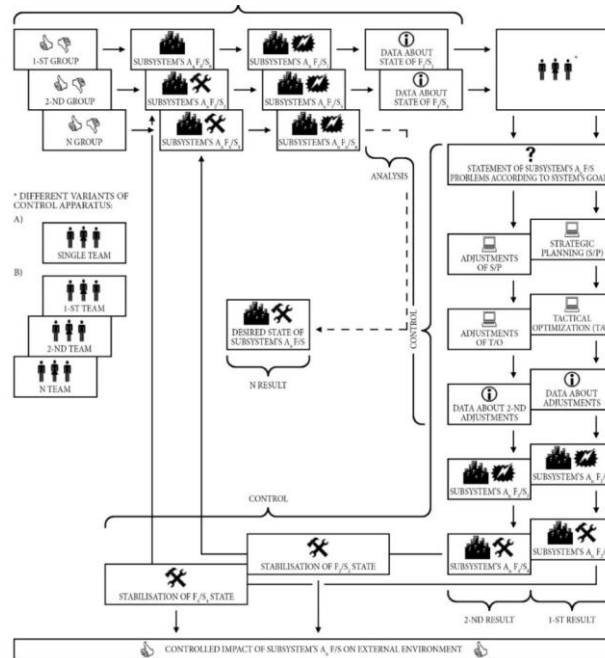

Fig. 14. Development management of subsystems of MPCKs' system (with system's emergent property formation)

Each cycle of this scheme contains four steps: “event”, “analysis”, “control” and “result”. The first step of transformations' cycle begins with the impact of external factors, positive and/or negative, on existing structure of subsystem An, that's how the third structural block of transformed subsystem's structure is formed. The result of the step “event”, and the first block of the step “analysis” is information about transformations and violations of the state. This block belongs to both steps as it is formed because of external factors' influence, but statement of this block is possible only at the step “analysis”, when in scheme's structure control apparatus is involved.

The step “analysis” consists of information about transformations and violations of a state, block of control apparatus, which forms four other blocks of analytical step. Therefore, as the third block of considered step is the statement of subsystem's problems according to the general purpose of whole system's functioning. The block is formed by experts during carrying out the first cycle of adjustments and, unlike others, does not change during the subsequent cycles. Constancy of the block is caused by invariance of the general purpose of system's existence, namely, satisfaction of various needs of the population

in the shortest terms with minimization of expenses. At the specified property of an invariance of this block, its existence is obligatory in structure of each cycle of control. This block forms the main task of control of any subsystem development. The following block of a considered step is strategic planning or long-term prediction of structure's state and prediction of necessary actions for its improvement. Based on the block of strategic planning the block of tactical optimization is formed, this block is the prediction of subsystem's A_n state after realization of one cycle of adjustments. The block that finishes the step is information about necessary adjustments. Four last blocks of the step "analysis" are the first blocks of the step "control". Interaction of the fourth block, the block of information about necessary adjustments, and the fifth block of the transformed functional and spatial structure forms the block of a new subsystem's structure, which is also a resultant step of the scheme (step "result"). The sixth block of the step "control" and feedback of the scheme is the stabilization of new structure's state. This block forms the beginning of the new control cycle, keeping gained during the management process state until the impact of new external factors' group. In addition, after the block of stabilization the block of controlled new structure's influence on its environment follows.

The considered model includes the idea of recurrence adjustments cycles, and also possibility of one experts' team involvement, or its replacements due to specific design tasks and other types of works.

It is necessary to notice the importance of interrelation between management processes of various hierarchical levels subsystems. So management of subsystem A_n is interconnected with sum of management processes of this subsystem's components, and with each process separately. Thus management of subsystem's A_n development is linked with management of subsystems of similar hierarchical level. Sum of all these processes and each of them separately consists is interacted with management of higher hierarchical level subsystem. It is important to note that stated example of subsystem's control model does not change depending on hierarchical level of any subsystem.

4 Conclusions

Based on analysis and synthesis of all noticed in the article schemes, their generalization, the uniform model of urban system's development management appeared. Created scheme is rational and effective interconnected sequence of necessary procedures, which

form reference model of management of any town-planning object's development. The main idea of received control model is its adaptability to any urban system's regulation.

Carried out adaptation of Control Theory to the process of town-planning objects' management, in particular, MPCKs' system's functional and spatial structure, plays an important role in searching of the way for increasing the efficiency of experts' work, for optimization of adjustments' implementation process and for minimization of risks during transformation of any urban environment's object. Application of system principles to urban objects' formation and involvement of Control theory's methods in their functioning and development lead to the regression of urban environment's tendencies of its self-organization, self-regulation, which are reasons of its stochastic and unpredictable transformations.

Structured Abstract

Purpose – This paper describes how the city of Tampere in Finland developed its knowledge-based management, organized its strategic knowledge management and systemized its knowledge-based decision-support.

Design/methodology/approach – Theoretical background of the paper is on strategic knowledge management and public management. The main empirical data was gathered in an intense action research process, which was carried out between December 2013 and January 2014. This process included three development workshops and several preliminary and follow-up discussions where workshops were planned, analyzed and iterated. As secondary data, strategy documents, reports from previous development initiatives and the key findings of a maturity analysis on the state of knowledge-based management were used for mapping the starting point of the development work.

Originality/value – The paper contributes with its holistic perspective to public knowledge management and by providing empirical illustration on the strategic knowledge management at the city level. The literature has pointed out the narrow focus of earlier approaches. Their focus has been, for example, on the role technology and e-government or in some specific branches of public service provision.

Practical implications –The paper lays a foundation for developing a knowledge-based management culture in public organizations. Simultaneously, it puts in evidence the central role of the municipality and its knowledge management in fostering the vitality of the wider service ecosystem. Without proper knowledge and understanding about the efficiency and effectiveness of service operations, service providers and ways of organizing it is not possible to make informed decisions.

Keywords – knowledge management, public management, public services

Paper type – Academic Research Paper

1 Introduction

The Nordic welfare model is built on a strong role of the state and public service provision. In Finland, municipalities are responsible of providing many basic services (e.g., health and social services, transport and infrastructure services) and can therefore be considered as keystones of their local service ecosystems. This is followed by a responsibility of ensuring effective and efficient service provision as well as vitality of the service ecosystem. These tasks raise many managerial information needs. This paper addresses the gap in current understanding about the role of knowledge-based management of public service provision.

Public services are provided by a complex and integrated service system where individual organizations continuously interact and collaborate with each other to provide value for customers (e.g., Laihonon et al., 2014; Grönroos and Helle, 2010; Spohrer et al., 2007; Tucker and Pitt, 2009). Furthermore, a need for interaction is stressed also internally between functions and administrative sectors. Public management literature has responded to this change in management practice by introducing New Public Management approach (NPM) (Hood, 1995; Pollitt et al., 2007). Decentralization of decision-making, customer-orientation and management by results are some practical results of NPM (e.g., Sanderson 2001; van Helden et al., 2008).

More recently New Public Governance (NPG) approach has been introduced in public management domain (e.g., Billis, 2010; Kylänen et al., 2012; Vuori, 2011). The main strength of the NPG relates to its aim to understand the fragmented production and delivery of public services. In an environment of contradictory interpretations on the goals between public agencies severe problems may arise. However, both NPM and NPG pay only modest attention to information flows and knowledge process. Their main contribution relates to the recognition of knowledge as an important resource for public decision making and acknowledging that networked and systemic nature of public service provision increases the complexity of knowledge-based decision support and respective information and knowledge processes.

On the other hand, knowledge management literature states that “current examples of public sector knowledge management are narrowly focused and do not provide rich data on the strategies and experiences of those engaged in the process at the organizational level” (Edge, 2005, p. 45). Focus has been on the role of technology or e-government (Ling, 2002) or in some specific branch of public services, such as, police (Luen & Al-

Hawamdeh, 2001), education (Edge, 2005; Syysnummi & Laihonen, 2014), and health care (van Beveren, 2003; Laihonen, 2012; 2014).

Also the practical need for new understanding and solutions to support public decision-making at various levels of the system is high. Public managers need timely information for example, about the costs, customer needs, efficiency of operations, as well as quality and effectiveness of services. However, lack of understanding about knowledge management as a tool for supporting municipalities in attaining their goals seems to prevail. To bridge this gap, this paper describes how the city of Tampere in Finland approached managerial information needs, organized its strategic knowledge management and systemized its knowledge-based decision-support. The framework is intended for the use of the whole city in fostering the ‘managing with knowledge’ thinking, which has a high priority in strategic management of the city and is directed by one of central administration’s directors. Figure 1 summarizes the research design.

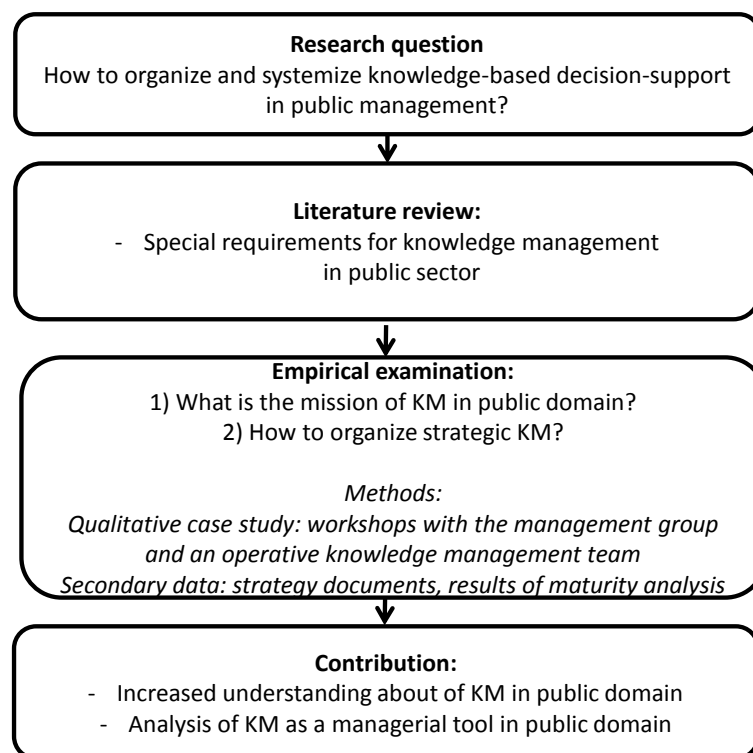

Figure 1. Research design.

The rest of the paper is organized according to the research design. Section 2 reviews the literature and presents the conceptual framework of the paper. Section 3 describes the

empirical research methods and the process of developing knowledge-based management in Tampere. Section 4 analyzes the empirical process from the viewpoint public knowledge management. The concluding section summarizes the key findings of the paper and suggests directions for further research.

2 Theoretical framework

2.1 Public management

Criticism towards efficiency and effectiveness of public services was raised in many OECD countries in 1980s (Hood, 1995; Pollitt et al., 2007). As a result, along with many other changes, new management techniques were applied as a part of the New Public management approach, which aimed to overcome the self-orientation of bureaucratic systems (Hood, 1995; Pollitt and Summa, 1997; Ongaro, 2004). Since then, the principles of NPM have been widely practiced with varying interpretations and implementations (Lane, 2000; Pollitt et al, 2007).

Although NPM changes its appearance and the practices vary (Pollitt et al, 2007), there are also common trends among different applications (Lane, 2000; Pollitt, 1993; Pollitt et al., 2007; Sanderson, 2001; van Helden, 2005). NPM introduced the decentralization of decision-making, which was followed by various outsourcing and privatization initiatives. It also increased customer-orientation and turned the whole public ‘business logic’ upside down by focusing on service operations instead of organizational functions and structures. Furthermore, an underlying theme in all NPM approaches concerns productivity awareness and management by results. Public organizations are expected to link costs to outputs and to demonstrate their value for money.

The most recent shape of public management is New Public Governance (NPG). NPG is an approach to understand the production and delivery of public services in a fragmented and pluralist society (e.g., Billis, 2010; Kylänen et al., 2012; Vuori, 2011). The conceptual framework of the NPG was introduced in 2006 and has thereafter gained increasing popularity among the methods of service delivery (Osborne, 2007; 2010). NPG can be defined as “the third wave” of the management reforms which have developed from the traditional Public Administration (PA) and the New Public Management (NPM) approaches (Klijn, 2008; Osborne 2007; Salamon 2002; Torfing & Triantfillou, 2012).

An essential feature of the new public governance is that it does not completely reject earlier administrative reforms, but rather complements them with new solutions. NPG is based on the view that the public administration is no longer able alone to control society, but the success of governance is based on the partnership with the private and third sectors as well as with the citizens (Peters, 2011; Salamon, 2002; Hakari, 2013). The most essential elements of the NPG are the crossing of all borders and the case-specific building of horizontal co-operation, partnership and network relations with various co-operating bodies (Haveri et al., 2009). It has been understood that instead of developing individual organizations and improving their results, the development should support cooperation and networking between different actors (Klijn, 2008). This demands leadership capacity that goes beyond a search for efficiency gains or a customer orientation to take on the challenge of working across boundaries and to take the goal of holistic working which has greater effectiveness in tackling the problems that the public must care about (cf. Sullivan & Skelcher, 2002).

Bovaird and Löffler (2002) argue that the shift from local government to new local governance entails moving from the development of organizations to the development of communities, changing the focus from defining customer needs to communal participation and shifting from differentiating politics and administration to interactive processes between them. Within the NPG framework one can, at least to some extent, identify three distinct trends. Discussion of the new public governance started in network governance. Next, the NPG was discussed from the perspective of democratic decision-making and public participation. The third emphasis seems to be on the new public governance as a development of customer-focused services and co-production (cf. Hakari, 2013).

2.2 Strategic knowledge management

Knowledge as a strategic resource and a source of competitive advantage has aroused a lot of academic interest since the first contributions of resource- and knowledge-based views of the firm (Barney, 1991; Grant, 1996; Spender, 1996). A knowledge management strategy defines which knowledge resources are valuable, unique and inimitable and how those resources support organization's business strategy (Hansen et al., 1999; Zack, 1999; Earl, 2001).

A review to strategic knowledge management literature reveals that three types of studies dominate the discussion. First, a predominant stream of literature categorizes knowledge management strategies based on their key characteristics (e.g., Hansen et al., 1999; Earl, 2001; Donate & Canales, 2012; Bierly & Chakrabarti, 1996). Second, a group of studies have focused on the impacts of knowledge management strategy on organizational performance (e.g. Yang, 2010; Hitt et al., 2000; Choi et al., 2008; Choi & Lee, 2002; 2003). Third, the most practice-oriented studies provide guidelines for developing, choosing and implementing a knowledge management strategy (Zack, 1999; Soliman and Spooner; 2000; Earl, 2001; Haggie and Kingston, 2003). Whereas the two previous approaches aim externally to categorize or evaluate knowledge management strategies, here the main driver is an internal need to understand how knowledge management can support value creation.

Earl (2001) and Zack (1999) focus on the recognition of performance gaps in discovering where firm's capabilities do not match the intended strategy. The next step in defining a knowledge strategy is to ask how knowledge can make a difference in filling these gaps. Zack uses knowledge-based SWOT analysis as a tool and states that every strategic decision has a profound influence on knowledge, skills, and core competencies. In parallel, what an organization does know limits the ways it can compete. Thus, an analysis of organizations' knowledge assets (Edvinsson & Malone, 1997; Sveiby, 1997; Lev, 2001; Seetharaman et al., 2002; Halawi et al., 2005) lays the foundation for recognizing knowledge gaps and constituting a knowledge management strategy. Finally, one of the most important reminders of the strategic knowledge management literature is that the identification and selection of the knowledge management initiatives and tools should always be a derivative of the business strategy, not the other way around.

For public management, knowledge management offers new options, capabilities, and practices to assist public administration in strengthening public service effectiveness and improving the society (Wiig, 2002). Wiig (2002) identifies four areas of public knowledge management: decision support, public participation; building of competitive societal intellectual capital and developing knowledge-competitive work force. Edge (2005) recognizes that the literature on public knowledge management has been approached mainly from the technological perspective and by concentrating predominantly on certain functional areas like police (Luen & Al-Hawamdeh, 2001),

education (Edge, 2005; Syysnummi & Laihonen, 2014) of health care (van Beveren, 2003; Laihonen, 2012; 2014).

The recognized cultural challenges in public knowledge management relate to resistance to change and hoarding of knowledge (Sveiby & Simons, 2002). Other challenges arise, for example, from incompatible information systems, hierarchical and bureaucratic organizations and multiple purposes for managerial information (Behn, 2003; Liebowitz & Chen, 2003).

2.3 Summary: Knowledge management in public management framework

The main task of this literature-based section was to recognize the main aspects of modern public management and to illustrate the complex environment where knowledge perspective could provide valuable contributions. Figure 2 summarizes the key notions of the literature review and constructs a conceptual framework and a basis for the empirical phase.

Public management and its particular knowledge-based management challenges as a phenomenon originate from the changes in public environment. NPM and NPG literatures have identified several aspects that need to be considered. These have changed also the role of knowledge management and expanded managerial knowledge needs. Empirical part of the paper studies how knowledge management could support public management at the city level. Analysis is based on the conceptual framework, which combines ideas from public management literature and strategic knowledge management. With this approach the paper provides valuable practical viewpoints for public managers to survive in multi-voiced society and contributes also to the literature by developing a basis for knowledge-based public management.

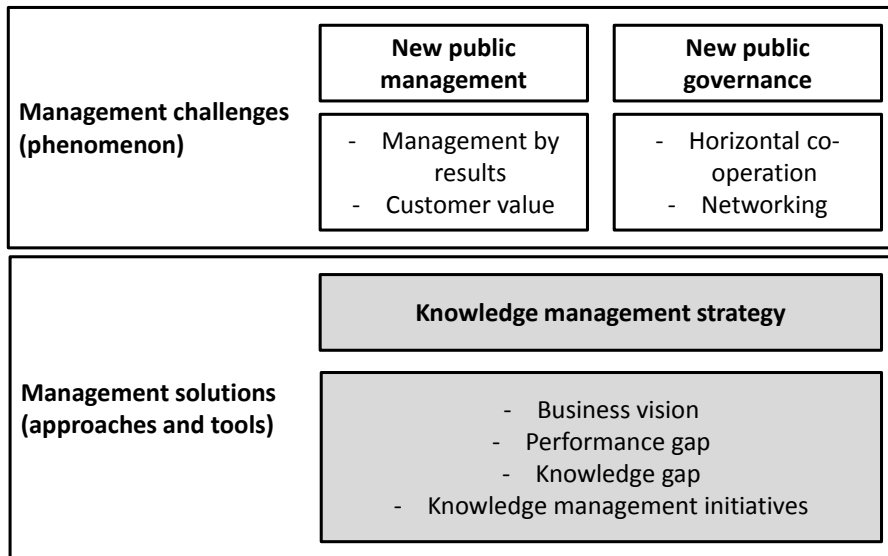

Figure 2. Public management and knowledge management – the conceptual framework.

The two empirical questions arising from the theoretical part are: 1) what should be the overall aim of the knowledge-based management initiatives at the city level? and 2) how to organize and share responsibilities between organizational functions in a complex organizational structure? Empirical part of the paper aims to provide answers to these difficult but essential questions of public management.

3 Research context and empirical data

3.1 City of Tampere as a research context

Tampere is a city in southern Finland. It is the most populous inland city in any of the Nordic countries. The city has a population of 220,609. Tampere is the second-largest urban area and third most-populous municipality in Finland. The city is also the largest employer in the area (15 152 employees) and annual expenditure of the services is € 1,380 million. Welfare services (health care, social care and education) is the biggest sector (76 % of employees) and 59% of these services is provided by city's own production.

The supreme decision-making body in the City of Tampere is the City Council with its 67 members. Council members and their deputies are elected in a municipal election

held every four years. Tampere made an administrative reform – which, in the context of Finnish municipalities, can be described as historic – at the beginning of 2007 by adopting a new model of leadership with a politically elected Mayor. The reform also implemented the multiple-provider model in all municipal operations and organized purchaser activities into customer-oriented process organization. The management reform laid strongly to New Public Management (business-logic, customer-orientation), but also recognized the weaknesses of the NPM model. Later on the management model has been developed more towards New Public Governance such as local democracy, participation, networks and transparency of government. (Hakari, 2013.)

The city ensures the availability and quality of services for which it is responsible, regardless of the manner in which they are produced. In this operational model purchaser activities have been organized into customer-oriented core processes supervised by purchasing committees (Figure 3). At the same time, the city's own service production has been decreased and organized in a customer-oriented way.

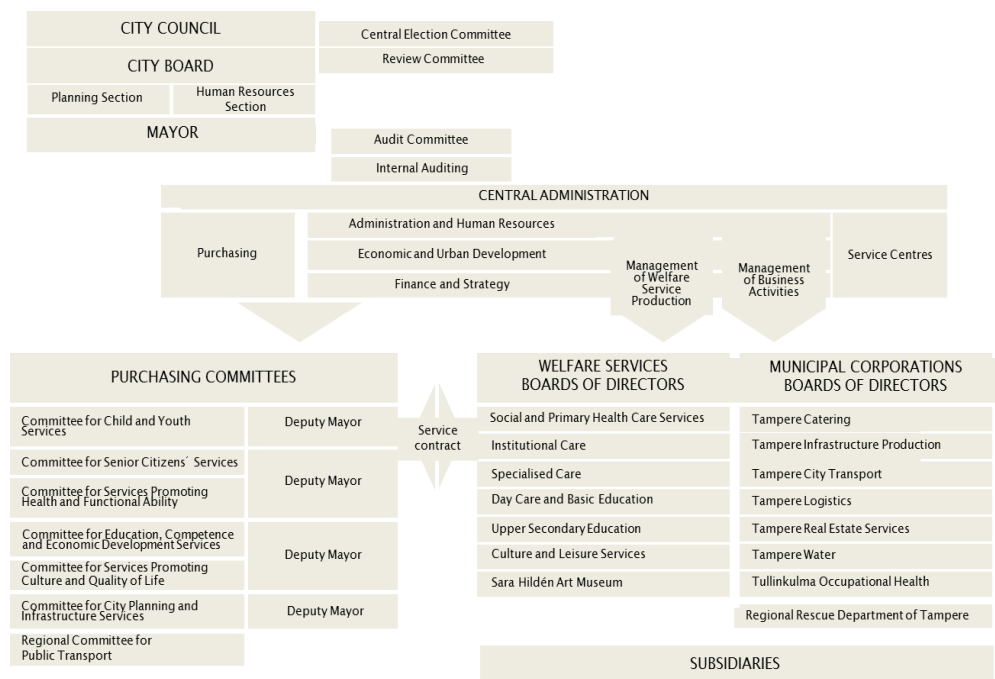

Figure 3. Operational model of the city of Tampere.

3.2 Empirical methods and data

The management reform and its process-based approach led the organization to focus on knowledge-based management of service provision. At the same time, a need to oversee service processes instead of administrative functions or organizational units was perceived. Outcomes and effectiveness of services were set as performance objectives and various projects were launched for developing measurement of cross-functional processes. The focus was transferred from organization units to services and customer benefits. Furthermore, the productivity of public services was concerned and the city launched a Productivity Program in 2009 and performance measurement was raised into central role in managing service efficiency and taking quality and effectiveness of services into account. These, and some other measurements projects/initiatives, have initiated new kind of managerial information needs and lead knowledge management into a new direction.

In 2013, the maturity of city's knowledge management was evaluated. Four main development areas were recognized:

- Operating model for knowledge management is needed to ensure reliable and timely decision support
- Communication and training plan (competence development)
- Harmonizing of the technical architecture
- Recognizing and modelling of the service processes

Results of the maturity analysis, earlier experiences on productivity program and performance measurement initiatives laid the foundation for the research project concerning knowledge-based management this paper focuses on. All these were used as secondary data for the analysis of this paper. The primary data for the paper was gathered in an intense action research process between December 2013 and January 2014. This process included three development workshops and several preliminary and follow-up discussions where the contents of the workshops were planned, analyzed and iterated.

Three workshops were arranged with two different groups, one for each and one joint gathering. The two groups were: management group of knowledge-based management (steering-group) and more operative group of key actors around knowledge-based management. Participants of both workshops represented general management,

information management, service management and administrative specialists. Each has their particular view to knowledge-based management, either as decision-makers or information producers. A dialogue between technical and service oriented officials was considered necessary.

The main aims of the process was to: 1) compose a shared understanding about knowledge-based management, 2) create a holistic view and rules for knowledge-based management within the city, and 3) specify the future steps for knowledge-based management. The focus of the first workshop with the management group was on the linkage of knowledge-based management and city strategy. This discussion acted as the starting point for the second workshop, which focused more on the concrete steps for advancing knowledge-based management. Two researchers participated to all workshops; while the other led the discussion, the other made detailed notes. The next section describes how the process was carried out in practice. The process reflects the new managing model, new strategic aims, customer-oriented approach and governance of fragmented service provision, which all call for new solutions also for knowledge-based management in public domain.

4 Knowledge management as a public management strategy

4.1 Positioning knowledge management strategically in Tampere

Knowledge-based management, or managing the city with knowledge, is a strategic development area within the city of Tampere and is directed by the director of Administration and Welfare services Group in central administration. City strategy is operationalized through four plans of action documents. One of these concerns organization's internal operations and management. This document highlights knowledge-based management as a concrete objective for the period of 2014-2017. The aim of this initiative is that the needed information is available to support decision-making and management. Operations should be based on the availability and application of accurate and timely information. Knowledge-based management also has a high priority on top10 list of structural changes accepted by the city executive board in 2013 for the period of 2013-2016. Balancing the city budget necessitates structural changes aiming for financial savings in the long run. Knowledge-based management is also a

binding target in the budget for 2014: “cost-efficiency and effectiveness of social and health services have improved through knowledge-based management”.

To support knowledge-based management various development tasks have been implemented during the last years. However, preliminary discussions with the city officials revealed that development work is scattered into unrelated projects and the overall picture is unclear. This interpretation was confirmed in workshops and has complicated both internal and external communication. Thus, it was considered important to connect knowledge-based management to wider, city-level objectives. This is expected to clarify the overall aim and meaning of knowledge-based management and ease the communication and building of a shared knowledge culture. The ultimate aim of knowledge-based management in Tampere is to improve performance of the city. Performance was considered widely to retain productivity, efficiency, quality and effectiveness of services. To concretize this overall aim it was divided into three sub-objectives, service provision, internal efficiency and new opportunities, as presented in Figure 4.

Figure 4. Knowledge-based management supports performance improvement.

Each sub-objective improves overall performance and was considered to encompass strategic focus areas (working together, preventive measures and narrowing disparities in well-being, vitality and competitiveness, sustainable community, balanced finances and innovative organization). In this way knowledge-based management becomes a central medium for implementing city strategy. Two main questions arise: “What are the specific tasks advancing these aims” and “What information and knowledge is needed in order to reach these aims?” answering these questions creates a basis for all knowledge-based development.

In addition to strategic aims, an important aspect of knowledge-based management is its connection to general management system of the city. It creates real knowledge needs,

which helps in resource allocation and prioritization of information requests. Naturally, there will simultaneously origin ad-hoc knowledge needs on a regular basis and requires efficient organization and handling of these needs as well. Without a linkage to a basic task of the city, information provision and knowledge-based management remain detached from the every-day management. Thus, a knowledge-based management culture requires a tight linkage between service operations and knowledge. Currently, this was considered too weak.

Workshops focused especially on service provision and the knowledge base that their intelligent purchasing requires. Tampere has been active in this area. For example, productivity measurement has been developed and management information needs mapped. Recently, the focus has been increasingly on integrating previous work. This integrative approach aims to recognize leading indicators and other managerial information that is needed in decision-making. In the context of service provision, the underlying question is: what knowledge is needed to manage the service provision. Figure 3 provides an example of this work from the home care unit (own production).

Figure 5. Leading indicators of service management in Tampere.

Steering group decided that it is reasonable to continue the work on leading indicators. However, the group stressed the importance of connecting these indicators to the wider aims of service provision. Provided information should guide towards management of cross-functional service provision and customer value, serve practical decision-making situations and support knowledge-based management more generally. The existing productivity measures need to be updated to serve this purpose and requires changing the focus from organization units to services and strategic aims. In practice this means that in addition to measuring home care as an organizational unit, the measurement

should also provide information about the success of the city in supporting elderly people to live at home (strategic objective).

4.2 Towards a knowledge strategy in Tampere

In workshop discussions, four essential tasks were recognized as the main development areas for knowledge-based management: 1) recognition of the leading indicators and other managerial information, 2) representing and modelling the information need, 3) gathering and presenting information, and 4) refining and analysing information. These are essential tasks of the support function enabling the actual knowledge-based management. Also the issues like reliability of the data (Master Data Management, Data Warehousing etc.) and definition of roles, responsibilities and tools were underlined in workshops. Currently, a clear juxtaposition between supply and demand for management information prevails. Information provision and strategic knowledge needs do not meet.

Refining and analyzing information is strongly dependent on the quality and reliability of the underlying data. Currently the quality of the data is not on a satisfying level. This problem is recognized and the city has already started a process for purchasing a master data management system, which should improve the quality of the data. This is not merely a technical process, it is important also to carefully design and implement a rigid process for guaranteeing the quality in the future. Again, these processes need to be developed and technological selections made in line with the managerial information needs and strategic aims. Managerial needs and service operations should guide the information provision and the related knowledge processes.

There is also work to be done on creating a shared language between actors. For example, in the joint workshop different interpretations between information management and service managers on the concept of 'service process' became evident. This relates and concretizes also a bigger change taking place in the public sector. When management focus is transferring to inter-organizational and cross-functional service processes a shared language depicts a crucial determinant enabling collaboration and knowledge sharing. Focusing on the leading indicators is expected not only to diminish the amount of knowledge requests received but also clarify where the management focus should be. Thus, it creates a common language for managers by defining key concepts and performance objectives. Further, this should help in resourcing and prioritizing. It is also

expected that this streamlines the flow of knowledge within the organization and brings ease to information overflow from the viewpoint of individual employees.

Overall, it is expected that recognition of the leading indicators creates a starting point for knowledge-based management. Both workshops recognized the need for special capabilities related to this task. In this role, a holistic and in-depth understanding of the city strategy and the various paths for implementing it plays a crucial role. Service architecture and strategic objectives need to be assimilated in order to recognize and prioritize knowledge needs. Only from these, a coherent knowledge strategy and the supporting infrastructure can be derived and designed. Thus, understanding of the information infrastructure, information modelling and a basic understanding about the technological possibilities are needed as well.

The first steps to produce and utilize the leading indicators were taken by launching a project, which aims to identify the clients who use many (high-cost) social- and health services and to map out the services and service chains they use. The objective is that the findings of the project can be used to improve the processes inefficiency and low effectiveness as well as cut down costs. This is set to concretize the defined target: “Cost-efficiency and effectiveness of social and health services have improved through knowledge-based management”.

5 Analysis: The Tampere way – managing with knowledge

Contribution of the paper relates to two aspects. First, the paper links the literature on knowledge management to public management stream. Previously this has been made primarily through certain service area or process, here the focus was on strategic management and a city level perspective was chosen (Edge, 2005). The paper also acknowledges the continuously evolving public environment (Sanderson 2001; van Helden et al., 2008) and considers how this should be taken into account in public knowledge management. Second, to knowledge management stream, the paper provides a practical illustration on how to apply knowledge management and to compose a holistic knowledge strategy for a complex service system like a city (cf. Hansen et al., 1999; Zack, 1999; Earl, 2001) and thus implements a knowledge-based view in public environment (Grant, 1996; Spender, 1996).

As the empirical examination illustrated, the Tampere model is built on basis of democracy and regulation of traditional public administration as well as quasi-markets of the NPM. The more recent NPG reform is transferring the focus more towards customer-oriented service development (cf. Hakari, 2013). Thus, the City of Tampere has passed through two design and delivery regimes of traditional public administration and New Public Management and is currently introducing the third, New Public Governance. Along with these new ways of governance management focus and managerial knowledge needs have evolved.

Under the public administration regime public services and organizations were managed with a hierarchical chain of command (Hartley, 2005; Osborne, 2010). The managerial knowledge needs related mostly to cost management and measurement of service outputs (i.e. units of service usage). Focus was on individual organizations and specific services, not on service chains and customer-perceived value. The role of a client was passive. Nevertheless, the provided information served well the needs of hierarchal decision-making because services were mostly produced by the city itself and the need for external information was low. Some of the existing management practices still go well back to this management regime.

The city's administrative reform in 2007, especially the multiple-provider model and increased customer-orientation, represents the move towards NPM regime in many ways. Customer-orientation and requirement for responsiveness turned the whole public "business-logic" upside down by focusing on service operations instead of organizational functions (Sanderson, 2001; Hartley, 2005; Pollitt et al., 2007). This also turned the management focus from organizations to service chains. Within NPM, citizens are expected to become active consumers and exercise choice between various providers of public services (public, private and nonprofit). When customer value is provided by a service system, also managerial information needs change. In addition to individual organizations, fluency of co-operation and customer-perceived value need to be continuously evaluated (cf. Lönnqvist and Laihonon, 2012; Laihonon et al., 2014). This highlights long-term effectiveness instead of direct service outputs.

More recently, the spread of network society (Hartley, 2005) and New Public Governance (Osborne, 2007; Osborne, 2010) implies a more pluralist model of governance and provision of public services. NPG puts much greater emphasis on citizen participation and third sector as a service provider than either traditional public

administration or New Public Management (Hartley, 2005; Osborne, 2010). Managing and governing this, even more fragmented and decentralized network of service providers, brings new challenges to public knowledge management. At the moment, it seems that three different cultures, management conventions and even generations of public managers collide, which leads to many problematic situations.

From the knowledge management perspective, city of Tampere is still relying strongly on those information and knowledge processes that were developed for the purposes of public administration. Focus is on organization- or function-specific information production not on the ability of the service system to bring added value for the customers. Despite the many development initiatives and strong strategic will to measure effectiveness and advance knowledge-based decision-making, the system is not ready to take the next step to New Public Governance. However, many of the weaknesses have been identified and as illustrated knowledge-based management has a high priority in all future plans.

NPM and NPG have brought several new requirements for knowledge management by raising new kind of information needs and adding variety to the system. However, those pay only modest attention to information flows and knowledge process. Their main contribution relates to the recognition of knowledge as an important resource for public decision making and acknowledging that networked and systemic nature of public service provision increases the complexity of knowledge-based decision support and respective information and knowledge processes. Knowledge management has been introduced as a tool for conceptualizing, planning, deciding, and implementing public actions as well as for providing general support (Wiig, 2002).

Based on the ideas presented in knowledge management literature (e.g., Zack, 1999; Earl, 2001) Tampere approached its knowledge management by beginning from the overall aim and purpose of city. As described, service provision was chosen as a target for more specific analysis. Here, performance was considered widely to retain productivity, efficiency, quality and effectiveness of services. A key to successful knowledge management is a tight connection to organizations business strategy (Zack, 1999). Thus, city strategy should define objectives and key measures that are used for following the success of the service system. These top-level objectives are operationalized through the management system, which should create a structure for information utilization in everyday decisions where knowledge-based management actually happens.

One of the most important findings and a real eye-opener for practitioners in Tampere was the central role the service architecture in understanding the actual knowledge needs. Service architecture refers to all cross-functional service process that influence and relate to each other. Their success requires seamless knowledge flow and collaboration and set new kind of managerial knowledge needs as described earlier in this paper. Previously Tampere has recognized knowledge needs by asking managers what information they need for their decision making. This has not led to desired results. Now the focus is turned to leading indicators and purpose is by this way guide information gathering towards the most essential tasks and aims. This approach follows the basic idea presented in strategic knowledge management literature (Zack, 1999; Earl, 2001) adding the perspective and complexity of public service system.

First step towards operationalization of the above thinking was the recognition of central roles and capabilities needed. In order to encourage and support the recognition of the leading indicators, a service architect is needed. Persons in this role have an important role in operationalizing city strategy. After the key information needs are recognized those need to be modelled and linked to the underlying information architecture. Information and enterprise architects are responsible for this task and coordinating the needed sub-activities. Then, gathering and presenting of information depicts the task, which brings the information to the availability of decision-makers. The work for clarifying the roles, responsibilities and structure of the knowledge-based management support started this year. Related to this work, the following tasks were identified: 1) guaranteeing data reliability, 2) refining data to decision-support, and 3) integrating knowledge to general management system.

Finally, it is important to understand the difference between knowledge-based decision support and the actual decision-making. Value of knowledge-based management is realized only if managers and other employees utilize the provided information and knowledge by making better decisions based on it.

6 Conclusions

The literature has considered knowledge management mainly as separate tasks supporting public administration and management. The novelty value of this paper lies in the very simple argument – public management is increasingly about knowledge

management. This paper calls for a shift towards more informed and knowledge-based management in public domain. Decisions should be based on the best available knowledge and lead to benefit of citizens. This puts knowledge-based management into a new position and a managerial challenge is to communicate this perspective.

The paper discussed knowledge-based management in a changing public management domain. It considered public administration, new public management, new public governance and noted that each of these has left a trace in public management. As a consequence, different cultures, management conventions and generations of public managers collide and challenge the creation of a shared understanding on the role of knowledge. The paper made several important notions on developing a knowledge strategy in public environment and complements the literature on strategic knowledge management in business-driven environments.

Both the literature and empirical findings highlight the importance of connecting knowledge-based management to strategic objectives, recognizing knowledge gaps and aiming knowledge initiatives to fulfilling these. In public service systems, it is often difficult to compose a shared understanding about the objectives but the paper described how this was done in one particular service system. Then, the implementation of the cultural change rests on the management system. Strategic objectives need to be operationalized into units' and individuals' targets and these have to be regularly followed. This kind of knowledge-based and performance-driven culture is very slowly gaining ground also in public sector.

The issue of public knowledge management offers several avenues for future research. Highly important one relates to implementation and operationalization of knowledge-based management as a part of the general management system. Central question is "How to build a management culture, which relies on knowledge-based management and informed decision-making". And further, what kind of management system would be most suitable for contemporary public organizations. Other interesting research questions relate to the role of customer and knowledge that is needed to better respond and manage the increasing demand for public services. The main limitation of the paper relates to having only one case organization. On the other hand, it is also a key strength of the paper: the action-oriented approach of the paper made it possible to study the process of developing a knowledge strategy under certain contextual settings.

Despite of its weaknesses, the paper lays a foundation for developing a knowledge-based management culture in public organizations. Simultaneously it puts in evidence the central role of the municipality and its knowledge management in fostering the vitality of the service ecosystem. Without proper information and understanding about the effectiveness of services, efficiency of service providers and ways of organizing it is not possible to make informed decisions.

Structured Abstract

Purpose – The purpose of the paper is to study “lean & safety” projects, which are those ones that combine Health Lean Management (HLM) and Clinical Risk Management (CRM). Thus, the research objective is to understand how “lean and safety” projects can be implemented, investigating the significant features that characterize them: organizational aspects, phases and activities, tools, techniques and practices and key factors.

Methodology – As it is a new subject, case study methodology has been adopted; the selected project is one of the first cases where HLM is required firstly to reduce incidents and secondly to obtain efficiency improvements and HLM is fostered by who are in charge of patient safety. After creating an interview protocol based on literature, data has been collected conducting semi-structured interviews with the key informants involved in the implemented project. To guarantee triangulation, also relevant archival documentation has been collected and observations have been executed. Data were finally analysed to obtain a framework that answers the defined research objective.

Originality/value – The connection between HLM and CRM is not studied in literature yet. To this extent, organizational aspects, phases followed, tools and practices adopted and key factors for a successful “lean & safety” project implementation is described in this paper. This is one of the first researches that investigate characteristics of a HLM project adopted to solve CRM issues. The results suggest HLM and CRM should be considered in a new synergic methodology. First indications about how developing it are provided boosting future research, also in other contexts and contributing to the development of more safe and sustainable health care systems.

Practical implications – The outcomes of this research is valuable for hospital units or health organizations that need to achieve efficiency enhancement, improving quality and patient safety at the same time. For an improved management of clinical processes, hospital managers could consider the results of this research to solve their CRM problems. The indications about phases to follow for the implementation of a “lean & safety” project could be cogitated as guidelines during the application of this emerging methodology. In addition, they could grasp from this research the characteristics for a

successful implementation of projects that pursue multiple objectives in a challenging environment.

Keywords – lean management, clinical risk management, healthcare management, case study

Paper type – Academic Research Paper

1 Introduction

Healthcare systems have to afford multiple challenges especially during a crisis period in which many governments have to spending review in order to comply with international agreements. Particularly for healthcare systems that are guaranteed and funded by public institutions, efficiency should be increased cutting wastes and costs. On the other hand, accreditation standards require high performance in terms of quality and safety improvements. In a context where resources are scant and customers and ethical principles ask for high quality, new managerial solutions should be developed, in order to abandon the trade-off approach between diverging performance objectives and to take advantages of the benefits of different methodologies.

An increasing interest has been devoting to HLM in academic and managerial literature. It has been cogitated as a managerial approach that could contribute to efficiency improvements, identifying and eliminating any wastes, attributing more value to the patient and reducing costs. Few researches have analysed the impact of this methodology on quality and safety improvements; in particular, till now the possibility to combine HLM and CRM has received scarce attention.

Through the analysis of a single case study that is peculiar for its synergic approach adopted, this research aims to grasp guidelines and key lessons from the implementation of a successful project that has led to efficiency and patient safety improvements. In the project, elements of CRM and of HLM are integrated, contributing to the development of an original process managerial methodology. Considering not only the hardware but also the software elements of the projects, the organizational and contextual aspects will be highlighted. After presenting the national and regional context of the hospital in which the project has been developed, in the third section the emerging managerial approaches adopted in healthcare will be described. After defining the research objectives and justifying the followed research methodology, the analysis of the case will be reported

(section 5). Discussion of results and lessons learned will be presented in the sixth section and finally conclusion will be drawn (section 7).

2 The national and regional context

The Spanish National Healthcare System is based on the article 43 of the Spanish Constitution that recognizes the citizens' rights and the universality of the system, which must be guaranteed through territorial division of powers and equity distribution of health care resources, as well as equal access to health care. In 1986 the application of these principles started with the General Health Care Act, through which the healthcare system was conceived as decentralized, universal and tax-based financed (Segura, 1999; Reverte-Cejudo & Sánchez-Bayle, 1999). The insurance-oriented model of Bismack was substituted with the model of Beveridge financed by taxes, even if the system today includes also out of pocket payments that mean co-payment by citizens and private insurance in addition to public coverage (Veneziano & Specchia, 2010; García-Armesto, et al., 2010; Rajmil, et al., 2000). The contemporaneous decentralization process finished in 2002 attributing high responsibility and autonomy to the 17 Autonomous Communities, whose cohesion, strengthened also by Cohesion and Quality Law in 2003, is assured by the Interterritorial Council of the NHS (CISNS), composed by regional ministers and the national minister (García-Armesto, et al., 2010; Duran, et al., 2006; Lopez-Casasnovas, et al., 2005). The central government is responsible for several strategic areas (García-Armesto, et al., 2010). Each autonomous community can define a different territorial organization that is distinguished into Health Areas and Basic Health Zones, and the latter ones are the smallest unit of organizational healthcare (García-Armesto, et al., 2010; Borkan, et al., 2010). While regional health legislation, health insurance, health services planning management and provision fall within the competence of Autonomous Communities, the local authorities are responsible for sanitation, collaboration in health services provision and public health and community services (García-Armesto, et al., 2010). In health areas primary and specialized care are provided with few differences in the management among Autonomous Communities.

This healthcare system has been studied by different authors and someone (e.g. De Magistris & Bobbio, 2004; Lopez-Casasnovas, et al., 2005; Rico & Costa-Font, 2005) has emphasized the diversity among regions especially for the 7 Autonomous Communities that have acquired independency before the others. In particular, Catalonia, being the first

Autonomous region, has developed gradually a peculiar Catalan health care system (Departament de Salut, 2014) with a direct management of the public structures by the Catalan Institute of Healthcare and service coverage assigned to other public or private suppliers through an accreditation mechanism (De Magistris & Bobbio, 2004; Rajmil, et al., 2000).

Lopez-Casasnovas et al. (2005) underline this decentralized system has not generated inequalities; rather, it has increased quality improvements at least for what concerns patient satisfaction. Borkan et al. (2010) report that in 2007 the National Health System developed a Quality Plan: with inputs from local authorities, twelve strategies for quality and efficiency improvements and reduction of unnecessary costs and wait times for patients were developed and executed at the national, regional, and local levels.

According to Veneziano and Specchia (2010) the Spanish Health care system stands out for its efficiency and the peculiarity of its primary care organization. Based on the last OECD data (OECD, 2013), Spain performs well: in particular, the life expectation is within the highest in Europe and the hospital beds and the mortality rate are the lowest ones. Considering the waiting times calculated by OECD (2013), Spain reports lower values than the OECD average for almost the indicators.

Despite the good indicator for public debt in 2010, Spain presented poor performance for employment and economic growth and public deficit (Catan, 2008; García-Armesto, et al., 2010; Gené-Badia, et al., 2012). The latter problems has been faced decreasing the social spending (García-Armesto, et al., 2010), criticizing by Genè- Badia et al. (2012) that signal a reduction in surgical and clinical activities and in major investments, an increase of delay in payments to providers and salary reductions, which were still the lowest in Europe (OECD, 2013). This occurs together with a pressure to provide high-quality universal care in a context of population growth, even more aging people besides the global financial crisis (Martin-Moreno, et al., 2009; Carrasco-Garrido P, et al., 2009).

Genè- Badia et al. (2012) are concerned about the risk of increase people on waiting lists, bad condition in chronic patients and low health status for population. Borkan et al. (2010) state the agenda of Ministry officials encompasses the promotion of optimal levels of quality, equity, and innovation, improvement of human resources management and financial sustainability of the system. These multiple performance could be achieved by single hospital only adopting different managerial approaches, overcoming the trade-off

theory developed by Skinners (1985) and Hayes and Wheelwright (1984), as discussed by Crema & Verbano (2013a).

3 New managerial approaches in healthcare

According to Department of Health (1998, p. 6), clinical governance is “the process by which each part of the National Healthcare System quality assures its clinical decisions”. A system of continuous improvement into the operation of the whole system has to be introduced (Department of Health, 1998). In fact, through clinical governance, “organizations are accountable for continuously improving the quality of their services and safeguarding high standards of care by creating an environment in which excellence in clinical care will flourish” (Scully & Donaldson, 1998, p. 62). Clinical governance is based on integration of different approaches that requires attention to infrastructure, coherence, poor performance, culture, risk avoidance and quality methods. This means a cohesive programme of actions that should involve all the organization in addition to managerial commitment, leadership and creativity (Scully & Donaldson, 1998).

Clinical governance is an organizational innovation that needs a cultural change, which is not easily achievable (Walshe, 2000; Smith, 2001). Reale (2007) identifies the tools and practices to implement clinical governance (tab. 2).

Tab. 2 - Tools for an operative clinical governance according to Reale (2007).

TOOLS AND PRACTICES				
involvement of the patient and its family (through patient centered paths and assessment of patient satisfaction)	strategic capacity (vision and mission definition)	economic resource management of clinical processes	staff management	performance management
information and communication management (through ICT support)	multidisciplinary team working	open organizational culture	leadership involving top management	clinical risk management

3.1 Clinical Risk management

Clinical risk management (CRM) is an approach to improve quality in healthcare that places special emphasis on the identification of circumstances, which put patient at risk of harm, acting to prevent or control those risks. The aim is to both improve safety and quality of care for patient and to reduce the costs of such risk (Walshe & Dineen, 1998). CRM can be defined also as the system of guidelines, protocols, steps, organizational and clinical procedures adopted by a hospital to reduce the probability that events and actions, which might potentially produce negative or unexpected effects on patients health, occur

(Floreani, 2005). According to Borghesi (1985), CRM is a complex activity to reduce risks (in terms of frequency and severity) and the economic impact of their effects. Based on ISO 31000 the phases of CRM process are: establishment of the context, risk assessment (risk identification, risk analysis and risk evaluation), risk treatment and two phases continually acting, such as communication with internal and external stakeholders, and monitoring and review (Purdy, 2010).

The most used tools are (Verbano & Venturini, 2011): incident reporting, analysis of clinical records and clinical documentation, analysis of administrative data, client reports, brainstorming, Root Cause Analysis, checklist, Failure Mode and Effects Analysis - Failure Mode, Effects, and Criticality Analysis (FMEA-FMECA), Hazard Risk Assessment (HRA), Hazard and Operability Analysis (HAZOP), decision-making trees.

These instruments should be adopted to manage clinical risks that are the probability that a patient suffers any damage or inconvenience caused, even if unintentionally, by medical care provided during the period of hospitalization, causing a prolongation of hospital stay, a deterioration of health or death (Kohn, et al., 1999).

Clinical risks can be classified based on (Cinotti, 2004): the safety of structures, machines, electrical systems, hazardous substances, fire / explosion; the presence of chemicals, physical and biological agents and the risks linked with the work organization, psychological and ergonomic factors and difficult work conditions.

According to Reason (1990), a human error can be interpreted and analyzed adopting a “person approach” or a “system approach”. The first one was the most diffused and eradicated during last century and it considers the human behavior as a source of error, whose variability has to be reduced. This approach stresses the human component of the safety, such as the human factor and the cognitive processes at the base of errors (Damen & Novaco, 2004). Thus, in order to prevent risks, knowledge improvement and individual training are necessary as “bad things happen to bad people” (Reason, 1990). Instead, following a “system approach”, people make mistakes also in the best organization. Error is the result of a failure of a system composed by human and technological elements that are connected, integrated and aimed to common objectives. For this reason, it is necessary to redesign processes, understanding “how and why the defenses failed” instead of finding “who blundered”. Categories of errors reported by Ministry of Healthcare (2004) are: the error in the use of medicines, surgical errors, errors in the use of equipment, tests

or diagnostic procedures not executed or executed in a not appropriate way, errors in the timing.

Reason (1990) identifies three typologies of error: slips, lapses and mistakes. Slips and lapses are execution errors, while mistakes are errors that occur in the strategic planning phase (Reason, 1990; Ferner & Aronson, 2006). Furthermore, Reason (2000) introduces the “theory of latent error”, that constitutes the system approach; according to this theory the potential errors, called near miss events, become errors only when they bypass each defense system created by the organization, based on the Swiss cheese model. Adopting the person approach only the unsafe act (the active error) is identified, while the latent errors are far from the direct contact with the final customers. Reason (2000) claims "we cannot change the human condition, but we can change the conditions under which humans work". A lack in a defense organizational system is not sufficient to transform a near miss event into an error, an alignment of all of them is necessary through a trajectory of accident opportunity.

3.3 Health Lean Management and Clinical Risk management

Jacobs (2006) underlines it is not corrected to state that in healthcare it is not possible to achieve a condition of zero-defect, as complications are unavoidable; no other business would survive if it was permitted a certain percentage of defective products. Also Six Sigma allows a low percentage of errors that is not acceptable dealing with human lives (Bohmer & Ferlins, 2006). In order to face this issue, a strategy of real-time error reporting and decentralized problem solving are encouraged, but it is very hard to implement (Sirio, et al., 2003).

From a research carried out in United States by American Society for Quality (2009), it emerges that 53% of the American hospitals have adopted lean methodology even if only 4% of hospitals report a “full deployment” of this methodology that has been adopted to improve hospital throughput (73%), to satisfy business or cost need (68%) and to increase the service quality (56%). Health lean management (HLM) can be defined as a managerial approach, to identify and eliminate waste improving flow of activities to maximize value to the customer. It considers standardization and specification of work processes, organization of work in such a way that unexpected events are easy to spot, and deployment of activities that find and fix mistakes (Ohno, 1988; Womack & Jones, 2003).

In a complex organization, as an healthcare organization, error and the possibility of an incident are not eliminable, so all the possible interventions should be adopted at least to control such risks (Ministry of Healthcare, 2004).

Nolan (2000) suggests three strategies to design assistance and care system that guarantees safety to the patient. The first one is to prevent errors caused by the seven factors of Vincent (1998) (patient factors, task factors, individual factors, team factors, working conditions, organizational factors and institution context). The second strategy regards making errors visible, to eliminate the causes of errors. The third strategy concerns the mitigation of the effect of an error. An optimal error management integrates all these strategies. In order to implement at least the first two strategies of Nolan (2000), HLM with its principles, techniques and tools and practices could be a support for a proactive CRM. As mentioned by Ben-Tovim (2007), error is an absolute waste for a lean thinker. He states that retrospective error analysis is not so valuable when patient safety errors occur in one in five hospital admissions and also to add another incident reporting seems not the solution. Care processes examination and redesign allow to pursue the right thing preventing errors and to identify weaknesses and opportunities of improvement, fostering to act at system level rather than at individual blame (Ben-Tovim, 2007; Ben-Tovim, et al., 2008).

4 Research design

In the previous section, the pressure from external environment to achieve efficiency and quality improvements at the same time has been stressed. From industrial sector, managerial approaches are spreading into healthcare, reporting positive results. New methodologies that combine principles, tools and practices of CRM and HLM could be the solution. A previous research has demonstrated connections between HLM and CRM (Crema & Verbano, 2013b); based on this starting point, it is necessary to understand how it is possible to implement “lean & safety” projects defined by the same authors as HLM projects with impact on quality or safety improvement.

Detailing this purpose, the research objective is to understand how “lean and safety” projects can be implemented, investigating the significant features that characterize them: organizational aspects, phases and activities, tools, techniques, practices and key factors.

Starting from the guidelines grasped in Crema & Verbano (2013b), through a systematic literature review, according to the suggestion of Miles and Huberman (1994),

a research framework has been created after the formulation of research objective (fig. 1), describing the features that have to be analyzed in this research.

Fig. 1- Research framework.

The analysed subject is new, consequently considering the maturity cycle of the research, case studies and qualitative research with in-depth case studies for exploration and theory building are suggested as the knowledge are uncertain (Voss, et al., 2002; Eisenhardt, 1989; Yin, 2009; Malhotra & Grover, 1998). Benbasat et al. (1987) indicate to follow case study methodology if data are collected by multiple means, the analysis regards one or only a few entities, the complexity of the unit is high and deserves to be studied intensively. This methodology is justified also by the research questions «what, how» adopted in an exploratory study (Benbasat, et al., 1987; Meredith, 1998; Yin, 2009; Hedrick, et al., 1993). Deep single case study allows a rich description of a phenomenon in particular circumstances (Eisenhardt & Graebner, 2007; Voss, et al., 2002).

A single case study research design has been adopted, as the selected case is a critical and unique one (Yin, 2009). The aim is to analyse “lean & safety” projects, examining HLM projects with impact on quality or safety improvements. The selected project is one of the first cases where HLM is adopted firstly to reduce incidents and secondly to obtain efficiency improvements. This project has been implemented in a particular hospital (further called Omega) in the Spanish context, and it is one of the few hospitals that have implemented HLM projects. It has been built after the year 2000, it employs about 2500-3000 people to serve a catchment area of 500-1.000.000 persons, with about 400 beds. Its mission is to offer an excellent technical quality and to guarantee assistance continuity in an organization that emphasizes patient needs. This is a very peculiar context, as Omega promotes teaching, research and innovation and considers lean healthcare among the improvement approaches of the hospital. The development of the “Omega Production System” is a medium-long-term aim, so the lean management of processes is an integral

part of the hospital strategy. Omega reports high experience in HLM project implementation and plenty of HLM procedures have been formalized and documented.

Also the organization chart of the hospital is peculiar: inside the department of planning and patient safety (in staff to the general direction) HLM & quality unit and CRM unit are included.

In order to guarantee reliability of the analysis, a research protocol has been developed (Saunders, et al., 2009; Yin, 2009; Voss, et al., 2002); based on literature and on the research objective, an interview protocol has been created for data collection, including the following sections: general information, context, objectives, organization, planning, implementation, monitoring, feedback, future developments and suggestions. Data have been collected during 2013 by three researchers, one of whom was involved as observer in the project team. In this way three sources of evidences have been considering for data triangulation to assure research validity (Patton, 2002; Yin, 2009; Eisenhardt & Graebner, 2007; Healey & Rawlinson, 1994): open and semi-structured interviews, researcher observation, analysis of documentation and archival records. Considering the different possible roles of an observer, in this case it has been chosen observer-as-participant; with a moderate participation, it was possible to have access to the field and observe it without influencing it (Gold, 1958; Spradley, 1980; Kawulich, 2005; Flick, 2014). The interviews were formally conducted with the lean manager of the hospital and the manager responsible for patient safety, involved in the implemented project, in order to gain a multidisciplinary point of view. Data analysis was conducted according to indications of scholars about case study methodology (Neutens & Rubinson, 2002; Miles & Huberman, 1994; Strauss & Corbin, 1990; Glaser & Strauss, 1967). Data were reduced through coding, creating categories and variables further described. A matrix has been finally created to explain the obtained results and answer to the research objective.

5 Results of the analysis

The selected project regards the process of drug administration and the chain of activities that precedes it. Drug is required to the internal pharmacy by the inpatient unit, the internal storage of this unit is then supplied and drug is stored before its preparation.

5.1 Triggers, Objectives

In the analyzed hospital, HLM project is usually implemented in four circumstances. The first one occurs after a future state value stream map. The second one regards an auto evaluation; after that, if the requested improvement actions are complex and involved different processes and figures, the guide of the HLM unit is considered fundamental. HLM projects can be also implemented following a 5S audit that needs actions similar to those of the previous point. In this hospital a HLM project can also be started after the analysis of process incidents or adverse events, which are eradicated in complex causes and which cannot be solved with a daily kaizen (Hamel, 2010). The analyzed project started in this last circumstance where a high error percentage in the drug administration process was reported. The intervention was required by the person in charge of patient safety. Thus, the first objective of the project was the reduction of adverse events. In particular, the team aimed to reduce them by 80%. Moreover, other secondary objectives included cost reduction of 5%, for drug supplying, drug stock optimization, reduction of expired and wasted material, increase of the trust to the provider and of the collaboration between pharmacy and inpatient unit, and methodology learning.

5.2 Organizational aspects

In the analyzed organization where more than 350 people are trained in HLM, an external support for this project was considered not helpful. They started to adopt HLM in 2008, with the help of a consulting company for two years and then they continue to apply HLM by themselves. However, in the first day of the kaizen one-hour lesson was provided by the HLM manager. Inserting HLM in the strategic plan of the hospital, management staff was involved (even if with a not active role) also in the multidisciplinary team created for the project, where two management engineers, two nurses, a person of patient safety unit, a pharmacy technician, a pharmacist and the responsible of the inpatient unit were considered. The team was engaged full-time in the project and the CRM manager was the propeller of the project. According to the usual kaizen procedure, the role of tutor has to be assigned to who has raised the issue; nevertheless, for this project, instead of attributing it to CRM manager, this role was assigned to the responsible of inpatient unit, who was also the leader of the project, while the referent was HLM manager.

Four weeks before starting the project, the tutor informed all the involved operators about the motivation and the objectives of the project and he sent a written communication to each member about his specific assigned role. People that work in the field was consulted before the implementation: suggestions and opinions of employees were gathered in an initial brainstorming and several coordination meetings were executed. Two of them were carried out before the project starting: the first one involved the two management engineers and the patient safety manager and the second one involved also the inpatient unit manager. At the beginning of the project implementation two management engineers, the patient safety manager and the patient safety manager met together. During all the kaizen lasted three days, all the team took part in a daily meeting. A final meeting was executed to approve the improvement actions and to present what has been implemented. The same presentation was repeated with the top management. A closure meeting was carried out involving the leader, the tutor, the referent of the project and the responsible of economics and finance of the hospital in order to verify whether the objectives of the project were achieved or not.

5.3 Phases and tools implemented

Through the analysis of the errors, it was discovered the highest percentage of notifications came from the process of drug administration. 49% of them caused patient damages, 19% did not cause patient injuries, and the 32% were near miss events. After the identification of this problem an HLM project was required; therefore, objectives were defined and activities planned. First of all, the project was presented to motivate the team to the achievement of its objectives. A short lecture was provided, data were gathered and elaborated and the possible causes of problems were identified through problem analysis adopting brainstorming, 5 Whys and Ishikawa chart. The main sources of the issues regarded the lack of adequate procedures, the presence of not followed procedures, the lack of tasks distribution and responsibilities definition, no communication channel between the pharmacy and the inpatient unit. Another brainstorming was executed for gathering the 52 ideas generated for the process improvement. The created post-its were imported in an impact-effort matrix, in order to identify the interventions to be carried out. The implemented actions concerned: firstly the definition of new safety rules, that imposed to write any treatment variations in the medical records, secondly the preparation and administration of medicines one by one according to the one-piece-flow logic, and

finally a double check of their name. Procedures for the requirement of urgent and not-urgent drugs were also defined, in addition to the delineation of methods for consumption and reposition, through the use of Kanban system and other visual management tools (shadowing, visual signals and illustrative procedures). Other activities carried out regarded the determination of roles and responsibilities for: management of the labels, revision of the amount and cleanness of the medicines stock, revision of the loop to return medicines to the pharmacy, management and adoption of new and expired drugs, revision and updating of the existing procedures. Moreover, the stock had to be adequate to the actual consumption, defining the current codes and the respected quantities, identifying medicines at risk and similar ones. Supporting this intervention, Pareto analysis was conducted to identify the most used codes, the safety coefficient was calculated (1.2 = medicine not indispensable; 1.6 = medicine not replaceable, but that stops patient assistance; 1.4 = other cases) to eliminate medicines not necessary and never required; moreover, visual signs were created to recognize the risky medicines. Quantitative and qualitative tools supported the phase of monitoring and evaluation of the adverse events through also the submission of questionnaires to the personnel.

5.3 Outcomes and tools for assuring continuity

Of course, the implemented actions have led to efficiency improvements, eliminating activities and material costly and not necessary, but especially they have provoked positive results in terms of patient safety. An incidents-causes matrix was created, reporting the percentage of each incident that has been prevented eliminating a specific cause in the kaizen event. Applying this computation for all the eliminated causes, adverse events, near miss events and errors were totally reduced by 84.38%. Through a better identification of medicines and new procedures for drugs administration, patient safety improvements were achieved. With the new methods for consumption and reposition of medicines, also irregularities of the flow have been reduced. Staff involved were satisfied and their expectations were met. From the questionnaires it emerges they have appreciated in particular time management, the approach adopted for problem solving and the active participation of all the people. Time constraints were notified as a project limit. However, an increase of the participation and motivation has been reported in addition to a more proactive use of HLM tools.

The implemented project could be the reference point for others. Its replication has been planned for other similar processes, but potentialities for different processes have been also recognized. In order to guarantee the continuity of HLM adoption, it is fundamental to share the achieved improvements, whereby all the personnel has to be involved, aligned and updated about all the procedures, through training sessions, documentation sharing in the intranet, information panels and illustrative procedures. It is important to share all the results of the project, as they are feedback about HLM effectiveness. After this project, plenty of ideas have been generated and will be considered for future implementations according to PDCA logic.

5.4 Enablers and obstacles

Some factors have facilitated the project implementation, whereas some others hindered it. First of all the responsible of inpatient unit was already trained about HLM philosophy and tools; he had already taken part in other kaizen projects, besides being respected and esteemed by his collaborators. Other key elements for a successful implementation of the project are: the creation of a multidisciplinary team, the search of continuous improvement and the continuous application of the methodology in a favorable climate where the culture of HLM is spreading.

On the front of the hindering factors, the first was the lack of importance perception of the alignment between the core processes and the support ones. Other obstacles were recognized in the inexperience of operators, little time for the implementation of the project and the difficulties to identify the patient and what is valuable for him.

6 Discussion and lessons learned from the analysed case

After the project analysis it is possible to grasp the lessons learned. First of all it has to be underlined that the project has been required and promoted by the CRM unit. The linkages between HLM and CRM seem to appear firstly from the organizational chart, as their organizational units are inside the same department and this facilitates their interaction. Moreover, HLM is normally adopted in this hospital to solve complex problems connected to CRM. Solving the research objective, the key characteristics of the analyzed project are summed up in table 2. The peculiarity of this case is that the linkage between HLM and CRM starts at the initial phase of the implementation. In this particular organization, the key trigger of the examined project is the requirement of the responsible

of patient safety and the first objective of the project is errors reduction, while efficiency improvements were secondary objectives. The support of the top management is expressed first of all in the strategic plan, which fosters the adoption of HLM for all the organization processes.

Tab. 2 – The key characteristics of the project.

PROCESS OF DRUG ADMINISTRATION				
Motivation and objectives	Trigger	Incident analysis due to complex causes		
	Objectives	<ul style="list-style-type: none"> • safety improvement (reduction of adverse events) • efficiency improvement (reduction of drug supplying costs and of expired and wasted material, optimization of the drug stock) • increase of the trust to the provider (pharmacy) and of the collaboration between pharmacy and inpatient unit • learn the methodology 		
Organizational aspects	Key figures	Leader: person responsible for inpatient unit Referent: HLM manager Tutor: person responsible for inpatient unit	External support	Not necessary
	Top management support	Definition of a strategic plan where HLM is a methodology for innovation and improvement and a long term objective is the 'Omega production system', Top management involved in the project	Employees involvement	Informed, involved, consulted
	Training	Short, at the beginning, plenty of people already trained	Team	Multidisciplinary Full-time
	Role of CRM	Propeller of the project, CRM objectives, Involvement from the beginning	Meetings	Before, during and at the end of the project
Phases (Tools)				
1. Identification of the problem (incident reporting)				
2. Definition of the objectives				
3. Planning of activities (Timetable, Plan Do Check Act (PDCA), checklist)				
4. Communication and training				
5. Data collection and analysis of the problem (Brainstorming, 5 Whys, Ishikawa chart)				
6. Generation and collection of ideas for the improvement (Brainstorming with post-it)				
7. Prioritization and planning of the activities to implement (Impact-effort matrix, PDCA)				
8. Implementation (Definition of procedures, Determination of roles and responsibilities, Visual management, One-piece flow, New safety rules, Double checks, Perfection of the Kanban, Pareto analysis, Safety coefficient)				
9. Monitoring and evaluation (Monitoring and closure meetings, n° of reported notifications, incidents-causes matrix questionnaire for feedback, final presentation, PDCA, archiving and sharing of the material)				
Outcomes	Results	Reduction of adverse events, > normality of the flow		
	Changes of the organizational system	Clear definition of tasks, roles and responsibilities, small modifications of some tasks		
	Changes of the organizational climate	Proactive adoption of the tools, increase of participation and motivation		
	Employees satisfaction	Operators expectations are largely met, adequate training, high participation and motivation		
Sustainability & lean continuity	Ideas development for future, personnel involvement, future training sessions, questionnaires of feedback, project archiving and sharing, reference project for future, demonstration of effectiveness of HLM approach			
Enablers	Manager of inpatient unit already trained, inpatient manager' leadership, multidisciplinary team, continuous application of the methodology, climate and culture	Obstaclers	Inexperienced operators, limited time, cultural aspects, no perception of the importance of support processes, difficulties to identify the patient and the value of activities	

Besides the high multidisciplinary of the formed team, the definition of key figures has to be highlighted, in addition to the selection of the responsible for the inpatient unit as tutor of the project, exploiting his leadership and his HLM knowledge.

The collaboration of people with different backgrounds and points of view has been fundamental for the success of the project implementation.

Discussing the causes of the adverse events it emerges errors can be prevented improving organizational aspects, instead of identifying individual and personal faults that need to be punished and better trained. In this way the knowledge of the physicians are guaranteed and protected against organizational factors not well cogitated (mistakes rather than slips and lapses). Besides the use of hospital intranet and basic tools, no other particular ICT have been adopted. ICT seems not indispensable for the adoption of a system based approach that avoids human errors.

The phases and the tools to be followed for a successful implementation of the project that permits to achieve CRM objectives are reported in tab.2.

The presence of many empty answers in the feedback questionnaires, due probably to the lack of adequate experience, and the key project enablers, illustrated in the previous section, highlight the importance of the “soft” aspects (Shah and Ward, 2003; 2007) of a good implementation of “lean & safety” projects. Cultural aspects and the involvement of people already trained result fundamental. Moreover, archival documentation is considered relevant to assure the continuity of the adoption of these managerial approaches. This contributes to the organizational learning, providing formalized guidelines that could be adopted by others units to replicate the project. As emerged from the project analysis, for an organization that intends to develop the “Omega production system”, the capture and dissemination of the knowledge created during the project are vital, in order to guarantee the transfer of the knowledge according to knowledge management processes identified in literature (Carlucci & Schiuma, 2004; Wiig, 1997) that comprises generation, codification, application, storing, mapping, sharing, and transfer of knowledge. Dombrowski et al. (2012) underline Lean Production System is not simply a process redesigning; in order to create sustainable changes people's knowledge has to be modified. Moreover, the definition of key roles and the contribution of experts, which provide their experience in the project implementation, emphasized by Dombrowski et al. (2012), have been found also in the analyzed project.

7 Conclusions

The connection between HLM and CRM is not studied in literature yet, as this research stream is still at its early stage and requires extensive investigations (Crema & Verbano, 2013a). Giving a contribution to fill in this gap, context of application, organizational aspects, phases, tools and practices and key factors for a successful “lean & safety” project implementation have been described in this paper. This is one of the first researches that investigate the characteristics of a project in which HLM is adopted to solve CRM issues. The results suggest that HLM and CRM should be considered in an integrated methodology. First indications about how developing it have been provided stimulating future research, to test and exploit it, also in other contexts, such as different hospital units inside the same hospital, or other healthcare organizations that need to achieve efficiency enhancement, improving quality and patient safety at the same time. A second contribution of this study is the creation of a research framework, which could be considered as the basis for coding other cases, in order to carry out a comparison and a multiple case study to generalize the obtained results. Moreover, a further monitoring and evaluation of the first obtained results could be useful to refine the present research. Elements of knowledge management have emerged as enablers of the examined project. Creating a model of knowledge flows and studying the knowledge management tools helpful for these kind of projects could be an opportunity for further research, to study in more details how it is possible to implement sustainable “lean and safety” projects. The indications provided in this research contribute to the definition of guidelines to follow during the application of a synergic methodology, permitting to pursue multiple objectives in a challenging environment and fostering the development of more safe and sustainable health care systems for the benefit of the entire community.

Structured Abstract

Purpose – Health policy-makers are increasingly promoting programs that embed cost-opportunity logics. Their implementation requires the mobilization and exploitation of expert knowledge controlled by professionals dispersed in the territory, unaccustomed to share/integrate their knowledge with others, and sometimes adversary to cost-opportunity logics. The success and viability of these programs thus depends on experts' commitment to mobilize and integrate their knowledge. Past studies highlight reasons why policy might not be able to stimulate change because of institutional forces that hinder knowledge mobilization and professionals' micro-processes and narratives that oppose new practices that alter their autonomy or their routines. The present study investigates if and how policy-makers can pursue a strategic change in their eco-system.

Methodology – We investigated the case of a new Health Technology Assessment (HTA) program in Lombardy. Our unit of analysis relates to the strategy implemented by Region Lombardy to implement the HTA program. We triangulated data from: (i) archival analysis of normative and documents; (ii) quantitative analyses measuring experts' participation in program, etc.; (iii) presentations and web reports; (iv) direct interviews with key informants; (v) participant observations of meetings and workgroups. Interviews involved the regional staff implementing the HTA program and a panel of 28 experts involved in its application.

Originality/value – Our study highlights the contribution of learning mechanisms on professionals' commitment to the new practice. The strategy implemented by Region focused upon professionals' learning and relied on three mechanisms: (i) cognitive mechanisms supporting learning through common language, frameworks and values; (ii) structural mechanisms supporting learning with inter-organizational infrastructures; (iii) procedural mechanisms supporting learning through methods and tools that institutionalized the new practice. The interplay of learning mechanisms was not sufficient to achieve the full-fledged diffusion of the practice in the territory, but 'only' to

disrupt indifference locally, and stimulate early HTA experiences that added up to the gradual legitimization of the practice.

Practical implications – Our analysis provides indications to policy-makers regarding the relevance and limitations of strategy of change entirely focused on learning mechanisms. It highlights the interplay of OLMs in creating an understanding of the change (instrumental for motivating individuals to engage in it) as well as a proper context, made of norms and infrastructures that are instrumental for allowing individuals the practical opportunity to mobilize and implement their knowledge.

Paper type – Academic Research Paper

1 Introduction

Healthcare systems and organizations worldwide are experiencing expectations to do ‘more with less’, i.e. balance the contrasting goals of constantly improving the quality of care while reducing its costs. Most recently, the financial crisis has made this call even more pressing and urgent. The diffused emphasis on ‘austerity’ in public spending, in particular, has reduced the amount of resources available to healthcare providers which are now, on their part, expected to take important decisions that regard eliminating, streamlining or grouping wards, departments and staff units; constraining the employment of new staff; limiting the acquisition of new technologies (Stine and Choksi, 2012; Karanikolos, Mladovsky et al., 2013).

Such limitations can be understood as an attempt to preserve the *universalistic* nature of Italian NHS by preserving its *financial sustainability*. The Italian constitutional law shapes NHS universalism by demanding that “the Republic safeguards health as a fundamental right of the individual and as a collective interest, and guarantees free medical care to the poor” (art. 32). This article – which explicitly defines health-care as a ‘merit good’ with no possibility for exclusion – successfully established the NHS as a fundamental pillar for *social sustainability*, since health care is provided with limited or no out-of-pockets costs for citizens. As a result, the Italian NHS is mostly managed by the State and Regions, and made of public hospitals, whose behaviors and expenditures have a direct and massive impact on Regions’ and State’s budget. It immediately ensues that, in a time of large deficits, the debate is wide open on how this universalistic model can be made financially sustainable, or might need to be challenged. How cost reductions can be

pursued in the act of a continuous improvement of care represents one of the most eloquent and central issue that the NHS is called to address.

As an alternative to linear budget cuts – which have intrinsic limitations to push forward the introduction of new technologies – a few policy-makers have recently sought to implement a logic of *cost-opportunity*, according to which a structured approach to delist obsolete technologies and practices might generate the financial conditions for the adoption of new ones. The cost-opportunity logic is based on the evidence that healthcare providers host a number of inefficiencies and wastes that consume resources without providing any impact on patient-related outcomes. By spotting these inefficiencies, subtract them from the system and replace them with better performing technologies, the cost-opportunity logic hold the promise of achieving continuous improvement within the boundaries of financial sustainability.

In this regard, Health Technology Assessment (HTA) programs are emerging as an increasingly popular solution. HTA provides in fact a structured approach to identify which technology, among different alternatives, is most adept to address a specific clinical problem. It does so by comparing these alternatives through an evidence-based and multidisciplinary approach, i.e. by comparing their impacts on clinical effectiveness, costs, safety, organizational impacts etc. (Battista, 1992; 2006). HTA is consistent with logics of cost-opportunity since it considers if and how new technologies can substitute established technologies and to which extent obsolete technologies can be removed to create the ‘financial space’ for investments (Battista et al., 1998). Building on this premise, HTA experiences are spreading worldwide, with several agencies (e.g. NICE, ADTH, DHMA, DIMDI, HAS, IQWiG, Osteba) now actively involved in the production of HTA assessments.

Despite this interest, HTA programs still struggle to exert the expected balance between financial sustainability and the continuous improvement of care. A key reason for such struggle is the difficulty to *legitimize* HTA programs and outcomes to the various stakeholders involved in the HTA process. The problem of legitimization lies in the fact that HTA programs simultaneously affect and are affected by a heterogeneous *ecosystem of stakeholders* – citizens, professionals, healthcare administrators, policy makers and private firms – which (i) hold specific, and at times contrasting, needs and expectations about the introduction of new technologies, (ii) often consider HTA programs either irrelevant, alien or adversary to their interests. As a matter of fact, the outcomes of HTA

program directly affect stakeholders' decisions— to such an extent that the acquisition of a new technology might be inhibited or obsolete technologies might be delisted. This consequence leaves open the possibility that stakeholders might defy HTA outcomes and nullify the relevance of HTA programs. Yet, at the same time, stakeholders need to be involved in the production of HTA assessments. Regions cannot possess the expert knowledge required to assess the comparative appropriateness of new technologies. Such knowledge lies almost entirely on experts from the ecosystem – who thus must be engaged in the HTA process not just as passive recipients, but as active agents.

On top of these considerations, the present manuscript describes the implementation process of the new HTA program in Lombardy Region with the theoretical perspective of Organizational Learning Mechanisms (OLMs). This study aims at discussing the journey undertaken by the Lombardy Region to develop a regional network of multi-specialty experts through the implementation of a variety of OLMs. The main insights from this case provide leading practitioners and academics with new elements for furthering the debate about the complexity of learning processes.

2 The context

The Lombardy Regional Healthcare System is part of the Italian National Healthcare System (NHS) that is nowadays organized on a regional basis. The Italian NHS provides universal coverage free of charge. Due to near universal coverage, voluntary healthcare insurance providers have a marginal role in funding healthcare. The capability at the regional level to allocate the available tax-based resources effectively and efficiently is then essential.

In Lombardy, the total expenditure for healthcare delivery has risen from 7.9% GDP in 1990 to 9.1% GDP in 2011. These resources are employed to serve the 9.8 million inhabitants through the presence of 15 Local Health Agencies, 34 public hospitals and another 200 healthcare organizations - responsible for 2 million discharges annually. Healthcare delivery is possible through the daily work of 150,000 highly-specialized health and social care professionals who are employed in hospitals or other healthcare organizations, 8,150 General Practitioners and Pediatricians. Additionally, the private sector comprises 2,500 private healthcare organizations. The total bed capacity is thus around 30,000 beds. The annual expenditure amounted around 17b€ (17% of Italian total) in 2011.

The Lombardy Regional Healthcare System is considered the leading healthcare system in Italy because of its capability to deliver state-of-the-art care while containing its healthcare expenditure. In fact, this system is one of the few in Italy that shows equilibrium between cash inflows and outflows, while other Regional Systems collected relevant deficits. Despite this favorable situation, the Lombardy Region has to face the continuous shrinking of financial resources available for care, and find new paradigms for assuring the same care to future patients, or potentially better regarding quantity and quality of health and social care services. Within this context, technology plays a relevant double-faceted role. On one hand, technology is a major lever for elevating the current standards of care; on the other, it is one of the most critical factors for cost increases (Chandra and Skinner, 2011). This implies that the Region can govern this transformation process only by offering patients and professionals only those technologies that proved safe and offered value for the-money.

2.1 Lombardy technology assessment program

The capability of assessing healthcare technologies has become an urgent worldwide issue for policy-makers, practitioners and scholars of different disciplines. The Health Technology Assessment (HTA) framework has affirmed itself as the golden standard in all of the most industrialized countries. A variety of educational programs has grown around this discipline in order to educate a multitude of healthcare professionals (physicians, economists, engineers etc.). This has also occurred in the Lombardy Region, which has delivered many courses over the last five years.

Within this context, in 2008 the Lombardy Region decided to implement an HTA regional process aimed at supporting health policy-makers in deciding which technologies to introduce. The process grounds significantly on experts (mainly physicians, economists and engineers). The reason is straightforward: professionals are the only ones who possess the know-how and know-why to appreciate and substantiate what kind of innovative technology should be utilized in a context of limited resources. The Region is able to coordinate its efforts and implement its vision and strategy in the process, but the actual assessment activities need professional expertise.

Through a formal scouting process, the Lombardy Region selected around 200 experts from different fields: medicine, pharmacy, healthcare economics, engineering, information systems etc. Unfortunately, professional involvement was far from obvious

for at least two reasons. Firstly because very few had had any experience of HTA, as most simply did not know what HTA was or how they could contribute to it. Secondly, professionals are often skeptical of contributing to efforts they often do not recognize as relevant, but simply perceive as highly time consuming.

At the beginning, the efforts of engaging experts in the assessment activities were focused on providing them with state-of-the-art competencies regarding HTA. Despite high-quality instruction, results were modest in the early stages: only few “opinion leaders” contributed to HTA activities, while the majority intermittently attended meetings and rarely delivered value-adding contributions.

This initial failure pushed the Lombardy Region to revise its strategy and integrate teaching efforts with the activation of different Organizational Learning Mechanisms (OLMs). The new strategy produced surprising results since now the Region is able to leverage its HTA process on a community of 200 experts who all participate actively to its community life. Additionally, this community is today able to systematically learn and continuously improve its processes, practices and behaviors. A major part in this “success” was passed through the capacity to educate professionals about the use of HTA through a more articulated delivery of teaching methods and learning activities.

In the next sections we will describe what the Lombardy Region has done, and has kept on doing, to achieve these goals. These interventions can be characterized in terms of OLMs, so we will first outline the key concepts of OLMs, and then describe the specific interventions put into place by the Lombardy Region.

3 Organizational learning mechanisms

OLMs are the arrangements that allow organizations to systematically collect, use and disseminate information that is relevant to the effectiveness of the organization (Argote, 2011; Popper and Lipshitz, 2000). This definition implies that learning does not only emerge through the routine activities performed within the organization. Different OLMs can be designed to introduce new concepts and behaviors that are external to ongoing routines. OLMs thus concur to describe learning processes that take place beyond the mind of employees. OLMs can also be understood as concrete social arenas where knowledge is shared by individual members and becomes the property of the entire organization through dissemination and changes in standard routines and procedures.

Shani and Docherty (2003, 2008) provided a classification that distinguishes three broad categories of OLMs. First, cognitive mechanisms support learning by providing language, concepts, symbols, theories, frameworks, and values for thinking, reasoning, and understanding learning issues coherent with the strategy of the organization. Language learning is used mainly in the human resources field, in which one can equally find the term learning capability. Cognitive mechanisms allow for creating an understanding among all employees about the nature of organizational strategies and about the learning required to support these changes. Mission statements, strategy documents, policies and plans are some examples. Second, structural mechanisms concern organizational and technical infrastructures that encourage practice-based learning. They include communication channels; changes to work organization, the establishment of teams with the mutual need to learn; formal and informal forums; and learning-specific structures such as parallel learning structures and process improvement teams. Third, procedural mechanisms include the rules, routines, methods, and tools that can be institutionalized within the organization to promote and support learning (Pavlovsky et al., 2001). They may include assessment tools and methods, standard operating procedures, methods for collective learning (e.g., action learning) and de-briefing routines. Work-based dialogue and de-briefing procedures are two examples of methods that allow participants to learn from each other's experience. We use this classification to understand the Lombardy Region interventions and deliver the main insights.

4 Methodology

Our research interests were addressed through a holistic longitudinal case study on the design and implementation of the HTA program of design to answer this question. This methodology is adept to address exploratory and explanatory questions – which also reflect the criteria of focusing on contemporary events, not requiring control of behavioral events (Yin, 2009). Our unit of analysis related to the design of the HTA program, and to the implementation initiatives put forward in the years 2009-2012. We triangulated data from different sources. First, an important source of information related to the documentation and archival data produced by the Region over the years. The Regional law DGR 7856/2008 represents a relevant source of information on the key design choices made by Lombardy Region concerning the objectives, process and actors of the

HTA program. Subsequent regional laws provide further refinement to the HTA program and were taken into account in our analysis. A second important source of information related to the 'Multidimensional Impacts Form' that experts have to fill to make the assessment of the new technology. This document represents the primary source of information on the design choices made by Lombardy Region concerning the model of the HTA program

Second, interviews with key informants were the primary data source. Key informants were both the regional staff responsible for developing and implementing the HTA project as well as a panel of 28 experts involved in the assessment activities. We selected experts who showed a different level of engagement (very active, moderate active, and limited) and different backgrounds (17 physicians from different specialties, 5 health economists, 4 clinical engineers and 2 hospital information systems managers). The semi-structured interview consisted of three parts: (a) a description of the involvement in the HTA process, with particular attention to the willingness and ability to perform HTA-related activities and to take part in community life; (b) a description of the teaching activities and of the OLMs implemented by the Lombardy Region; (c) a description of the current state and performance of the Regional HTA process. The interviews were conducted from January-June 2012 by a research team comprised of two investigators who are the authors of this manuscript. The first investigator led the interview and personally interacted with the informants. The second investigator remained more detached as his primary role was taking notes and filling in gaps during the questioning. All interviews were tape-recorded. In the close aftermath of the interview, the tape-recording was transcribed by an investigator.

Third, the investigators directly participated in the HTA program, as members of the prioritization/appraisal groups. This participation allowed direct observations of the dynamics involved in the production of the HTA outcomes as well as of experts' involvement in the program.

5 Findings

The problem of getting professionals' involvement and providing education could not be entirely unraveled. A striking recursive relation could be immediately observed: (1) professionals' commitment toward HTA mostly depended on how much they had learnt about the use and benefits of HTA, while (2) professionals' acquisition of competencies

about HTA heavily depended on how much they were committed to the method. OLMs were then closely linked in an effort to provide commitment while providing competencies. Recognizing this problem resulted in two solutions: (1) to provide a wide spectrum of OLMs, comprising cognitive, structural and procedural mechanisms, since a single typology was unlikely to exert the expected results; (2) to provide a deepening of the structure to each OLM, so to encompass both education and commitment. Table 1 provides an overview of the key initiatives.

Table 1. Organizational Learning Mechanisms Initiatives

OLM	Definition	Initiatives
Cognitive	Learning is supported by providing language, concepts, symbols, theories, frameworks and values for understanding	✓ The regional law DGR 7856 (July, 30th 2008) formalized both language and concepts.
		✓ Publications and reports are shared among the members of two teams (NVP-CI and TTRAM) to promote a common language and the engagement of behaviours oriented to evidence-informed and multi-specialty assessment of new healthcare technologies
		✓ Interactions among the members of the NVP-CI and TTRAM teams are encouraged to create an enabling social context that can leverage on a shared cognitive social capital
Structural	Learning is supported by all the organizational, physical, technical and work system infrastructures that encourage practice-based learning.	✓ A dedicated website has been built to converge all the information and the debate about the assessment of new healthcare programs and technologies
		✓ Monthly meetings for the NVP-CI team and monthly meetings for the TTRAM have been established to build the community and facilitate a common understanding of the goals and the methods by leveraging on the social context and face-to-face exchanges
		✓ A set of KPIs have been defined and monitored to inform the task force about the level of engagement of the community that is under development and the level of learning
		✓ Politecnico di Milano has been identified as a key partner for implementing audit activities and assuring a third-party appraisal of the HTA-related activities
		✓ A systematic relationship with EVIDEM has been established to allow EVIDEM to monitor the progress in the Lombardy Region and suggest ideas for improvement
Procedural	Learning is supported by the rules, routines, methods and tools that can be institutionalized in the organization to promote and support learning.	✓ The regional law DGR 7856 (July, 30th 2008) formalized goals, methods and phases.
		✓ A tool-kit for education and diffusion is under development. This case is part of it.
		✓ Members of the task-force are systematically invited to conferences, workshops and masters to diffuse the methods implemented and the results achieved
		✓ A manual has been developed to clarify the HTA process step-by-step, its goals and methods are to facilitate learning by practitioners and feedback from academics

The first set of interventions involved lectures and (mini-)courses to teach professionals and experts the core aspects of HTA, and to explain how their contributions would fit into the novel HTA process. Notably, this set of interventions exerted a minor impact on professionals who had limited time to dedicate to HTA courses. As a matter of fact, it became quickly evident how professionals' learning was not able to occur before, but only during their involvement with HTA activities. We thus had a straightforward case of "learning-by-doing" in which the know-how and know-why were learnt during practice. The primary role of learning-by-doing stressed the importance of having professionals actually "doing" HTA at some point. How to get them involved was the fundamental issue.

In this regard, four initiatives sorted out most problems. First, a regional law formalized the introduction of HTA in the Lombardy Region. It moved in two directions. On one hand, it was a procedural learning mechanism, intended to communicate the set of concepts, methods and phases that were about to be implemented through the HTA program. As such, it was a first milestone and a permanent reference point for any professional and expert involved with HTA. On the other, it was intended to trigger a cognitive learning mechanism. The Region decided to use a formal intervention to recognize (and legitimize) how professionals and experts were about to have an increasingly relevant role. The latter aspect was intended to push the diffusion of HTA concepts and practice among professionals. Second, the Lombardy Region put forward a website completely dedicated to the HTA process. The language, goals and methods are consolidated here, deepened and updated. Its relevance is twofold: (1) it is the reference medium through which Regional staff and professionals are connected and interact; (2) it is a dynamic tool, through which the Region is able to provide instructions to professionals and share previous experience. Last, regular meetings are organized every month. These meetings are occasions for professionals to meet with Regional staff. More than the website, meetings are the occasion for opinion leaders – which also include some professionals – to support others in specific HTA activities, to promote more active involvement and share knowledge. The Lombardy Region has been working to build formal relationships with Italian leading Institutions to reinforce the cognitive legitimacy of HTA. A formal agreement was signed with AGENAS, i.e. the national Agency coordinating all the Italian Regional Agencies for healthcare. AGENAS has been appointed by the Italian Ministry of Health as the reference institution in Italy for the promotion of HTA and the development of shared practices among the Italian Regions. The Lombardy Region joined the RIHTA (i.e. Italian Network for HTA) project and made the practices and knowledge developed in the last three years available to all the other Regions. By becoming part of both the international and national networks, the Lombardy Region was actually able to promote professionals' willingness to learn and deepen HTA-related concepts and methods, and to actively participate in the HTA community. Matching educational programs with an external legitimization has both triggered and enabled this transformational journey towards a sustainable effectiveness by developing a legitimized decision-making practice.

6 Discussion

The transformational journey led by the Lombardy Region for building a community of HTA multi-specialty experts offers new insights for furthering the current debate about the complexity of learning processes. With HTA being a complex and non-routine task, the Lombardy Region could not leverage on pre-existing competencies among its professionals, or on a diffused conviction that HTA was an important thing to do. The Lombardy Region had to exploit the knowledge assets embedded in the constellation of organizations that populate the healthcare eco-system. In particular, the Regional task force understood that the dynamic knowledge among its people was increasingly more relevant, for decision-making, than the codified organizational knowledge embedded e.g. in tools, tasks, technologies. However, this type of expert knowledge is not fully accessible to Region executives, since it is controlled and protected by experts from the “bottom level”. Because of this information asymmetry, executives can foster experts’ willingness to share knowledge by leveraging their social context.

The initiatives then worked to support knowledge sharing and decision-making improvement by creating internal mechanisms for learning and developing environments conducive to learning. Various initiatives were experimented with to institutionalize structural and procedural arrangements allowing experts to systematically collect, disseminate and use information relevant to HTA. The Lombardy Region worked on three broad categories of initiatives that leverage on cognitive, structural and procedural learning mechanisms, to promote and sustain change. It is crucial to observe the role that cognitive legitimization has played in supporting these learning mechanisms. The very possibility of learning came from a diffused legitimization of HTA as something relevant and “worth taking time for”. Each initiative was always considered an occasion to push the legitimization of HTA by “making things easier” for the professional (e.g. the website), promoting its strategic relevance (e.g. the regional law) and bringing together the opinion leaders with less proficient experts (e.g. meetings). Each initiative was multi-faceted, and retained a double track: (i) providing knowledge and (ii) providing legitimacy. The relation is recursive: by providing knowledge, the virtues of HTA become more apparent and more legitimate; by making HTA more legitimate, professionals are more active in using and sharing their knowledge.

On further analysis, knowledge represented a major trigger and enabler of such cognitive legitimization. The fact that this knowledge was largely unspoken and

contained to the experts meant that the Lombardy Region had to face the challenge of mobilizing this knowledge to leverage on it. Experts are expected to engage the technology assessment challenge and share their precious, complex and tacit knowledge with others to allow for improvements. Improvements will be the result of both the exploitation of current knowledge and the exploration of new knowledge. With this respect, the Lombardy Region became aware that knowledge sharing is an intentional act, meaning that, in order for experts to share knowledge they must not only be able but also willing to do so. Neglecting this evidence may prejudice the understanding of which organizational strategies and levers effectively promote and facilitate knowledge sharing among experts. With this respect, knowledge sharing is a socially embedded phenomenon, and experts' willingness and ability to share their knowledge and perspectives about new healthcare programs and technologies are the result of complex interactions among individuals within a social setting. Accordingly, social relations are thus considered as more efficient mechanisms for sharing both tacit and explicit knowledge among individuals and help them learn, rather than other mechanisms, such as information systems and formal control. In fact, the task force is stressing the need to 'go beyond information systems' and to implement a bundle of different organizational arrangements – e.g. flexible work structures, clan-fostering initiatives, trans-specialist development - to facilitate knowledge sharing.

7 Conclusion

Our case illustrates an example of policy-makers organizing (and strategizing) for sustainable effectiveness. The problems faced by policy-makers might appear paradoxical: multiple actors in the eco-system separately contribute to a shared greater good (e.g. care effectiveness, safety, patient accessibility) maximizing their local practices – however they struggle to integrate their efforts in new practices that put together their peculiar disciplinary perspective.

The case advances the notion that the logic of 'cost-opportunity' might mediate the logics of 'appropriateness' and 'efficiency' pursued by professionals and managers (Llewellyn, 2001). In order to do so, however, OLMs are crucial to create not only an understanding of the change, but also the learning context - rules, norms, infrastructures that allow professionals to implement that logic in their practice.

Structured Abstract

Purpose – This paper describes a “work in progress” research project being carried out with a public health care provider in the UK, a large NHS hospital Trust. Enhanced engagement with patients is one of the Trust’s core principles, but it is recognised that much more needs to be done to achieve this, and that ICT systems may be able to provide some support. The project is intended to find ways to better capture and evaluate the “voice of the patient” in order to lead to improvements in health care quality, safety and effectiveness.

Design/methodology/approach – We propose to investigate the use of a patient-orientated knowledge management system (KMS) in managing knowledge about and from patients. The study is a mixed methods (quantitative and qualitative) investigation based on traditional action research, intended to answer the following three research questions:

- (1) How can a KMS be used as a mechanism to capture and evaluate patient experiences to provoke patient service change
- (2) How can the KMS assist in providing a mechanism for systematising patient engagement?
- (3) How can patient feedback be used to stimulate improvements in care, quality and safety?

Originality/value –This methodology aims to involve patients at all phases of the study from its initial design onwards, thus leading to an understanding of the issues associated with using a KMS to manage knowledge about and for patients that is driven by the patients themselves.

Practical implications – The outcomes of the project for the collaborating hospital will be firstly, a system for capturing and evaluating knowledge about and from patients, and then as a consequence, improved outcomes for both the patients and the service provider. More generally, it will produce a set of guidelines for managing patient knowledge in an NHS hospital that have been tested in one case example.

Paper type – Academic Research Paper

1 Introduction

Knowledge management in health services has concentrated almost exclusively on clinicians and managers. Patient knowledge has rarely been considered except where the service is being provided in the patient's home (Cegarra-Navarro et al., to appear). With health service providers trying to meet the growing demands of an ageing population with limited resources, it is time to seize this missed opportunity. There is potential to use this knowledge to improve the outcomes for both healthcare providers and patients.

Patient knowledge as a concept should not seem very unusual to those in the knowledge management (KM) field, even if the phrase is unfamiliar. It is the specific form that customer knowledge takes in health care. Customer knowledge management has been an active field of research since the paper by Davenport et al. (2001). Two central concepts emerging from customer knowledge management are the categorisation of different types of customer knowledge, and the attributes of "attractive quality".

Using these and other concepts from research on customer knowledge management, and from broader research on service management, including service quality and service productivity, we plan an action research investigation of the use of a patient-orientated knowledge management system (KMS) in managing knowledge about and from patients. The study is to be conducted in a large UK National Health Service (NHS) public hospital. It is a mixed methods (quantitative and qualitative) investigation intended to address the following three research questions:

- (1) How can a KMS be used as a mechanism to capture and evaluate patient experiences to provoke patient service change?
- (2) How can the KMS assist in providing a mechanism for systematising patient engagement?
- (3) How can patient feedback be used to stimulate improvements in care, quality and safety?

We intend to concentrate in the first instance on elderly patients and their carers. The elderly represent the greatest users of healthcare services, but also the group least likely to be familiar with ICT systems. Specific objectives with this group are to clarify what matters most to elderly patients, and what a UK NHS hospital as service provider needs to know about/from them; to develop a method to capture the voice of this group of patients; and further, to feed this back into the management of NHS service provision.

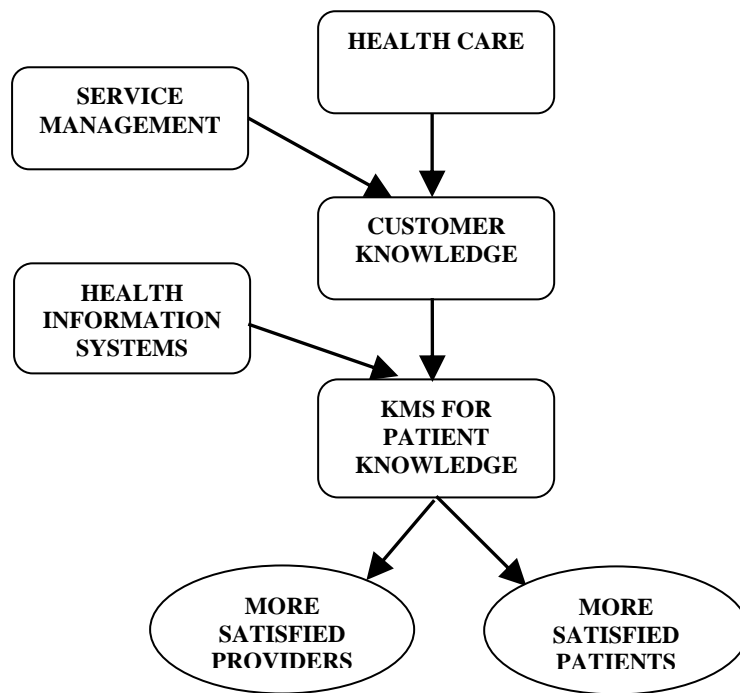

Figure 1: Logical structure of paper

Figure 1 illustrates the logical flow of this paper. Beginning with our domain of health care, the next section reviews ideas from service management and in particular the role of the customer and therefore customer knowledge. The focus then turns to customer knowledge management systems (KMS), bringing in ideas from the health information systems field, with the overall project aim being to help deliver better outcomes for both patients and health care providers. The project is "work in progress" at the time of the IFKAD 2014 conference.

2 Health care as a service and the role of customer knowledge

Lovelock and Wright (1999, p.6) define services as follows: "Services are economic activities that create value and provide **benefits** [emphasis in the original] for customers at specific times and places, as a result of bringing about a desired change in—or on behalf of—the recipient of the service." Thus there can be no doubt that health care is a service, even if it may include some tangible elements such as surgery and provision of drugs.

The role of the customer in a service is known to be important: Cook et al. (2002) view the "service encounter" as a triad, consisting of the customer, the service organisation and the customer-facing contact personnel. However, there is still a long way to go on the journey towards truly regarding patients in a public health care system as customers. In this section we review relevant concepts from the literatures on service management and service productivity, and then on customer knowledge management.

2.1 Service management and service productivity

Given the central involvement of the customer as the recipient of the service, the conventional manufacturing concept of value creation is not sufficient: it is more useful to consider a service as a process of value *co*-creation by the provider and the customer (Parasuraman, 2002). This immediately raises the point that the customer's perspective is not necessarily the same as that of the service provider organisation, even if the real situation in health care is not as extreme as the old saw "the operation was a success but the patient died" implies!

Chase and Dasu (2001, p.84) advise those designing and managing services to "put yourself in your customer's shoes and imagine their journey". Parasuraman (2002, p.8) sets out five questions for such service executives, including two of particular relevance in health care:

- What inputs do our customers and we currently channel into our service process?
- In evaluating the results of our service operations, do we define the outcomes sufficiently broadly and from the perspective of our customers as well?

Vargo et al. (2008) consider the concept of value *co*-creation further, arguing that the distinction that matters is not simply that between goods and services, but between

"goods-dominant logic" and "service-dominant logic". The latter can apply even to the provision of goods, so that a car, for example, can be viewed not as an object but in terms of what one can do with it, even if that is simply show it off rather than using it to travel somewhere. Service-dominant logic is tied to the long-established concept of value-in-use, Vargo et al. ascribing the latter term to Adam Smith and the original idea to Aristotle. Vargo et al. go on to extend value-in-use to value-in-context, the latter based on the premise that "Value is always uniquely and phenomenologically determined by the beneficiary" (p.148). The money-based value-in-exchange may thus have no association at all with value-in-use. There is a clear linkage between the two to explain why the price paid for an "old master" painting varies so dramatically according to who is believed to have painted it, but it is much less clear in public healthcare provision, where there is often no direct cost for a specific service, the choice for the patient/customer is simply whether to have the service or not, and concepts of substitution or opportunity costs are far less well-defined than in conventional money-based economic theories. Nevertheless, the importance of customer inputs and perspective is well-established in this literature.

2.2 Service productivity in public health care and welfare

This lack of a direct link between value-in-exchange and value-in-context raises the question of defining service productivity in public services. Lönnqvist and Laihonon (2012) examine social service productivity in Finland. They first set out to define service productivity appropriately in what they term "welfare services" (which includes health care). The definition they offer (pp.132-133) is:

"Welfare service system productivity (WSSP) refers to the ratio between the services offered to the service user and the resources consumed by all organizations involved in the service process.

WSSP is affected by the productivity of the activities of each member organization of the system. In addition, at the core of system-level productivity lays the co-operation of participants, clearly defined and communicated system roles and agreed system-level objectives. System-level productivity stresses the customer perspective and, instead of focusing on direct service outputs, it turns the focus on the outcomes of a service."

Overall objectives in public health care usually at least partially meet this definition. In the UK, typically they are framed in terms of high quality of care, better patient

outcomes and cost effectiveness. The fact that "high quality of care" normally comes first appears to meet the requirement of the Lönnqvist and Laihonen (2012) definition to stress the customer perspective.

Another issue discussed by Lönnqvist and Laihonen (2012) is the complexity of public welfare provision, with several organisations involved. The need for a systemic approach in public health care to avoid sub-optimisation and assist focus on the overall outcomes has also been pointed out by others, for example Edwards et al. (2005). We will not discuss the complexity and coordination issues further here, as the first phase of our project concerns only services provided onsite by a single hospital.

2.3 Customer knowledge management

Having established the importance of the customer perspective both in service provision and in understanding improvements in service productivity, it is necessary to consider how an organisation might know what the perspective of its customers actually is - customer knowledge management. The benefits to an organisation of actively managing knowledge about its customers were first described by Davenport et al. (2001), on the basis of interviews with 24 for-profit organisations with headquarters in North America, and it has been an active field of study within KM ever since. Two concepts from customer knowledge management that are especially relevant to the research proposed here are the categorisation of different types of customer knowledge, and the attributes of "attractive quality".

Three types of customer knowledge have been identified (Garcia-Murillo and Annabi, 2002): knowledge *for* customers, knowledge *about* customers, and knowledge *from* customers. The organisation must manage knowledge for customers in order to better satisfy customers' needs for knowledge on products/services, the market, and other relevant items. Managing knowledge about customers enables the organisation to capture customers' background, motivation, expectation, and preference about products or services. Managing knowledge from customers is central to the organisation's understanding of customers' usage patterns or consumption experiences of products or services.

Chen and Su (2006) then combined these three types of customer knowledge with the earlier work by Kano and others (Kano et al., 1984) on "attractive quality". The three key dimensions of the latter are "must-have" quality, originally called "must-be" quality (the

essential elements of a product or service, often taken for granted and whose absence leads to dissatisfaction), attractive quality (unexpected elements that surprise or delight the customer but whose absence would not leave them dissatisfied), and measurable quality (one-dimensional aspects where a strict quality comparison is possible).

The relationship between the three types of knowledge and these three dimensions of quality is not an entirely straightforward one. However, in thinking about - and managing - attractive quality - Chen and Su present a logical progression through the three types of customer knowledge. First, the organisation's knowledge of product/service benefits is used to provide knowledge for customers, then knowledge about customers yields customer satisfaction categorisation, then comes an interpolated step of market segmentation which Chen and Su see as codifying tacit knowledge, and finally knowledge from customers enables the organisation to understand customer usage patterns for the product/service.

In the next section, we look at how to manage this customer knowledge, especially in public health care.

3 Knowledge management and KMS in health care

Our position regarding knowledge in this paper is a pragmatic one - the knowledge to be managed is whatever those involved (clinicians, managers, patients and their carers) think of as knowledge. Space does not permit discussion of the many definitions of KM and KMS. For knowledge management we prefer the early definition of Wiig (1994):

“In its broadest sense, knowledge management (KM) is a conceptual framework that encompasses all activities and perspectives required to making the organization intelligent-acting on a sustained basis. KM includes activities for gaining overview of, dealing with, and benefiting from the areas that require management attention by identifying salient alternatives, suggesting methods for dealing with them, and conducting activities to achieve desired results.”

For knowledge management systems, we prefer that of Gallupe (2001): “Knowledge management systems (KMS) are the tools and techniques that support knowledge management practices in organisations.” However, it needs to be understood that these tools and techniques do not have to be ICT-based, and may rely on people or process rather than technology (Edwards, 2009). Progress in ICT nevertheless offers new forms of

support for managing knowledge, i.e. new forms of KMS. An additional element that may be either a problem or an opportunity for KM is that large public health care organisations are large users of ICT, and often have to link their own systems with even larger regional or national systems.

Myllärniemi et al. (2012) study the management of organisational knowledge flows in health care, specifically a laboratory and a radiology unit in South Karelia, Finland. They take an approach based on defining use case categories that trigger the need for these services. They observe (p.61): "a common challenge for knowledge management in healthcare relates to excessive focus on patient data [as opposed to information or knowledge], though, the important role of interpretation and a human aspect on knowledge management were emphasized".

Cross-functional knowledge sharing was also identified as a general challenge (p.62): "From the point of view of knowledge dynamics the challenge seemed to lay in combining the actors' knowledge assets into a coherent and timely support for decision-making."

Chua and Banerjee (2013) examine how four types of social media (blogs, social networking sites, location-aware mobile services, and corporate discussion forums) can be used to support the three types of customer knowledge management explained in section 2.3, using Starbuck's as a case example. They assert on theoretical grounds that all four social media types can be used to support any of the three types of customer knowledge, and present evidence that eleven of the twelve combinations are already in use by Starbuck's. The lessons they draw may not, however, transfer to the NHS because of the more personal nature of the interaction between a healthcare organisation and its customers, and its position as the sole provider of public healthcare in the UK.

Berg (2004) categorizes important information types for informative-intensive organizations like hospitals and other healthcare organizations as follows:

- information about the patients;
- management information that contains information about the processes and outcomes of the organization;
- professional knowledge required to handle the patients optimally.

These categories offer some encouraging similarities to the customer knowledge types, but the use of the term "optimally" demonstrates that the crucial point about the difference between provider and customer perspectives is not part of this view. Thus,

although we might term it “outcome-informed”, it is a rather more passive approach than is generally associated with KM.

With a more active viewpoint, Gastaldi et al. (2012) examine Electronic Medical Record systems (EMR) in three large Italian hospitals in Lombardy, looking at the “feasibility of EMR as a trigger and an enabler of improved knowledge asset dynamics within hospitals” (p.17). The potential for improvement using the EMR is considered using the contrast between knowledge exploration and knowledge exploitation (Henderson and Clark, 1990, March, 1991). Gastaldi et al. define 14 different types of “ICT-based solution” which they look for in the three case hospitals. The EMR (on their definition this is the local system, i.e. in that hospital only) and links with the (broader regional) Electronic Health Record are two of the 14. They find three emergent strategies of EMR development:

- horizontal, mainly to achieve efficiency in clinical data management (low level, across all specialisms, exploitation comes first);
- vertical, mainly to achieve effectiveness in clinical data management (pervasively in one specialism before moving on to others, exploration comes first);
- transversal, to simultaneously achieve effectiveness and efficiency in clinical data management (most critical areas first, wherever they are, exploration and exploitation alternate).

Returning to the types of customer knowledge management, providing knowledge for customers has been core to the work of the UK NHS for many years, especially with the growth of online resources such as NHS Choices. However, there has been less emphasis on knowledge about customers, except within specific research projects about innovations, and less emphasis still on knowledge from customers. In many cases, what the NHS has about and from customers is a great deal of data but not much knowledge, as with the findings of Myllärniemi et al. (2012) in Finland.

4 Research project design

4.1 Project aims and research questions

This project is conceived as action research: research “which focuses on simultaneous action and research in a participative manner” (Coghlan and Brannick, 2010, p.43). The purpose is to make better use of knowledge about and from customers/patients. Given that

health care is a service, and so the outcomes must be considered from a customer perspective, greater patient involvement has the potential to improve the outcomes, certainly from the patient perspective and almost certainly from the NHS perspective. Note that we are moving back and forward between the words “customers” and “patients” here. The theory we use in this research is definitely about customers, but too much use of that term still tends to alienate many NHS workers. Thus apart from the term “KMS”, the research questions are phrased in ‘NHS language’ rather than ‘KM language’:

(1) How can a KMS be used as a mechanism to capture and evaluate patient experiences to provoke patient service change?

(2) How can the KMS assist in providing a mechanism for systematising patient engagement?

(3) How can patient feedback be used to stimulate improvements in care, quality and safety?

The emphasis on “how” signifies the action research focus, taking the “that” in each element for granted, but accepting that the research challenge is implemented these concepts effectively in public health care. Theory relating to knowledge about and from customers provides the foundation for the first two questions - that a KMS can help capture and evaluate patient (customer) experiences and help systematise patient (customer) engagement. Theory relating to service management, as well as customer knowledge management more generally, justifies the third - patient (customer) feedback is essential to properly incorporate the customer perspective in understanding and improving outcomes.

The research questions are also chosen to resonate with the “core principles” of the collaborating NHS Hospital Trust, especially the core principle relating to Patient Experience: “To ensure shared decision making and enhanced engagement with patients.” Note that a Trust hospital has more autonomy within the NHS than a non-Trust hospital.

A point to note is that NHS managers and clinicians have to act on the patient feedback. The collaborating Trust has made a good start here by formally monitoring and responding to comments made on the NHS Choices website: as Gorry and Westbrook (2012) have observed, product and service providers even in the for-profit sector by no means always do this.

4.2 Project stages and activities

The research element of the project is designed in three stages (after a preliminary stage), as shown in Figure 2. However, the intention of the ‘action’ part is not just to do this project as a one-off, but to set up a system that will carry out the key activities on an ongoing basis. Returning to the research questions, these are capturing and evaluating patient experiences, provoking patient service change, systematising patient engagement and stimulating improvements in care, quality and safety.

The research project necessarily has to place more emphasis on the capture and evaluation to help develop the ongoing systems that are needed, and hence these are distinguished as the first two phases before moving on to ensuring impact. Note also that the second phase (evaluate) explicitly incorporates the possibly different perspectives of clinicians and managers.

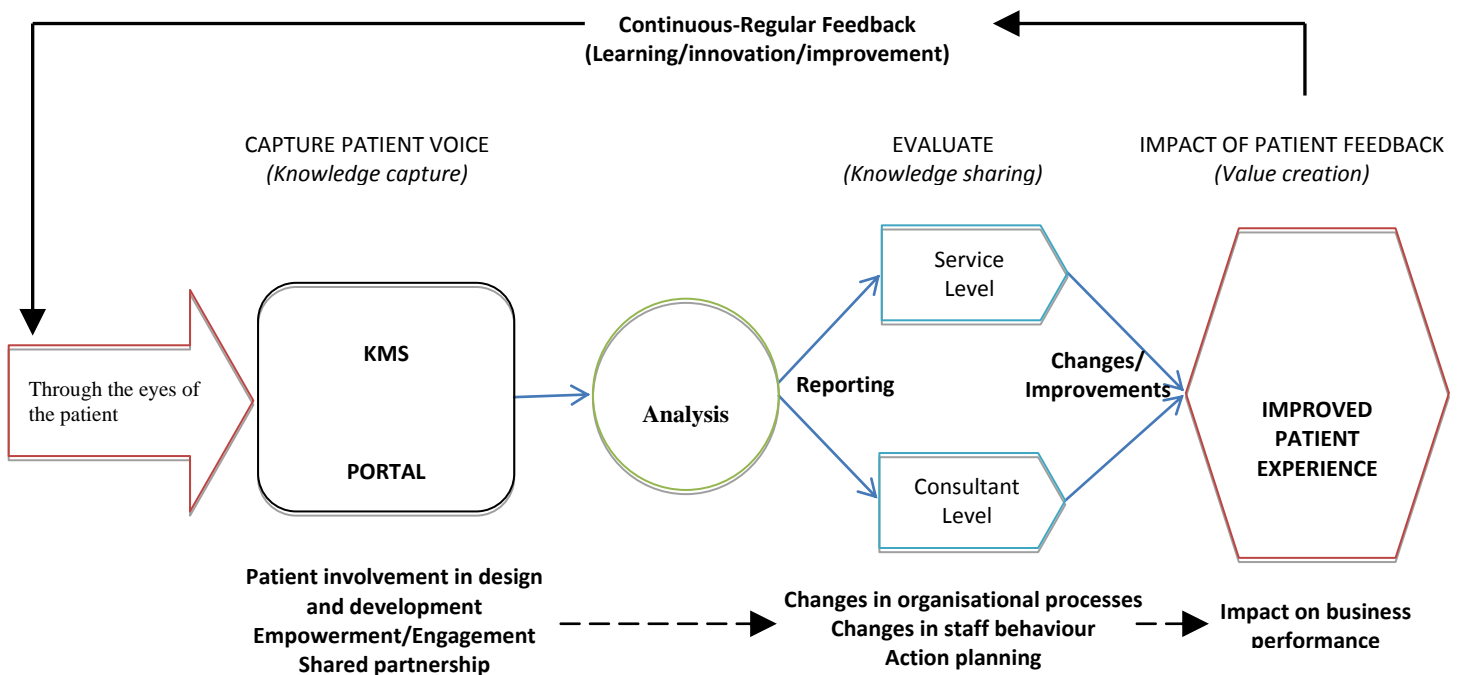

Figure 2: Research project stages and objectives

A most important caveat is that the preliminary phase of the project is to involve a selection of patients in the final design and development of the project as a whole. Thus

Figure 2 at present represents not a fixed plan, but rather a proposal for their discussion and if necessary amendment. hence we will not go into more detailed discussion of precise details at this stage.

4.3 Research method

Figure 2 is constructed around the “action” part of the project, but also guides the “research” part. Specifically it will be traditional action research (Coghlan and Brannick, 2010) as conceived by, for example, Lewin (1973). As in the previous section, our comments here have the status of proposals until the preliminary phase has been completed. Nevertheless, the project will definitely be a mixed methods (quantitative and qualitative) investigation. Qualitative semi-structured interviews will take place with patients, clinicians and managers, and focus groups with patients. The interview guides will be based on the theory from service management, customer knowledge management and KMS: as with the research questions, they will be phrased in health care rather than KM terms. At least three sets of interviews are envisaged: the preliminary study; guiding the development of the KMS; and once the KMS is in use. The latter in particular may need to be repeated. The main quantitative element is expected to be the analysis of performance and outcomes from the provider perspective (before and after implementation of the KMS), although if it is possible to carry out quantitative outcome analyses from the patient perspective we shall do this as well. Standard “provider” outcome measures are well-defined and recorded across the UK NHS. By contrast, devising appropriate patient outcome measures is part of this research project.

Broadly, therefore, the design of the implemented KMS will be based mainly on qualitative analysis, while the assessment of whether there are improvements as a result of the implementation will be based on both quantitative and qualitative analysis.

5 Conclusions

There appears to be considerable potential to use patient knowledge to improve the outcomes for both healthcare providers and patients. The theories of service management and of customer knowledge management both offer examples from other sectors of the benefits that the use of this knowledge could potentially provide. The challenge facing this action research project is to devise and implement ways to realise these benefits in the specific context of a public health care provider, a large UK NHS Trust hospital.

The project is work in progress at present. We hope to be able to report further developments (but not final results) by the time the IFKAD conference takes place.

Structured abstract

Purpose – The paper explores the relationship between learning process and innovative behaviour of employees in large and medium-sized manufacturing companies in Russia. The authors assume that intrinsic motivation, leadership, flexible organizational structure, culture of self-organization and self-development are supporting factors for employees' learning.

Design/methodology/approach –The constructs for dependent and independent variables are developed drawing on a literature review. Hypotheses on casual path dependence were put forward. The model is tested on a database collected in 2013 containing the responses of 95 employees from 15 companies. The Partial Least Squares Structural Equation Modelling (PLS-SEM) technique is applied.

Originality/value – This methodology provides evidence that suggests that for Russian companies the learning process and work context are the antecedents of innovative behaviour.

Practical implications – The findings suggest that to facilitate innovative behaviour managers should build a supportive environment for learning processes. This environment should be based on intrinsic motives, encouraging leadership, self-organization and self-development principles.

Keywords – learning, work context, innovative behaviour, empirical study, Russian companies.

Paper type – Academic Research Paper

1 Introduction

A knowledge-driven economy determines innovation as a key source of competitive advantage (Nonaka and Takeuchi, 1995; Sankowska, 2013; Fernández-Mesa et al. 2013). The factors that influence innovative behaviour are investigated from a theoretical and practical point of view (Smith et al. 2008). The studies such as Scott and Bruce (1994), Saros et al. (2008) underline the holistic perspective of innovative behaviour of employees. This means that innovative behaviour is influenced by a variety of different factors, which in turn interrelate. One of the core factors which impact on innovative behaviour is learning (Sankowska, 2013). If we define innovative behaviour as a process of new knowledge creation, learning becomes a prerequisite. At the same time, the learning environment and other company building blocks that create new knowledge are essential for effective innovation (Nonaka, 1998; Garvin et al., 2008). The authors assume that intrinsic motivation (Thomas and Velthouse, 1990), flexible organizational structure (Martins and Terblanche, 2003), leadership (Jong and Hartog, 2007; Sarros et al., 2008), culture of self-organization and self-development (Sarros et al., 2008) are supporting factors for learning that precede employees' initiative behaviour. The authors found out that the proposed combination of mentioned factors and their simultaneous impact on learning and further on innovative behaviour were not explored empirically although determined theoretically. This was the start point of this research and motivation for database collection oriented on exploration of the phenomenon of innovative behaviour.

The main research question addressed in this study aims to find empirical evidence of a relationship between learning and innovative behaviour, taking into account work context. Moreover, authors explore these processes in the companies which work in the developing market. According to Jamali and Sidani (2008) the field of empirical exploration of learning organization in a context of developing countries is underdeveloped. Such kinds of studies contribute to the theoretical issues of learning organization as well to its practical implementation.

The paper is organized as follows. Next section presents theoretical background and hypothesis development. Section 3 is devoted to methodology and data description. Further the results of econometric modelling are analysed. And section 5 provides the conclusions and discussion.

2 Theoretical background and hypothesis development

The concept of learning organization (Senge, 1995; Pedler et al., 1997) connects innovative behaviour and learning. In line with Garvin et al. (2008) and Holsapple and Singh (2005), the authors emphasize the significance of work context as an enhancer of and mediator between learning and innovation in a company. The research design of this study includes identifying four exogenous constructs: supporting elements for learning – motivation system, organizational structure, leadership and organizational culture. And two endogenous constructs: learning and innovative behaviour of employees. Figure 1 presents the proposed model.

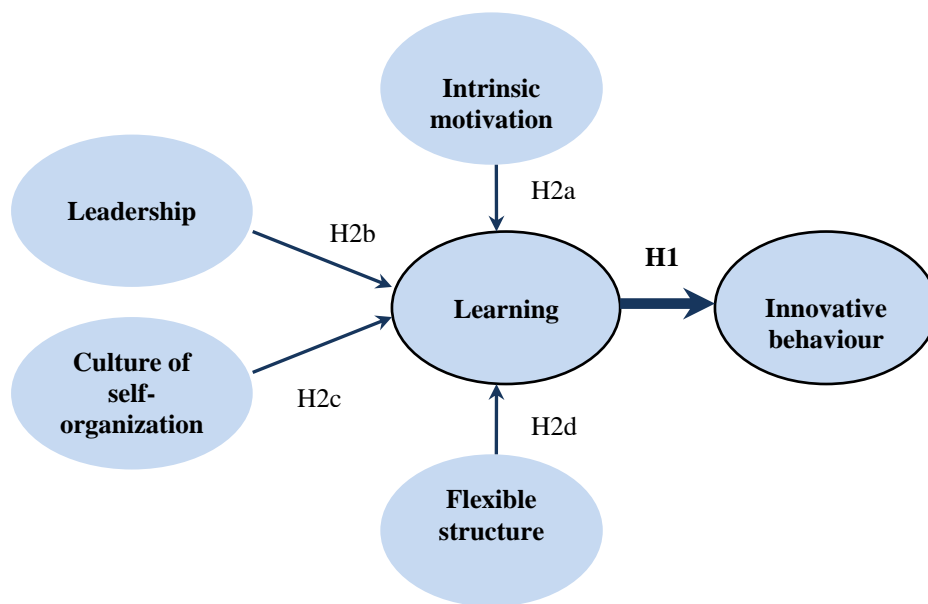

Figure 1. Framework of research

Innovative behaviour

This study considers innovative behaviour as employee activities directed at improving products and services as well as implementing new management tools and work techniques and excelling in knowledge creation in a wide sense. The link between innovative behaviour and companies' performance is explored profoundly. Meanwhile, the factors that determine innovative behaviour are less investigated due to the specific nature of explored phenomenon. The theoretical and empirical studies such as Scott and Bruce (1994); Smith et al. (2008) provide the evidence that the motivation to innovate is influenced by learning, management style, organizational structure, available resources, organizational culture and corporate strategy. In this study the authors assume that all these factors matter for innovative behaviour but the casual link should be built through learning.

Learning

The main characteristic of a learning organization is that learning processes are mandatory and on-going (Nonaka and Takeuchi, 1995; Pedler et al., 1997). Such organizations invest continuously in training and upgrading of individual and organizational skills. Knowledge is transferred between individuals, groups, and departments effectively and on a voluntary basis. The organization constantly identifies and accesses new external and internal opportunities, developing dynamic capabilities (Sankowska, 2013).

The main hypothesis tested in this study is:

H1: Learning has a significantly positive effect on innovative behaviour.

The next factors help create an environment that is supportive of the learning process. The second group of hypotheses reflect the relationship between different factors and learning.

Intrinsic motivation

Theoretically, there exists both intrinsic and extrinsic motivation (Deci and Ryan, 1985). The first means that motives are internal to the employee and that there is a self-evaluation mechanism at work. Intrinsic task motivation is achieved through: (1) meaning, i.e., value of work goal or purpose, competence, and self-determination; (2) autonomy in the initiation and continuation of work; and (3) impact, where employees

influence work results (Thomas and Velthouse, 1990). The literature supports the view that employees who are empowered, self-determined and intrinsically motivated have a greater degree of willingness to learn. The authors put forward the following hypothesis:

H2a: Intrinsic motivation is positively related to learning.

Leadership

Leadership is an essential element of a learning organization (Holsapple and Singh, 2005). As noted by Garvin et al. (2008) organizational learning is strongly influenced by the behaviour of leaders. Leaders in learning organizations inspire people to accomplish extraordinary results by applying charismatic leadership, creating larger-than-life mindsets, inspiring everyone to do their best, and mobilizing individual initiative (Garvin et al., 2008). More level leadership is developed through cultivating internal leaders by encouraging people to become leaders, filling positions with internal talent, and promoting from within. Such leaders stimulate change and improvement by continuously striving for self-awareness and renewal and developing dynamic managerial capabilities to enhance flexibility. Although several studies like Jong and Hartog (2007), Sarros et al. (2008) have found direct impact of leadership on innovative behavior, this study assumes that leaders motivate employees for learning and then they exhibit innovative behavior. Taking this into consideration the next hypothesis is:

H2b: Leadership is positively related to learning.

Culture of self-organization and self-development

The principles of self-organization and self-development suppose that an organization fosters individual growth and achievement by developing self-reliance and encouraging learning, probing, and discovering. Such a culture makes people feel that they are part of a bigger thing, and inspires them to achieve greatness; it instils in employees a sense of confidence, collective will, can-do attitude, and emotional energy (Chang and Lee, 2007). Employees have a shared strategic vision. As noted by Steiber and Alänge (2013) for continuous improvements the companies should select and facilitate self-organizing individuals in innovation processes. The empirical findings of Jamali and Sidani (2008) confirmed that in developing countries culture of self-organization plays a pivotal role for learning process. In the framework of this study the following hypothesis is put forward:

H2c: Culture of self-organization and self-development is positively related to learning.

Flexible organizational structure

The organizational structure determines the flexibility of business processes, the speed and quality of knowledge transfer, the possibility of the creation of new structural units and project development. Martins and Terblanche (2003) argue that structure is a key factor which promotes innovation and initiative behavior. According to their findings flat structure, empowerment, decision making and autonomy will promote new ideas, willingness to learn. The traditional organizational hierarchy should be broken down, establishing an agile organizational structure. Such a structure is characterized by highly transparent communication networks, clear rules for initiative implementation and resource distribution. All this enables an organization to be better in problem solving, experimentation and organizational learning (Holsapple and Singh, 2005). The last hypothesis is:

H2d: Flexible organizational structure is positively related to learning.

Five constructs are proposed to be the factors that facilitate innovative behaviour. They are concerned to be the part of learning organization. As mentioned by Garvin et al. (2008), a lack of empirical studies and concrete practical prescriptions on learning organizations impedes the development of this concept. This paper contributes to the empirical analysis of learning roles for innovative behaviour, taking into account the environmental factors that support or obstruct this link.

3 Methodology and data

For econometric justification of the hypotheses, the authors implement PLS-SEM analysis. This technique allows building the unobservable and hard-to-measure latent variables; and visually examines the relationships that exist among variables of interest. (Ringle et al., 2005). According to Hwang et al. (2010) and Wong (2010) PLS-SEM is proposed for application when a sample is small and there is little available theory. This study faces both restrictions; consequently PLS-SEM technique was chosen. The authors used Smart PLS software which is freely available to the research community across the globe and has been deployed in many fields, such behavioural science, marketing, organization and business strategy (Wong, 2013).

Data for this study were collected in 2013. The questionnaire was sent to the medium- and large-sized companies of Perm region per email. The authors received 112 responses from 18 companies. The final empirical data consist of questionnaire responses

of 95 employees from 15 Russian medium- and large-sized companies. Among the respondents 64% were male and 36% female; the distribution according to their position was as follows: 43% - top-manager; 34% - middle managers; 23% - specialists; 62% of respondents work in the company more than three years. All companies were from manufacturing industry.

The questionnaire was developed considering the previous studies of Watkins and Marsick (1998), Garvin et al. (2008), Jamali and Sidani (2008), and Galisir et al. (2013). The challenge that has been faced by the authors was the translation of metrics used by mentioned studies into Russian language. In order to adapt all metrics carefully the preliminary testing of each question was provided.

Learning activities and work context were measured questioning employees about the appearance of each item in their practice, on a scale ranging from 1 (does not appear) to 5 (appears very often). Questionnaires to measure innovation initiative had a scale from 1 to 5 as well. For all latent constructs depicted on the figure 1 the items (questions) were defined. Initially the questionnaire contains 60 items (questions), but after several iterations the constructs included in the model were described through 33 items. The criteria for selection were loading factors and item reliability. Table 1 presents items for each latent variable as well as values of item reliability.

Table 1. Latent construct and item reliability

Latent variable	Items	Loadings	Item reliability
Innovative behaviour	In my organization people frequently discuss and initiate the improvement of their work	0.877	0.769
	In my organization people frequently experiment with new ways of working	0.859	0.737
	In my organization people initiate the implementation of new ways of working	0.830	0.688
	In my organization people initiate experiments and development regarding new products or service offerings	0.762	0.580
	In my organization people learn new requirements, standards, rules without assistance	0.840	0.706
	In my organization people solve conflicts and establish effective communication without assistance	0.777	0.604
Learning	My organization identifies, develops and retains talented employees	0.851	0.723
	In my organization people help each other learn	0.773	0.597

	In my organization people are eager to share information and experience	0.817	0.668
	In my organization leaders generally support requests for learning opportunities and training	0.802	0.643
	My organization frequently compares its performance with that of competitors and best-in-class organizations	0.789	0.622
	The best practice of one department quickly diffuses within the organization	0.640	0.410
Intrinsic motivation	In my organization people are eager to solve new, atypical problems	0.702	0.493
	In my organization people demonstrate the willingness to participate in team-work	0.760	0.578
	In my organization people attempt to achieve best results even to the detriment of personal interests	0.872	0.761
	In my organization people are ready to use private time for education and training	0.853	0.728
	In my organization people are able to achieve results with minimum external intervention	0.783	0.613
Culture based on self-organization and self-development	My organization invites people to contribute to the development of strategy	0.665	0.442
	My organization builds alignment of visions across different levels	0.777	0.604
	In my organization learning and self-development are valued	0.896	0.803
	My organization supports and rewards team-work	0.921	0.848
	My organization encourages initiative and objective-oriented behaviour	0.870	0.756
Leadership	Managers effectively exhibit the role of mentor and coacher	0.748	0.559
	In my organization leaders inspire others to accomplish extraordinary results	0.875	0.765
	Managers encourage multiple points of view	0.910	0.827
	Managers provide time, resources, and venues for identifying problems and organizational challenges	0.822	0.676
	Leaders acknowledge their own limitations with respect to knowledge, information or expertise	0.773	0.597
	Leaders are the example of entrepreneurial and self-development behaviour	0.841	0.707
Flexible organizational structure	Organizational structure facilitates more equal leadership	0.713	0.508
	New units, departments and projects can be launched quickly	0.827	0.684
	Managers delegate authority and decision-making	0.753	0.567
	My organization provides resources for innovation initiatives and projects	0.800	0.640
	Clear and transparent regulations support implementation of innovation initiatives	0.793	0.628

As we can see, all of the indicators have individual item reliability values that are larger than the minimum acceptable level of 0.4, and most of them are close to the

preferred level of 0.7. All reflective latent variables show high levels of internal consistency reliability. The value of composite reliability for all variables is larger than 0.6. To check convergent validity, each latent variable's Average Variance Extracted (AVE) was evaluated. All of the AVE values are greater than the acceptable threshold of 0.5, so convergent validity is confirmed (Wong, 2013).

4 Results

In the framework of this study several models were tested using the smart PLS program. The authors choose the best model to explain casual path dependencies among the above-presented variables. The criteria of selection were the level of significance of each path and the explanation power of dependent variable. Figure 2 visualised the results obtained in this study.

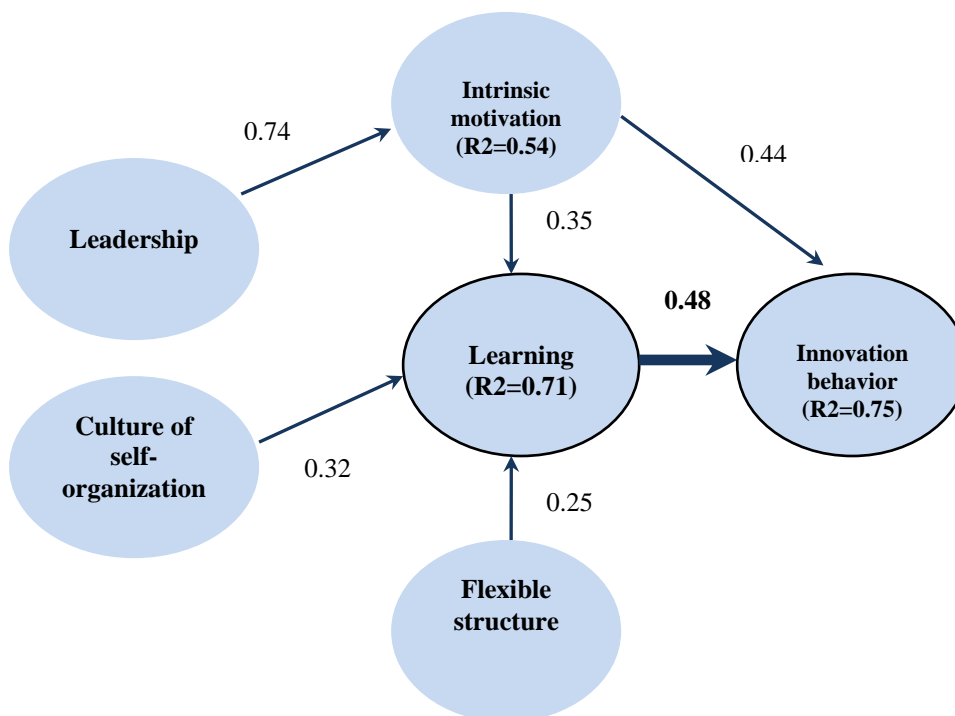

Figure 2. Results of PLS-analysis

Learning and intrinsic motivations explain 75% of the variance in the endogenous latent-variable innovation initiative, which is substantial. Meanwhile,

intrinsic motivation, flexible organizational structure, culture of self-organization and self-development explain 71% of the variance in learning. Leadership determines 54% of the variance in intrinsic motivation. The structural path significance was checked with the bootstrapping procedure. All indicators (see Table 2) show t-statistics larger than 1.96, which means the values are highly significant.

Table 2. Results of checking structural path significance

	Original sample (O)	Sample mean (M)	Standard deviation (STDEV)	Standard error (STERR)	T statistics ((O/STERR))
Learning -> innovative behaviour	0.48	0.4852	0.05	0.05	9.6721
Motivation -> innovative behaviour	0.43	0.436	0.0514	0.0514	8.5021
Leadership -> motivation	0.74	0.7375	0.0182	0.0182	40.3165
Motivation -> learning	0.35	0.3534	0.0362	0.0362	9.7666
Culture -> learning	0.32	0.3182	0.0461	0.0461	6.8903
Structure -> learning	0.25	0.247	0.0452	0.0452	5.4464

The implemented methodology provides evidence for the positive impact of learning on the innovation initiative of employees. This fact is reflected by the positive and significant coefficient – 0.48. The first hypothesis is confirmed.

Contrary to our expectations, not all factors influence learning directly. As we can see in Figure 2 and Table 2, flexible organizational structures as well as a culture based on self-organization and self-development principles have a significant positive impact on learning; intrinsic motivation has a significant positive influence on both innovative behaviour and learning. The most important factor for learning according to the PLS_SEM analysis is intrinsic motivation with standard coefficient value - 0.35. For innovative behaviour intrinsic motivation and learning are practically equally significant considering the value of their standard coefficients.

Leadership influences learning indirectly through intrinsic motivation. Hypothesis H2b is rejected but the findings show that leadership should not be excluded

from the framework of analysis. The results obtained in the database of Russian companies determine the role of leaders as enhancers of innovative behaviour and learning through developing intrinsic motivation of employees.

Summarizing the results of PLS-SEM analysis the authors revealed that the first hypothesis was confirmed and the second group of hypotheses were partly confirmed.

5 Conclusions

The study contributes empirical evidence on the implications of learning-organization principles in developing countries. It extends the ideas of Watkins and Marsick (1998) and Pedler et al. (1997), investigating learning-organization mechanisms and their impact on a company's innovation (Galısir et al., 2013) in practice.

The findings of this study confirm the pivotal role of learning for innovation in the context of developing markets. Moreover, the authors justify empirically that self-involvement, self-development, intrinsic motivation, decentralization and a more agile organizational structure are essential for the learning and consequently for the creation of new knowledge. The findings extend the results obtained for developing markets by Calısir et al. (2013) and Fernández-Mesa et al. (2013), confirming the hypothesis of the positive impact of learning as well as work context on a company's innovation.

The results of this study make evidence that all five factors proposed in the model matter for employees' innovative behaviour. Staying in consistence with studies of Nonaka (1998), Scott and Bruce (1994), Saros et al. (2008) this paper underlines the holistic view and systemic approach for investigating of innovative behaviour. For Russian companies the phenomenon of innovative behaviour is explained through learning and intrinsic motivation. For managers these empirical facts designate the spheres of interventions for effective innovation management. In order to facilitate learning process managers should create special environment based on self-determination, self-development and self-evaluation. This study confirms the argumentation of Garvin et al. (2008) that for effective learning the company needs supportive learning environment.

The authors consider the potential value of the presented study to be twofold: firstly, the methodology provides a questionnaire which is adapted from English into Russian and allows further exploration of Russian companies; secondly, the study provides unique empirical evidence of the enabling of innovation for Russian companies through learning and work contexts. The outcomes are expressed in practical recommendations for

managers to build learning organizations by designing and implementing organizational learning mechanisms.

The limitation of this study concerns the small size of the sample that can be extended in future research. Additionally, the fact of indirect impact of leadership on innovative behaviour stands in contradiction to the previous studies and therefore should be explored more carefully. The issues of cross industry comparison might be addressed in the future research too.

Revealing innovation potential in complex environments

Structured Abstract

Purpose – In this study the complex environments are approached with help of the concepts distance and proximity. The distance between innovating partners presents both a problem and an opportunity. This study is interested in what kind of distances there are in complex environments. In attempts to create innovation, different kinds of distances would need to be exploited knowingly. The purpose of this study is also to define different kind of methods to reveal innovation potential in distance.

Design/methodology/approach – This study uses a case study as a research strategy. The case study is a research strategy that focuses on understanding the dynamics present within single settings. This study builds on the MOTION! project which aims to develop the exercise and well-being industry, and create new collaboration models for co-operation between the private, public and third sectors.

Originality/value – In order to foster innovation and strengthen competitiveness, it becomes important to integrate different types of knowledge, competences and experiences into a cooperative perspective. However, it is far from clear how co-operative innovation processes including innovating partners with very different backgrounds and interests can be conducted successfully. This study attempts to shed light on the problem and outline methods applicable in such situations.

Practical implications – The identifying the distances between innovation actors facilitates the planning and coordination of the innovation activities. Distances may explain why some of the actions have not been successful or why some of the actions should be repeated several times. This study also gives practical examples how distances could be exploited knowingly.

Keywords – Complex Environments, Innovation Potential, Distance, Case Study

Paper type – Academic Research Paper

1 Introduction

The knowledge era is characterized by the forces of globalization, technology, deregulation and democratization collectively creating an extremely complex operating environment for organisations. This uncertainty and complexity creates risks but also opportunities, making innovation vital to achieving and maintaining competitive advantage. (Hyypiä, 2013; Uhl-Bien, Marion and McKelvey, 2007; Halal and Taylor, 1999.)

Companies are trying to respond to the increasing uncertainty and complexity in various ways. Development of open innovation and networking have already been well documented; they are based on the notion that tackling challenges in contemporary business environments demands a recognition of a shift in competitive factors from the company and industry level towards constellations of companies and other stakeholders linked together through knowledge flows and shared value creation processes. (Bakhshi, Freeman and Potts, 2011; Desai, 2010.)

In this study the complex environments are approached with help of the concepts distance and proximity. The distance between innovating partners presents both a problem and an opportunity. As distance increases, it has a positive effect on innovation by interaction because it yields opportunities for novel combinations of complementary resources. Knowledge building requires dissimilar, complementary bodies of knowledge (Boschma, 2005). However, at a certain point distance becomes so large as to preclude a sufficient mutual understanding needed to utilize opportunities of distance (Nooteboom et al., 2006). This study is interested in what kind of distances there are and how these distances prevent the use of innovation potential in complex environments. In attempts to create innovation, different kinds of distances would need to be exploited knowingly. The purpose of this study is also to define different kind of methods to reveal innovation potential in distance.

2 Innovation in complex environments

As Schumpeter splendidly crystallised almost a century ago, an innovation does not have to be something completely novel. Nor does it have to be radical; innovations can take the form of incremental social and organisational changes as well as technological advances. They are not solely the results of scientific work in laboratory-like environments; they are also developed in networks where actors of different backgrounds are involved in a process that demands innovativeness. The science-push effect as the driving force of innovations is the exception rather than the rule (Schienstock and Hämäläinen, 2001). More and more often, innovations emerge in practical contexts, leading to, for example, middleground innovations, in which knowledge from different disciplines as well as practical interests and scientific interests are combined (see e.g. Johansson, 2004; Harmaakorpi and Mutanen, 2008).

Innovation generation in organisations can be viewed as being dependent on two fundamental processes: analysis and interpretation (Lester and Piore 2004, pp. 5-7). The analytical process is generally assumed to be easier and more natural for business management, as it is based on the rational, linear decision-making models taught in engineering and business schools. But innovation generation entails more than problem-solving alone: innovation processes are affected by issues that cannot be 'solved' or unified in a logical, linear and analytical fashion. This has led to the recognition of interpretative innovation, which is often based on co-creation, a fragmented, on-going, open-ended, multi-voiced, dialogue-based process that emphasises interaction and communication (Lester and Piore 2004, pp. 6-8; 97-98). Harmaakorpi and Melkas (2012) support this interpretative type of innovation in their approach known as practice-based innovation.

From the perspective of innovation, knowledge provides the organisation with the potential for novel action, and the process of constructing novel actions often entails finding new uses or new combinations of previously disparate ideas (Weick, 1979; Hargadon and Sutton, 1997). Through the dynamics of creating knowledge, people can foster innovation, share knowledge and create new ideas (Nonaka and Takeuchi, 1995). For example, practice-based innovation highlights the fact that collaboration among people with expertise in different domains creates an environment conducive to the

emergence of knowledge sharing. (Parjanen, Harmaakorpi and Frantsi, 2010; Hennala, Parjanen and Uotila, 2011; Harmaakorpi and Melkas, 2012.)

Integrating various actors into the innovation process brings different kinds of knowledge into the organisation. Different kinds of innovative networks are important tools for getting new ideas and information from outside the organisation. The relations like the proximity and distance between the actors in networks can be described as strong ties and weak ties. Strong ties are characterized by common norms and high network density. These strong ties are easier for innovations, since they normally include a relatively high amount of trust, common aims and the same kind of language with which to communicate. However, strong ties add little value when one is searching for resources such as new knowledge because everyone within the network has access to the same resources (Granovetter, 1985). If the network relations are related to specific trading partners, diversity decreases and it becomes difficult for the organisation to adapt to new trends and directions (Andersson, 2001). Over-embeddedness can reduce the flow of novel information into the network because the redundancy of ties to the same network partners means that there are only few or no links to outside members who could potentially contribute innovative ideas (Burt, 1992).

3 Research strategy

3.1 Case study

This study uses a case study as a research strategy. The case study is a preferred strategy when the investigator has little control over events, and when the focus is on a contemporary phenomenon within some real-life context. Thus, the distinctive need for a case study arises out of the desire to understand complex social phenomena. Importantly and specifically, a case study is the method of choice when the phenomenon under study is not readily distinguishable from its context (Yin, 2003). As Stake (1995: xi) emphasizes: “A case study is expected to catch the complexity of a single case ... We study a case when it itself is of very special interest. We look for the details of interaction with its contexts ... coming to understand its activity within important circumstances.” As Yin (2003) argues, the case study method allows investigators to retain the holistic and meaningful characteristics of real-life events.

3.2 The case

The need for health enhancing sports activities has increased dramatically in the past decade. A resident who does not get enough exercise for his/her health, who is overweight and who is in poor physical condition is at a higher risk of falling ill and thereby creating social welfare and health care expenditure for the local authority. Physical activity is fundamental in improving people's physical and mental health. It reduces risks of many diseases. Thus, different kinds of innovations both in public and private sector are needed to encourage physical activity.

The study builds on the MOTION! project which aims to develop the exercise and well-being industry, and create new collaboration models for co-operation between the private, public and third sectors. Physical activity referral schemes aim to identify inactive adults in the primary care setting. The primary care professional refers the patient to a third party service, with this service taking responsibility for prescribing and monitoring an exercise program tailored to the needs of the client. To enhance physical activity counselling and referral process the MOTION!-project is establishing an online physical activity pharmacy. Physical activity pharmacy platform will provide a toolbox to support physical activity counselling and referral. It will also offer private sector companies an opportunity to offer their services at all levels of the health and exercise service chain and to find new service and product concepts.

This case study is qualitative. Qualitative researchers tend to collect data in the field at the site where the participants experience the issue or problem under study. This up-close information gathered by actually talking to people directly and seeing them behave and act within their context is a major characteristic of qualitative research. (Creswell, 2007.) The data collection in case study research is typically extensive, drawing on multiple sources of information (Creswell, 2007; Eriksson and Koistinen, 2005). The empirical data of this study consists of innovation and development sessions, workshops, questionnaire, focus group interview and written material (Table 1).

Table 1. Summary of the data collection

Innovation/development sessions	3 development sessions for experts of health enhancing sports an innovation session for sport service providers and third sector
---------------------------------	---

Seminars with workshops	2 health communication seminars for researchers, developers, planners, health care professional and representative of private and third sectors
Workshops	1 for sports counsellors 2 for nurses and physiotherapists 1 for local councillors evaluation workshop for managers, employees and partners in co-operation 2 sub-projects' workshop about the results of the project
Questionnaire	for employees in primary health care organisation
Focus group interview	for sport counsellors
Written material	reports for the financier, notes of meetings

4 Distances in complex environments

Innovation often requires dissimilar, complementary bodies of knowledge. Cognitive diversity will increase the likelihood that creative new knowledge emerges (Boschma, 2005; Nooteboom et al., 2006). In this case study the cognitive challenge was related to missing expertise. For example, sport service providers had no knowledge or experience about the demands of inactive people. Neither did they have any services focused for inactive persons. They also considered that it was difficult to market their services because “they have no expertise in marketing”.

In the public sector physical activity promotion was considered as a co-operation of many experts from different fields of operation. The co-operation is done mostly between health care professionals and sport counsellors from sport departments or third sector organisations. However, according to the questionnaire every fourth health care professional did not take a stand whether s/he cooperates with sport counsellor. Also in the workshops there was a clear wish that co-operation between sport counselling and physiotherapy should be tighten. One respondent said that “co-operation between sports counsellors and health care professionals is one of the most important issues” in successful physical activity counselling. However, many respondents found that there are many things that should be developed between social and health care sector and sport

department. For example, many considered that responsibilities and duties are unclear. Also the sport counsellors felt that the health care professionals do not know enough about their expertise.

Too little of cognitive diversity means lack of sources of novelty, while too much cognitive diversity implies problems in communication (Nooteboom et al., 2006). In this case study the expertise in public and private sector was so different that there were misunderstandings. For example, some concepts like “basic service of municipality” or “exercise service” were understood differently. One participant even noticed that “doctors and sport counsellors are not speaking the same language”.

There were also lacks of knowledge how to bring up physical activity with the client or how to discuss about the need of physical activity promotion inside the organisation. For example, many health care professionals considered that they would like to have more conversation about the role of physical activity counselling and referral in health promotion. This was considered as a responsibility of the management. One respondent explained that organisation “should give a clear presentation about why physical activity counselling is important in the organisation and how it should be given”. It was also considered important to increase the knowledge of local councillors about the effects of health enhancing sport as a preventive method.

An ability to communicate and exchange ideas is an important part of innovation processes. The innovation partners’ success in reaching a common vision, exchanging creative ideas and evaluating them depends on the ability to devise a shared language, which is an essential asset in developing a common understanding. Sharing of a common language facilitates people’s ability to “gain access” to other people and the information that they possess (Nahapiet and Ghosal, 1998).

Innovation depends also on a capacity to coordinate the exchange of complementary pieces of knowledge within the organisation and between organisations. According to the data it is difficult to share information in “too large organisations” and especially when “roles are unclear”. Some pointed also that some organisations or teams are “withholding of necessary information”. Gittel and Weiss (2004) noticed that the boundaries between inter and intra-organisational relationships are often blurred, with, for example, intra-organisational boundaries across departments or units sometimes being more sharply

defined than relationships across organisations. However, interaction between different departments has been shown to influence innovation (Moenaert et al., 2000).

Knowledge sharing is also difficult if “development teams are too small and tight and new members are not welcome”. Organisational proximity is believed to be beneficial for innovations, because new knowledge creation goes along with uncertainty and opportunism. For example, sport services providers were pondering to whom it is wise to tell ideas. However, too much of organisational proximity is accompanied by lack of flexibility. There is a risk of being locked-in in specific exchange relations. Search for novelty often requires going out of the established channels. (Boschma, 2005).

Economic relations are to some extent always embedded in social contexts, and social ties or relations in turn affect economic outcomes (Boschma, 2005; Granovetter, 2005). Social proximity may facilitate the exchange of tacit knowledge, in particular, because of trust-based relations. According to the data “envy, prejudice and fear prevent co-operation in the networks”. In the data the social distance between health care professionals and sport counsellors came up very clearly. Health care professionals hesitate to give physical activity referral to clients because they do not know sport counsellors personally or they are not familiar with the content or methods of physical activity counselling process. The importance of social proximity lies in the fact that social relations not only coordinate transactions but are also vehicles that enable the exchange of knowledge because of mutual trust, kinship and experience as well as external resources to be mobilised (Boschma, 2005; Oerlemans and Meeus, 2005). When there is a close relationship, people are willing to support and encourage innovative ideas, as the individuals involved are able to give the confidence needed to turn ideas into successful projects (Carmona-Lavado, Cuevas-Rodríguez and Cabello-Medina, 2010).

On the other hand, too trust-based relations may weaken the innovative capacity of organisations. One participant of the workshop said that there are “secret development teams that do not tell what they are doing or invite outsiders to the teams”. Closed network systems may incur opportunity costs because outsiders with new ideas and knowledge are denied entry. Long-term relations or relations with too much commitment may lock members of social networks into established ways of doing things at the expense of their own innovative and learning capacity. (Boschma, 2005.)

Every organisation and even its subunits have a culture of their own, which influences the ways in which its members think, feel and act. For example, health care professionals acknowledged that “own attitudes are in important role” when adopting new ways of doing. In the workshops it was noticed that there are still many organisations or departments that “never tries anything new because they are such a stick-in-the-mud”. Also “I do know myself” attitude inhibits common development activities in the organisations. Especially, this was highlighted in small companies. For example, they were “not used to develop their business with help of outsiders”. In many organisations there were also tendency that employees prefer working with those who they know very well and who thinks like they themselves. That way “diversity is not valued”.

The temporal complexity is related to, for instance, how organisations perceive future and how they use their networks to get weak signals (Parjanen, 2012). Innovation is often considered to be path-dependent. This path-dependency may lead to lock-ins to existing production and systems (Pihkala, Harmaakorpi and Pekkarinen, 2007). In the workshops it was noticed that “public and private sectors operate temporally differently” and that may hinder common development. It also takes time before new ways of doing are rooted to organisational routines. Temporal challenge may also be related to the fact that employees are “too busy with the routine work that they have no time to develop their work”. According to one sport service provider she has “time to plan only the next day”. Also sport services providers considered that they are “caution” and “do not take risks”.

5. Revealing innovation potential in complex environments

The development of health enhancing sport is challenging because the extensive network of actors ranges from groups within the public sector’s social and healthcare services as well as private companies to third sector organisations and sports institutes. As seen in previous chapter in this kind of innovation processes change is required at the employee, organisational and network level. Therefore, innovations are highly uncertain and successful innovation paths cannot be predicted. Innovation generation entails more than problem-solving alone. Instead innovation generation is based on co-creation emphasising interaction and communication (Lester and Piore, 2004). The development of health enhancing sports is also situated, context-specific and takes place in very practical environments like in prime care organisations, private companies or third sector

organisations. According to the data the development could be defined as interpretative (Lester and Piore, 2004) and practice-based (Harmaakorpi and Melkas, 2012).

Practice-based innovations are seen to be triggered in different places of practically oriented social and economic networks using, for example, the weak ties and structural holes of the innovation system. The diversity perspective on innovation emphasises the importance of the connectivity of a heterogeneous group of actors. Based on the data the formation and functioning of these kinds of innovation networks can be problematic because of the existence of several distances between innovating actors. In order to use these distances as an innovation potential, there is a growing attention to having brokers to facilitate innovation processes (van Lente et al., 2003).

According to this case study to reveal the innovation potential in distances there may be need to different kind of brokerage – internal and external. Internal brokerage is needed inside the organisation where different distances create problems in communication, knowledge sharing and innovation. In this case study internal brokers organised official and unofficial occasions where employees from different departments could meet each other and have a possibility to get information about physical activity counselling. They also built cross-sectoral and multi-professional development teams to break organisational silos.

The challenges of an internal broker are related to the fact that people usually perceive in their environment things which strengthen already existing matters or ways of doing. Many health care professionals still think that treatment goes before prevention and health promotion and there is reluctance to accept health promotion task as responsibility. In organisations, things are often done in a familiar manner. This is especially true if the operations have been successful in the past. In innovation processes, it is central that the internal broker gets people to perceive things in a new way. Social proximity between internal broker and employees at different departments and knowledge about organisational practises were considered essential in internal brokerage. Also the managerial support was considered important as one broker explained “it is good to find someone at management level who has enthusiasm to health promotion”.

External knowledge and ideas can only be recognised; accessed and assimilated when organisations develop new practices and change their organisational structure to facilitate practice-based innovation processes. According to the evaluation workshop in prime care

organisation “the cross-sectoral work has increased in the organisation”. This has been possible, because the focus of development has been defined, the own role in cooperation has been clarified and understanding of the need for co-operation between different departments has been increased. It was also seen that the cross-sectoral collaboration has “changed the organisational culture”.

The external brokerage functions relate to the providing of the links, knowledge sources and tools so that organisations can accelerate and increase the effectiveness of innovation processes. In this case study external brokers identified possible stakeholders at regional and national level. At the regional level it was important to include local councillors in the activities of the projects. In practice brokers organised data gathering among local councillors about their attitudes and ideas related to health enhancing sport. Based on the data a participatory info and exhibition was organised as part of municipal decision-making seminar. Welfare and health services are mainly produced in the public sector and because there is a strong societal concern over them, political agendas may prepare ground for spreading of innovations in this sector.

To answer the challenges of private service providers possibilities to network with other services providers and public sector organisations were arranged. As a result a network of 40 service providers was organised where the brokerage included to “inform the participants” and “being present”. Brokers’ role was seen as “building bridges” between different actors and “sparring”. Brokers also developed different kind of tools to facilitate the innovation processes in private sector. For example, to help participating companies to design services so that they meet the needs of the physical activity referral customers the model for productization was developed. Also, business clinics were used to recognize potential development targets and to refine the development targets boot camps were organised.

Practice-based innovation highlights the enriching interaction between innovation actors. The origins of innovations are not only networks but also employees, users and customers (Harmaakorpi and Melkas, 2012; Hennala, Konsti-Laakso and Harmaakorpi, 2012; Nilsen and Ellström, 2012). One principal of the project was to engage users and user communities as active participants in development of health enhancing sport. In this case study users were those who will use the online physical activity counselling platform. During the project developers, future users and service providers from public,

private and third sector were brought together to discuss and to innovate what the physical activity pharmacy could be, what purposes it needs to fill. The focus group of 50 has included: doctors, managing nurses, public health nurses, physiotherapists, physical education instructors, entrepreneurs, planning officers and development personnel from local and national institutions. The user-driven development was mentioned several times in reports as an essential factor to reach the results.

Practice-based innovation requires a set of instruments. Those tools may enable users to participate in innovation or enable organisations to integrate external problem solvers or idea creators to innovation process. For example, to develop the physical activity pharmacy's contents and its quality system innovation sessions were organised. The idea of the innovation session is based on open innovation (Chesbrough, 2003) and the fact that there is huge innovation potential in combining different fields of knowledge and expertise (Leonard, 1995; Johansson, 2004, Carlile, 2004).

A Living Lab offers services and methods which enable the users to actively take part in development and innovation. The Living Lab laboratory is located where the people are, that is, at home, in school, in the workplace, in town, and among hobbyists. (Niitamo et al., 2006; Eriksson et al., 2006.) For example, workshops have been organised where the users are like in prime care organisations or sport service companies.

The increasing complexity of most potential innovations requires collaborative creative efforts. The source of individual and collective creativity in practice-based innovation could be found in different kinds of distances, between individuals, groups, departments, organisations and networks in the region or outside the region (Parjanen, 2012). There are possibilities for collective creativity, when more people from diverse backgrounds bringing to bear different experiences are going to offer a greater variety of ideas to use for ideation. That way, the variation of the ideas proposed as the solutions to a particular problem also increases. That way groups are going to bring their increased depth of experience and expertise to bear against the weighting of criteria used for selections of new ideas. (Kozinets, Hemetsberger and Schau, 2010.) In a group context, diversity between group members is considered as potential for creative ideas in practice-based innovation. The facilitation of the group work focuses on shortening social distances between participants so that the group could better use cognitive distance as the source of creativity (Parjanen, 2012). The sessions and workshops have been facilitated

by a trained facilitator. Also different kinds of creativity methods have been used. These include for example learning café, perspective change, game and speed dating.

The practice-based innovation processes aim at combining knowledge interests from theory and practice alike, as well as knowledge from different disciplines (Harmaakorpi and Mutanen 2008). In this case study different kind of communicative challenges were highlighted. To develop health communication scientific knowledge was combined to practical context. In health communication seminars there were health communication and health promotion researchers. This communicative distance was the base for many ideas to develop more effective and suitable ways of communicating about health enhancing sports. As a result new material for clients were made, new channels to inform citizens about health enhancing sports were piloted and new way to inform local councillors was organised.

Table 2 introduces the distances found in this study, methods to use distances as innovation potential and examples of the innovations generated in the project. As seen in the Table 2 innovations are, for example, new services (physical activity counselling as a group format), models (model for lifestyle guidance, model for productization), or way of doing (cross-sectoral collaboration, user-driven development). Many of these innovations are not totally new, but they are new in the context. For example, cross-sectoral collaboration in prime care organisation was considered “exceptional also at national level”.

Many of these innovations are ways to shorten distances found within and between organisations. Actually, one innovation could shorten many distances. For example online physical activity counselling platform reduces cognitive and communicative distance between different professionals. It also creates a virtual place where different professionals may discuss about health promotion issues reducing social distance. At its best, these discussions reduce temporal distance revealing weak signals and possible innovation.

Table 2. Methods used in revealing innovation potential.

Challenges	Methods	Innovations
Cognitive	Practice-based innovation Brokerage functions	Online physical activity pharmacy Quality work book for wellbeing companies Orientation material for new employees in the public sector Model for lifestyle guidance
Communicational	User-driven innovation Cross-sectoral collaboration Diversity (practical and scientific knowledge) Creative and participatory methods	The definition of health communication The communication plan of health enhancing sport in organisations Material for physical activity promotion (leaflets, magazine, poster, hand-outs) Health communication pilots with new media (videos, Facebook, Twitter) “Appealing websites” workshops for public and private sector (marketing, communication)
Social		Physical activity counselling as a group format User-driven development as a new way develop services
Organisational		Contact persons in health enhancing sports in public sector Collaborative network for sport and wellbeing companies Unification of ways of doing between departments in public sector Work partner pattern for social and health care services between public health nurse and physical education instructor
Temporal		New services for inactive persons Model for productization
Cultural		Cross-sectoral working groups Common steering committee between two projects (prime care organisation and third sector organisation) Networking

7 Conclusions

The results of this case study indicate that it is practical to identify the distances which may slower or even hinder innovation activities. The study suggests that realization of innovation entails linking of developments at multiple levels and interaction between multiple stakeholders. Innovation takes place in networks and is collective in its nature. It

is about moderating the collaborative process that aims at development, utilization and spreading of innovation. The collaborative process should not be regarded as a fixed path; the steps need to be continuously evaluated based on interim objectives formulated by the stakeholders.

In this case the innovation activities were based on practice-based and user-driven innovation. Innovations involve the challenge of enabling renewal based on diversity and facilitating the integration of knowledge in a creative way. Innovation potential lies in distances. Interaction between diverse knowledge bases in an organisation and with the external knowledge bases is necessary in order to experience the effect of diversity, but the presence of relevant knowledge does not imply that the inflow of new ideas into the organisation is an automatic or easy process. Especially, the role of brokerage functions was considered essential. Whilst spontaneous cooperation between organisations can occur, it appears that a brokerage intervention can help cooperation, for example, by advising on the advantages of cooperation, giving information, identifying opportunities, catalysing discussions between different actors or bringing organisations together (Shaw, 1998.)

This study has some limitations. Firstly, the role of the other researcher was not passive observer. Instead, she has participated in the project as a planner of the sessions, participant of the sessions and also facilitator of the sessions. She is aware that her internal positioning at the project has influenced the way she has interpreted the data. Secondly, there are limitations concerning generalizability of the results. This case study focuses on a single unit, a single instance, the issue of generalizability looms larger here than perhaps with other types of qualitative research. However, much can be learned from a particular case. What we learn in this case can be transferred to similar situations. It is the reader, not the researcher, who determines what can apply to his or her context. .

Ancillary knowledge advancement of employee-driven innovation: a personal-interactive services innovation perspective.

Farag Edghiem

Liverpool Business School
Liverpool John Moores University
Redmonds Building, Clarence Street
Liverpool, L3 5UG, UK

Structured Abstract

Purpose – This study aims to explore the nature and role of knowledge relevant to service employees' individual innovative behaviour and leading to initiating innovation within the sub-sector of personal-interactive services.

Design/methodology/approach – A case study research method was applied to achieve the research objectives that examined and compared two personal-interactive service environments of two hotel properties. Semi-structured interviews were conducted along with other qualitative research methods, including; direct observation of employees, review of management archives/literature and 'micro cases' assessment.

Originality/value – The study outcome contributes to service innovation research by identifying additional implications of the nature and ancillary role of knowledge and also by unravelling four patterns of service employees' individual innovative behaviour.

Practical implications – The study recommends practical measures to encourage knowledge integration at internal and intra-organisational levels.

Keywords – Case-Study, Individual Innovative Behaviour, Personal-Interactive Services, Service Innovation, Ancillary Knowledge.

Paper type – Academic Research Paper.

1. Introduction

Innovation in services has been widely recognised as a source of competitive advantage and a key element of retaining customers' loyalty, and therefore has received significant attention from academics and practitioners alike. Arguably, this is due to the increasing competition between service firms leading to higher customer expectations and to the growing trend of introducing services by the world's dominant manufacturing firms and economies in response to the greater than ever competition from low-cost production countries.

Despite that the amount of research on innovation in services increased significantly, it is still considered relatively less explored in comparison to innovation in the manufacturing sector. In fact, the synthesis approach (Gallouj and Weinstein, 1997; Coombs and Miles, 2000; Nightingdale, 2003; Drejer, 2004; Howells, 2006; Nijssen *et al.*, 2006) that represents the efforts to bring together theories from both services and manufacturing sectors, after addressing service characteristics, is gaining more popularity. This study adopts the synthesis perspective of service innovation by considering the peculiarities of services, embedded in the high degrees of intangibility and perishability of services delivered within the hospitality sector to be investigated, and equally recognising the applicability of theories developed within the manufacturing sector at the employee's individual level.

Within innovation literature knowledge was frequently considered a key determinant of employees' ability to innovate. However, from a service innovation point of view the implication of knowledge has not been sufficiently explored and most studies in the field focus knowledge in knowledge intensive business services KIBS. This paper recognises the sub-sector differences within the service sector and intends to determine the nature and impact of knowledge from a personal-interactive service perspective.

The aim of the study is to explore the nature and role of knowledge relevant to service employees' individual innovative behaviour and leading to initiating innovation within the sub-sector of personal-interactive services. The research findings came to verify the ancillary role of knowledge to the interlinked process of idea generation and development in service innovation and to distinguish two types of knowledge as *prior* and *dependent* knowledge. The research outcome also added further insight into service employees' individual innovative behaviour by highlighting four constructs of innovative behaviour patterns related to knowledge.

2. Theoretical Background

2.1. Innovation in Services

The relationship between services and innovation has come considerably to the fore after Gershuny's (1978) study of the 'self-service economy', and by the 1980s a number of early studies finally emerged within this field to consider services innovation and the impact of technical change. These included Gershuny and Miles (1983), who argued that in fields such as entertainment, information and education, information technology presents the technical inputs for a new wave of social innovation; and the study by Barras (1986), who proposed that the process of innovation in services is preceded by the adoption of new technologies developed in other sectors.

Publications on innovation in services eventually started to grow rapidly in the 1990's, and mainly dealt with various types of new services, success factors and aspects of the *New Services Development* NSD process (Vermeulen and Van der Aa, 2003). Yet, it has been remarked at this stage that most innovation studies in service firms had not explicitly discussed how processes of other types or modes of innovation, such as architectural or organisational innovations, are conducted (Gadrey *et al.*, 1995; Gallouj and Weinsrein, 1997; Miles, 1997); and more recently Menor and Roth (2007) concluded that current strategies and tactics for developing new services are inadequate. In fact, compared with the manufacturing sector there is a considerable paucity in the literature concerned with the organisation and management of services innovation (Adams *et al.*, 2006; Drejer, 2004; Miles, 2000; Nijssen *et al.*, 2006; Spohrer, 2008; Tidd *et al.*, 2001). However, in the last decade the number of publications concerned with managing services innovation increased rapidly and the study of services innovation emerged as an important research field (IFM and IBM, 2008; Menor and Roth, 2007).

Within service innovation literature it is widely accepted that innovation involves more complicated implications; service firms develop both radical and incremental innovations in the form of existing services, changes to processes or adjustments to personnel behaviour (Rubalcaba *et al.*, 2012). In particular, four schools of thought emerged in the literature of services innovation (Droege *et al.*, 2009). The **Technologist** school was *first*, and under this perspective services innovation is dependent on technological competence gains and development in information technology (Barras, 1986, 1990). The technologist approach has been conceptualised as a reversed product

life cycle that begins with innovations and subsequently leads to totally new services (Linton and Walsh, 2008). Gallouj (2002) proposed a contrasting critical view by concluding that services innovations are frequently non-technological, such as a new form of insurance policy or developing a new area of legal expertise.

The *Second* school, the *Assimilation* perspective, assumed that the theories and concepts developed in manufacturing contexts can easily be transferred to innovation in services (Coombs and Miles, 2000; Drejer, 2004; De Vries, 2006; Nijssen *et al.*, 2006). Scholars following this approach found that differences between services and tangible products seemed to be smaller than the services and manufacturing sectors (Sirilli and Evangelista 1998; Hughes and Wood, 1999). Akamavi (2005) criticised the *Assimilation* school of thought and claimed that studies developed under this school derive their analytical frameworks from the manufacturing sector without taking into account the idiosyncrasies of services. The *Synthesis* perspective was the *Third* school of thought identified. Synthesis studies dedicated more effort to bring together innovation in both services and manufacturing sectors rather than to study each field separately (Gallouj and Weinstein, 1997; Coombs and Miles, 2000; Nightingdale, 2003; Drejer, 2004; Howells, 2006; Nijssen *et al.*, 2006), after illuminating the important elements of services innovation such as the involvement of customers (Sanden *et al.*, 2006). This approach seemed to be preferred by service innovation scholars (i.e. Den Hertog, 2010; Gallouj and Djellal, 2010; Rubalcaba, 2011; Tether, 2005; Windrum, 2009).

The *Fourth* school of thought or the *Demarcation* perspective focused on the distinctive features of services that make it difficult to transfer theories from the manufacturing to the services sector (Droege *et al.*, 2009). Den Hertog's (2000) remarkable study within the *Demarcation* stream of literature takes a conceptual perspective of services innovation by presenting taxonomy of services innovation patterns and a framework to better understand what parts of services are affected by innovation.

This study adopts the *Synthesis* perspective of service innovation by considering the peculiarities of services, embedded in the high degrees of intangibility and perishability of services delivered within the hospitality sector to be investigated, and equally recognising the applicability of theories developed within the manufacturing sector at the employee's individual level.

2.2. *Employee-Driven Innovation*

Previous studies suggest that organisations can benefit from employees' innovation and many popular studies in the management field were focused around this topic, including total quality management (Ehigie and Akpan, 2004), continuous improvement schemes (Fuller *et al.*, 2006), corporate venturing (Elfring, 2003), creative problem solving (Basadur, 2004) and organisational learning (Senge, 1990). Employees' participation is increasingly regarded as an important element to realise innovation, and previous research has suggested that employees' individual innovation is recognised as a decisive factor of an organisation's 'innovativeness'. For example, de Jong and den Hartog (2007) claimed that organisations capitalise on employees' ability to innovate, while Campbell *et al.* (1996) empirically identified a positive relationship between innovative behaviour and organisational performance, and Getz and Robinson (2003) posited that 80% of improvement ideas come from employees and only 20% come through planned innovation activities.

Despite the wide acceptance of employees' contribution to services innovation there has been little understanding in earlier research of the relationship between employees' roles and services innovation. For example, the study of Sundbo and Gallouj (2000) recognises the important role of professional employees for services innovation without analysing how those professional employees might initiate services innovation. Another early stream of research has led to the development of a comprehensive view of how employees' role may help initiate innovation. The research on employees' individual innovation has originally progressed in four main ways. It has been underpinned *firstly* in terms of cognitive styles, where Kirton (1976) measured two distinct cognitive styles as adaptors who solve problems within existing perceptual frames and innovators who restructure these frames. *Secondly*, employees' innovative behaviour has been examined in terms of personality characteristics (Hurt *et al.*, 1977), *thirdly*, in terms of innovation output (West, 1987), while *fourthly* and most lately viewed from a behavioural perspective (Janssen, 2000).

In the context of this research the concept of *Individual Innovative Behaviour* will be adopted. *Individual Innovative Behaviour* refers to the multidimensional extra-role of innovative behaviour beyond the scope of job requirements which is important for organisations' survival through initiating innovation (Tuominen and Toivonen, 2007). The reasons for adopting the Individual Innovative Behaviour perspective are, *firstly* that

the Individual Work Behaviour IWB concept has been examined primarily in the manufacturing organisations context, and therefore an alternative terminology should be applied for the services sector. *Secondly*, the Individual Innovative Behaviour concept captures more comprehensively individual based interactions and relationships between employees inside and outside the services work environment and between employees and the services customers. *Thirdly* the Individual Innovative Behaviour concept helps unravel the dominant individual role within the service provided and the individual factors that influence employees' innovative behaviour (i.e. motivation).

2.3. Knowledge and Service Innovation

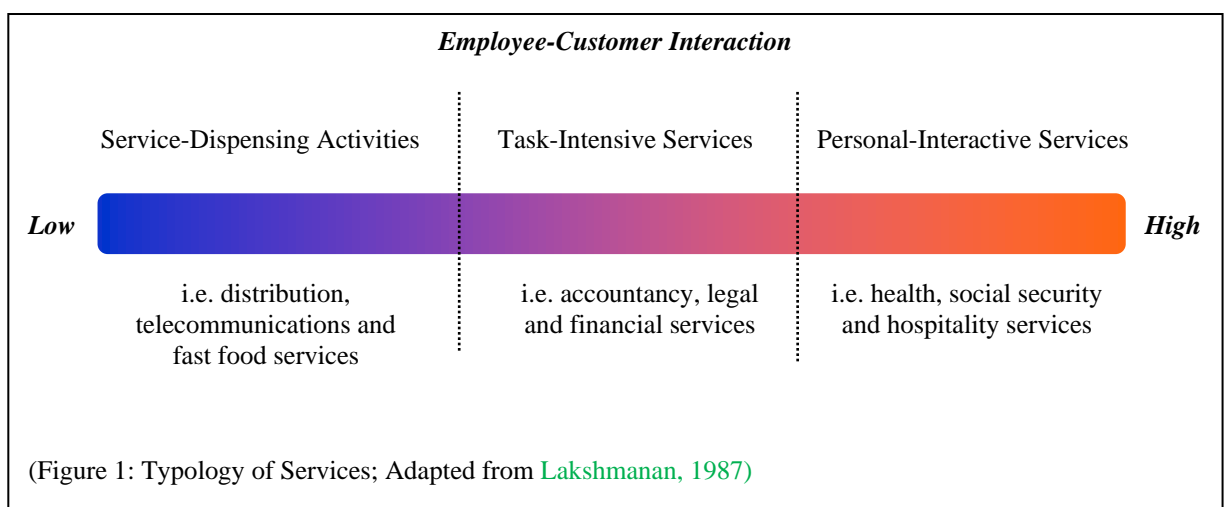

Employees' '*employability*' or intellectual capital i.e. skills, expertise and knowledge, is widely recognised as a key determinant of employees' ability to innovate (Subramaniam and Youndt, 2005). Van der Heijden (2005) conceptualised employees' employability in association with the five constructs of *Occupational Expertise, Anticipation and Optimisation, Personal Flexibility, Corporate Sense and Balance*. However, there were other attempts in the literature that conceptualised employees' repertoires of knowledge that may help them to innovate, such as *Worker's Talent Intelligence* (Glynne, 1996) that is defined by the capability to solve problems or meet task challenges.

The concern in this research is with the employees' knowledge base that supports idea generation and development. In this context it is widely accepted in services innovation literature that *Prior Knowledge* influences the *Opportunity Recognition* aspect of idea generation (Fischer, 2011). *Prior Knowledge* of customer problems and markets help draw meaningful conclusions from observed events, trends and changes (Baron, 2006; Grégoire *et al.*, 2010; Shane, 2000). Idea generation itself is widely recognised as a cognitive process involving both the retrieval of existing knowledge from long-term memory and the combination of various aspects of existing knowledge into novel ideas (Mumford *et al.*, 1991; Ward *et al.*, 1997; Nijstad and Stroebe, 2006).

Hunter and Ligon (2008) identified the ancillary role of five types of knowledge in relevance to idea generation and problem-solving: (1) *Schematic Knowledge* that is based on concepts and principles abstracted from previous experience (Phye, 1990; Sakamoto and Love, 2004) provides the basis for analogical problem-solving with the application of feature search and mapping mechanisms (Reeves and Weisberg, 1994; Hummel and Holyoak, 1997); (2) *Associational Knowledge* that appears to be acquired with less effort

and reflects regularities in experience based on probabilistic linkages between stimuli and response (Estes, 1991); (3) *Case-Based Knowledge* that entails formation of a mental model describing critical aspects of past performance (Hammond, 1990; Kolodner, 1997). In this respect knowledge is viewed as a form of contextual knowledge that provides a model for action when individuals encounter similar situations (Hershey *et al.*, 1990). Another growing body of literature recognises the significance of the Knowledge Management role in helping individual learning and sharing of knowledge, and concludes in relevant management mechanisms, for example, by applying care in organisational relationships (Von Krogh, 1998) or by creating a shared space for emerging relationships (Nonaka and Konno, 1998).

In the service sector, research began to focus more on knowledge relationship to innovation since the 1990's along with the growing interest in knowledge intensive business services KIBS contribution to Innovation (Shearmur and Doloreux, 2013). KIBS are by definition intermediate services that usually deliver knowledge or know-how and can deliver and implement systems (such as accounting or computer systems) (Muller and Doloreux, 2009) and they mainly consist of survey, consultancy, research and engineering services targeted at other businesses (Desmarchelier, 2013). However, the research on knowledge contribution to service innovation lacked consideration of other subsectors of the service industry. For instance, among the service sub-sectors highlighted in Figure (1) there is a considerable gap in the literature that addresses knowledge contribution to innovation from a personal-interactive sub-sector viewpoint.

3. Research Methodology

The application of a case study research method to achieve the research aims is strongly justified by the need to comprehend the complexities associated with human behaviour. Another justification is that the research area is empirically under-explored and therefore the nature of enquiry requires direct observation and interaction (Ghauri, 2004). The potential advantages of applying a case study research method largely include: the large theoretical and practical relevance to the research subject, the thoroughness of analysis and interpretation, and the triangulation of research methods (Scapens, 1990; Silverman, 1985; Spicer, 1992; Yin, 1994).

Case study research methodology may also entail some limitations, including the inability to provide justifiable generalisations or causal laws and the extensive length of the research period (Yin, 1994); case study research sometimes does not distinguish between what is unique to the case and what is common to the class of events as a whole (Achen and Snidal, 1989). To confine the effect of these limitations a comparative-case research method was applied to investigate two main case studies, where multiple data collection methods were applied in each case study. Semi-structured interviews were conducted along with other qualitative research methods, including; direct observation of employees, review of management archives/literature and 'micro cases' assessment. The researcher also depended on field notes and interview recording to organise the collection of data and prepare it for analysis.

Identifying an 'ideal' case study was very challenging, not only due to the difficulty in gaining access to companies' strategic information (i.e. innovation expenditure and other non-financial innovation indicators), but also due to the difficulty in identifying valid indicators for a representative model of an 'innovative' hotel company. Similarly, in the SI4S¹ project, Sundbo and Gallouj (1998) asserted that it would be extremely difficult to establish innovation indicators in the services sector. Some traditional innovation indicators such as R&D expenditure, R&D staff or other measures related to R&D, proved to be unreliable since very few services firms have formalised R&D departments, or other non-R&D indicators such as acquisition of patents, training, market research,

¹ *The SI4S project is one under the TSER programme launched by the EU commission in 1995 with the aim of developing concepts, empirical evidence, and proposals for practical action concerning the role of services in European innovation systems. The project included studies of innovation activities in services themselves as well as services firms' role in creation and diffusion of innovations in other sectors. The project started in March 1996 and ended in June 1998, with research teams from nine European countries participating in the project. These countries are Denmark, France, Germany, Greece, Italy, Netherlands, Norway, Sweden and the UK (Sundbo and Gallouj, 1998).*

number of educated people, etc. Although all the mentioned indicators may be relevant, they do not comprehensively reflect all innovation activities. Sundbo and Gallouj (1998) also concluded that no sufficient indicators had yet been identified and more work needs to be done towards identifying reliable indicators.

To overcome this problem, an alternative strategy that does not rely on probability indicators was adopted; that is, adopting *Criterion-Based Selection* strategy (Le Compte *et al.*, 1993) also known as *Purposeful Selection* (Light *et al.*, 1990) or *Purposeful Sampling* strategies (Patton, 1990). The case selection strategy was primarily based on identifying two main criteria related to the key themes generating from both reviewing the industry literature and interviewing the president of the European Hotel Manager's Association. The selection criteria depended on, (1) the history of innovation; the innovations developed in the prospect case studies (2) the corporate culture that supports innovation activities and initiatives.

4. Cases Backgrounds

4.1. Case I

Case I became one of the flagship hotel properties since the owning company was established in 2003. The company's rapid success was ascribed to investing in unique hotel properties and preserving the idiosyncrasies of each hotel property; this management policy was based on implementing uniformed management practices and services standards across the group's hotel properties portfolio, and at the same time ensuring that each hotel property had individualistic characteristics such as hotel name, structure and interior. The hotel properties also varied in terms of location, from countryside to the city centre, and also in terms of size and structure.

The company managed its portfolio of hotel properties across the United Kingdom through four designated regional management teams. Each team consisted of a regional general manager, a regional HR manager and a regional sales manager, who all reported to the company head office. At the most senior level of management, the company was controlled by a board of directors including the managing director, the finance director, the operations director and the sales director. At the local management level, the hotel manager managed 392 employees in conjunction with six other department managers. However, the regional manager also acted as a non-resident general manager of the hotel.

The original Victorian architecture of Case I hotel property has been well maintained, even after much maintenance work has been carried out over the years. The hotel's exterior architecture remains in its original design, and the main restaurants and banqueting halls have kept their authentic layout and atmosphere, even though the hotel interior has been equipped with modern technological hardware. Case I hotel property was also nominated as a centre of excellence in banqueting and events services among the company's portfolio of hotel properties. Factors like hotel location, conference halls facilities and the expertise of hotel staff in managing conferences and events are believed to have helped it achieve excellence in the banqueting and events services.

4.2. Case II

Case II hotel property is managed by one of the most renowned hotel brands and since it was established in the 1940's it has held a long standing reputation for luxury and distinguished hotel service. The group ascribes its success to maintaining guest-focused strategic orientation, and the diversity of the group brands that serve different market segments of the hotel industry. In 2014 the company managed and owned a portfolio of over 4600 hotel properties around the globe.

The corporate management structure consists of three main constructs: the Americas, Asia Pacific, and Europe Middle East and Africa. The hotel property in Case II falls within the South Europe and Mediterranean division, one of six management subdivisions that comprise the Europe, Middle East and Africa EMEA area. The company's management policy depends on limiting corporate intervention in the management of the hotel properties and delegating a considerable level of authority to the local management teams to assume daily responsibilities; the corporate management set the services standards and invest in training and educating the management executive teams who receive continuous training to conduct their duties in line with corporate systems of practice.

The case study hotel employs 463 employees including part-time contractors, and the management structure is characterised by role specialisation rather than the traditional hierarchical structure design. The highest level of the management hierarchy is the executive committee which includes six of the most senior management executives. The next level of the management hierarchy is the hotel heads of departments and their assistants and the lowest level of the management hierarchy represents the department supervisors, restaurant managers and the rest of the junior employees.

5. Presentation of Data

5.1. Ancillary Role of Knowledge

The difficulty associated with defining the term ‘knowledge’ reflected inconsistencies in respondents’ views on how to identify the contribution of knowledge to idea generation and development, where in some cases knowledge was referred to by interviewees as management guidelines or education. It was therefore an urgent requirement to brief the interviewees about the theoretical framework which identifies ‘knowledge’, and the differences between ideas, information and knowledge. Yet, evidence emerged from the two researched case studies confirming that knowledge played an ancillary role to the interlinked process of idea generation and development by, (1) inspiring individuals’ innovative behaviour to come up with new ideas, and (2) developing new ideas in coherence with the hotel’s local context and corporate standards.

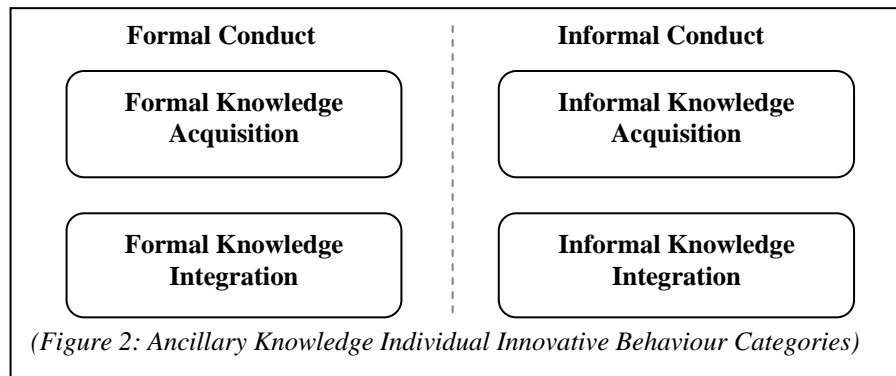

Consequently, it would be also possible to identify the ancillary role of knowledge to idea generation and development at two levels: as *prior knowledge* which is the collective experiences learnt by individuals throughout their professional and personal progression, and through their daily interaction with work and work related environments that may both lead to generating new ideas for innovation, and as *dependent knowledge* that is sought after initiating new ideas and which is normally combined with prior knowledge to help develop ideas consistently with the local environment settings. Table (1) demonstrates examples of knowledge contribution to idea generation and development.

Table 1: Examples of Knowledge Contribution to Idea Generation and Development

Knowledge Type	Idea Development Contribution
<i>Prior Knowledge</i>	<p><i>Case I</i></p> <ul style="list-style-type: none"> • The hotel manager applied prior knowledge to come up with the idea of ‘Express Check-Out’, which was implemented in the hotel he managed previously. • The front office department manager applied prior knowledge of the IT system Fidelio to implement consistent guest profile creating within his department.
	<p><i>Case II</i></p> <ul style="list-style-type: none"> • The human resources director’s work experience and prior knowledge of corporate standards helped initiating the innovation of corporate values dice toy that was placed on employees desks to remind them of the corporate values.

	<ul style="list-style-type: none"> The front office department director conducted competitor analysis of other hotels and compared systems of practice to improve front office procedures.
Dependent Knowledge	<p>Case I</p> <ul style="list-style-type: none"> The hotel manager reviewed corporate systems of practice and consulted regional management and then applied dependent knowledge to ensure reconstructing the hotel restaurants in compliance with corporate standards. The security department manager researched new premises' security systems and applied dependent knowledge to update the hotel's security installations.
	<p>Case II</p> <ul style="list-style-type: none"> The food and beverage department manager conducted competitor analysis of nearby restaurants and cafes and applied dependent knowledge to reintroduce the lobby lounge restaurant. The marketing and sales director conducted a survey on the hotel guests and applied dependent knowledge to improve the hotel beach club facilities and services.

Furthermore, the analysis of the behavioural patterns related to ancillary knowledge contribution identified four main interrelated categories; including, *formal ancillary knowledge acquisition*, *formal knowledge integration*, *informal ancillary knowledge acquisition* and *informal knowledge integration* (see Figure 2).

5.2. Formal Knowledge Acquisition

When asking respondents to describe the scope of their activities to gain knowledge prior to generating a new idea, it was extremely difficult to draw a timeline of when individuals start acquiring prior knowledge. The scope of *prior knowledge acquisition* in this context can be described as the collective life time experiences prior to the generation

of a new idea, that its extrapolation to the context of the hotel by the employees' leads to generating new ideas.

Before commencing employment, all employees were very likely to have acquired *prior knowledge* through university/college education or by other work experiences, etc., and after starting work at the hotel all employees also received induction training to be able to conduct their job roles consistently with management standards. Eventually and throughout their employment, employees were continuously offered various training opportunities to help them develop their knowledge of the hotel industry and advance their careers. The human resources Assistant Manager of Case I commented on this: *'we fully appreciate the fact that the standard of our services is dependent on how good our employees are and therefore we have carefully designed training programmes for helping our employees to continuously improve and increase their awareness of the latest developments in the hotel sector'*. In Case II other noticed forms of formal *prior knowledge acquisition* included programmes of higher levels of professional education and training, such as the corporate Continental Manager Programme, which aims to recruit new university graduates and provide them with a combination of professional training and work experience so they would be appointed to managerial positions within the company upon their completion of the programme. The human resources department in Case II additionally offered a wide range of training sessions including hotel management software, IT applications, management skills, accounting and finance, etc., and also outsourced other training and development programmes from external bodies such as the Institute of Tourism Studies.

Cross-training in other departments or in other inter-organisational hotel properties was another identified form of formal *prior knowledge acquisition*. The hotel General Manager in Case II explained: *'we work closely with other hotels in our region. Our hotel in Rome is one of the longest established hotels in the Southern Mediterranean region and Athens hotel is one of the best hotels in the same division; we aim to match with both hotels' preparations and achievements...We worked with human resources departments to arrange cross-training for our employees in these two hotels...Our employees benefit from this by learning new levels of standards in hotels that have a lot of similarities with our hotel'*. Table (2) outlines examples of formal prior knowledge acquisition.

Table 2: Examples of Formal Prior Knowledge Acquisition

<i>Formal Prior Knowledge Acquisition</i>	
<i>Micro Case 1</i>	<ul style="list-style-type: none"> ▪ The housekeeping department manager experienced difficulty in maintaining systematic order of rooms cleaning procedure while conducting work responsibilities.
<i>Micro Case 2</i>	<ul style="list-style-type: none"> ▪ The general manager identified the opportunity to generate further revenue through offering family rooms when reviewing guests' feedback.

Dependent Knowledge acquisition commenced after identifying an idea with the aim to develop the initial idea into a form of innovation. Following the identification of the initial idea and gaining management approval, employees' formal dependent knowledge acquisition takes place as mandated by the hotel management or the innovation project team. The task of acquiring dependent knowledge was identified to be delegated to individuals of more experience in a certain aspect and on contextual factors relevant to the idea. Examples of informal dependent knowledge acquisition were highlighted in Micro Cases one and two (see Table, 3).

Table 3: Examples of Formal Dependent Knowledge Acquisition

<i>Formal Dependent Knowledge Acquisition</i>	
<i>Micro Case 1</i>	<ul style="list-style-type: none"> ▪ The housekeeping department manager and the project team assessed the feasibility of the 20 steps cleaning procedure idea by training the housekeeping attendants and implementing the procedure for a trial period.
<i>Micro Case 2</i>	<ul style="list-style-type: none"> ▪ When developing the family rooms idea, guests' views and preferences were collected by inviting the hotel guests to research sessions. ▪ An interior architectural design company was consulted to provide prospective family rooms interior designs.

5.3. *Informal Knowledge Acquisition*

Voluntary informal acquisition of knowledge was highlighted throughout the research. Two types of informal knowledge acquisition were marked: *informal prior and dependent knowledge acquisition*. In relation to *informal prior knowledge acquisition*, in addition to the training provided by the human resources department, some employees elected to participate in other forms of training or experiences that were not formally organised by the human resources department. Employees' individual motivation was identified as a key determinant of *informal prior knowledge acquisition*. Factors such as

career development and self actualisation were found to be the most influential determinants that encourage informal prior knowledge acquisition behaviour among employees.

Informal acquisition of prior knowledge was encouraged by management in both cases. However, additional evidence of corporate support of employees' *informal prior knowledge acquisition* was identified in Case II, where employees were educated on how to become active seekers of knowledge through training sessions organised by the human resources department as part of the employees' personal development plans. The human resources executives helped the hotel employees identify areas of interest and development, and encouraged them to undertake the appropriate informal training and education to realise their potential. The highlighted examples of the human resources department support of employees' *informal prior knowledge acquisition* included the support of many of the hotel employees to enrol in courses provided by the local Institute of Tourism Studies by reducing work hours and approving employees' time-off requests during exams periods.

From another perspective, *informal dependent knowledge acquisition* started as early as the idea was identified by the individual. Before formally reporting the idea, employees attempted to adjust/adapt idea development to their own framework of inference. In Case I the Housekeeping Manager explained: '*if I come across an idea, say on cleaning materials, I do my own homework first and then I decide if the idea is worth reporting to the next level. I do some research in specialist magazines and online resources about the idea and based on my conclusion I make up my mind if the idea is realistic and advisable*'. Table (4) demonstrates additional examples of informal dependent knowledge acquisition highlighted in Micro Cases one and two.

Table 4: Examples of Informal Dependent Knowledge Acquisition

<i>Informal Dependent Knowledge Acquisition</i>	
<i>Micro Case 1</i>	<ul style="list-style-type: none"> ▪ The housekeeping department manager consulted the trainee hotel manager about the difficulty in maintaining order for the rooms cleaning procedure. The trainee manager provided the 20 steps cleaning procedure solution based on previous work experience. ▪ The housekeeping department manager reviewed the training literature of the 20 steps cleaning procedures provided by the trainee manager.
<i>Micro Case 2</i>	<ul style="list-style-type: none"> ▪ The hotel general manager consulted the general manager of Rome hotel on pricing structure and marketing strategy to launch the hotel's family rooms.

Informal dependent knowledge acquisition through innovation groups also emerged as another method to acquire dependent knowledge. *Innovation groups* denote the collaborative relationships between individuals to share knowledge that are created simultaneously and may include within them members of various professions and backgrounds. Employees sought to gain dependent knowledge from other group members when they experienced difficulties in acquiring knowledge by self-dependent means. The highlighted examples by the interviewees of *informal dependent knowledge acquisition through innovation groups* varied from consultation on developing innovation initiatives to ‘shadowing’ fellow group members to gain knowledge on certain aspects. An example of *informal dependent knowledge acquisition through innovation group* emerged in Micro Case 2 when the general manager in Case II consulted the general manager of Rome hotel property about the project initiative and received guidelines about the pricing structure and marketing strategy of the innovation initiative.

5.4. Formal Knowledge Integration

Despite that the formal mechanisms to transfer knowledge were designed by the company’s head office in Case I, there was no evidence of a central management structure to manage knowledge at the corporate level. The only centralised systems detected to integrate knowledge were, (1) the corporate intranet programme ‘Citrix’ that was managed by the central IT department, (2) the hotel review reports that were submitted to the head office on a weekly and monthly basis, and (3) the guest satisfaction questionnaire that was managed by Retail Eyes¹. Otherwise, managing knowledge was more of a shared responsibility between the central office managers, the regional management and the hotel departments’ managers.

In Case I, the movement of knowledge was not only directed from the hotel property to the company’s head office, rather it was transferred into three directions. One was directed from the hotel property to the head office (bottom-up), the second was directed from the head office to the hotel property (top-down) and the third flow of knowledge was moving horizontally at the bottom level. Formal bottom-up mechanisms included employees’ feedback through formal reports submitted to senior management and also employees’ feedback during the research projects conducted by the human resources

¹ *Retail Eyes is a market research, evaluation and development agency that combines technology with innovative research. Retail Eyes is a UK leading agency in helping clients in learning about their customers through novel feedback technology.*

department. Another example of bottom-up mechanisms is the transfer of knowledge through the corporate intranet (Citrix) e-mailing system, and this would also allow contacting managers at the head office level. Examples of the top-down transfer of knowledge from the central office to the hotel management, and eventually to the rest of the hotel staff, included systems of practice manuals, training sessions and the contents of the corporate intranet programme Citrix, where employees could access a large database of corporate resources.

The hotel's front office manager in Case I provided an example of the horizontal flow of knowledge that moved between different parties at the bottom level, which was the cross-training exchange between hotel properties. However, there were two types of cross-training mentioned, one was arranged locally at the hotel property by the human resources department to place employees on training in other departments, and the other type was managed by the group's training management department where employees were dispatched to 'centres of excellence' at other hotel properties.

Two centralised IT systems to interlink its hotel properties were operated by corporate management in Case II; Holidex, the central reservations system, and the corporate intranet. Yet, although the company had a dedicated department to manage customer knowledge and insight in the company's head office, there was no evidence of direct involvement in knowledge management dealings at the local hotel level by this department while conducting research. The main knowledge transfer interaction with the company's head office was through the corporate intranet interactive tools (i.e. the hotel management reports submissions). The corporate reservation system Holidex, on the other hand, interlinked the hotel properties through the guests' reservation information and the guests' profiles on the company's loyalty scheme database.

The movement of knowledge in Case II was also recognised to be moving in three directions: (1) from the hotel property to the group head office and regional management (bottom-up), (2) from the group's head office to the hotel property (top-down), and (3) moving horizontally at the bottom level. The highlighted examples of bottom-up mechanisms included the hotel management's performance reports to the group's head office, such as the Monthly Quality Assessment (MQA) report and also the hotel management feedback received via e-mail and other communication means. However, it was also recognised that communication via the corporate intranet was not restricted to

executive employees, rather it was also possible for junior staff to e-mail any of the listed corporate contacts.

The top-down movement of knowledge from the group head office to the hotel property involved the transfer of corporate systems of practice and the other corporate standards through formal channels in Case II: namely, the human resources department training and development programmes and the corporate intranet. Other methods of top-down knowledge transfer included the corporate training programmes such as the Revenue Academy and the annual meeting of the regional division directors.

The horizontal movement of knowledge on another account was highlighted by interviewees to have transferred through cross-training of employees in other departments. Other cross-training also took place between hotels within the southern Mediterranean area in the regional division, i.e. Rome and Athens hotels, where the interviewed participants in this type of training programme confirmed that they had applied the experience they had developed while cross-training in these centres of excellence to enrich their present job roles. Examples of specific cross-training experiences included front office systems of practice, Opera hotel management software, food and beverage systems of practice and events management.

5.5. Informal Knowledge Integration

Within a hotel service environment, which is a highly interactive social environment, it would be expected that the simultaneous sharing and transfer of knowledge is part of everyday work routine, and therefore it would not be possible to directly manage all aspects of employees' exchange of knowledge only through directive formal methods. However, formal knowledge management may still provide the appropriate tools and create a suitable climate to encourage knowledge sharing and transfer among employees.

At the hotel property level and in both researched cases the most dominant individual knowledge integration behaviour among the interviewed employees was transferring and sharing knowledge through informal communication. During observing employees in Case I while in the staff canteen and when operating in public areas, it was recognised that most employees at all levels communicated freely without any noticeable barriers of bureaucracy. It was also recognised when observing the hotel employees in Case II that there was a high level of openness in communication between employees of junior positions and the hotel management team. Accordingly, in both cases junior employee

respondents' answers confirmed that they were able to share work experiences and knowledge with management directors with minimal or no restriction.

The review of the statement of corporate values in Case II reflected further evidence of corporate management enthusiasm to nurture informal communication between employees. It was also recognised in Case II that the human resources department encouraged informal communication between the hotel employees by instigating initiatives such as the Social Committee. This Committee was set up by the Human Resources department to encourage social interaction between the hotel staff by organising recreation and sports events, and other forms of social gathering to promote team work, spirit and eliminate bureaucratic barriers between the hotel employees.

The other informal knowledge integration behaviour recorded in both cases was the transfer and sharing of knowledge through informal relationship networks. However, as these networks may include within them individuals from outside the hotel, there would be a risk of revealing confidential knowledge to external parties, i.e. industry competitors. Adversely, if knowledge was integrated through internal and intra-organisational networks it could be a very useful method to transfer knowledge. For instance, the interviewees who were involved in internal or intra-organisational networks explained that they could become aware of what was happening in other departments or other hotels of the company through sharing other associated employees' knowledge and experiences.

6. Discussion

This study aimed to explore the nature and role of knowledge relevant to service employees' individual innovative behaviour and leading to initiating innovation within the sub-sector of personal-interactive services. To achieve this aim an objective was set to unravel patterns of employees' innovative behaviour in relation to knowledge contributing to the interlinked process of idea generation and development. Another set objective is to review the established literature relevant to the implication of knowledge in progressing service innovation and add further insight to previous research underpinning service employees' role in initiating service innovation.

The exploration of the nature and role of knowledge in relation to employees' individual innovative behaviour leading to initiating innovation was achieved by detailed assessment of micro cases, which are critical incidents of innovation projects. The

evidence that emerged from the two cases researched distinguished between two types of knowledge as *prior knowledge* and *dependent knowledge* that together play an ancillary role to the interlinked process of idea generation and development aspects of the service innovation. As previous research has suggested, idea generation involves the retrieval of knowledge from the long-term memory, and the combination of various aspects of existing knowledge into novel ideas (Mumford *et al.*, 1991; Ward *et al.*, 1997; Nijstad and Stroebe, 2006) and postulates the importance of *Prior Knowledge* for idea generation (Baron, 2006; Grégoire *et al.*, 2010; Shane, 2000). This study also confirms the ancillary contribution of *prior knowledge* to idea generation and development and also adds a further category as *dependent knowledge* which supports the development of a new idea in accordance with context peculiarities.

The objective to unravel patterns of employees' innovative behaviour in relation to knowledge contributing to the interlinked process of idea generation and development was also achieved by highlighting four behaviour patterns. This has added insight in explaining service employees' participation in initiating innovation and addressed the behavioural perspective of innovation (Janssen, 2000) in the personal-interactive service context.

6.1. Case Comparison

In both case studies, it was remarked that prior knowledge supported idea generation and development by inspiring individuals' innovative behaviour to come up with new ideas. The acquisition of prior knowledge started before an idea was initiated and even before commencing employment at the hotel. Formal prior knowledge acquisition continued after induction training through corporate education and training. In both cases, management arranged training programmes and personal development plans after employees received the initial induction training and starting employment. However, in Case I a further diversity of programmes was offered for employees' learning and development.

It was similarly highlighted in both case studies that employees also elected to take up training programmes that were not organised by the hotel management. The perceptible difference between the two researched case studies was that the human resources department in Case II followed more consistent corporate guidelines to encourage employees' informal prior knowledge acquisition.

Dependent knowledge acquisition was recognised as another form of formal ancillary knowledge acquisition in both cases, that emerged after identifying the idea, and which is gained with the aim of developing the initial idea into a form of innovation. Formal dependent knowledge acquisition activities in both case studies were mainly management mandated and determined by the innovation project team, where the methods exercised to acquire dependent knowledge were also decided by the innovation project team.

On the other hand, acquiring dependent knowledge through informal individual means similarly developed at an earlier stage of idea generation and development in both cases. The aim of informal dependent knowledge acquisition was mainly to develop the idea initiative into a presentable form before reporting the idea to the management. Informal dependent knowledge acquisition progressed through diverse methods in both case studies; employees acquired dependent knowledge through dissimilar methods depending on contextual factors and on the type of knowledge required to develop the generated idea.

The main difference between the two researched case studies in relation to formal knowledge integration was that Case II owning company had a central department for managing customer knowledge and insight. However, while conducting the research in Case II there was no evidence detected of direct involvement by this department in managing innovation projects.

Informal communication emerged as a predominant method to integrate knowledge in both case studies. Employees shared knowledge through informal interaction with each other and with other individuals who came from outside the hotel environment. In the Case II, the Social Committee distinctly facilitated informal integration of knowledge by encouraging informal communication and innovation groups' formation. Innovation groups similarly emerged as a dominant informal method to integrate ancillary knowledge in both cases, and helped to integrate knowledge at the local, intra-organisational and external levels.

6.2. Management Implications

Amid the managements' efforts to promote teamwork and coordination between employees within the two researched case studies was the encouragement of communication and social interaction between employees. Communication and social interaction between employees was also encouraged to eliminate the traditional bureaucratic barriers that inhibit communication between the hotel management and

employees of junior positions. Furthermore, and in relation to individual innovative behaviour, the social interactive environment of the hotel services workplace implied that a large proportion of knowledge sharing was facilitated through social interaction between the hotel employees on one account, and the hotel guests and the surrounding social environment on the other.

Informal dissemination of knowledge through informal network relationships was detected in both case studies. Employees in both hotels created informal networks and links with other employees, and even with other individuals who did not work in the same hotel. The entailed advantage of informal networks was that unlike formal mechanisms, knowledge integration was facilitated with less bureaucratic barriers and more diversity in knowledge sources.

It is proposed that forming informal innovation networks should be encouraged at two levels: (1) at the corporate level to interlink employees from the hotel property and other employees from other company associated hotels, and employees from regional management and head office, and (2) at the hotel property local level to interlink the hotel employees with individuals from the surrounding environment. The management role in encouraging the creation of informal networks would not be expected to achieve much progress by directly mandating these networks, rather it would be the management's support and appreciation of building ties and relationships that will create the appropriate environment to form innovation networks.

Maintaining the essence of the previous discussion, it is expected that direct management intervention in processing informal communication and integration of knowledge may not always be realistically attainable; rather the management role could be more effective in creating an incubating environment for informal communication. The following practical steps are proposed to encourage informal knowledge integration:

i. Cross-training

The valuable opportunity to share knowledge through cross-training should be effectively exploited at both inter-hotel and intra-organisational levels; the interaction between employees during cross-training proved to allow direct integration of knowledge, and also encourages forming informal innovation networks. Fundamentally, it is advisable to increase cross-training sessions at the intra-organisational level and

broadening up the trainee selection criteria to include members of executive and non-executive positions to create innovation networks with more diversity among its actors.

ii. IT Integration

Integration of ideas and knowledge through corporate intranet was another dominant method throughout the research. The utilisation of information technology integration was mainly to disseminate corporate literature and standards on the one hand, and to upload management performance reports on the other. Further investment in the corporate cyber infrastructure to allow informal interaction between employees at both the intra-organisational and inter-hotel levels is recommended.

The inadequate usage of corporate intranet by non-executive employees within the two researched case studies should be increased by the appropriate means to increase informal interaction and communication between employees. A suggested method to realise this objective is by creating corporate Internet blogs and social interactive Internet web pages, and also by creating the incentive for employees to communicate with each other through such methods.

6.3. Research Limitations

The applied research methodology was the most appropriate to achieve the aims of this research; the complex relationships and patterns related to the case studies required closer assessment and observation that were best attained through case study methodology. Further thorough examination was needed to obtain detailed explanations of events and behaviour patterns related to employees' innovative behaviour, and this was best possibly achieved by applying qualitative research methods. Yet, there were also drawbacks and limitations to consider when appraising the validity of the research methodology used, and some of these limitations may be considered as traditional or unavoidable. In general, the limitations associated with the research methodology can be highlighted under two headings: the *Problem of Sampling* and the *Problem of Generalisation*.

Despite that the sampling strategy adopted a balanced approach in selecting employees from all levels of the management hierarchy, criticism may still be raised in both studies over the selective criteria, based on interviewing employees involved in critical incidents or innovation projects. The critical viewpoint would raise the concern

that the selective criteria may produce a biased outcome and therefore may advocate for random selection of interviewees.

On another account, the involvement of the human resources departments in short-listing the appropriate interviewees in both case studies may be perceived as another reason to raise additional concern over the biased selection of interviewees. Despite that, it would have been extremely difficult for the researcher to identify the most suitable interviewees without the relevant information provided by the human resources departments, and despite this, it could still be argued that the human resources departments would only provide the information that would reflect employees' efficiency.

The problem of generalisation is one of the classical problems associated with case study methodology at large. The precept of this critical view is the inability of case study research to provide justifiable generalisations or causal laws (Yin, 1994). Despite that case study methodology may generally provide thorough and useful insights in exploring complex human behaviour patterns, its findings are very often unique to the population researched, and sometimes do not distinguish between what is unique to the case and what is common to the class of events as a whole (Achen and Snidal, 1989).

The application of comparative case study methodology and the triangulation of evidence by investigating micro case studies and implementing other triangulation methods are very likely to strengthen the validity of findings in this research. However, reservation and criticism may still arise in regard to producing universal generalisations and causal laws based on investigating a limited number of case studies.

7. Conclusions

The outcome of the research distinguished between two types of ancillary knowledge: *Prior Knowledge* and *Dependent Knowledge*. *Prior Knowledge* consisted of the previous collective life time experience that helps individuals identify ideas for innovation, while *Dependent Knowledge* is contextual and acquired with the aim of developing the identified idea into a form of services innovation. The relationship between knowledge and the interlinked process of idea generation and development was discerned as inseparable.

Four patterns of ancillary knowledge related behaviour were identified to support idea generation and development during the conduct of research: *Formal Ancillary Knowledge Acquisition*, *Formal Ancillary Knowledge Integration*, *Informal Ancillary Knowledge*

Acquisition and Informal Ancillary Knowledge Integration. It is important to mention that not all employees equally participated in the four mentioned activities, the level of involvement and participation varying from one context to another depending on individual and motivational factors.

The review of previous literature reveals significant paucity in research on knowledge implicated within service innovation. Most relevant studies address the relationship between knowledge and service innovation from knowledge intensive business services KIBS perspective and less evidently consider other subsectors of the service industry, such as personal-interactive services that involve a significant level of interaction between employees and service customers.

The study makes the following contributions; first it introduces a theoretical framework related to the nature and ancillary role of knowledge in personal-interactive services. A novel classification of two types of knowledge is presented for future assessment and research in service innovation. Secondly, the study provides new insight into the relationship between knowledge and service innovation in personal-interactive services that have been mainly addressed in knowledge intensive business services KIBS.

Appendices

Micro Case I: 20 Steps Cleaning Sequence

The '20 Steps' cleaning sequence is a system of practice implemented by the housekeeping department to clean the hotel rooms. The main objective for applying this system of practice was to enable better control and efficiency of room service attendants' performance when cleaning rooms.

According to the housekeeping department manager, *'before we had the 20 Steps cleaning sequence, we had problems with applying some kind of order for how should the room service attendants clean the hotel rooms. Some attendants were really good and finished cleaning rooms in shorter time, while others needed more training and attention. The problem was that despite we trained the attendants to follow cleaning guidelines, each attendant used his own way of cleaning. Therefore there was a need for some kind of system to use for measurement and correction'*.

By having a structured order for the cleaning steps it was easier to estimate the time the attendants spent on each step, and then identify the weakest areas of performance. It was also possible for the housekeeping department manager to make sure that the attendants followed the right cleaning order by reviewing the room cleaning record sheets signed by the room attendants and the housekeeping supervisors. Both the department manager and one of the housekeeping supervisors confirmed that after applying the '20 Steps' cleaning system they experienced less complaints from the hotel guests and more efficiency in how the attendants carried out room cleaning.

The idea for the '20 Steps' cleaning sequence came from a trainee hotel manager, while he was attending a training programme at the hotel before joining another hotel property as a general manager. The housekeeping department manager and the trainee general manager connected through idea/knowledge exchange relationship (innovation group), when the housekeeping department manager sought advice from the trainee manager about the problems she had with room cleaning.

The trainee manager suggested the '20 Steps' cleaning system that he knew about while he was previously working for another hotel company, and provided the housekeeping manager with further details in the form of training literature and other printed material (prior knowledge). The housekeeping department manager raised the issue with the hotel manager during the heads of departments' weekly meeting, and the management team appointed a project team including the hotel manager, the trainee manager, the housekeeping department manager and two housekeeping supervisors. The project team decided to delegate the trainee manager to train the room service attendants on the '20 Steps' cleaning system, and after completing the training the system was implemented for a trial period. The cleaning system was eventually approved by the hotel general manager after the housekeeping supervisors reported positive results.

Micro Case II: Family Rooms

Family rooms were designed to accommodate hotel guests accompanied with their children; the rooms were larger than the typical hotel room size and included one double bed, two children's beds and a baby cot upon request. The children's entertainment section of these rooms included Lego toys, a Sony Play Station console connected to a flat screen TV that could also be used to view a package of children's TV channels. The adults' section of the room had its own flat screen TV, a laptop work station and a larger than average refrigerator that was also used to preserve children's drinks and snacks.

The idea of family rooms came to the fore after numerous requests were received expressing the hotel guests' need for children's beds to be placed in the standard deluxe rooms instead of having to split the family between two rooms and having to pay for an extra room. The options available to the hotel guests accompanying children were to either book a hotel suite (minimum cost €700 per night) or book one of the suite apartments that were booked for a minimum period of seven days and did not have all the amenities of the hotel rooms.

The general manager of the hotel took notice of the guests' requests and concluded that there was an opportunity to convert some of the hotel's executive suites into larger rooms to accommodate family guests with children. According to the hotel general manager, *'we have realised that a large proportion of our guests were family holiday makers accompanied by their children. In the typical case a family of four people, two adults and two children, had to be split between two rooms. Some guests requested to include children beds in the same room, but that was only possible if they were accompanied by only one child due to the size of the room. The executive suites that we had weren't selling very well at that time so we thought why don't we make use of some of the suites and convert them into bigger rooms for families'*.

The general manager of the hotel advised the rest of the hotel's executive committee members in the weekly meeting about the rising demand for children's extra beds and proposed converting 15 of the hotel's executive suites into family rooms. The decision then was made to appoint a project team to study the feasibility of the general manager's idea and it was agreed that it would be very important to take into consideration guests' insights in the design of the family rooms. The project team included the hotel general manager, the revenue manager, the maintenance department director, the sales and marketing department director, and two other employees to undertake the guest insight research.

The sales and marketing department director suggested inviting family hotel guests to attend brainstorming sessions for the proposed room designs. A selected sample of returning guests and loyalty programme members were invited to attend the sessions and were asked to participate in making comments on a number of prospective room designs prepared by an interior architectural design company. In addition, the hotel general manager informally consulted the general manager in Rome hotel about the general pricing structure of the Family Rooms and the appropriate marketing channels and market sector to be targeted.

The guests' preferences and remarks were considered in the final room design and a proposal of the room layout, room booking price and a marketing communication strategy for the family rooms was introduced to the hotel's management team, where the proposal was thoroughly

Understanding Eco-Innovation Evolution: A patent Analysis in the field of Low-Carbon Technologies

Structured Abstract

Purpose – We aim at offering a deeper and more complete perspective on eco-innovations’ development in the field of low-carbon technologies, across different types of technological classes, geographical areas, industries, and considering a large time period. Accordingly, we aim at providing a comprehensive and unique overview of the evolution, and related policy initiatives, of a wide category of eco-innovations, namely low-carbon technologies. These are playing a crucial role in the current socio-economic agenda, given their capability of improving energy security, emission reduction, environmental protection, and economic growth.

Design/methodology/approach – We employed patent data to investigate the main dynamics characterizing the evolution and development of eco-innovation. Specifically, we searched for patents granted at the U.S.PTO. and belonging green energy technological classes, as identified by the IPC Green Inventory. Thus, we identified 131,809 patents filed from 1946 to 2010. For each patent, we then collected most relevant

bibliographic information. By using this unique database, we depicted eco-innovations' development trends and identified countries and organizations more involved into these innovative activities. Furthermore, we related these descriptive statistics to low-carbon technologies evolution with relevant national and international environmental policies and programs, hence building a comprehensive picture of the main environmental actions undertaken over time.

Originality/value – To our knowledge, this study is the first one that depicts a comprehensive scenario of eco-innovation evolution. Furthermore, it is based on a wide dataset allowing us to address this issue in such a complete and deep manner. Indeed, it covers all the main technological categories and their subclasses in the energy field. Thus, compared to previous studies, we have more deeply analyzed the differences among various types of eco-innovation. In addition, we collected patents filed from 1946 to 2010, hence tracing the entire history of energy eco-innovation's development starting from its origins. Furthermore, the considered patents are granted to organizations localized all over the world. Thus, not being referred to a bounded geographic region, this study captured the differences among countries' innovative capabilities.

Practical implications – This study allows both policy makers and companies to better understand the complexity characterizing the eco-innovation evolution in the field of low-carbon technologies, hence highlighting political and commercial determinants of their development, as well as how and to what extent countries and organizations have addressed their innovative efforts towards sustainability objectives. Accordingly, it provides new insights to set out future directions for eco-innovations' development. Particularly, it is suggested to plan adequate investments in research and development activities and technology transfer programs, as well as to establish new energy policies in order to set a political and economic environment by which technical, economic, and political knowledge could be better integrated in order to follow both environmental, business, and social needs.

Keywords – Eco-innovation; patents; low-carbon energy technologies; environmental sustainability; environmental programs.

Paper type – Academic Research Paper

1. Introduction

During the last years, the concept of eco-innovation (e.g., Rennings 2000) has attracted an increasing attention across many countries all over the world as a mean to address both economic and environmental priorities (Linton 2013). Since the Brundtland Report (WCED 1987), where the concept of sustainable development was first presented, an increasing demand for a new vision on innovation was claimed (OECD 2012; Rennings 2000). In addition, following the Brundtland Report, environmental protection should not be considered as a limit to the economic growth, but rather as a necessary condition for a long term development. Moreover, technology is deemed as the basis of

the economic growth, providing the means to act smarter and more sustainably, hence fostering the transition towards an environment-oriented lifestyle and low-carbon systems in industrial sector such as transport, energy, and waste treatment (European Commission 2006; McJeon et al. 2011). Thereby, technology seems to play a strategic role by influencing environmental impacts, risks, and costs (Kotha and Orne 1989; Shrivastava 1995; UNEP 2003), as revealed by a number of initiatives undertaken by international organizations, such as the Organisation for Economic Co-operation and Development (OECD) and the United Nations, which have recently introduced programs to deeply study the eco-innovations' development. For instance, in 2008 the OECD launched the "Green Growth and Eco-innovation" project, with the aim to better understand how innovation can result into new technological and systemic solutions for facing global challenges and leading the industrial system towards a sustainable growth (OECD 2008, 2010; Linton 2013;).

In this paper, we aim at studying the evolutionary trends of a specific type of eco-innovation, which has been demonstrated to play a key role in fostering sustainable development and business innovation (Sun et al. 2008), namely low-carbon energy technologies. Nowadays, these technologies are recognized as fundamental means to reduce the cost of stabilizing atmospheric carbon dioxide concentrations and lower the final cost of meeting environmental policy objectives (McJeon et al. 2011; IEA 2012), as well as to improve energy security, emission reduction, environmental protection, and economic growth (Nuttal and Manz 2008; Harmon and Cowman 2009; Palma and Coletta 2011). Nevertheless, although increasing environmental programs and initiatives, the diffusion of low-carbon energy technologies still remains limited, being largely dependent on public intervention (Johnstone, Haščík, Popp 2010; Demirel and Kesidou 2011). In this context, while several scholars have devoted their attention to define, classify, and measure eco-innovations (e.g., Demirel and Kesidou 2011; Kesidou and Demirel 2012), to our knowledge, a complete picture of the eco-innovative efforts undertaken by both companies and countries over time is still lacking. Thereby, this paper aims at developing a comprehensive overview of the low-carbon energy technologies' evolution. To this aim, we contribute to the extant literature by building a unique database of 131,801 patents granted at the United States Patent and Trademark Office (U.S.PTO) from 1946 to 2010 and belonging to the green technological classes "Nuclear power generation", "Alternative energy production", and "Energy conservation", as described by

the International Patent Classification (IPC) Green Inventory classification. For each patent, we retrieve several data, such as assignees and inventors details, technological classes, backward citations, scientific references, and forward citations. Then, we present an overview of patents' development trends and identify countries and organizations mainly engaged in these innovative activities, as well as describe the most relevant actions undertaken by both private and public organizations in the eco-innovation evolution process. Finally, we provide some insights on the most valuable patented inventions in the field.

The paper is structured as follows. In the next section, we discuss the use of patent data as proxy for analyzing technology development and present a brief literature review on eco-innovation. Then, the third section presents the data collection methodology and the sample. The fourth section contains descriptive analyses on the patenting activity and possible explanations for these results. Finally, discussion, implications, and conclusion are presented.

2. Theoretical Background

2.1. Defining eco-innovation

The big global challenges posed by the growth rate of the human-induced climate change, as well as the sustainability goals recently set, such as Europa2020 targets (European Commission, 2010), have led to the need to redefine the concept of innovation (Rennings 2000; OECD 2012). In fact, the term “innovation” is generally referred to the implementation of a wide range of new products, processes, or organizational methods (OECD 2005) without focusing on the related environmental impacts. Differently, sustainability issues aim at boosting innovative activities towards sustainability objectives (Rennings 2000; OECD 2012). Indeed, despite it has been widely recognized that innovation is the central issue in economic prosperity (Hargroves 2005), nowadays innovation is more and more considered as the key factor to pursue sustainable development targets while continuing to promote competitiveness as well (Nidumolu, Prahalad, Rangaswami 2009; OECD 2011). Accordingly, the concept of eco-innovation has rapidly gained much attention across both policymakers and researchers.

In the literature, different definitions of eco-innovation have been proposed and different terms have been adopted interchangeably (e.g., eco, green, environmental, or

eco-friendly innovation). Nevertheless, despite a wide range of definitions, some common features emerge, highlighting that an eco-innovation is an innovation that primarily contributes to reduce environmental impacts and open new sustainable pathways in the market (e.g., Arundel and Kemp, 2009; Fussler and James, 1996; OECD, 2009a). In particular, several debates on eco-innovations have focused on topics that directly address environmental technologies (European Commission 2004; Stern 2007), recognized as the keys to guarantee the co-existence of economic growth and environmental progress (Shrivastava 1995; OECD 2000), in turn defined by the European Commission (European Commission 2004, 2) as “[...] all technologies whose use is less environmentally harmful than relevant alternatives. They include technologies to manage pollution (e.g., air pollution control, waste management), less polluting and less resource-intensive products and services (e.g., fuel cells) and ways to manage resources more efficiently (e.g., water supply, energy-saving technologies)”. Specifically, technologies aimed at reducing Greenhouse Gas (GHG) emissions and energy consumption, as well as technologies devoted to restructure the global energy system (e.g., solar cells, electric engines) have been deemed to play a crucial role in fostering sustainable development and business innovation (e.g., Messeni Petruzzelli et al. 2011). Accordingly, in this paper we analyze a specific type of eco-innovation, namely low-carbon energy technologies, discussing their evolutionary trends across countries and organizations and the impact exerted by related policy initiatives and events on their emergence and development.

2.2. Patents as measure of eco-innovation

In the last years, both academics and policymakers have made an increasing use of patent data as a source of information for analyzing innovation activities. Indeed, patents have a close link to economic relevant inventions (Dernis and Guellec 2001), as well as they have been recognized as strongly correlated with other indicators of innovative activity, such as R&D expenditures and new product introduction (e.g., Comanor and Scherer 1969; Griliches 1990; Hagerdoon and Cloudt 2003). Furthermore, patent data are publicly available for a long time series and provide a number of valuable information on the technological content, geographical location of assignees and inventors, and citations made and received by the patent.

Accordingly, in the literature, there are many examples of using patent data to study eco-innovations (e.g., Oltra, Kemp, de Vries 2010) and their evolution. For instance, Pilkington and others (2002) used a sample of 268 U.S. patents in the IPC class “Electric propulsion with power supplied within the vehicle” (IPC code B60L/11) in order to analyze the development of the electric vehicle. Brunnermeier and Choen (2003) provided evidences on the increased development of eco-innovations by U.S. manufacturing firms, as reflected by patent count, in response to the increment in pollution abatement expenditures, especially in internationally competitive industries. Sun and others (2008) analyzed the temporal and spatial distribution of eco-patents in China. In particular, the authors found that the development of environmental technologies is particularly relevant in the East of China, where they have shown an increasing application of new patents, although still lagging in a global perspective. In addition, Oltra and Saint Jean (2009) used patent applications in order to understand the competition among companies in the development of engine technologies for low emission vehicles. The OECD (2011) included patent data in its study to analyze environmental technologies’ diffusion and transfer. Finally, Leu and others (2012) studied the patenting activity in the field of bio-fuel and bio-hydrogen energy from 2000 to 2011 through the use of patent bibliometric analysis. These studies, however, offer a partial scenario to policymakers and companies in explaining the main dynamics underlying eco-innovation evolution. Principally, they refer to small samples of patents, which could be not so relevant to bring out significant results. Furthermore, they refer to a bounded geographic area or a limited time period, which cannot allow to depict a complete scenario of innovative efforts in eco-innovations’ development. Finally, most studies focus their attention to a specific sector or technological class, so limiting the generalizability of their outcomes.

Our paper extends previous studies through the creation of a wide and unique database that collects all patents related to eco-innovation activities in the energy field by including all the main technological energy-related categories and their subclasses. Hence, this allows us to more deeply analyze the differences across various types of eco-innovation. In addition, our database collects patents filed from 1946 to 2010, hence giving us the possibility to trace the entire history of eco-innovation’s development in the energy field starting from its origin. Furthermore, the considered patents are granted to organizations spread all over the world, thus making us able to capture differences among countries and

organizations' eco-innovative capabilities. Finally, we also offer a nuanced picture of breakthrough eco-innovations in the energy field.

3. Data and Methodology

We employ patent data to investigate the main dynamics characterizing the development of eco-innovations, as well as their breakthrough nature. Differently from previous studies, we refer to the IPC Green Inventory in order to collect patented technologies providing environmental benefits, rather than adopting other less rigorous approaches as those based on keywords (Oltra and Saint Jean 2009; Leu, Wu, Lin 2012). These, in fact, may suffer from a number of drawbacks, as unobserved heterogeneity and failure to capture the dynamism of the technologies under investigation, making these search strategies less reliable than the employment of wide and largely accepted technological classifications. The IPC Green Inventory was launched in 2008 by the World Intellectual Property Organization (WIPO) in the attempt to create a concordance between the IPC classification and Environmentally Sound Technologies (ESTs), as defined during the Rio Earth Summit in 1992 (Agenda 21, Chapter 34). Accordingly, the IPC Green Inventory takes into account seven different technological classes, in turn divided into hierarchical sets of subclasses. Each subclass is linked with the most relevant IPC code(s), as identified by a panel of experts¹. In particular, we considered the classes related to the energy field, namely, “Nuclear power generation”, “Alternative energy production”, and “Energy conservation”. This approach allows us to rely upon consistent and rigorous criteria to identify low-carbon energy patents and provides a large sample upon which conducting our analyses.

Then, we searched for patents granted at the U.S.PTO. and belonging to the selected technological classes. Thus, we identified 131,809 patents granted from 1946 to 2010. For each patent, we collected relevant data, such as title, filing date, issue date, number of claims, number of backward, forward and scientific citations, inventors and assignees' details (name, city, state, and country), and technological fields. To identify breakthrough eco-innovations we used patent forward citations, which have been widely adopted in the literature to assess innovation value and impact (e.g., Singh and Fleming, 2010). Indeed, patent citations are largely employed to evaluate differences in patent quality, especially

¹ See <http://www.wipo.int/classifications/ipc/en/est/>

in large datasets where in-depth qualitative evaluations of individual patents are very hardly (NREL 2011). Nevertheless, the literature has questioned the use of forward citations, by noticing that older patents are more likely to be cited than younger ones (e.g., Hall, Jaffe, Trajtenberg 2001), hence calling for solutions to avoid such a bias. Accordingly, we calculated the citation rate per year in order to reduce the effect of patent age. Furthermore, comparing the samples sorted by citation rate and number of forward citations (top 1, 3, and 5 percent of our sample), we found at least in the 90% of cases the same patents for each category, hence increasing our confidence in the selection criteria. To conduct out analyses we considered the top 5% most cited patents as breakthrough technological innovations (e.g., Singh and Fleming 2010).

4. Analysis and Results

In this section, we provide a comprehensive overview of eco-innovation evolution in each technological class, by focusing on the development trends of patented low-carbon energy technologies. Specifically, we used patent count as a measure of the innovative effort (Zoltan, Anselin, Varga 2002; Singh, 2008), the average number of scientific citations to approximate the willingness of inventors to build upon science (e.g., Narin, Hamilton, Olivastro 1997; Meyer 2000; Czarnitzki 2001; Callaert et al. 2006), the number of forward citations as a proxy of the quality and subsequent impact of an invention (e.g., Singh and Fleming 2008), the main assignee information to analyze development trends at organization level, and, finally, the main inventor state in order to proxy the geographical origin of an invention (Sharif 1986; Deyle and Grupp 2005). As time scale, we used the filing year, since it better captures the invention development period than the issue year (Verspagen and Loo 1999). However, the time lag between application and issue may be even large. Hence, patents filed more recently generally have less likelihood to be granted at the time of data retrieval. Thus, the last ten year analysis is used more for comparison than for an actual trend evolution analysis. Finally, we also referred to major environmental programs and geopolitical circumstances in order to better understand evolutionary trends of low-carbon energy technologies as the result of national and international policies, as well as to highlight historical events and private sector initiatives that may have fostered such innovations.

4.1. Nuclear power generation

This main class is divided into two different subclasses. However, the second subclass (“Gas turbine power plants using heat source of nuclear origin”) has only a negligible contribution in explaining the nuclear energy eco-innovation evolution, as revealed by the low share of patents (0.3% of the total amount in the field). Thereby, we analyze “Nuclear power generation” technologies without differentiating the two subclasses.

Figure 1 presents the patenting application activity since 1946, as measured by patent count per year, both globally and per different geographic regions (U.S., Europe, Japan, and BRIC - Brazil, Russia, India, and China). The global trend (indicated by “ALL”) shows a sharp growth of the number of patents in the 1970s. Furthermore, almost all the analyzed countries contribute in the “Nuclear power generation” technological development in its first coming, except for BRIC. This trend could be explained by examining geopolitical issues occurred in those years. In fact, while nuclear energy and nuclear weapons technologies were closely related to military aspirations during World War II, since mid-1950s some governments started to reorient countries’ resources towards the development of nuclear power plants for commercial purposes. Thus, such commercialization efforts pushed organizations in protecting their inventions to gain greater profits. In addition, in 1967 the Arab-Israeli War (also known as Kippur War) caused a serious petrol crisis, when the Organization of Arab Petroleum Exporting Countries (OAPEC) proclaimed an oil embargo. Thereby, Western countries increased their investments in nuclear power, in order to face such an energy crisis (Anadon 2012). A number of reactors, in fact, came about all over the world. To name few examples, in 1971 diverse commercial nuclear power plants were in full operation in the U.S.. Also European countries, such as France, Italy, Germany, and UK, saw the birth of many reactors in those years. Particularly relevant was the action taken in place by the French Prime Minister Pierre Messmer in 1974, when he declared the so named “Messmer Plan” with the aim of generating from nuclear power the whole France’s electricity need (Sovacool, Victor, Valentine 2012).

Figure 1. Trend of “Nuclear power generation” patent applications

Furthermore, the graph depicts an alternate patenting activity trend across the countries during the period from 1976 to the mid-1990s. Particularly, it reflects that patenting activity in Europe fell down immediately after 1988, whereas it grows in the U.S. and especially in Japan, which assumed a predominant innovative role in this field. Explanations may be identified in a number of different reasons that caused some concerns in the use of nuclear power, such as the reduction of the oil price in the early 1980s and some nuclear accidents, like the Three Mile Island incident in Pennsylvania in 1979 and the well-known Chernobyl disaster in 1986. Nevertheless, at global level the effects produced were not the same. In fact, while some countries drastically reduced their attention towards nuclear power and R&D efforts in the field, others continued to invest. For instance, nuclear energy was totally abolished in Italy by a public referendum in 1987. Moreover, at the end of 1989 the UK government stopped the build of nuclear stations, until a review of UK nuclear policy would be carried out, and in August 1986 Germany approved a resolution to abandon nuclear power within ten years. Differently, other nations still promoted nuclear energy. Indeed, the project International Thermonuclear Experimental Reactor (ITER) represents an important signal in that direction. ITER was a research and engineering project signed in 1985 by Soviet Union, the U.S., Japan, and European Union and launched in 1988 with the aim to have a full

scale production of electricity from power plants. Nowadays, the projects is still working and includes also South Korea (since 2003), India (since 2005), and China (since 2007).

Finally, Figure 1 depicts another increase in patenting activity starting from 1996, which seems to highlight a renewed interest in the nuclear power in Europe, Japan, and some other countries (e.g., South Korea and Israel). This probably finds its roots in the rise of developing economies that started investments in such a direction. Indeed, that period is recognized as “nuclear renaissance” just because of a new interest in the nuclear power industry driven by the rising of fossil fuel prices and environmental concerns (Nuttal 2005). Thereby, despite some incidents happened around the world, a third generation of reactor was developed during these years. In addition, in 1999, in the U.S. the Nuclear Energy Research Initiative (NERI) was established in order to foster collaborative researches in high technological nuclear solutions. Further, President George W. Bush signed the Energy Policy Act in 2005, which made significant changes in nuclear policy, fostering utility companies to establish more nuclear plants to cope with the country’s growing energy demand (Public Law 109-58 2005). More recently, other countries started nuclear energy programs, such as China, South Korea, and India that, as above mentioned, joined the ITER project. Finally, several states, particularly from Africa, are currently carrying on nuclear power programs in this “nuclear renaissance” scenario, mainly pushed by abundant uranium resources (OECD and IAEA 2006).

In Figure 2, we examined the global patent share across countries by trying to highlight the other relevant contributors. As noted in the previous graph, the three main actors are represented by the U.S., Japan, and European countries. Within European countries, France and Germany are the most innovative. Looking for other contributors, we checked for the BRIC innovative efforts, due to their significance in the current and future economic scenario. However, the analysis points out that they are still not so relevant in R&D activities in this specific field. Finally, we highlighted two other important actors, namely South Korea and Israel. While it is reasonable that South Korea may be involved in developing nuclear technologies due to its entry in the ITER project, Israel has no nuclear power plants, hence making these technologies mainly originated from researches conducted in the military field.

Figure 2. "Nuclear power generation" eco-innovation patent share by geographic area

Figure 3. "Nuclear power generation" scientific citations analysis

By analyzing the citations' rate of scientific documents made by all patents, it turned out an interesting aspect of the innovation activity. Specifically, by looking at the graph shown in Figure 3, where the y-axis reports the average number of scientific citations made by all patents in a specific year, it is possible to note that, before 2002, inventors tend to cite only patent documents. Differently, recently, references made to scientific literature have grown. Thus, it is possible to observe how from 2002 organizations have changed their approach in research activities, shifting to a closer relationship between theoretical and applied research than in the past. In turn, this may depend on the strengthening of the link occurring between science and technology. This is in accordance with previous studies that highlighted the positive influence of basic science for economic growth (Jaffe 1989; Adams 1990) and new technologies' development (Narin, Hamilton, Olivastro, 1997). Main explanations have been recognized in the key role of science to foster technological advances by providing new technological ideas (Brooks 1994) and expanding firms' absorptive capacity, hence underscoring how the interplay between science and technology significantly impact on both individuals and organizations capability to successfully innovate (Dasgupta and David 1994; Cockburn and Henderson 1998; Fleming and Soreson 2004; Cassiman, Veugelers, Zuniga 2008). In particular, looking at nuclear technologies, this linkage could be referred to the need of new

materials and chemical processes that can meet safety and efficiency goals (U.S. Department of Energy 2006).

Figure 4 reveals the top ten organizations in terms of number of granted patents, operating both in public and private sectors. Each bubble identifies an organization and its dimension represents the number of its successfully filed patents. Furthermore, in each bubble it is inserted the flag of the country where the organization is located. In addition, other two measures were employed to enrich the analyses. In particular, the first one (x-axis) aims at indicating when an organization has undertaken the major efforts in developing nuclear technologies. Thus, we calculated the average year in which each company has filed its patents. The second one (y-axis), instead represents the quality of the inventive efforts as measured by the average number of forward citations in order to estimate the impact of organizations' innovations. Results point out two main aspects. First, as we mentioned earlier in the paragraph, public sector, mainly represented by the U.S. government and the Commissariat à l'Énergie Atomique, has a significant role in supporting and pushing these types of power generation method. The effort devoted by public organizations is largely focused in the first period of nuclear power commercial use, whereas later in time private companies have assumed a major role. This trend confirms the importance of public research in exploring innovative technological solutions, hence opening the doors towards their subsequent exploitation by the private industrial sector (e.g., Adams 1990; Mansfield 1991; Cohen, Nelson, Walsh 2002; OECD 2007). Second, high valuable patents are mainly owned by actors located in the U.S. and their innovative activity is concentrated before the 1990s; whereas after this cut-off point (maybe related to the Chernobyl accident) the development of nuclear solutions is quite homogeneous across Europe, U.S., and Japan, while the innovative quality and impact seem to decrease.

Figure 4. Top ten organizations in the “Nuclear power generation” class in terms of patent intensity (as represented by bubble size), period of the highest patenting activity (x-axis), and outcome quality (y-axis)

Finally, we also showed the temporal period when breakthrough eco-innovations in the “Nuclear power generation” class were filed, as well as their geographical distribution. Specifically, Figure 5a reveals that high valuable innovations are owned almost totally by the U.S. and European countries, being these pioneers in the adoption nuclear plants for commercial purposes. Furthermore, Figure 5b shows that breakthrough eco-innovations were all filed between 1955 and 1976, hence depicting a reduction of the innovation value after this period. A possible explanation may be related on the necessity to make previous solutions safer rather than develop really new ones. Indeed, organizations tended to be more focused on the exploitation of existing technological solutions in order to extend life and reliability of current reactors, enable nuclear energy to meet climate change goals, develop sustainable nuclear fuel cycles, and manage nuclear waste (I-NERI 2001).

Figure 5a. “Nuclear power generation” breakthrough patent share by geographic area

Figure 5b. “Nuclear power generation” breakthrough eco-innovation’s development trend

4.2. Alternative energy production

The IPC Green Inventory recognized 13 subclasses related to the “Alternative energy production” class. Firstly, we present the patenting activity as a whole without discerning the different subclasses. Then, we provide a brief analysis for each of them.

As shown in Figure 6, the global patenting activity (indicated by “ALL”) in the alternative energy field presents three clear different trends. It grew in the early 1970s. Then, it shows a slow decrease till the end of 1980s, after which a still growing trend is visible. As we noted in paragraph 4.1, the initial growing trend could be explained by considering the oil price shock triggered by OAPEC oil embargo that contributed to create awareness about the limits of global resources in respect of energy. Indeed, this concern attracted funds and concerted efforts for the development of new solutions through which untapped renewable resources may be harnessed on a large scale to partially replace the use of fossil fuels. The R&D expenditures for renewable resources were, in fact, equal to \$65 million in 1974, while they reached a peak of about \$2 billion in 1980 (Sellers 2004). In addition, Figure 6 depicts a common trend for each country under analysis.

Figure 6. Trend of “Alternative energy production” patent applications

Nevertheless, the enthusiasm towards renewable energy went on through the mid-1980s, but after the oil prices fall, a season of stagnation lasted for almost two decades. As a result, R&D efforts collapsed to less than a third by 1987 (Sellers 2004). Furthermore, as we also showed in paragraph 4.1, the period from the mid-1980s to mid-1990s saw the pursuit of the investments made in nuclear power (Jacobson and Johnson 2000). Thereby, especially in the U.S., which more than other countries suffered from the oil embargo, after the Kippur war (1973), the innovative efforts towards alternative energy solutions drastically decreased. Finally, the increasing trend characterizing the last two decades can be reasonable explained by the perceived growing economic opportunities and the rising attention on climate change, as well as the scarcity of crude oil in the West countries. Indeed, several actions were made by different countries and organizations. For example, in 1988, the United Nations established the International Panel on Climate Change in order to assess the scientific, technical, and socio-economic information for understanding the risk of human-induced climate change. Furthermore, following what emerged during the United Nations Conference on the Human Environment (1972) on global environmental problems, several conferences took place in order to address the challenges of sustainable development and foster new innovative efforts regarding the improvement and renewal of national energy systems as well. To name some examples, the United Nations Conference on Environment and Development

(1992) addressed issues related to environmental, social and economic sustainability. Particularly, as an outcome of the conference, it was signed the Agenda 21, which highlighted the relevance of conservation and management of resources, as well as the importance of using and diffusing technologies with good environmental performances in several sectors, especially referring to energy issues. More recently, the Johannesburg Declaration on Health and Sustainable Development (2002) stressed over the concept of sustainable development and was particularly aimed at triggering actions to access “[...] to reliable, affordable, economically viable, socially acceptable and environmentally sound energy services and resources, taking into account national specificities and circumstances” (UN, 2002). Other international treaties, such as the Maastricht Treaty (signed in 1992), with the attempt to promote stable growth while protecting the environment, the Amsterdam Treaty (signed in 1997), and the ratification of the well-known Kyoto Protocol in 1997, further set the basis for a change in the energy system.

Figure 7 shows the leading countries in patenting alternative energy technologies. It emerges that the U.S., Europe, and Japan represent the most innovative countries. Differently, India, China, and Brazil are not among the top patenting countries, despite they strongly rely on clean energy (Lewis 2007; Levi, O’Neil, Segal 2010). This may suggest that those countries mainly adopt technology transfer systems, such as the Clean Development Mechanism defined in the Kyoto Protocol, and knowledge spillovers from developed countries to adopt alternative energy technological solutions, rather than being directly engaged in their creation (Koefoed and Buckley 2008; Schneider, Holzer, Hoffman 2008).

Figure 8 shows the linkage between basic and applied research. The graph depicts that, before 1991, patent references are mostly directed to patent documents. Differently, later on a high propensity in citing also scientific publications emerges. This is in accordance with some policy interventions taking place in those years. For instance, since the early 1990s the U.S. Department of Energy fostered basic research in the energy field to enhance technological development (EIA 1998). Moreover, starting from the same years, the Framework Program for Research and Technological Development, created by the European Union, funded projects in order to support and encourage research and technological development in the energy field. More recently, the International Science Panel on Renewable Energies and the Energy Innovation Hubs were established in order

to integrate worldwide research centers that combine basic and applied research and provide analysis and strategic guidance for renewable energy R&D activities.

Figure 7. "Alternative energy production" patent share by geographic area

Figure 8. "Alternative energy production" scientific citations analysis

Following the same criteria used in the previous paragraph, we examined the top ten assignees by looking at the number of granted patents (see Figure 9). Firstly, the chart shows that, despite governments foster eco-innovative actions, no national institution seems to strongly affect the patenting activity in this class. Secondly, companies have mainly produced high cited patents at the beginning of the development phase, despite later a greater amount of technological solutions has been patented. For instance, it emerges that Pioneer Hi-Bred International Inc. and Monsanto Technology LLC present low quality inventions, despite they patent a lot compared to Hitachi Ltd. and Shell Oil Company. Explanations may depend on the fact that nowadays companies are exploiting established technologies instead of developing new ones. Finally, the figure also reveals that the University of California appears among the top ten organizations, hence confirming the fundamental role of research-based organizations (e.g., Saxenian 1994; Fabrizio 2009; Messeni Petruzzelli 2011). Figures 10a and 10b present where and when breakthrough eco-innovations have been developed, respectively. The former highlights that innovative efforts made in the U.S. figured out as the most relevant. The latter

confirms that the most valuable patents were filed between 1973 and 1979, representing the first stage of the technology’s development.

Figure 9. Top ten organizations in the “Alternative energy production” class in terms of patent intensity (as represented by bubble size), period of the highest patenting activity (x-axis), and outcome quality (y-axis)

Figure 10a. “Alternative energy” breakthrough patent share by geographic area

Figure 10b. “Alternative energy” breakthrough innovation’s development trend

We extended the analysis of “Alternative energy production” technologies by considering their specific subclasses. Specifically, we divided them into two different categories by distinguishing the term “renewable” from the wider “alternative”. Accordingly, we referred to renewable energy innovations as those that rely on resources that can be totally replaced or are always naturally available, as well as are practically inexhaustible (Gicquel 2011), as sunlight, wind, water, and geothermal heat. Differently, we considered non-renewable energy innovations as those solutions that

allow the production of energy without the undesirable consequences of the burning of fossil fuels, but still require physical and chemical processes. Tables 1a and 1b show the different subclasses of renewable and non-renewable energy technologies, respectively, and the related innovative activity both globally and within different geographic areas. Looking at Table 1a, it is worthy of note that renewable energy technologies only account for the 26.14% of all inventions and that the 18% of them is related to solar energy technologies. Furthermore, analyses depict that each country contributes in a similar way to the development of these innovations. Indeed, for each subclass, the U.S., Europe, and Japan are the leading innovative countries, while a scant contribution is provided by BRIC, Taiwan, Australia, and South Korea. Table 1b points out the relevance of bio-fuel technologies (46.73% of the overall eco-innovations) in the “Alternative energy production” technology portfolio. Probably, this is due to the need of replacing fossil fuels with solutions that do not suffer from the number of limitations linked to the production of energy by renewable sources, such as the variability of energy supply (Masini and Menichetti 2012) and the high level of required investments (Painuly 2001). In addition, innovative efforts’ distribution across countries is similar to that seen in Table 1a except for “Fuel cells” and “Geothermal energy” classes, where Japan is more innovative than Europe. This could be explained considering that most active geothermal resources are usually found along major plate boundaries where earthquakes and volcanoes are concentrated. Thus, Japan is actually a better candidate for this solution. In addition, the high development of fuel cells technologies was triggered by a government funded demonstration project involving multiple manufacturers, such as Panasonic, Toshiba, and Eneos, which was dedicated to supply the commercial market by installing over 5000 residential fuel cell systems to provide heat and power in homes. Nowadays, in fact, thousands of residential fuel cell systems are being sold in Japan (IPHE 2010).

<i>Total</i>	73.86									

Following our distinction between renewable and non-renewable innovations, Figures 11a and 11b show how eco-innovations in the “Alternative energy production” class evolved. To better present these trends, we took into account the time period between 1970 and 2010, excluding the previous phase during which only 20 patents were filed. Figure 11a describes the evolutionary trend of technologies for producing energy from renewable sources. In particular, it reveals that all of them present an U-shaped trend, hence highlighting that, despite their environmental advantages, these technologies have not been used for a long time. In fact, their growing trend is visible during the oil shock, due to the need of new sources of energy, and, after that a number of environmental programs, such as the Kyoto protocol, have fostered the use of less polluting electricity production technologies. In particular, while “Hydro energy” and “Wind energy”

solutions initially received only a marginal attention, in the last few years the interest towards their use seems increased. For instance, in 2005 the Global Wind Energy Council was launched to provide a credible and international representative forum for the entire wind energy sector. Differently, Figure 11b depicts a steady growing development trend for all the different technological classes (except for “pyrolysis or gasification of biomass” that probably reached its peak in the maturity phase in the early 1990s). This trend may be reasonable due to the fact that those solutions have been principally promoted by the environmental concerns came up in the late 1980s to replace oil-based energy sources.

Figure 11a. "Renewable" technologies' development trend

Figure 11b. "Non-renewable" technologies' development trend

4.3. Energy conservation

Reducing carbon emissions, as well as bridging the energy gap between energy production and consumption, let energy conservation practices receive an increasing attention in several countries (ES 2012). As made in the previous paragraph, we first present the patenting activity as a whole. Then, we provide a brief analysis for each subclass.

Figure 12 presents the patenting application activity since 1946, both globally and per different geographical regions. It shows that, before the late 1980s, the interest towards energy conservation technologies is not comparable with the innovative efforts made between 1970 and 1986 in the “Alternative energy production” and “Nuclear energy” fields (see Figure 1 and 5, respectively). In fact, only in the U.S., after the oil crisis, there is presented a slow growth of the innovative effort in energy conservation technologies, whereas a time of stagnation is depicted from 1976 till the end of 1980s. This could be explained by considering that, differently from the solutions developed in the other two technological classes, in this case innovative efforts are directed towards the reduction of energy consumption, rather than the exploitation of new energy sources. Thereby, the main exogenous shocks have probably not determined, at the global level, an analogous attention towards conservation energy issues. Indeed, only in the U.S. there were some government initiatives toward energy conservation, thus promoting spending on research, new laws, incentives, as well as the introduction of novel solutions (Wulfinghoff 2000).

Figure 12. Trend of “Energy conservation” patent applications

By considering the years from 1985 to 2000, Figure 12 shows that “Energy conservation” patenting activity revealed a sharp growth rate, even higher than that characterizing the “Alternative energy production” one. This is especially true for the U.S. and Japan. Accordingly, the number of patents granted in the “Alternative energy production” class in that period had an increase of 150%, while the number of patents granted in the “Energy conservation” class raised of 250%, thus suggesting that the relevance of energy conservation started under the banner of environmental protection and resources scarcity problems, as highlighted during several international conferences and in related documents, such as the 1972 Stockholm Conference on the Human Environment and the Brundtland Report (WCED 1987). Indeed, the growing trend could be explained by referring to several policy initiatives taken place starting from late 1980s in response to those concerns. For example, in the U.S. a collaboration of manufacturers and energy efficiency advocates resulted in the 1987 National Appliance Energy Conservation Act, which set specific Federal energy conservation standards for many household products (Gillingham, Newell, Palmer 2006). A further energy efficiency legislation was represented by the 1992 Energy Policy Act (Public Law 102-486 1992), which extended standards for other products, like motors, lamps, commercial heating, and cooling equipment, in order to improve the overall energy efficiency. In addition, in Japan from 1993 to 2008, after the Earth Summit held in 1992, a series of amendments were enacted so as to deal with global environmental issues and set energy conservation goals². In particular, the New National Energy Strategy in 2006 and the Basic Energy Plan in 2007 specified that a clear technology strategy was mandatory, especially to identify a roadmap regarding long term technology development. In Figure 13 another interesting finding emerges. Specifically, Europe doesn’t seem to have significantly invested in energy conservation technologies. In fact, it is possible to notice that relative few efforts have been devoted in this area compared to the other technological domains previously discussed. Differently, U.S. and Japan’s patenting activities reveal a noteworthy attention paid towards energy conservation technologies, similar to that demonstrated for the production of renewable energy. Figure 13 also reveals that other countries like South Korea and Taiwan have invested considerable resources for the development of these solutions, differently from what occurred for alternative energy technologies. This may be

² <http://www.asiaeec-col.eccj.or.jp/contents02.html>

explained by taking into account that energy conservation technologies, such as low energy lighting lamps or new solutions for buildings' energy efficiency, result more marketable (Lopez-Pena, Perez-Arriga, Linares 2012), hence reducing R&D investments' risks while assuring good environmental performances. In addition, especially for Japan, energy conservation solutions are probably the best way to cope with an increasing energy demand relying only on the imports of fuel resources. In fact, despite Japan relied on oil and gas imports to meet about the 60% of its energy needs in recent years, it is shown that from 2000 to 2010 self-produced resources were less than the 1% of those consumed (EIA 2012). As highlighted for the other two categories, even in this case inventors rely also on non-patent literature in developing "Energy conservation" technologies (see Figure 14). This could be explained by looking at the actions discussed in the previous paragraph, even though this behavior appears to be more recent in this technological class than in the "Alternative energy production" class.

Figure 13. "Energy conservation" patent share by geographic area

Figure 14. "Energy conservation" scientific citations analysis

Figure 15, showing the leading organizations in terms of number of patents owned, provides other important findings. First, European organizations are not classified in the top ten rank. Second, Japanese firms present a significant patenting activity, especially referring to recent years. However, their invention quality, as measured by forward citations, is lower than that characterizing the U.S. companies. Finally, the U.S. Eastman Kodak Company, commonly known as Kodak, behaves differently from the other

companies. In fact, it seems the only organization undermining the Japanese leadership in terms of both quantity and quality. Probably, it is the only firm that is trying to move towards new technological trajectories, thus developing high impact and valuable solutions. Figures 16a shows the distribution of breakthrough inventions among the analyzed regions. It reveals that the U.S. companies hold the majority of high quality patents, probably because of the Japan's late entry in the patenting activity. Interestingly, despite the little efforts showed, European countries have generated a higher number of breakthrough eco-innovations in the field than Japanese firms. In addition, Figure 16b also reveals that highly cited patents were filed between 1971 and 1982, thus revealing that despite innovative activity in those years was not so relevant in terms of quantity of patented technologies, it set the basis for future developments in the in the "Energy conservation" class.

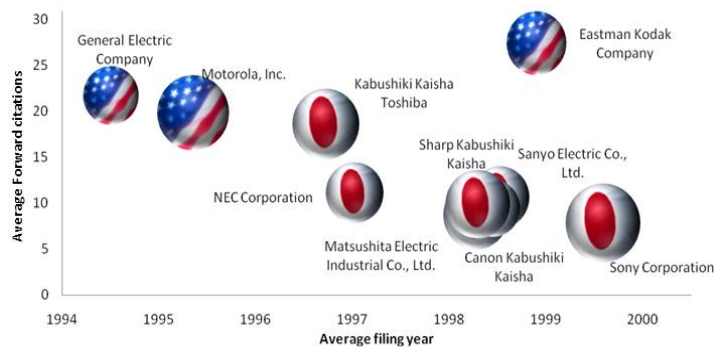

Figure 15. Top ten organizations in the "Energy conservation" class in terms of patent intensity (as represented by bubble size), period of the highest patenting activity (x-axis), and outcome quality (y-axis)

Figure 16a. “Energy conservation”
breakthrough patent share by
geographic area

Figure 16b. “Energy conservation”
breakthrough innovation’s development trend

Table 2 presents “Energy conservation” subclasses. It shows that, differently from the other two main classes, U.S. does not always own the majority of patents in each category. Indeed, the number of patents in the “Low energy lighting” and “Measurement of electricity consumption” subclasses owned by Japan exceeds the number of patents granted by U.S.. This may be due to the fact that in the last energy plan the Japanese government actively promotes the use of LED lighting to replace the traditional style incandescent bulbs and other related initiatives (IEA 2010), which include technologies for measuring energy consumption, likely to have stimulated innovative efforts in these two subclasses.

Table 2. Total patent share and percentage of patents owned by geographic area for “Energy conservation” technologies

	Patent share	U.S.	EU	JP	BRIC	CAN	TAIWAN	KOR	OTHERS	Total by geographic area
Storage of electrical energy	30.47	49.71	9.50	27.11	0.74	3.20	4.65	3.27	1.82	100
Power supply circuitry	2.08	61.33	11.78	16.00	0.44	1.33	6.22	1.56	1.33	100
Measurement of electricity consumption	1.74	35.88	11.61	47.49	0	1.58	0.53	1.58	1.32	100
Storage of thermal energy	4.20	62.84	21.17	10.47	0.44	1.43	1.21	0.88	1.54	100
Low energy lighting	40.01	30.57	10.20	44.03	0.37	1.30	6.21	5.94	1.39	100
Thermal building insulation, in general	20.45	66.65	20.15	4.76	0.34	5.39	0.71	0.39	1.62	100
Recovering mechanical energy	1.05	65.35	18.86	5.26	0.44	5.26	1.32	0.44	3.07	100
Total	100									

Finally, Figure 17 shows temporal trends in patenting activity for each subclass. It highlights that only “Low energy lighting” and “Storage of electrical energy” had an increasing trend. On the contrary, the other categories provide a little contribution to the overall trend.

Figure 17. "Energy conservation" subclasses evolution

5. Discussion and Implications

This paper analyzes the evolution of eco-innovations in the energy field, specifically focusing on low-carbon energy technologies, by investigating patenting activity trends both globally and in specific geographic areas. To our knowledge, this study is the first attempt to depict a comprehensive scenario of eco-innovations evolution in the field of energy. Furthermore, this paper tries to explain evolutionary trends as a result of related country policies and historical events that may have fostered the development of such innovations. To this aim, a unique database of patented inventions filed at the U.S.PTO. between 1946 and 2010 and belonging to the "Nuclear power generation", "Alternative energy production", and "Energy conservation" IPC technological classes has been created and analyzed. Several interesting findings concerning the dynamics and distribution of low-carbon energy technologies emerged.

First, the global evolutionary trends of eco-innovations show the key role played by geopolitical circumstances. In fact, the eco-innovative activity increases with the highest growth rate during the petrol crisis period and in the early 1990s, as a result of the global warming awareness, except for few technological categories, as "Pyrolysis or gasification of biomass", "OTEC", and "Storage of thermal energy". This highlights that governments' strategies and energy programs set important frameworks and initiatives to foster and sustain eco-innovation development (Popp 2006). The main example is represented by the substantial contribution in developing nuclear power solutions provided by the U.S. government and the French Commissariat à l'Énergie Atomique,

which appear in the top ten patents' assignee classification in the nuclear energy class. A further example is given by Japan, which developed a governmental plan fostering the use of LED lighting and became the leading country for low energy lighting. Nevertheless, as shown through the analysis of the leading innovative organizations, private companies own the majority of the developed eco-innovations. Thereby, this reveals that commercial activities have an important role in the eco-innovation's development. This is in line with previous studies (e.g., Teece 1986; Henderson 1993), which highlighted how economic motivations act as the key driver in enabling the innovation process, hence making profit organizations as central actors. Furthermore, this is also the result of the strategic relevance assumed by climate change issue in business competition (Porter and Reinhardt 2007), which has in turn significantly influenced and oriented firms' innovation strategies. Second, data analyses depict a great discrepancy between subclasses in each main technological area. In fact, some of them represent less than 1% of the total amount of patents developed within a specific class. In particular, what is worthy to note is that, although certain subclasses include hot technologies upon which current debates are focusing, this does not necessarily corresponds to a higher patent share, such as in the case of "Alternative energy production". In fact, patent analyses demonstrate that wind, geothermal and hydro technologies represent only the 8% of the total amount of granted patents, despite their widely recognized important role in the next future as effective and sustainable technologies (ISPRES 2009). Nevertheless, the current wholesale rate is certainly far from the required level. By taking into account what occurred for the development of some low-carbon technologies, such as nuclear plants and solar cells, the eventual push to full commercialization through the use of effective demand pull policies, which in turn allow the creation of new markets by protecting emerging technologies from the competition with established designs, may significantly foster their spread and boost innovation (e.g., Nill and Kemp 2009), hence again highlighting how commercial opportunities can enhance innovative efforts (Teece 1986).

Third, our study sheds new light on the major inventing countries in the field under investigation. Specifically, innovation in low-carbon energy technologies is mostly generated in U.S., which accounts for more than a half of the total inventions. The innovative performance of Japan is also particularly impressive, since in a number of subclasses, such as in solar energy and low energy lighting technologies, it ranks equal to or better than Europe. Other countries, such as South Korea, Canada, Taiwan, and

Australia, present significant contributions in the patenting activity only in some particular technological fields. For instance, Canada owns the 5% of all patents in the thermal building insulation category and the 3% of breakthroughs in the energy conservation class, while it does not contribute to the development of renewable energy technologies at all. Furthermore, South Korea and Taiwan primarily focus on energy conservation solutions. Looking at BRIC, it seems that they are still far from intensive innovative activity, despite their environmental awareness as well as the use of eco-innovation solutions are growing (Lewis 2007; Levi, O'Neil, Segal 2010). Nevertheless, it should be noticed that our analysis looks at the trends of patents filed until 2010. During more recent years, BRIC investments in low-carbon energy technologies have significantly grown (e.g., PEW 2010; Lema, Berger, Schmitz 2012), thus suggesting an increasing tendency to patent which will likely be evident in next years. Another important result emerges from the analysis of scientific-based citations. Specifically, in recent years, the number of patents which are also based upon scientific literature is growing. This indicates that the international initiative aimed at strengthening the role and the appliance of scientific knowledge to support sustainable development are becoming effective (Agenda 21 Chapter 35). Thus, inventors are probably more deeply focusing on scientific research than in the past, hence making use of scientific knowledge to increase their understanding of environmental problems and creating suitable technological solutions (e.g., Fleming and Soreson 2004). Finally, we analyzed breakthrough eco-innovations developed in the three different technological areas. Results show that for "Alternative energy production" and "Nuclear power generation" classes breakthroughs' development occurred in the earliest stage of eco-innovation evolution and that it is limited within few years. Reasonable explanation lies in the fact that knowledge about using wind, water, sun, or nuclear power dates back to earlier than 1970s, but it was never fully exploited due to the widespread use of carbon and petroleum. Nevertheless, from the early 1970s, resource scarcity problems and environmental concerns attracted funds and shifted global attention towards new forms of energy generation. Hence, new business opportunities have emerged, pushing organizations towards the development of valuable solutions to successfully compete in these new markets. Similarly, "Energy conservation" breakthroughs were developed early in time, but in a longer period compared to the other two classes. This could be explained by considering that energy efficiency needs emerged as a new concept under the banner of resource scarcity issues, thus needing more time to

develop effective actions and technologies. It should be noticed that these results may also be related to the choice of our measure for identifying breakthrough eco-innovations, as described by forward citations. Indeed, early filed patents have less likelihood to be cited, hence being not fully recognized and appreciated by our proxy.

In terms of managerial and policy implications, our suggestions are threefold. First, our study highlights that the development of eco-innovations is due to both private and public efforts. Thus, we encourage corporate executives and policymakers to invest in strengthening their networks, by which technical, economic, and political knowledge could be better integrated in order to follow both business and social needs, as well as integrate all the competences needed to address the complexity characterizing eco-innovation development (Messeni Petruzzelli et al. 2011). Second, our study shows that different types of low-carbon energy technologies have been developed in response to environmental and geopolitical concerns. As a result, companies and policymakers are engaged in the development of different types of eco-innovations, which are, however, very difficult to be fully studied, assessed, and regulated. Thereby, a centralized organism that looks over the intensity and dynamics of their applications and their interaction with the society is needed. Furthermore, clear national policies on eco-innovations should be underpinned by international agreements through which all countries commit to take action to reduce their environmental impacts and can keep pace with the ever-changing technologies that are developed. Third, since environmental problems, such as pollution and climate change, are global externalities, with consequences all over the world (irrespective of who generated them), the development and the diffusion of eco-innovations is a global issue. Thereby, transferring appropriate solutions by taking into account specific local needs, as well as ensuring their effective implementation, can help to address global environmental problems and reach sustainability targets. This is especially true for developing countries where the assimilation, adaptation, and maintaining of the imported technologies are essential conditions to support sustainable development (UN 2012).

6. Limitations, Future research directions, and Conclusion

This study has some limitations that should be acknowledged. First, the innovation process is described by means of patents, which do not represent the whole innovative

portfolio. Indeed, some innovations are not patentable and patents do not always represent the most suitable appropriation mechanisms (Levin et al. 1987; Bessen 2006). Furthermore, the rate at which new innovations are patented varies across industry (e.g., Bessen 2006; Gittelman 2008). Second, comparisons at global scale raises some biases since the value of patents vary across countries and the characteristics of appropriation regimes significantly affect the propensity to patent (Archibugi and Pianta 1996; OECD 2009b). Third, we focused on a specific type of eco-innovation, as technological eco-innovation, although other kinds of eco-innovations, such as organizational and business ones, can be recognized and investigated (e.g., Kemp and Pearson 2008).

In addition to address these limitations, future research should place more emphasis on eco-innovation commercialization. We highlighted the relevance of commercial activities to spread those technologies. Thereby, empirical studies on how firms' capabilities, technological characteristics, and environmental circumstances interact in order to bring those technologies to the market are needed. Furthermore, the economic impacts of eco-innovations are still not fully measured. Here, further research should be conducted in order to map out the diffusion of eco-innovations and related socio-technical changes, as well as to assess their main macro-economic impacts. Moreover, scholars could focus their attention on investigating which policies have more effectively influenced eco-innovations' development, thus providing policymakers with more detailed insights. In conclusion, we believe that this study has taken the literature one step further in the on-going debate on the evolution of eco-innovations and hope that this work may stimulate further theoretical refinement and empirical investigation in this relevant area of research.

Abstract

Open innovation literature suggests that firms can improve their innovation performance by learning from users, customers, suppliers, universities, research centers. However, the success of such new paradigm is still debatable and literature is searching for its determinants. In particular, the firms' internal organizational context seems to be crucial to explain the success or failure of open innovation: firms which attempt to leverage partners' knowledge must design an appropriate internal organization, made of organizational practices and human resources attitudes. Despite this assumption, the firm internal context is still poorly investigated as concerns its role to support open innovation success. Therefore, the aim of this study is to explore the relationships among collaboration behavior, organizational practices, internal collaborative attitudes, thus investigating firms capacity to reach high levels of innovative performance through an open approach. Our study, relied on a survey research developed in Finland, Italy and Sweden, suggests that collaborations with different typologies of partners should be carefully managed, through the development and implementation of organizational and HR practices, in order to foster ambidexterity. In this way both the scientific network (made up of organizations that are not permanently linked in a direct economic sense) and the business networks (made up of partners who belong to a common supply chain or are situated at the same level of a supply chain) allow the achievement of exploitative and explorative innovations: in the former case, only the use of an appropriate and formal set of collaborative practices and employees' attitude towards openness leads to the development of ambidexterity.

Key words: open innovation, innovative performance, ambidexterity, managerial and organizational practices, collaborative mindset

1. Introduction

Open innovation literature (Chesbrough, 2003) suggests that firms can improve their innovation performance by learning from users, customers, suppliers, universities, research centers. However, the success of such new paradigm is still debatable (Laursen and Salter, 2006) and literature is searching for its determinants. In particular, the firms' internal organizational context seems to be crucial to explain the success or failure of open innovation (Foss et al. 2011): firms which attempt to leverage partners' knowledge must design an appropriate "internal organization" made of organizational practices and human resources (HR) attitudes. Despite this assumption, the firm internal context is still poorly investigated as concerns its role to support open innovation success.

At the same time, scholars on organizational learning have mainly investigated the role that internal drivers have in fostering ambidexterity, defined as the ability of firms to pursue exploratory and exploitative innovation simultaneously (He and Wong, 2004). At the moment there are only few attempts to analyse how the combination of internal mechanisms and collaboration behavior leads to the achievement of ambidexterity (Raisch and Birkinshaw, 2008; Schamberger et al., 2013), even if it is recognized that it is a particularly fruitful area for further research (Lichtenthaler and Lichtenthaler, 2009).

Therefore, the aim of this study is to explore the relationships among collaboration behavior (i.e. openness with two different typologies of subjects, named scientific and business partners), organizational practices, internal collaborative attitudes and ambidexterity, thus investigating firms capacity to reach high levels of innovative performance through an open approach. We attempt to understand why some companies are able to extract value from collaborations and others are not, by investigating whether the firm's internal context mediates the relationship between collaborative behavior and firm's ambidexterity.

2. Literature review and hypothesis

The theoretical foundations of our work can be found in the apparently recent stream of literature about the open innovation paradigm (Chesbrough, 2003), but in effect

grounded in the more longstanding strand focused on knowledge management, intellectual capital, human resource management (HRM) and innovation.

2.1 Openness and firms' internal context

A contingency perspective (Smith and Lewis, 2011) suggests that models with a different degree of openness exist and that they are all strategically valuable (Chesbrough, 2003). However, literature claims also that they show a growing complexity with the increasing of the degree of openness (Enkel and Bader, 2012; Dahlander and Gann, 2010; Foss et al., 2011). Complex collaboration with many partners calls also for the involvement of various individuals and departments, able to exchange information and thus characterized by appropriate socio-psychological features or mindset (Hillebrand and Biemans, 2004; Cabrera and Cabrera, 2005; Jolink and Dankbaar, 2010). Moreover, managing different sources (actors) of knowledge requires high levels of coordination and thus more sophisticated (and more intensively applied) project management systems (Foss et al., 2011). Therefore, it can be supposed that higher levels of openness need a higher level of propensity to collaborate and to share knowledge as well as a high intensity of organizational procedures in order to achieve innovative performance, as the following hypothesis states:

Hp 1 The more the focal firm collaborates with business partners, the higher its collaborative mindset will be.

Hp 2 The more the focal firm collaborates with scientific partners, the higher its collaborative mindset will be.

Hp 3 The more the focal firm collaborates with business partners, the higher its use of collaborative organizational practices/mechanisms will be.

Hp 4 The more the focal firm collaborates with scientific partners, the higher its use of collaborative organizational practices/mechanisms will be.

2.2 Firms' internal context and ambidexterity

Knowledge management and intellectual capital literature has shown the crucial role of social capital (in particular of its relational dimension) in favoring knowledge sharing and innovative performance within the company (Subramaniam and Youndt, 2005; Cabrera and Cabrera, 2005; Cabello-Medina et al., 2011) and among companies (Jolink and Dankbaar, 2010). Firms which are already used to internally cooperate, thanks to high

levels of internal communication skills, are also inclined to be flexible and to share information with external partners (Hillebrand and Biemans, 2004; Foss et al., 2011). Individual communication skills aimed to internally cooperate as well as close and frequent interactions between R&D and other functions serve to interpret, to evaluate, to disseminate and to apply new knowledge acquired from external partners, by allowing better integration and coordination of different bodies of knowledge (Hillebrand and Biemans, 2004). In other words, people who are already used to communicate and internally cooperate are likely to be more receptive and able to foster different types of learning (i.e. explorative and exploitative), creating the premises for all the facets of innovative performance. Accordingly, we suppose a beneficial effect provided by internal communication and interactions on innovative performance achieved in collaboration. Thus, we state that:

Hp 5 The presence of a collaborative mindset will lead to higher levels of ambidexterity.

The literature analysis has highlighted the crucial role of the organizational capital (i.e. structures, processes and systems) and the related HRM practices in creating a context which favour knowledge sharing and exchange (and thus innovative performance) within the company (Gittell, 2000; Cabrera and Cabrera, 2005; Yang and Lin, 2009; Cabello Medina et al., 2011; Camelo-Ordaz et al., 2011), but not only: appropriate roles, structures, procedures and systems are also relevant to allow effective knowledge flows when innovation is carried out in collaboration (Ritala, 2009; Jolink and Dankbaar, 2010; Petroni et al., 2012). Following in particular those studies which call for further investigation when the number of partners and the relationship complexity are increasing as in the case of open innovation (Foss et al., 2010; Foss et al. 2011; Brunswicker and Vanhaverbeke, 2011; Ihl et al., 2012), we know that systems to manage collaborations (e.g. project management techniques as milestones, scheduled meeting among partners, goals and plans that are formalized or written down, active management involvement, etc.) reduce the likelihood that people will deviate from established behavior; enhance the causal links among tasks and thus increase the likelihood that people will identify opportunities for transformation of new external knowledge (Nonaka, 1994; Zollo and Winter, 2002); allow to identify best practices so as to facilitate knowledge application (Lin and Germain, 2003; Thuc Anh et al., 2006; Lawson et al., 2009). In sum, managerial and organizational mechanisms, put together, create a conducive context which enables

firms to share, exchange and transform knowledge and foster different types of learning (i.e. explorative and exploitative), creating the premises for all the facets of innovative performance. Thus, in general we state that:

Hp 6 The use of collaborative organizational practices/mechanisms will lead to higher levels of ambidexterity.

2.3 Openness, firms internal context and ambidexterity

Supposing that antecedents enable innovative performance from collaborations, we make a step forward wondering what would happen if they were not existing or well-operating, which means to investigate their mediating role between openness and innovative performance. Foss et al., (2011) find that customer interaction enhance innovative performance only *through* the operating of some organizational practices. This allows supposing that, without the beneficial operating of such practices, customer interaction does not improve innovative performance. Hillebrand and Biemans (2004) find that, *without* internal communication and cooperation, organizations are unable to implement the externally acquired knowledge throughout the organizations. Supported by the fact that the success (in terms of innovation performance) of open innovation is still debatable (Laursen and Salter 2006; Rothaermel and Deeds, 2006) and that what happens within the company (i.e. firms' internal organization and social context) is crucial to explain the success or failure of open innovation (Dahlander and Gann, 2010), we state the following:

Hp 7 The collaborative mindset mediates the relationship between business partners and ambidexterity.

Hp 8 The collaborative organizational practices/mechanisms mediate the relationship between business partners and ambidexterity.

Hp 9 The collaborative mindset mediates the relationship between scientific partners and ambidexterity.

Hp 10 The collaborative organizational practices/mechanisms mediate the relationship between scientific partners and ambidexterity.

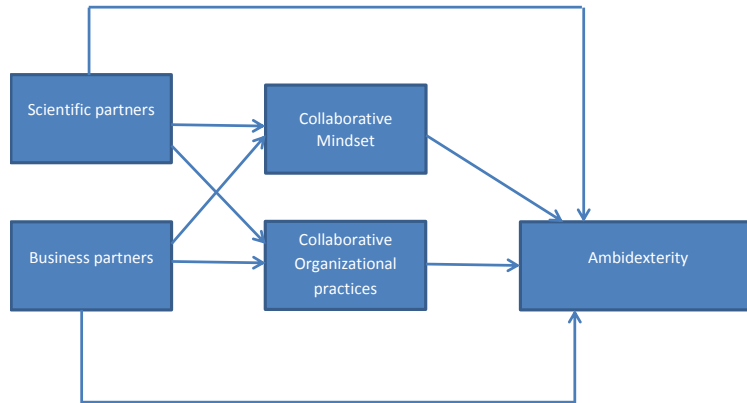

Figure 1 summaries our hypotheses as follows:

3. Research Method

3.1 Sampling and data collection

3.2 Measure and operationalization

We utilize a 7 point Likert-type scale with end points of “strongly disagree” and “strongly agree” to measure the items of all variables. The exact wording of the employed items is shown in Appendix A.

Business partners (BP) and scientific partners (SP) take inspiration from the works of Faems et al. (2005), Laursen and Salter (2006) and Faems et al (2010), which employ two different constructs to measure external partnership, since relationships with customers and suppliers differ from those with universities and research institutes. Thus, the independent variable scientific partners refers to the presence of collaboration with research actors such as universities and research institutes, while the independent variable business partners refers to collaborations with industrial actors such as customers, suppliers, competitors and other firms.

The measurement scale for the first mediation variable, i.e. collaborative mindset (CM) has got theoretical foundations in the Nahapiet and Ghoshal (1998) social capital conception and, in particular, in its internal relational aspect. Antecedents are then practically operationalized by following suggestions by Hillebrand and Biemans (2004), Subramaniam and Youndt (2005); Ritala et al., (2009); Lawson et al., (2009); Yang and Lin (2009); Cabello-Medina et al., (2011), focusing attention on individual communication skills (e.g. capacity of listening and paying attention to others; employees'

propensity to collaborate, interact and work in groups to solve problems; close and frequent interactions between R&D and other functions).

The measurement scale for the second mediation variable, i.e. collaborative organizational practices (COP) is defined following Subramaniam and Youndt (2005), Jansen et al. (2005), Lin and Chen (2006), Yang and Lin (2009) and Volberta et al. (2010): the attention is focused on the existence of procedures and systems used to manage collaborations.
